C7.2.124 FMLAL, FMLAL2 (vector)

Floating-point fused Multiply-Add Long to accumulator (vector). This instruction multiplies corresponding half-precision floating-point values in the vectors in the two source SIMD&FP registers, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

C7.2.125 FMLS (by element)

Floating-point fused Multiply-Subtract from accumulator (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and subtracts the results from the vector elements of the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

`<Hd>` Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Hn>` Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

`<V>` Is a width specifier, encoded in the "sz" field. It can have the following values:

- `S` when `sz = 0`
- `D` when `sz = 1`

`<d>` Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

`<n>` Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `4H` when `Q = 0`
- `8H` when `Q = 1`

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:

- `2S` when `Q = 0`, `sz = 0`
- `4S` when `Q = 1`, `sz = 0`
- `2D` when `Q = 1`, `sz = 1`

The encoding `Q = 0`, `sz = 1` is reserved.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vm>` For the half-precision variant: is the name of the second SIMD&FP source register, in the range V0 to V15, encoded in the "Rm" field.

For the single-precision and double-precision variant: is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.

`<Ts>` Is an element size specifier, encoded in the "sz" field. It can have the following values:

- `S` when `sz = 0`
- `D` when `sz = 1`

`<index>` For the half-precision variant: is the element index, in the range 0 to 7, encoded in the "H:L:M" fields.

For the single-precision and double-precision variant: is the element index, encoded in the "sz:L:H" field. It can have the following values:

- `H:L` when `sz = 0`, `L = x`
- `H` when `sz = 1`, `L = 0`

The encoding `sz = 1`, `L = 1` is reserved.

C7.2.126 FMLS (vector)

Floating-point fused Multiply-Subtract from accumulator (vector). This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, negates the product, adds the result to the corresponding vector element of the destination SIMD&FP register, and writes the result to the destination SIMD&FP register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `4H` when `Q = 0`
- `8H` when `Q = 1`

For the single-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `2S` when `Q = 0`
- `4S` when `Q = 1`

`<imm>` Is a signed floating-point constant with 3-bit exponent and normalized 4 bits of precision, encoded in "a:b:c:d:e:f:g:h". For details of the range of constants available and the encoding of `<imm>`, see *Modified immediate constants in A64 floating-point instructions* on page C2-240.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();

V[rd] = imm;
```

C7.2.130 FMOV (register)

Floating-point Move register without conversion. This instruction copies the floating-point value in the SIMD&FP source register to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 19 18 17	16 15	14 13 12 11 10	9 5	4 0

C7.2.133 FMSUB

Floating-point Fused Multiply-Subtract (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, adds that to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.134 FMUL (by element)

Floating-point Multiply (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean mulx_op = (U == '1');
```

Assembler symbols

`<Hd>` Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Hn>` Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

`<V>` Is a width specifier, encoded in the "sz" field. It can have the following values:

- `S` when `sz = 0`
- `D` when `sz = 1`

`<d>` Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

`<n>` Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `4H` when `Q = 0`
- `8H` when `Q = 1`

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:

- `2S` when `Q = 0, sz = 0`
- `4S` when `Q = 1, sz = 0`
- `2D` when `Q = 1, sz = 1`

The encoding `Q = 0, sz = 1` is reserved.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vm>` For the half-precision variant: is the name of the second SIMD&FP source register, in the range V0 to V15, encoded in the "Rm" field.

For the single-precision and double-precision variant: is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.

`<Ts>` Is an element size specifier, encoded in the "sz" field. It can have the following values:

- `S` when `sz = 0`
- `D` when `sz = 1`

`<index>` For the half-precision variant: is the element index, in the range 0 to 7, encoded in the "H:L:M" fields.

For the single-precision and double-precision variant: is the element index, encoded in the "sz:L:H" field. It can have the following values:

- `H:L` when `sz = 0, L = x`
- `H` when `sz = 1, L = 0`

The encoding `sz = 1, L = 1` is reserved.

C7.2.135 FMUL (vector)

Floating-point Multiply (vector). This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, places the result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.137 FMULX (by element)

Floating-point Multiply extended (by element). This instruction multiplies the floating-point values in the vector elements in the first source SIMD&FP register by the specified floating-point value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If one value is zero and the other value is infinite, the result is 2.0. In this case, the result is negative if only one of the values is negative, otherwise the result is positive.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

`<Hd>` Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Hn>` Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

`<V>` Is a width specifier, encoded in the "sz" field. It can have the following values:

- `S` when `sz = 0`
- `D` when `sz = 1`

`<d>` Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

`<n>` Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `4H` when `Q = 0`
- `8H` when `Q = 1`

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:

- `2S` when `Q = 0`, `sz = 0`
- `4S` when `Q = 1`, `sz = 0`
- `2D` when `Q = 1`, `sz = 1`

The encoding `Q = 0`, `sz = 1` is reserved.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vm>` For the half-precision variant: is the name of the second SIMD&FP source register, in the range V0 to V15, encoded in the "Rm" field.

For the single-precision and double-precision variant: is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.

`<Ts>` Is an element size specifier, encoded in the "sz" field. It can have the following values:

- `S` when `sz = 0`
- `D` when `sz = 1`

`<index>` For the half-precision variant: is the element index, in the range 0 to 7, encoded in the "H:L:M" fields.

For the single-precision and double-precision variant: is the element index, encoded in the "sz:L:H" field. It can have the following values:

- `H:L` when `sz = 0`, `L = x`
- `H` when `sz = 1`, `L = 0`

The encoding `sz = 1`, `L = 1` is reserved.

0	Q	1	0	1	1	1	0	1	sz	1	0	0	0	0	0	1	1	1	1	1	0	Rn		Rd	
		U																							

Encoding

```
FNEG <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then UNDEFINED;
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<T> For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0

8H when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    if neg then
        element = FPNeg(element);
    else
        element = FPAbs(element);
    Elem[result, e, esize] = element;

V[d] = result;
```

C7.2.140 FNEG (scalar)

Floating-point Negate (scalar). This instruction negates the value in the SIMD&FP source register and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20	19	18	17	16	15	14	13	12	11	10	9 5	4 0
0	0	0	1	1	1	1	0	ftype	1	0	0	0	0	1	0	1	0	0	0	0	Rn	Rd
														opc								

Half-precision variant

Applies when `ftype == 11`.

```
FNEG <Hd>, <Hn>
```

Single-precision variant

Applies when `ftype == 00`.

```
FNEG <Sd>, <Sn>
```

Double-precision variant

Applies when `ftype == 01`.

```
FNEG <Dd>, <Dn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize;
case ftype of
    when '00' esize = 32;
    when '01' esize = 64;
    when '10' UNDEFINED;
    when '11'
        if HaveFP16Ext() then
            esize = 16;
        else
            UNDEFINED;
```

Assembler symbols

C7.2.141 FNMADD

Floating-point Negated fused Multiply-Add (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, subtracts the value of the third SIMD&FP source register, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.144 FRECPE

Floating-point Reciprocal Estimate. This instruction finds an approximate reciprocal estimate for each vector element in the source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<T>
: For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

  4H
  : when Q = 0

  8H
  : when Q = 1

  For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

  2S
  : when sz = 0, Q = 0

  4S
  : when sz = 0, Q = 1

  2D
  : when sz = 1, Q = 1

  The encoding sz = 1, Q = 0 is reserved.

<Vn>
: Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm>
: Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```
if elements == 1 then
    CheckFPEnabled64();
else
    CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

C7.2.146 FRECPX

Floating-point Reciprocal exponent (scalar). This instruction finds an approximate reciprocal exponent for the source SIMD&FP register and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision

C7.2.147 FRINT32X (vector)

Floating-point Round to 32-bit Integer, using current rounding mode (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values that fit into a 32-bit integer size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

A zero input returns a zero result with the same sign. When one of the result values is not numerically equal to the corresponding input value, an Inexact exception is raised. When an input is infinite, NaN or out-of-range, the instruction returns for the corresponding result value the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.154 FRINT64Z (scalar)

Floating-point Round to 64-bit Integer toward Zero (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value that fits into a 64-bit integer size using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A zero input returns a zero result with the same sign. When the result value is not numerically equal to the {corresponding} input value, an Inexact exception is raised. When the input is infinite, NaN or out-of-range, the instruction returns {for the corresponding result value} the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.155 FRINTA (vector)

Floating-point Round to Integral, to nearest with ties to Away (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.161 FRINTN (vector)

Floating-point Round to Integral, to nearest with ties to even (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.165 FRINTX (vector)

Floating-point Round to Integral exact, using current rounding mode (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

When a result value is not numerically equal to the corresponding input value, an Inexact exception is raised. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.167 FRINTZ (vector)

Floating-point Round to Integral, toward Zero (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.168 FRINTZ (scalar)

Floating-point Round to Integral, toward Zero (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.169 FRSQRTE

Floating-point Reciprocal Square Root Estimate. This instruction calculates an approximate square root for each vector element in the source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

`4H` when `Q = 0`

`8H` when `Q = 1`

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

`2S` when `sz = 0`, `Q = 0`

`4S` when `sz = 0`, `Q = 1`

`2D` when `sz = 1`, `Q = 1`

The encoding `sz = 1`, `Q = 0` is reserved.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

bits(esize) element1;
bits(esize) element2;
bits(esize) diff;
FPCRType fpcr = FPCR[];
bits(datasize) result;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    diff = FPSub(element1, element2, fpcr);
    Elem[result, e, esize] = if abs then FPAbs(diff) else diff;

V[d] = result;
```

C7.2.174 FSUB (scalar)

Floating-point Subtract (scalar). This instruction subtracts the floating-point value of the second source SIMD&FP register from the floating-point value of the first source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0
0	0	0	1	1	1	1	0	ftype	1	Rm	0	0	1	1	1	0	Rn	Rd
														op				

Half-precision variant

Applies when `ftype == 11`.

```
FSUB <Hd>, <Hn>, <Hm>
```

Single-precision variant

Applies when `ftype == 00`.

```
FSUB <Sd>, <Sn>, <Sm>
```

Double-precision variant

Applies when `ftype == 01`.

```
FSUB <Dd>, <Dn>, <Dm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer esize;
case ftype of
    when '00' esize = 32;
    when '01' esize = 64;
    when '10' UNDEFINED;
    when '11'
        if HaveFP16Ext() then
            esize = 16;
        else
            UNDEFINED;
```

Assembler symbols

`<Dd>`	Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
`<Dn>`	Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
`<Dm>`	Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
`<Hd>`	Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

C7.2.175 INS (element)

Insert vector element from another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (element). The alias is always the preferred disassembly.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	11	10	9	5	4	0
0	1	1	0	1	1	1	0	0	0	0	imm5		0	imm4		1	Rn		Rd	

Encoding

```
INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;

integer dst_index = UInt(imm5<4:size+1>);
integer src_index = UInt(imm4<3:size>);
integer idxdsize = if imm4<3> == '1' then 128 else 64;
// imm4<size-1:0> is IGNORED

integer esize = 8 << size;
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ts>` Is an element size specifier, encoded in the "imm5" field. It can have the following values:

- `B` when `imm5 = xxxx1`
- `H` when `imm5 = xxx10`
- `S` when `imm5 = xx100`
- `D` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<index1>` Is the destination element index encoded in the "imm5" field. It can have the following values:

- `imm5<4:1>` when `imm5 = xxxx1`
- `imm5<4:2>` when `imm5 = xxx10`
- `imm5<4:3>` when `imm5 = xx100`
- `imm5<4>` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<index2>` Is the source element index encoded in the "imm5:imm4" field. It can have the following values:

`imm4<3:0>` when `imm5 = xxxx1`

`imm4<3:1>` when `imm5 = xxx10`

`imm4<3:2>` when `imm5 = xx100`

`imm4<3>` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];
bits(128) result;

result = V[d];
Elem[result, dst_index, esize] = Elem[operand, src_index, esize];
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.176 INS (general)

Insert vector element from general-purpose register. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (from general). The alias is always the preferred disassembly.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	1	0	0	1	1	1	0	0	0	0	imm5		0	0	0	1	1	1	Rn		Rd	

Encoding

```
INS <Vd>.<Ts>[<index>], <R><n>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);

if size > 3 then UNDEFINED;
integer index = UInt(imm5<4:size+1>);

integer esize = 8 << size;
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ts>` Is an element size specifier, encoded in the "imm5" field. It can have the following values:

- `B` when `imm5 = xxxx1`
- `H` when `imm5 = xxx10`
- `S` when `imm5 = xx100`
- `D` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<index>` Is the element index encoded in the "imm5" field. It can have the following values:

- `imm5<4:1>` when `imm5 = xxxx1`
- `imm5<4:2>` when `imm5 = xxx10`
- `imm5<4:3>` when `imm5 = xx100`
- `imm5<4>` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<R>` Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:

- `W` when `imm5 = xxxx1`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

W	when `imm5 = xxx10`
W	when `imm5 = xx100`
X	when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<n>` Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(128) result;

result = V[d];
Elem[result, index, esize] = element;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.177 LD1 (multiple structures)

Load multiple single-element structures to one, two, three, or four registers. This instruction loads multiple single-element structures from memory and writes the result to one, two, three, or four SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

No offset

One register variant

Applies when `opcode == 0111`.

```
LD1 { <Vt>.<T> }, [<Xn|SP>]
```

Two registers variant

Applies when `opcode == 1010`.

```
LD1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]
```

Three registers variant

Applies when `opcode == 0110`.

```
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>]
```

Four registers variant

Applies when `opcode == 0010`.

```
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>]
```

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
boolean tag_checked = wback || n != 31;
```

Post-index

One register, immediate offset variant

Applies when `Rm == 11111 && opcode == 0111`.

```
LD1 { <Vt>.<T> }, [<Xn|SP>], <imm>
```

One register, register offset variant

Applies when `Rm != 11111 && opcode == 0111`.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
LD1 { <Vt>.<T> }, [<Xn|SP>], <Xm>
```

Two registers, immediate offset variant

Applies when `Rm == 11111 && opcode == 1010`.

```
LD1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>
```

Two registers, register offset variant

Applies when `Rm != 11111 && opcode == 1010`.

```
LD1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>
```

Three registers, immediate offset variant

Applies when `Rm == 11111 && opcode == 0110`.

```
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <imm>
```

Three registers, register offset variant

Applies when `Rm != 11111 && opcode == 0110`.

```
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>
```

Four registers, immediate offset variant

Applies when `Rm == 11111 && opcode == 0010`.

```
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>
```

Four registers, register offset variant

Applies when `Rm != 11111 && opcode == 0010`.

```
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>
```

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
boolean tag_checked = wback || n != 31;
```

Assembler symbols

`<Vt>` Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

`<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`8B`	when `size = 00`, `Q = 0`
`16B`	when `size = 00`, `Q = 1`
`4H`	when `size = 01`, `Q = 0`
`8H`	when `size = 01`, `Q = 1`
`2S`	when `size = 10`, `Q = 0`
`4S`	when `size = 10`, `Q = 1`
`1D`	when `size = 11`, `Q = 0`
`2D`	when `size = 11`, `Q = 1`

`<Vt2>` Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<Vt3>` Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

`<Vt4>` Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<imm>` For the one register, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

`#8` when `Q = 0`

`#16` when `Q = 1`

For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

`#16` when `Q = 0`

`#32` when `Q = 1`

For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

`#24` when `Q = 0`

`#48` when `Q = 1`

For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

`#32` when `Q = 0`

`#64` when `Q = 1`

`<Xm>` Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

```
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = if Q == '1' then 128 else 64;
integer esize = 8 << UInt(size);
integer elements = datasize DIV esize;

integer rpt;    // number of iterations
integer selem;    // structure elements

case opcode of
    when '0000' rpt = 1; selem = 4;    // LD/ST4 (4 registers)
    when '0010' rpt = 4; selem = 1;    // LD/ST1 (4 registers)
    when '0100' rpt = 1; selem = 3;    // LD/ST3 (3 registers)
    when '0110' rpt = 3; selem = 1;    // LD/ST1 (3 registers)
    when '0111' rpt = 1; selem = 1;    // LD/ST1 (1 register)
    when '1000' rpt = 1; selem = 2;    // LD/ST2 (2 registers)
    when '1010' rpt = 2; selem = 1;    // LD/ST1 (2 registers)
    otherwise UNDEFINED;

// .1D format only permitted with LD1 & ST1
if size:Q == '110' && selem != 1 then UNDEFINED;
```

Operation for all encodings

```

C7.2.179 LD1R

Load one single-element structure and Replicate to all lanes (of one register). This instruction loads a single-element structure from memory and replicates the structure to all the lanes of the SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	0	1	0	1	0	0	0	0	0	0	1	1	0	0	size		Rn		Rt	
									L	R						opcode			S						

Encoding

```
LD1R { <Vt>.<T> }, [<Xn|SP>]
```

Decode for this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
boolean tag_checked = wback || n != 31;
```

Post-index

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	0	1	1	1	0	Rm		1	1	0	0	size		Rn		Rt	
									L	R			opcode			S						

Immediate offset variant

Applies when `Rm == 11111`.

```
LD1R { <Vt>.<T> }, [<Xn|SP>], <imm>
```

Register offset variant

Applies when `Rm != 11111`.

```
LD1R { <Vt>.<T> }, [<Xn|SP>], <Xm>
```

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
boolean tag_checked = wback || n != 31;
```

Assembler symbols

`<Vt>` Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

`<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`8B` when `size = 00`, `Q = 0`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1
1D	when size = 11, Q = 0
2D	when size = 11, Q = 1

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> Is the post-index immediate offset, encoded in the "size" field. It can have the following values:

#1	when size = 00
#2	when size = 01
#4	when size = 10
#8	when size = 11

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

```

C7.2.180 LD2 (multiple structures)

Load multiple 2-element structures to two registers. This instruction loads multiple 2-element structures from memory and writes the result to the two SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see `LD3 (multiple structures)`.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

Assembler symbols

`<Vt>` Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

`<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`8B` when `size = 00`, `Q = 0`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1
1D	when size = 11, Q = 0
2D	when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> Is the post-index immediate offset, encoded in the "size" field. It can have the following values:

#2	when size = 00
#4	when size = 01
#8	when size = 10
#16	when size = 11

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

```

C7.2.183 LD3 (multiple structures)

Load multiple 3-element structures to three registers. This instruction loads multiple 3-element structures from memory and writes the result to the three SIMD&FP registers, with de-interleaving.

The following figure shows the operation of de-interleaving of a LD3.16 (multiple 3-element structures) instruction:.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

1D	when size = 11, Q = 0
2D	when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> Is the post-index immediate offset, encoded in the "size" field. It can have the following values:

#3	when size = 00
#6	when size = 01
#12	when size = 10
#24	when size = 11

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

```
integer init_scale = UInt(opcode<2:1>);
integer scale = init_scale;

C7.2.186 LD4 (multiple structures)

Load multiple 4-element structures to four registers. This instruction loads multiple 4-element structures from memory and writes the result to the four SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see `LD3 (multiple structures)`.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.189 LDNP (SIMD&FP)

Load Pair of SIMD&FP registers, with Non-temporal hint. This instruction loads a pair of SIMD&FP registers from memory, issuing a hint to the memory system that the access is non-temporal. The address that is used for the load is calculated from a base register value and an optional immediate offset.

For information about non-temporal pair instructions, see *Load/store SIMD and floating-point non-temporal pair* on page C3-261.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.191 LDR (immediate, SIMD&FP)

Load SIMD&FP Register (immediate offset). This instruction loads an element from memory, and writes the result as a scalar to the SIMD&FP register. The address that is used for the load is calculated from a base register value, a signed immediate offset, and an optional offset that is a multiple of the element size.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

8-bit variant

Applies when `size == 00 && opc == 01 && option != 011`.

```
LDR <Bt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

8-bit variant

Applies when `size == 00 && opc == 01 && option == 011`.

```
LDR <Bt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

16-bit variant

Applies when `size == 01 && opc == 01`.

```
LDR <Ht>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

32-bit variant

Applies when `size == 10 && opc == 01`.

```
LDR <St>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

64-bit variant

Applies when `size == 11 && opc == 01`.

```
LDR <Dt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

128-bit variant

Applies when `size == 00 && opc == 11`.

```
LDR <Qt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
integer scale = UInt(opc<1>:size);
if scale > 4 then UNDEFINED;
if option<1> == '0' then UNDEFINED;    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

`<Bt>` Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<Dt>` Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

`<Ht>` Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

`<Qt>` Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

`<St>` Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` For the 8-bit variant: is the index extend specifier, encoded in the "option" field. It can have the following values:

`UXTW` when `option = 010`

`SXTW` when `option = 110`

`SXTX` when `option = 111`

For the 128-bit, 16-bit, 32-bit and 64-bit variant: is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

`UXTW` when `option = 010`

`LSL` when `option = 011`

`SXTW` when `option = 110`

`SXTX` when `option = 111`

`<amount>` For the 8-bit variant: is the index shift amount, it must be `#0`, encoded in "S" as `0` if omitted, or as `1` if present.

For the 16-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

`#0` when `S = 0`

`#1` when `S = 1`

For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

`#0` when `S = 0`

`#2` when `S = 1`

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

`#0` when `S = 0`

`#3` when `S = 1`

For the 128-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

`#0` when `S = 0`

`#4` when `S = 1`

C7.2.194 LDUR (SIMD&FP)

Load SIMD&FP Register (unscaled offset). This instruction loads a SIMD&FP register from memory. The address that is used for the load is calculated from a base register value and an optional immediate offset.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.195 MLA (by element)

Multiply-Add to accumulator (vector, by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.199 MOV (scalar)

Move vector element to scalar. This instruction duplicates the specified vector element in the SIMD&FP source register into a scalar, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the DUP (element) instruction. This means that:

- The encodings in this description are named to match the encodings of DUP (element).
- The description of DUP (element) gives the operational pseudocode for this instruction.

31 30 29	28	27 26 25 24	23 22 21 20	16	15	14 13 12	11	10 9	5 4	0
0 1 0	1	1 1 1 0	0 0 0 0	imm5	0	0 0 0 0	1	Rn	Rd	

Encoding

```
MOV <V><d>, <Vn>.<T>[<index>]
```

is equivalent to

```
DUP  <V><d>, <Vn>.<T>[<index>]
```

and is always the preferred disassembly.

Assembler symbols

`<V>` Is the destination width specifier, encoded in the "imm5" field. It can have the following values:

- `B` when `imm5 = xxxx1`
- `H` when `imm5 = xxx10`
- `S` when `imm5 = xx100`
- `D` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<d>` Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<T>` Is the element width specifier, encoded in the "imm5" field. It can have the following values:

- `B` when `imm5 = xxxx1`
- `H` when `imm5 = xxx10`
- `S` when `imm5 = xx100`
- `D` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<index>` Is the element index encoded in the "imm5" field. It can have the following values:

- `imm5<4:1>` when `imm5 = xxxx1`
- `imm5<4:2>` when `imm5 = xxx10`
- `imm5<4:3>` when `imm5 = xx100`
- `imm5<4>` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

Operation

The description of DUP (element) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Non-Confidential

C7.2.200 MOV (element)

Move vector element to another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the INS (element) instruction. This means that:

- The encodings in this description are named to match the encodings of INS (element).
- The description of INS (element) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	11	10	9	5	4	0
0	1	1	0	1	1	1	0	0	0	0	imm5		0	imm4		1	Rn		Rd	

Encoding

```
MOV <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
```

is equivalent to

```
INS  <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
```

and is always the preferred disassembly.

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ts>` Is an element size specifier, encoded in the "imm5" field. It can have the following values:

- `B` when `imm5 = xxxx1`
- `H` when `imm5 = xxx10`
- `S` when `imm5 = xx100`
- `D` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<index1>` Is the destination element index encoded in the "imm5" field. It can have the following values:

- `imm5<4:1>` when `imm5 = xxxx1`
- `imm5<4:2>` when `imm5 = xxx10`
- `imm5<4:3>` when `imm5 = xx100`
- `imm5<4>` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<index2>` Is the source element index encoded in the "imm5:imm4" field. It can have the following values:

- `imm4<3:0>` when `imm5 = xxxx1`
- `imm4<3:1>` when `imm5 = xxx10`
- `imm4<3:2>` when `imm5 = xx100`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`imm4<3>` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

Operation

The description of INS (element) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.201 MOV (from general)

Move general-purpose register to a vector element. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the INS (general) instruction. This means that:

- The encodings in this description are named to match the encodings of INS (general).
- The description of INS (general) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	1	0	0	1	1	1	0	0	0	0	imm5		0	0	0	1	1	1	Rn		Rd	

Encoding

```
MOV <Vd>.<Ts>[<index>], <R><n>
```

is equivalent to

```
INS  <Vd>.<Ts>[<index>], <R><n>
```

and is always the preferred disassembly.

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ts>` Is an element size specifier, encoded in the "imm5" field. It can have the following values:

- `B` when `imm5 = xxxx1`
- `H` when `imm5 = xxx10`
- `S` when `imm5 = xx100`
- `D` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<index>` Is the element index encoded in the "imm5" field. It can have the following values:

- `imm5<4:1>` when `imm5 = xxxx1`
- `imm5<4:2>` when `imm5 = xxx10`
- `imm5<4:3>` when `imm5 = xx100`
- `imm5<4>` when `imm5 = x1000`

The encoding `imm5 = x0000` is reserved.

`<R>` Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:

- `W` when `imm5 = xxxx1`
- `W` when `imm5 = xxx10`
- `W` when `imm5 = xx100`
- `X` when `imm5 = x1000`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The encoding `imm5 = x0000` is reserved.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

Operation

The description of INS (general) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.202 MOV (vector)

Move vector. This instruction copies the vector in the source SIMD&FP register into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the ORR (vector, register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (vector, register).
- The description of ORR (vector, register) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0
0	Q	0	0	1	1	1	0	1	0	1	Rm	0	0	0	1	1	1	Rn	Rd
								size											

Encoding

```
MOV <Vd>.<T>, <Vn>.<T>
```

is equivalent to

```
ORR  <Vd>.<T>, <Vn>.<T>, <Vn>.<T>
```

and is the preferred disassembly when `Rm == Rn`.

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `8B` when `Q = 0`
- `16B` when `Q = 1`

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

Operation

The description of ORR (vector, register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.203 MOV (to general)

Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the UMOV instruction. This means that:

- The encodings in this description are named to match the encodings of UMOV.
- The description of UMOV gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	0	0	0	0	x	x	x	0	0	0	0	1	1	1	1	Rn	Rd
											imm5											

32-bit variant

Applies when `Q == 0 && imm5 == xx100`.

```
MOV <Wd>, <Vn>.S[<index>]
```

is equivalent to

```
UMOV <Wd>, <Vn>.S[<index>]
```

and is always the preferred disassembly.

64-bit variant

Applies when `Q == 1 && imm5 == x1000`.

```
MOV <Xd>, <Vn>.D[<index>]
```

is equivalent to

```
UMOV <Xd>, <Vn>.D[<index>]
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Vn>`	Is the name of the SIMD&FP source register, encoded in the "Rn" field.
`<index>`	For the 32-bit variant: is the element index encoded in "imm5<4:3>". For the 64-bit variant: is the element index encoded in "imm5<4>".

Operation

The description of UMOV gives the operational pseudocode for this instruction.

C7.2.204 MOVI

Move Immediate (vector). This instruction places an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15 … 12	11	10	9	8	7	6	5	4	0
0	Q	op	0	1	1	1	1	0	0	0	0	0	a	b	c	cmode	0	1	d	e	f	g	h	Rd

8-bit variant

Applies when `op == 0 && cmode == 1110`.

```
MOVI <Vd>.<T>, #<imm8>{, LSL #0}
```

16-bit shifted immediate variant

Applies when `op == 0 && cmode == 10x0`.

```
MOVI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

32-bit shifted immediate variant

Applies when `op == 0 && cmode == 0xx0`.

```
MOVI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

32-bit shifting ones variant

Applies when `op == 0 && cmode == 110x`.

```
MOVI <Vd>.<T>, #<imm8>, MSL #<amount>
```

64-bit scalar variant

Applies when `Q == 0 && op == 1 && cmode == 1110`.

```
MOVI <Dd>, #<imm>
```

64-bit vector variant

Applies when `Q == 1 && op == 1 && cmode == 1110`.

```
MOVI <Vd>.2D, #<imm>
```

Decode for all variants of this encoding

```
integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
    when '0xx00' operation = ImmediateOp_MOVI;
    when '0xx01' operation = ImmediateOp_MVNI;
    when '0xx10' operation = ImmediateOp_ORR;
    when '0xx11' operation = ImmediateOp_BIC;
    when '10x00' operation = ImmediateOp_MOVI;
```

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.

    when '11111'
        // FMOV Dn,#imm is in main FP instruction set
        if Q == '0' then UNDEFINED;
        operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

Assembler symbols

`<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<imm>` Is a 64-bit immediate 'aaaaaaaabbbbbbbbcccccccddddddddeeeeeeeeffffffffggggggggghhhhhhhh', encoded in "a:b:c:d:e:f:g:h".

`<T>` For the 8-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

`8B` when `Q = 0`

`16B` when `Q = 1`

For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

`4H` when `Q = 0`

`8H` when `Q = 1`

For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

`2S` when `Q = 0`

`4S` when `Q = 1`

`<imm8>` Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

`<amount>` For the 16-bit shifted immediate variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:

`0` when `cmode<1> = 0`

`8` when `cmode<1> = 1`

defaulting to 0 if LSL is omitted.

For the 32-bit shifted immediate variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

`0` when `cmode<2:1> = 00`

`8` when `cmode<2:1> = 01`

`16` when `cmode<2:1> = 10`

`24` when `cmode<2:1> = 11`

defaulting to 0 if LSL is omitted.

For the 32-bit shifting ones variant: is the shift amount encoded in the "cmode<0>" field. It can have the following values:

`8` when `cmode<0> = 0`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

16	when cmode<0> = 1

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.205 MUL (by element)

Multiply (vector, by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19 … 16	15	14	13	12	11	10	9 … 5	4 … 0

Encoding

```
MUL <Vd>.<T>, <Vn>.<T>, <Vm>.<Ts>[<index>]
```

Decode for this encoding

```
integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UNDEFINED;

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- `4H` when `size = 01`, `Q = 0`
- `8H` when `size = 01`, `Q = 1`
- `2S` when `size = 10`, `Q = 0`
- `4S` when `size = 10`, `Q = 1`

The following encodings are reserved:

- `size = 00`, `Q = x`.
- `size = 11`, `Q = x`.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

- `0:Rm` when `size = 01`
- `M:Rm` when `size = 10`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:

`H` when `size = 01`

`S` when `size = 10`

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

`H:L:M` when `size = 01`

`H:L` when `size = 10`

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

Operation

```
CheckFPAdvSIMDEnabled64();

C7.2.207 MVN

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the NOT instruction. This means that:

- The encodings in this description are named to match the encodings of NOT.
- The description of NOT gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9 … 5	4 … 0
0	Q	1	0	1	1	1	0	0	0	1	0	0	0	0	0	0	1	0	1	1	0	Rn	Rd

Encoding

```
MVN <Vd>.<T>, <Vn>.<T>
```

is equivalent to

```
NOT  <Vd>.<T>, <Vn>.<T>
```

and is always the preferred disassembly.

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

`8B`	when `Q = 0`
`16B`	when `Q = 1`

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

The description of NOT gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.208 MVNI

Move inverted Immediate (vector). This instruction places the inverse of an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15 – 12	11	10	9	8	7	6	5	4	0
0	Q	1	0	1	1	1	1	0	0	0	0	0	a	b	c	cmode	0	1	d	e	f	g	h	Rd	
		op																							

16-bit shifted immediate variant

Applies when `cmode == 10x0`.

```
MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

32-bit shifted immediate variant

Applies when `cmode == 0xx0`.

```
MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

32-bit shifting ones variant

Applies when `cmode == 110x`.

```
MVNI <Vd>.<T>, #<imm8>, MSL #<amount>
```

Decode for all variants of this encoding

```
integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
    when '0xx01' operation = ImmediateOp_MVNI;
    when '0xx11' operation = ImmediateOp_BIC;
    when '10x01' operation = ImmediateOp_MVNI;
    when '10x11' operation = ImmediateOp_BIC;
    when '110x1' operation = ImmediateOp_MVNI;
    when '1110x' operation = ImmediateOp_MOVI;
    when '11111'
        // FMOV Dn,#imm is in main FP instruction set
        if Q == '0' then UNDEFINED;
        operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.

<T> For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0

8H when Q = 1

For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

2S when Q = 0

4S when Q = 1

<imm8> Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

<amount> For the 16-bit shifted immediate variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:

0 when cmode<1> = 0

8 when cmode<1> = 1

defaulting to 0 if LSL is omitted.

For the 32-bit shifted immediate variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

0 when cmode<2:1> = 00

8 when cmode<2:1> = 01

16 when cmode<2:1> = 10

24 when cmode<2:1> = 11

defaulting to 0 if LSL is omitted.

For the 32-bit shifting ones variant: is the shift amount encoded in the "cmode<0>" field. It can have the following values:

8 when cmode<0> = 0

16 when cmode<0> = 1

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;
```

C7.2.210 NOT

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MVN. The alias is always the preferred disassembly.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9 … 5	4 … 0
0	Q	1	0	1	1	1	0	0	0	1	0	0	0	0	0	0	1	0	1	1	0	Rn	Rd

Encoding

```
NOT <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `8B` when `Q = 0`
- `16B` when `Q = 1`

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = NOT(element);

`<imm8>` Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

`<amount>` For the 16-bit variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:

`0` when `cmode<1> = 0`

`8` when `cmode<1> = 1`

defaulting to 0 if LSL is omitted.

For the 32-bit variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

`0` when `cmode<2:1> = 00`

`8` when `cmode<2:1> = 01`

`16` when `cmode<2:1> = 10`

`24` when `cmode<2:1> = 11`

defaulting to 0 if LSL is omitted.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;
```

Operational information

If PSTATE.DIT is 1:

C7.2.213 ORR (vector, register)

Bitwise inclusive OR (vector, register). This instruction performs a bitwise OR between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (vector). See *Alias conditions* for details of when each alias is preferred.

31	30	29	28	27	26	25	24	23	22	21	20–16	15	14	13	12	11	10	9–5	4–0
0	Q	0	0	1	1	1	0	1	0	1	Rm	0	0	0	1	1	1	Rn	Rd
								size											

Encoding

```
ORR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

Alias conditions

Alias	is preferred when
MOV (vector)	`Rm == Rn`

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `8B` when `Q = 0`
- `16B` when `Q = 1`

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

result = operand1 OR operand2;

V[d] = result;

C7.2.214 PMUL

Polynomial Multiply. This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

For information about multiplying polynomials see *Polynomial arithmetic over {0, 1}* on page A1-54.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0
0	Q	1	0	1	1	1	0	size	1	Rm	1	0	0	1	1	1	Rn	Rd
		U																

Encoding

```
PMUL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if U == '1' && size != '00' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean poly = (U == '1');
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`8B` when `size = 00`, `Q = 0`

`16B` when `size = 00`, `Q = 1`

The following encodings are reserved:

- `size = 01`, `Q = x`.
- `size = 1x`, `Q = x`.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) product;

for e = 0 to elements-1
```

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if poly then
        product = PolynomialMult(element1, element2)<esize-1:0>;
    else
        product = (UInt(element1)*UInt(element2))<esize-1:0>;
    Elem[result, e, esize] = product;

V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

C7.2.215 PMULL, PMULL2

Polynomial Multiply Long. This instruction multiplies corresponding elements in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials see *Polynomial arithmetic over {0, 1}* on page A1-54.

The `PMULL` instruction extracts each source vector from the lower half of each source register. The `PMULL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

`8H` when `size = 00`

`1Q` when `size = 11`

The following encodings are reserved:

- `size = 01`.
- `size = 10`.

The '1Q' arrangement is only allocated in an implementation that includes the Cryptographic Extension, and is otherwise RESERVED.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when `size = 00`, `Q = 0`

16B when `size = 00`, `Q = 1`

1D when `size = 11`, `Q = 0`

2D when `size = 11`, `Q = 1`

The following encodings are reserved:

- `size = 01`, `Q = x`.
- `size = 10`, `Q = x`.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, 2*esize] = PolynomialMult(element1, element2);

V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.216 RADDHN, RADDHN2

Rounding Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see ADDHN, ADDHN2.

The `RADDHN` instruction writes the vector to the lower half of the destination register and clears the upper half, while the `RADDHN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.222 RSHRN, RSHRN2

Rounding Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the vector in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SHRN, SHRN2.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Encoding

```
RSHRN{2} <Vd>.<Tb>, <Vn>.<Ta>, #<shift>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
```

Assembler symbols

2 — Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd> — Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> — Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000, Q = x.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The encoding `immh = 1xxx`, `Q = x` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Ta>` Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

`8H` when `immh = 0001`

`4S` when `immh = 001x`

`2D` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

`<shift>` Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;

Vpart[d, part] = result;
```

C7.2.223 RSUBHN, RSUBHN2

Rounding Subtract returning High Narrow. This instruction subtracts each vector element of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see SUBHN, SUBHN2.

The `RSUBHN` instruction writes the vector to the lower half of the destination register and clears the upper half, while the `RSUBHN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.229 SADDL, SADDL2

Signed Add Long (vector). This instruction adds each vector element in the lower or upper half of the first source SIMD&FP register to the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The `SADDL` instruction extracts each source vector from the lower half of each source register. The `SADDL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0
0	Q	0	0	1	1	1	0	size	1	Rm	0	0	0	0	0	0	Rn	Rd
		U											o1					

Encoding

```
SADDL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- `[absent]` when `Q = 0`
- `[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- `8H` when `size = 00`
- `4S` when `size = 01`
- `2D` when `size = 10`

The encoding `size = 11` is reserved.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- `8B` when `size = 00`, `Q = 0`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.

16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

C7.2.230 SADDLP

Signed Add Long Pairwise. This instruction adds pairs of adjacent signed integer values from the vector in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20	19	18	17	16	15	14	13	12	11	10	9 5	4 0

C7.2.231 SADDLV

Signed Add Long across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register. The destination scalar is twice as long as the source vector elements. All the values in this instruction are signed integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20	19	18	17	16	15	14	13	12	11	10	9 … 5	4 … 0
0	Q	0	0	1	1	1	0	size	1	1	0	0	0	0	0	0	1	1	1	0	Rn	Rd
		U																				

Encoding

```
SADDLV <V><d>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:

- H when `size = 00`
- S when `size = 01`
- D when `size = 10`

The encoding `size = 11` is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when `size = 00, Q = 0`
- 16B when `size = 00, Q = 1`
- 4H when `size = 01, Q = 0`
- 8H when `size = 01, Q = 1`
- 4S when `size = 10, Q = 1`

The following encodings are reserved:

- `size = 10, Q = 0`.
- `size = 11, Q = x`.

C7.2.232 SADDW, SADDW2

Signed Add Wide. This instruction adds vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the results in a vector, and writes the vector to the SIMD&FP destination register.

The `SADDW` instruction extracts the second source vector from the lower half of the second source register. The `SADDW2` instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0
0	Q	0	0	1	1	1	0	size	1	Rm	0	0	0	1	0	0	Rn	Rd
		U											o1					

Encoding

```
SADDW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- `[absent]` when `Q = 0`
- `[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- `8H` when `size = 00`
- `4S` when `size = 01`
- `2D` when `size = 10`

The encoding `size = 11` is reserved.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

C7.2.233 SCVTF (vector, fixed-point)

Signed fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 001x

S when immh = 01xx

D when immh = 1xxx

The encoding immh = 000x is reserved.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

2D when immh = 1xxx, Q = 1

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000, Q = x.

The following encodings are reserved:

- immh = 0001, Q = x.
- immh = 1xxx, Q = 0.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:

(32-Uint(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

The encoding immh = 000x is reserved.

For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:

(32-Uint(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000.

The encoding immh = 0001 is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();

<T> For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0

8H when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];

FPCRType fpcr = FPCR[];
boolean merge = elements == 1 && IsMerging(fpcr);
bits(128) result = if merge then V[d] else Zeros();

FPRounding rounding = FPRoundingMode(fpcr);
bits(esize) element;
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FixedToFP(element, 0, unsigned, fpcr, rounding);

V[d] = result;
```

C7.2.235 SCVTF (scalar, fixed-point)

Signed fixed-point Convert to Floating-point (scalar). This instruction converts the signed value in the 32-bit or 64-bit general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20	19	18	16	15 10	9 5	4 0
sf	0	0	1	1	1	1	0	ftype	0	0	0	1	0	scale	Rn	Rd
										rmode		opcode				

32-bit to half-precision variant

Applies when `sf == 0 && ftype == 11`.

```
SCVTF <Hd>, <Wn>, #<fbits>
```

32-bit to single-precision variant

Applies when `sf == 0 && ftype == 00`.

```
SCVTF <Sd>, <Wn>, #<fbits>
```

32-bit to double-precision variant

Applies when `sf == 0 && ftype == 01`.

```
SCVTF <Dd>, <Wn>, #<fbits>
```

64-bit to half-precision variant

Applies when `sf == 1 && ftype == 11`.

```
SCVTF <Hd>, <Xn>, #<fbits>
```

64-bit to single-precision variant

Applies when `sf == 1 && ftype == 00`.

```
SCVTF <Sd>, <Xn>, #<fbits>
```

64-bit to double-precision variant

Applies when `sf == 1 && ftype == 01`.

```
SCVTF <Dd>, <Xn>, #<fbits>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPRounding rounding;
```

C7.2.237 SDOT (by element)

Dot Product signed arithmetic (vector, by element). This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.DP indicates whether this instruction is supported.

Vector

(FEAT_DotProd)

31	30	29	28	27	26	25	24	23 22	21	20	19 16	15	14	13	12	11	10	9 5	4 0
0	Q	0	0	1	1	1	1	size	L	M	Rm	1	1	1	0	H	0	Rn	Rd
		U																	

Encoding

```
SDOT <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.4B[<index>]
```

Decode for this encoding

```
if !HaveDOTPExt() then UNDEFINED;
if size != '10' then UNDEFINED;
boolean signed = (U == '0');

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(M:Rm);
integer index = UInt(H:L);

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP third source and destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `2S` when `Q = 0`
- `4S` when `Q = 1`

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `8B` when `Q = 0`
- `16B` when `Q = 1`

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.

C7.2.244 SHA1SU1

SHA1 schedule update 1.

31 30 29 28	27 26 25 24	23 22	21 20 19 18 17	16 15 14 13 12	11 10	9 5	4 0
0 1 0 1	1 1 1 0	0 0	1 0 1 0 0	0 0 0 0 1	1 0	Rn	Rd

Encoding

```
SHA1SU1 <Vd>.4S, <Vn>.4S
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HaveSHA1Ext() then UNDEFINED;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP source and destination register, encoded in the "Rd" field.

<Vn> Is the name of the second SIMD&FP source register, encoded in the "Rn" field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

bits(128) operand1 = V[d];
bits(128) operand2 = V[n];
bits(128) result;
bits(128) T = operand1 EOR LSR(operand2, 32);
result<31:0> = ROL(T<31:0>, 1);
result<63:32> = ROL(T<63:32>, 1);
result<95:64> = ROL(T<95:64>, 1);
result<127:96> = ROL(T<127:96>, 1) EOR ROL(T<31:0>, 2);
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.253 SHADD

Signed Halving Add. This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SRHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 16	15	14	13	12	11	10	9 5	4 0
0	Q	0	0	1	1	1	0	size	1	Rm	0	0	0	0	0	1	Rn	Rd
		U																

Encoding

```
SHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;

integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
```

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:

D when immh = 1xxx

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The encoding `immh = 0xxx` is reserved.

`<d>` Is the number of the SIMD&FP destination register, in the "Rd" field.

`<n>` Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

`8B`	when `immh = 0001`, `Q = 0`
`16B`	when `immh = 0001`, `Q = 1`
`4H`	when `immh = 001x`, `Q = 0`
`8H`	when `immh = 001x`, `Q = 1`
`2S`	when `immh = 01xx`, `Q = 0`
`4S`	when `immh = 01xx`, `Q = 1`
`2D`	when `immh = 1xxx`, `Q = 1`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`, `Q = x`.

The encoding `immh = 1xxx`, `Q = 0` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<shift>` For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the "immh:immb" field. It can have the following values:

`(UInt(immh:immb)-64)`	when `immh = 1xxx`

The encoding `immh = 0xxx` is reserved.

For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

`(UInt(immh:immb)-8)`	when `immh = 0001`
`(UInt(immh:immb)-16)`	when `immh = 001x`
`(UInt(immh:immb)-32)`	when `immh = 01xx`
`(UInt(immh:immb)-64)`	when `immh = 1xxx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = LSL(Elem[operand, e, esize], shift);

V[d] = result;
```

C7.2.255 SHLL, SHLL2

Shift Left Long (by element size). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, left shifts each result by the element size, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The `SHLL` instruction extracts vector elements from the lower half of the source register. The `SHLL2` instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20	19	18	17	16	15	14	13	12	11	10	9 5	4 0
0	Q	1	0	1	1	1	0	size	1	0	0	0	0	1	0	0	1	1	1	0	Rn	Rd

Encoding

```
SHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = esize;
boolean unsigned = FALSE;    // Or TRUE without change of functionality
```

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

`8H` when `size = 00`

`4S` when `size = 01`

`2D` when `size = 10`

The encoding `size = 11` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`8B` when `size = 00`, `Q = 0`

`16B` when `size = 00`, `Q = 1`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<shift> Is the left shift amount, which must be equal to the source element width in bits, encoded in the "size" field. It can have the following values:

8	when size = 00
16	when size = 01
32	when size = 10

The encoding size = 11 is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(2*datasize) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

Operational information

C7.2.256 SHRN, SHRN2

Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are truncated. For rounded results, see RSHRN, RSHRN2.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	1	0	!=0000	immb			1	0	0	0	0	1	Rn	Rd		
									immh								op					

Encoding

```
SHRN{2} <Vd>.<Tb>, <Vn>.<Ta>, #<shift>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000, Q = x.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The encoding `immh = 1xxx`, `Q = x` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Ta>` Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

`8H` when `immh = 0001`

`4S` when `immh = 001x`

`2D` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

`<shift>` Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;

Vpart[d, part] = result;
```

Operational information

C7.2.257 SHSUB

Signed Halving Subtract. This instruction subtracts the elements in the vector in the second source SIMD&FP register from the corresponding elements in the vector in the first source SIMD&FP register, shifts each result right one bit, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0

C7.2.258 SLI

Shift Left and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, left shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the left of each vector element in the source register are lost.

The following figure shows the operation of shift left by 3 for an 8-bit vector element.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

C7.2.261 SM3SS1

SM3SS1 rotates the top 32 bits of the 128-bit vector in the first source SIMD&FP register by 12, and adds that 32-bit value to the two other 32-bit values held in the top 32 bits of each of the 128-bit vectors in the second and third source SIMD&FP registers, rotating this result left by 7 and writing the final result into the top 32 bits of the vector in the destination SIMD&FP register, with the bottom 96 bits of the vector being written to 0.

This instruction is implemented only when FEAT_SM3 is implemented.

C7.2.262 SM3TT1A

SM3TT1A takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive OR.
- The result of the exclusive OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

This instruction is implemented only when FEAT_SM3 is implemented.

C7.2.263 SM3TT1B

SM3TT1B takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a 32-bit majority function between the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the 32-bit majority function.
- The result of the exclusive OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

This instruction is implemented only when FEAT_SM3 is implemented.

C7.2.264 SM3TT2A

SM3TT2A takes three 128-bit vectors from three source SIMD&FP register and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive OR.
- The 32-bit element held in the top 32 bits of the second source vector, Vn.
- A 32-bit element indexed out of the third source vector, Vm.

A three-way exclusive OR is performed of the result of this addition, the result of the addition rotated left by 9, and the result of the addition rotated left by 17. The result of this exclusive OR is returned as the top element of the returned result. The other elements of this result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 19.

This instruction is implemented only when FEAT_SM3 is implemented.

C7.2.269 SMAXP

Signed Maximum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.274 SMLAL, SMLAL2 (by element)

Signed Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element in the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

The `SMLAL` instruction extracts vector elements from the lower half of the first source register. The `SMLAL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20	19 16	15	14	13	12	11	10	9 5	4 0

C7.2.276 SMLSL, SMLSL2 (by element)

Signed Multiply-Subtract Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The `SMLSL` instruction extracts vector elements from the lower half of the first source register. The `SMLSL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

boolean sub_op = (o2 == '1');
```

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

`4S` when `size = 01`

`2D` when `size = 10`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`4H`	when `size = 01`, `Q = 0`
`8H`	when `size = 01`, `Q = 1`
`2S`	when `size = 10`, `Q = 0`
`4S`	when `size = 10`, `Q = 1`

The following encodings are reserved:

- `size = 00`, `Q = x`.
- `size = 11`, `Q = x`.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

`0:Rm`	when `size = 01`
`M:Rm`	when `size = 10`

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:

`H`	when `size = 01`
`S`	when `size = 10`

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

`H:L:M`	when `size = 01`
`H:L`	when `size = 10`

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxdsize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
```

C7.2.277 SMLSL, SMLSL2 (vector)

Signed Multiply-Subtract Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The `SMLSL` instruction extracts each source vector from the lower half of each source register. The `SMLSL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0
0	Q	0	0	1	1	1	0	size	1	Rm	1	0	1	0	0	0	Rn	Rd
		U											o1					

Encoding

```
SMLSL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- `[absent]` when `Q = 0`
- `[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- `8H` when `size = 00`
- `4S` when `size = 01`
- `2D` when `size = 10`

The encoding `size = 11` is reserved.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- `8B` when `size = 00`, `Q = 0`
- `16B` when `size = 00`, `Q = 1`

C7.2.278 SMMLA (vector)

Signed 8-bit integer matrix multiply-accumulate. This instruction multiplies the 2x8 matrix of signed 8-bit integer values in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

(FEAT_I8MM)

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	1	0	0	1	1	1	0	1	0	0	Rm		1	0	1	0	0	1	Rn		Rd	
		U															B					

Encoding

```
SMMLA <Vd>.4S, <Vn>.16B, <Vm>.16B
```

Decode for this encoding

```
if !HaveInt8MatMulExt() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);
integer d = UInt(Rd);
```

Assembler symbols

`<Vd>`	Is the name of the SIMD&FP third source and destination register, encoded in the "Rd" field.
`<Vn>`	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
`<Vm>`	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(128) operand1 = V[n];
bits(128) operand2 = V[m];
bits(128) addend = V[d];

V[d] = MatMulAdd(addend, operand1, operand2, FALSE, FALSE);
```

C7.2.279 SMOV

Signed Move vector element to general-purpose register. This instruction reads the signed integer from the source SIMD&FP register, sign-extends it to form a 32-bit or 64-bit value, and writes the result to destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	0	0	0	0	imm5		0	0	1	0	1	1	Rn		Rd	

32-bit variant

Applies when `Q == 0`.

```
SMOV <Wd>, <Vn>.<Ts>[<index>]
```

64-bit variant

Applies when `Q == 1`.

```
SMOV <Xd>, <Vn>.<Ts>[<index>]
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size;
case Q:imm5 of
    when 'xxxxx1' size = 0;    // SMOV [WX]d, Vn.B
    when 'xxxx10' size = 1;    // SMOV [WX]d, Vn.H
    when '1xx100' size = 2;    // SMOV Xd, Vn.S
    otherwise UNDEFINED;

integer idxdsize = if imm5<4> == '1' then 128 else 64;
integer index = UInt(imm5<4:size+1>);
integer esize = 8 << size;
integer datasize = if Q == '1' then 64 else 32;
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Ts>` For the 32-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:

`B` when `imm5 = xxxx1`

`H` when `imm5 = xxx10`

The encoding `imm5 = xxx00` is reserved.

For the 64-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:

`B` when `imm5 = xxxx1`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H when imm5 = xxx10

S when imm5 = xx100

The encoding imm5 = xx000 is reserved.

<index> For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:

imm5<4:1> when imm5 = xxxx1

imm5<4:2> when imm5 = xxx10

The encoding imm5 = xxx00 is reserved.

For the 64-bit variant: is the element index encoded in the "imm5" field. It can have the following values:

imm5<4:1> when imm5 = xxxx1

imm5<4:2> when imm5 = xxx10

imm5<4:3> when imm5 = xx100

The encoding imm5 = xx000 is reserved.

Operation

```
if index == 0 then
    CheckFPEnabled64();
else
    CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];

X[d] = SignExtend(Elem[operand, index, esize], datasize);
```

C7.2.280 SMULL, SMULL2 (by element)

Signed Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The `SMULL` instruction extracts vector elements from the lower half of the first source register. The `SMULL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.282 SQABS

Signed saturating Absolute value. This instruction reads each vector element from the source SIMD&FP register, puts the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

H	when size = 01
S	when size = 10
D	when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1
2D	when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    (Elem[result, e, esize], sat) = SignedSatQ(element, esize);
    if sat then FPSR.QC = '1';

V[d] = result;
```

C7.2.283 SQADD

Signed saturating Add. This instruction adds the values of corresponding elements of the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

C7.2.284 SQDMLAL, SQDMLAL2 (by element)

Signed saturating Doubling Multiply-Add Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMLAL` instruction extracts vector elements from the lower half of the first source register. The `SQDMLAL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

`4S` when `size = 01`

`2D` when `size = 10`

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`4H` when `size = 01`, `Q = 0`

`8H` when `size = 01`, `Q = 1`

`2S` when `size = 10`, `Q = 0`

`4S` when `size = 10`, `Q = 1`

The following encodings are reserved:

- `size = 00`, `Q = x`.
- `size = 11`, `Q = x`.

`<Va>` Is the destination width specifier, encoded in the "size" field. It can have the following values:

`S` when `size = 01`

`D` when `size = 10`

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

C7.2.285 SQDMLAL, SQDMLAL2 (vector)

Signed saturating Doubling Multiply-Add Long. This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMLAL` instruction extracts each source vector from the lower half of each source register. The `SQDMLAL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, doubles the results, and subtracts the final results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMLSL` instruction extracts each source vector from the lower half of each source register. The `SQDMLSL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

4S when size = 01

2D when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

The following encodings are reserved:

- size = 00, Q = x.
- size = 11, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<Va> Is the destination width specifier, encoded in the "size" field. It can have the following values:

S when size = 01

D when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vb> Is the source width specifier, encoded in the "size" field. It can have the following values:

H when size = 01

S when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

C7.2.288 SQDMULH (by element)

Signed saturating Doubling Multiply returning High half (by element). This instruction multiplies each vector element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SQRDMULH (by element).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.290 SQDMULL, SQDMULL2 (by element)

Signed saturating Doubling Multiply Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the final results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMULL` instruction extracts the first source vector from the lower half of the first source register. The `SQDMULL2` instruction extracts the first source vector from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.291 SQDMULL, SQDMULL2 (vector)

Signed saturating Doubling Multiply Long. This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, doubles the results, places the final results in a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMULL` instruction extracts each source vector from the lower half of each source register. The `SQDMULL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.292 SQNEG

Signed saturating Negate. This instruction reads each vector element from the source SIMD&FP register, negates each value, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.297 SQRDMULH (by element)

Signed saturating Rounding Doubling Multiply returning High half (by element). This instruction multiplies each vector element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see SQDMULH (by element).

If any of the results overflows, they are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.299 SQRSHL

Signed saturating Rounding Shift Left (register). This instruction takes each vector element in the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see SQSHL (register).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.300 SQRSHRN, SQRSHRN2

Signed saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SQSHRN, SQSHRN2.

The SQRSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001

4S when immh = 001x

2D when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001

H when immh = 001x

S when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001

S when immh = 001x

D when immh = 01xx

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

`<n>` Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

`<shift>` For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

C7.2.301 SQRSHRUN, SQRSHRUN2

Signed saturating Rounded Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are rounded. For truncated results, see SQSHRUN, SQSHRUN2.

The SQRSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001

4S when immh = 001x

2D when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001

H when immh = 001x

S when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001

S when immh = 001x

D when immh = 01xx

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

`<n>` Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

`<shift>` For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (SInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    (Elem[result, e, esize], sat) = UnsignedSatQ(element, esize);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

C7.2.302 SQSHL (immediate)

Signed saturating Shift Left (immediate). This instruction reads each vector element in the source SIMD&FP register, shifts each result by an immediate value, places the final result in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

C7.2.303 SQSHL (register)

Signed saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see SQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.305 SQSHRN, SQSHRN2

Signed saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts and truncates each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. For rounded results, see SQRSHRN, SQRSHRN2.

The `SQSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half, while the `SQSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Tb>` Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

`8B` when `immh = 0001`, `Q = 0`

`16B` when `immh = 0001`, `Q = 1`

`4H` when `immh = 001x`, `Q = 0`

`8H` when `immh = 001x`, `Q = 1`

`2S` when `immh = 01xx`, `Q = 0`

`4S` when `immh = 01xx`, `Q = 1`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`, `Q = x`.

The encoding `immh = 1xxx`, `Q = x` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Ta>` Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

`8H` when `immh = 0001`

`4S` when `immh = 001x`

`2D` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

`<Vb>` Is the destination width specifier, encoded in the "immh" field. It can have the following values:

`B` when `immh = 0001`

`H` when `immh = 001x`

`S` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

`<d>` Is the number of the SIMD&FP destination register, in the "Rd" field.

`<Va>` Is the source width specifier, encoded in the "immh" field. It can have the following values:

`H` when `immh = 0001`

`S` when `immh = 001x`

`D` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

`<n>` Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

`<shift>` For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

C7.2.306 SQSHRUN, SQSHRUN2

Signed saturating Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see SQRSHRUN, SQRSHRUN2.

The `SQSHRUN` instruction writes the vector to the lower half of the destination register and clears the upper half, while the `SQSHRUN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001

4S when immh = 001x

2D when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001

H when immh = 001x

S when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001

S when immh = 001x

D when immh = 01xx

The following encodings are reserved:

- immh = 0000.

C7.2.308 SQXTN, SQXTN2

Signed saturating extract Narrow. This instruction reads each vector element from the source SIMD&FP register, saturates the value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQXTN` instruction writes the vector to the lower half of the destination register and clears the upper half, while the `SQXTN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.311 SRI

Shift Right and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the right of each vector element of the source register are lost.

The following figure shows the operation of shift right by 3 for an 8-bit vector element.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

`<V>` Is a width specifier, encoded in the "immh" field. It can have the following values:

`D` when `immh = 1xxx`

The encoding `immh = 0xxx` is reserved.

`<d>` Is the number of the SIMD&FP destination register, in the "Rd" field.

`<n>` Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

`8B` when `immh = 0001`, `Q = 0`

`16B` when `immh = 0001`, `Q = 1`

`4H` when `immh = 001x`, `Q = 0`

`8H` when `immh = 001x`, `Q = 1`

`2S` when `immh = 01xx`, `Q = 0`

`4S` when `immh = 01xx`, `Q = 1`

`2D` when `immh = 1xxx`, `Q = 1`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`, `Q = x`.

The encoding `immh = 1xxx`, `Q = 0` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<shift>` For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:

`(128-UInt(immh:immb))` when `immh = 1xxx`

The encoding `immh = 0xxx` is reserved.

For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

`(128-UInt(immh:immb))` when `immh = 1xxx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2 = V[d];
```

C7.2.312 SRSHL

Signed Rounding Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see SSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.315 SSHL

Signed Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts each value by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift. For a rounding shift, see SRSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

C7.2.316 SSHLL, SSHLL2

Signed Shift Left Long (immediate). This instruction reads each vector element from the source SIMD&FP register, left shifts each vector element by the specified shift amount, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The `SSHLL` instruction extracts vector elements from the lower half of the source register. The `SSHLL2` instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias SXTL, SXTL2. See *Alias conditions* for details of when each alias is preferred.

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	1	0	!=0000	immb			1	0	1	0	0	1	Rn		Rd	
	U								immh													

Encoding

```
SSHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
boolean unsigned = (U == '1');
```

Alias conditions

Alias	is preferred when
SXTL, SXTL2	`immb == '000' && BitCount(immh) == 1`

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

`8H` when `immh = 0001`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

4S when immh = 001x

2D when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<shift> Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

(UInt(immh:immb)-8) when immh = 0001

(UInt(immh:immb)-16) when immh = 001x

(UInt(immh:immb)-32) when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.317 SSHR

Signed Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, places the final result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are truncated. For rounded results, see SRSHR.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

C7.2.319 SSUBL, SSUBL2

Signed Subtract Long. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are twice as long as the source vector elements.

The `SSUBL` instruction extracts each source vector from the lower half of each source register. The `SSUBL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.321 ST1 (multiple structures)

Store multiple single-element structures from one, two, three, or four registers. This instruction stores elements to memory from one, two, three, or four SIMD&FP registers, without interleaving. Every element of each register is stored.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

No offset

Applies when `Rm == 11111 && opcode == 1010`.

```
ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>
```

Two registers, register offset variant

Applies when `Rm != 11111 && opcode == 1010`.

```
ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>
```

Three registers, immediate offset variant

Applies when `Rm == 11111 && opcode == 0110`.

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <imm>
```

Three registers, register offset variant

Applies when `Rm != 11111 && opcode == 0110`.

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>
```

Four registers, immediate offset variant

Applies when `Rm == 11111 && opcode == 0010`.

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>
```

Four registers, register offset variant

Applies when `Rm != 11111 && opcode == 0010`.

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>
```

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
boolean tag_checked = wback || n != 31;
```

Assembler symbols

`<Vt>` Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

`<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`8B`	when `size = 00`, `Q = 0`
`16B`	when `size = 00`, `Q = 1`
`4H`	when `size = 01`, `Q = 0`
`8H`	when `size = 01`, `Q = 1`
`2S`	when `size = 10`, `Q = 0`
`4S`	when `size = 10`, `Q = 1`
`1D`	when `size = 11`, `Q = 0`

2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

<Vt4> Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> For the one register, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#8 when Q = 0

#16 when Q = 1

For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#16 when Q = 0

#32 when Q = 1

For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#24 when Q = 0

#48 when Q = 1

For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#32 when Q = 0

#64 when Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

C7.2.322 ST1 (single structure)

Store a single-element structure from one lane of one register. This instruction stores the specified element of a SIMD&FP register to memory.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
boolean tag_checked = wback || n != 31;
```

Assembler symbols

`<Vt>`	Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
`<Vt2>`	Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
`<index>`	For the 8-bit variant: is the element index, encoded in "Q:S:size". For the 16-bit variant: is the element index, encoded in "Q:S:size<1>". For the 32-bit variant: is the element index, encoded in "Q:S". For the 64-bit variant: is the element index, encoded in "Q".
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<Xm>`	Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

C7.2.325 ST3 (multiple structures)

Store multiple 3-element structures from three registers. This instruction stores multiple 3-element structures to memory from three SIMD&FP registers, with interleaving. Every element of each register is stored.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.328 ST4 (single structure)

Store single 4-element structure from one lane of four registers. This instruction stores a 4-element structure to memory from corresponding elements of four SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

No offset

C7.2.329 STNP (SIMD&FP)

Store Pair of SIMD&FP registers, with Non-temporal hint. This instruction stores a pair of SIMD&FP registers to memory, issuing a hint to the memory system that the access is non-temporal. The address used for the store is calculated from an address from a base register value and an immediate offset. For information about non-temporal pair instructions, see *Load/store SIMD and floating-point non-temporal pair* on page C3-261.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

128-bit variant

Applies when `size == 00 && opc == 10`.

```
STR <Qt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(opc<1>:size);
if scale > 4 then UNDEFINED;
bits(64) offset = LSL(ZeroExtend(imm12, 64), scale);
```

Assembler symbols

`<Bt>`	Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
`<Dt>`	Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
`<Ht>`	Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
`<Qt>`	Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
`<St>`	Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<simm>`	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
`<pimm>`	For the 8-bit variant: is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For the 16-bit variant: is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2. For the 32-bit variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4. For the 64-bit variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8. For the 128-bit variant: is the optional positive immediate byte offset, a multiple of 16 in the range 0 to 65520, defaulting to 0 and encoded in the "imm12" field as <pimm>/16.

Shared decode for all encodings

```
integer n = UInt(Rn);

C7.2.332 STR (register, SIMD&FP)

Store SIMD&FP register (register offset). This instruction stores a single SIMD&FP register to memory. The address that is used for the store is calculated from a base register value and an offset register value. The offset can be optionally shifted and extended.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31 30	29 28	27	26	25 24	23 22	21	20 16	15 13	12	11 10	9 5	4 0
size	1 1	1	1	0 0	x 0	1	Rm	option	S	1 0	Rn	Rt
					opc							

8-bit variant

Applies when `size == 00 && opc == 00 && option != 011`.

```
STR <Bt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

8-bit variant

Applies when `size == 00 && opc == 00 && option == 011`.

```
STR <Bt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

16-bit variant

Applies when `size == 01 && opc == 00`.

```
STR <Ht>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

32-bit variant

Applies when `size == 10 && opc == 00`.

```
STR <St>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

64-bit variant

Applies when `size == 11 && opc == 00`.

```
STR <Dt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

128-bit variant

Applies when `size == 00 && opc == 10`.

```
STR <Qt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
integer scale = UInt(opc<1>:size);
if scale > 4 then UNDEFINED;
if option<1> == '0' then UNDEFINED;    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

`<Bt>` Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<Dt>` Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

`<Ht>` Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

`<Qt>` Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

`<St>` Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` For the 8-bit variant: is the index extend specifier, encoded in the "option" field. It can have the following values:

`UXTW` when `option = 010`

`SXTW` when `option = 110`

`SXTX` when `option = 111`

For the 128-bit, 16-bit, 32-bit and 64-bit variant: is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

`UXTW` when `option = 010`

`LSL` when `option = 011`

`SXTW` when `option = 110`

`SXTX` when `option = 111`

`<amount>` For the 8-bit variant: is the index shift amount, it must be `#0`, encoded in "S" as `0` if omitted, or as `1` if present.

For the 16-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

`#0` when `S = 0`

`#1` when `S = 1`

For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

`#0` when `S = 0`

`#2` when `S = 1`

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

`#0` when `S = 0`

`#3` when `S = 1`

For the 128-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

`#0` when `S = 0`

`#4` when `S = 1`

Non-Confidential

C7.2.335 SUBHN, SUBHN2

Subtract returning High Narrow. This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values.

The results are truncated. For rounded results, see RSUBHN, RSUBHN2.

The `SUBHN` instruction writes the vector to the lower half of the destination register and clears the upper half, while the `SUBHN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0

C7.2.336 SUDOT (by element)

Dot product index form with signed and unsigned integers. This instruction performs the dot product of the four signed 8-bit integer values in each 32-bit element of the first source register with the four unsigned 8-bit integer values in an indexed 32-bit element of the second source register, accumulating the result into the corresponding 32-bit element of the destination vector.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

(FEAT_I8MM)

C7.2.337 SUQADD

Signed saturating Accumulate of Unsigned value. This instruction adds the unsigned integer values of the vector elements in the source SIMD&FP register to corresponding signed integer values of the vector elements in the destination SIMD&FP register, and writes the resulting signed integer values to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(datasize) operand2 = V[d];
integer op1;
integer op2;
boolean sat;

for e = 0 to elements-1
    op1 = Int(Elem[operand, e, esize], !unsigned);
    op2 = Int(Elem[operand2, e, esize], unsigned);
    (Elem[result, e, esize], sat) = SatQ(op1 + op2, esize, unsigned);
    if sat then FPSR.QC = '1';
V[d] = result;
```

C7.2.338 SXTL, SXTL2

Signed extend Long. This instruction duplicates each vector element in the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The `SXTL` instruction extracts the source vector from the lower half of the source register. The `SXTL2` instruction extracts the source vector from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the SSHLL, SSHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of SSHLL, SSHLL2.
- The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	1	0	!=0000	0	0	0	1	0	1	0	0	1	Rn		Rd	
		U							immh		immb											

Encoding

```
SXTL{2} <Vd>.<Ta>, <Vn>.<Tb>
```

is equivalent to

```
SSHLL{2}  <Vd>.<Ta>, <Vn>.<Tb>, #0
```

and is the preferred disassembly when `BitCount(immh) == 1`.

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

`8H` when `immh = 0001`

`4S` when `immh = 001x`

`2D` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

`8B` when `immh = 0001`, `Q = 0`

`16B` when `immh = 0001`, `Q = 1`

`4H` when `immh = 001x`, `Q = 0`

`8H` when `immh = 001x`, `Q = 1`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`2S` when `immh = 01xx`, `Q = 0`

`4S` when `immh = 01xx`, `Q = 1`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`, `Q = x`.

The encoding `immh = 1xxx`, `Q = x` is reserved.

Operation

The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.339 TBL

Table vector Lookup. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the result for that lookup is 0. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20 … 16	15	14 13 12	11	10	9 … 5	4 … 0
0	Q	0	0	1	1	1	0	0	0	0	Rm	0	len	0	0	Rn	Rd
													op				

Two register table variant

Applies when `len == 01`.

```
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B }, <Vm>.<Ta>
```

Three register table variant

Applies when `len == 10`.

```
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B }, <Vm>.<Ta>
```

Four register table variant

Applies when `len == 11`.

```
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B, <Vn+3>.16B }, <Vm>.<Ta>
```

Single register table variant

Applies when `len == 00`.

```
TBL <Vd>.<Ta>, { <Vn>.16B }, <Vm>.<Ta>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `8B` when `Q = 0`
- `16B` when `Q = 1`

`<Vn>` For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the "Rn" field.

For the single register table variant: is the name of the SIMD&FP table register, encoded in the "Rn" field.

`<Vn+1>` Is the name of the second SIMD&FP table register, encoded as "Rn" plus 1 modulo 32.

`<Vn+2>` Is the name of the third SIMD&FP table register, encoded as "Rn" plus 2 modulo 32.

`<Vn+3>` Is the name of the fourth SIMD&FP table register, encoded as "Rn" plus 3 modulo 32.

`<Vm>` Is the name of the SIMD&FP index register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) indices = V[m];
bits(128*regs) table = Zeros();
bits(datasize) result;
integer index;

// Create table from registers
for i = 0 to regs-1
    table<128*i+127:128*i> = V[n];
    n = (n + 1) MOD 32;

result = if is_tbl then Zeros() else V[d];
for i = 0 to elements-1
    index = UInt(Elem[indices, i, 8]);
    if index < 16 * regs then
        Elem[result, i, 8] = Elem[table, index, 8];

V[d] = result;
```

Operational information

C7.2.340 TBX

Table vector lookup extension. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the existing value in the vector element of the destination register is left unchanged. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20 … 16	15	14 13	12	11	10	9 … 5	4 … 0
0	Q	0	0	1	1	1	0	0	0	0	Rm	0	len	1	0	0	Rn	Rd
														op				

Two register table variant

Applies when `len == 01`.

```
TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B }, <Vm>.<Ta>
```

Three register table variant

Applies when `len == 10`.

```
TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B }, <Vm>.<Ta>
```

Four register table variant

Applies when `len == 11`.

```
TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B, <Vn+3>.16B }, <Vm>.<Ta>
```

Single register table variant

Applies when `len == 00`.

```
TBX <Vd>.<Ta>, { <Vn>.16B }, <Vm>.<Ta>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `8B` when `Q = 0`
- `16B` when `Q = 1`

C7.2.341 TRN1

Transpose vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

Note

By using this instruction with `TRN2`, a 2 x 2 matrix can be transposed.

The following figure shows the operation of TRN1 and TRN2 halfword operations where Q = 0.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.344 UABAL, UABAL2

Unsigned Absolute difference and Accumulate Long. This instruction subtracts the vector elements in the lower or upper half of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The `UABAL` instruction extracts each source vector from the lower half of each source register. The `UABAL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

0	Q	1	0	1	1	1	0	size	1	Rm	0	1	0	1	0	0	Rn	Rd
		U											op					

Encoding

```
UABAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean accumulate = (op == '0');
boolean unsigned = (U == '1');
```

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- `[absent]` when `Q = 0`
- `[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- `8H` when `size = 00`
- `4S` when `size = 01`
- `2D` when `size = 10`

The encoding `size = 11` is reserved.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) absdiff;

result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

C7.2.348 UADDL, UADDL2

Unsigned Add Long (vector). This instruction adds each vector element in the lower or upper half of the first source SIMD&FP register to the corresponding vector element of the second source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The `UADDL` instruction extracts each source vector from the lower half of each source register. The `UADDL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.351 UADDW, UADDW2

Unsigned Add Wide. This instruction adds the vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. The vector elements of the destination register and the first source register are twice as long as the vector elements of the second source register. All the values in this instruction are unsigned integer values.

The `UADDW` instruction extracts vector elements from the lower half of the second source register. The `UADDW2` instruction extracts vector elements from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0
0	Q	1	0	1	1	1	0	size	1	Rm	0	0	0	1	0	0	Rn	Rd

Encoding

```
UADDW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- `[absent]` when `Q = 0`
- `[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- `8H` when `size = 00`
- `4S` when `size = 01`
- `2D` when `size = 10`

The encoding `size = 11` is reserved.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.352 UCVTF (vector, fixed-point)

Unsigned fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page A1-65.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 001x

S when immh = 01xx

D when immh = 1xxx

The encoding immh = 000x is reserved.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

2D when immh = 1xxx, Q = 1

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000, Q = x.

The following encodings are reserved:

- immh = 0001, Q = x.
- immh = 1xxx, Q = 0.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:

(32-Uint(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

The encoding immh = 000x is reserved.

For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:

(32-Uint(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000.

The encoding immh = 0001 is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];

bits(esize) element;
FPCRType fpcr = FPCR[];
boolean merge = elements == 1 && IsMerging(fpcr);

C7.2.356 UDOT (by element)

Dot Product unsigned arithmetic (vector, by element). This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.DP indicates whether this instruction is supported.

Vector

C7.2.357 UDOT (vector)

Dot Product unsigned arithmetic (vector). This instruction performs the dot product of the four unsigned 8-bit elements in each 32-bit element of the first source register with the four unsigned 8-bit elements of the corresponding 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.DP indicates whether this instruction is supported.

Vector

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP third source and destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `2S` when `Q = 0`
- `4S` when `Q = 1`

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- `8B` when `Q = 0`
- `16B` when `Q = 1`

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

C7.2.358 UHADD

Unsigned Halving Add. This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see URHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.365 UMINV

Unsigned Minimum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20	19	18	17	16	15	14	13	12	11	10	9 … 5	4 … 0
0	Q	1	0	1	1	1	0	size	1	1	0	0	0	1	1	0	1	0	1	0	Rn	Rd
		U												op								

Encoding

```
UMINV <V><d>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');
```

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:

- B when `size = 00`
- H when `size = 01`
- S when `size = 10`

The encoding `size = 11` is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when `size = 00, Q = 0`
- 16B when `size = 00, Q = 1`
- 4H when `size = 01, Q = 0`
- 8H when `size = 01, Q = 1`
- 4S when `size = 10, Q = 1`

The following encodings are reserved:

- `size = 10, Q = 0`.
- `size = 11, Q = x`.

C7.2.366 UMLAL, UMLAL2 (by element)

Unsigned Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The `UMLAL` instruction extracts vector elements from the lower half of the first source register. The `UMLAL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

Decode for this encoding

```
integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UNDEFINED;

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
```

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

`4S` when `size = 01`

`2D` when `size = 10`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`4H` when `size = 01`, `Q = 0`

`8H` when `size = 01`, `Q = 1`

`2S` when `size = 10`, `Q = 0`

`4S` when `size = 10`, `Q = 1`

The following encodings are reserved:

- `size = 00`, `Q = x`.
- `size = 11`, `Q = x`.

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

`0:Rm` when `size = 01`

`M:Rm` when `size = 10`

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

Restricted to V0-V15 when element size <Ts> is H.

`<Ts>` Is an element size specifier, encoded in the "size" field. It can have the following values:

`H` when `size = 01`

`S` when `size = 10`

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

`<index>` Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

`H:L:M` when `size = 01`

`H:L` when `size = 10`

The following encodings are reserved:

- `size = 00`.
- `size = 11`.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxdsize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];

C7.2.370 UMMLA (vector)

Unsigned 8-bit integer matrix multiply-accumulate. This instruction multiplies the 2x8 matrix of unsigned 8-bit integer values in the first source vector by the 8x2 matrix of unsigned 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

(FEAT_I8MM)

C7.2.371 UMOV

Unsigned Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (to general). See *Alias conditions* for details of when each alias is preferred.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	0	0	0	0	imm5		0	0	1	1	1	1	Rn		Rd	

32-bit variant

Applies when `Q == 0`.

```
UMOV <Wd>, <Vn>.<Ts>[<index>]
```

64-bit variant

Applies when `Q == 1 && imm5 == x1000`.

```
UMOV <Xd>, <Vn>.<Ts>[<index>]
```

Decode for all variants of this encoding

```

```

Alias conditions

Alias	is preferred when
MOV (to general)	`imm5 == 'x1000'`
MOV (to general)	`imm5 == 'xx100'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Ts>` For the 32-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:

`B` when `imm5 = xxxx1`

`H` when `imm5 = xxx10`

`S` when `imm5 = xx100`

The encoding `imm5 = xx000` is reserved.

For the 64-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:

`D` when `imm5 = x1000`

The following encodings are reserved:

- `imm5 = x0000`.
- `imm5 = xxxx1`.
- `imm5 = xxx10`.
- `imm5 = xx100`.

`<index>` For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:

`imm5<4:1>` when `imm5 = xxxx1`

`imm5<4:2>` when `imm5 = xxx10`

`imm5<4:3>` when `imm5 = xx100`

The encoding `imm5 = xx000` is reserved.

For the 64-bit variant: is the element index encoded in "imm5<4>".

Operation

```
if index == 0 then
    CheckFPEnabled64();
else
    CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];

X[d] = ZeroExtend(Elem[operand, index, esize], datasize);
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.372 UMULL, UMULL2 (by element)

Unsigned Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The `UMULL` instruction extracts vector elements from the lower half of the first source register. The `UMULL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.373 UMULL, UMULL2 (vector)

Unsigned Multiply long (vector). This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are unsigned integer values.

The `UMULL` instruction extracts each source vector from the lower half of each source register. The `UMULL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.374 UQADD

Unsigned saturating Add. This instruction adds the values of corresponding elements of the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.375 UQRSHL

Unsigned saturating Rounding Shift Left (register). This instruction takes each vector element of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see UQSHL (immediate).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.376 UQRSHRN, UQRSHRN2

Unsigned saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are rounded. For truncated results, see UQSHRN, UQSHRN2.

The `UQRSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half, while the `UQRSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- `immh = 0000`.
- `immh = 1xxx`.

`<n>` Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

`<shift>` For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

C7.2.377 UQSHL (immediate)

Unsigned saturating Shift Left (immediate). This instruction takes each vector element in the source SIMD&FP register, shifts it by an immediate value, places the results in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.378 UQSHL (register)

Unsigned saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.379 UQSHRN, UQSHRN2

Unsigned saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see UQRSHRN, UQRSHRN2.

The `UQSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half, while the `UQSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Tb>` Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

`8B` when `immh = 0001`, `Q = 0`

`16B` when `immh = 0001`, `Q = 1`

`4H` when `immh = 001x`, `Q = 0`

`8H` when `immh = 001x`, `Q = 1`

`2S` when `immh = 01xx`, `Q = 0`

`4S` when `immh = 01xx`, `Q = 1`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`, `Q = x`.

The encoding `immh = 1xxx`, `Q = x` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Ta>` Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

`8H` when `immh = 0001`

`4S` when `immh = 001x`

`2D` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

`<Vb>` Is the destination width specifier, encoded in the "immh" field. It can have the following values:

`B` when `immh = 0001`

`H` when `immh = 001x`

`S` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

`<d>` Is the number of the SIMD&FP destination register, in the "Rd" field.

`<Va>` Is the source width specifier, encoded in the "immh" field. It can have the following values:

`H` when `immh = 0001`

`S` when `immh = 001x`

`D` when `immh = 01xx`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

`<n>` Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

`<shift>` For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

C7.2.381 UQXTN, UQXTN2

Unsigned saturating extract Narrow. This instruction reads each vector element from the source SIMD&FP register, saturates each value to half the original width, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `UQXTN` instruction writes the vector to the lower half of the destination register and clears the upper half, while the `UQXTN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00

4S when size = 01

2D when size = 10

The encoding size = 11 is reserved.

<Vb> Is the destination width specifier, encoded in the "size" field. It can have the following values:

B when size = 00

H when size = 01

S when size = 10

The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Va> Is the source width specifier, encoded in the "size" field. It can have the following values:

H when size = 00

S when size = 01

D when size = 10

The encoding size = 11 is reserved.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;
boolean sat;
```

C7.2.382 URECPE

Unsigned Reciprocal Estimate. This instruction reads each vector element from the source SIMD&FP register, calculates an approximate inverse for the unsigned integer value, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	0	1	sz	1	0	0	0	0	1	1	1	0	0	1	0	Rn		Rd	

Encoding

```
URECPE <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz == '1' then UNDEFINED;
integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

The encoding sz = 1, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(32) element;

for e = 0 to elements-1
    element = Elem[operand, e, 32];

C7.2.383 URHADD

Unsigned Rounding Halving Add. This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see UHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0

C7.2.384 URSHL

Unsigned Rounding Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

C7.2.388 USDOT (vector)

Dot Product vector form with unsigned and signed integers. This instruction performs the dot product of the four unsigned 8-bit integer values in each 32-bit element of the first source register with the four signed 8-bit integer values in the corresponding 32-bit element of the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

(FEAT_I8MM)

```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP third source and destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

`2S`	when `Q = 0`
`4S`	when `Q = 1`

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

`8B`	when `Q = 0`
`16B`	when `Q = 1`

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;

for e = 0 to elements-1
    bits(32) res = Elem[operand3, e, 32];
    for b = 0 to 3
        integer element1 = UInt(Elem[operand1, 4*e+b, 8]);
        integer element2 = SInt(Elem[operand2, 4*e+b, 8]);
```

C7.2.389 USDOT (by element)

Dot Product index form with unsigned and signed integers. This instruction performs the dot product of the four unsigned 8-bit integer values in each 32-bit element of the first source register with the four signed 8-bit integer values in an indexed 32-bit element of the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

C7.2.390 USHL

Unsigned Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift. For a rounding shift, see URSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1);    // 0 for left shift, 2^(n-1) for right shift
    element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else

C7.2.391 USHLL, USHLL2

Unsigned Shift Left Long (immediate). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, shifts the unsigned integer value left by the specified number of bits, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The `USHLL` instruction extracts vector elements from the lower half of the source register. The `USHLL2` instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias UXTL, UXTL2. See *Alias conditions* for details of when each alias is preferred.

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	Q	1	0	1	1	1	1	0	!=0000	immb			1	0	1	0	0	1	Rn		Rd	
	U								immh													

Encoding

```
USHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
boolean unsigned = (U == '1');
```

Alias conditions

Alias	is preferred when
UXTL, UXTL2	`immb == '000' && BitCount(immh) == 1`

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

`8H` when `immh = 0001`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

4S when immh = 001x

2D when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<shift> Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

(UInt(immh:immb)-8) when immh = 0001

(UInt(immh:immb)-16) when immh = 001x

(UInt(immh:immb)-32) when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

C7.2.393 USMMLA (vector)

Unsigned and signed 8-bit integer matrix multiply-accumulate. This instruction multiplies the 2x8 matrix of unsigned 8-bit integer values in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

C7.2.394 USQADD

Unsigned saturating Accumulate of Signed value. This instruction adds the signed integer values of the vector elements in the source SIMD&FP register to corresponding unsigned integer values of the vector elements in the destination SIMD&FP register, and accumulates the resulting unsigned integer values with the vector elements of the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

C7.2.395 USRA

Unsigned Shift Right and Accumulate (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, and accumulates the final results with the vector elements of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see URSRA.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:

D when immh = 1xxx

The encoding immh = 0xxx is reserved.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

2D when immh = 1xxx, Q = 1

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:

(128-UInt(immh:immb)) when immh = 1xxx

The encoding immh = 0xxx is reserved.

For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

See *Advanced SIMD modified immediate* on page C4-618 when immh = 0000.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;
```

C7.2.396 USUBL, USUBL2

Unsigned Subtract Long. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The destination vector elements are twice as long as the source vector elements.

The `USUBL` instruction extracts each source vector from the lower half of each source register. The `USUBL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.398 UXTL, UXTL2

Unsigned extend Long. This instruction copies each vector element from the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The `UXTL` instruction extracts vector elements from the lower half of the source register. The `UXTL2` instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the USHLL, USHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of USHLL, USHLL2.
- The description of USHLL, USHLL2 gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	Q	1	0	1	1	1	1	0	!=0000	0	0	0	1	0	1	0	0	1	Rn		Rd	
	U								immh		immb											

Encoding

```
UXTL{2} <Vd>.<Ta>, <Vn>.<Tb>
```

is equivalent to

```
USHLL{2}  <Vd>.<Ta>, <Vn>.<Tb>, #0
```

and is the preferred disassembly when `BitCount(immh) == 1`.

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

`8H` when `immh = 0001`

`4S` when `immh = 001x`

`2D` when `immh = 01xx`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

`8B` when `immh = 0001`, `Q = 0`

`16B` when `immh = 0001`, `Q = 1`

`4H` when `immh = 001x`, `Q = 0`

`8H` when `immh = 001x`, `Q = 1`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`2S` when `immh = 01xx`, `Q = 0`

`4S` when `immh = 01xx`, `Q = 1`

See *Advanced SIMD modified immediate* on page C4-618 when `immh = 0000`, `Q = x`.

The encoding `immh = 1xxx`, `Q = x` is reserved.

Operation

The description of USHLL, USHLL2 gives the operational pseudocode for this instruction.

C7.2.399 UZP1

Unzip vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

Note

This instruction can be used with `UZP2` to de-interleave two vectors.

The following figure shows the operation of UZP1 and UZP2 with the arrangement specifier 8B.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0

C7.2.402 XTN, XTN2

Extract Narrow. This instruction reads each vector element from the source SIMD&FP register, narrows each value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

The `XTN` instruction writes the vector to the lower half of the destination register and clears the upper half, while the `XTN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20	19	18	17	16	15	14	13	12	11	10	9 5	4 0
0	Q	0	0	1	1	1	0	size	1	0	0	0	0	1	0	0	1	0	1	0	Rn	Rd

Encoding

```
XTN{2} <Vd>.<Tb>, <Vn>.<Ta>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`[absent]` when `Q = 0`

`[present]` when `Q = 1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Tb>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`8B` when `size = 00`, `Q = 0`

`16B` when `size = 00`, `Q = 1`

`4H` when `size = 01`, `Q = 0`

`8H` when `size = 01`, `Q = 1`

`2S` when `size = 10`, `Q = 0`

`4S` when `size = 10`, `Q = 1`

The encoding `size = 11`, `Q = x` is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Ta>` Is an arrangement specifier, encoded in the "size" field. It can have the following values:

`8H` when `size = 00`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

4S when `size = 01`

2D when `size = 10`

The encoding `size = 11` is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, 2*esize];
    Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C7.2.403 ZIP1

Zip vectors (primary). This instruction reads adjacent vector elements from the lower half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

Note

This instruction can be used with `ZIP2` to interleave two vectors.

The following figure shows the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23 22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0

											op							

Encoding

```
ZIP1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

`8B`	when `size = 00, Q = 0`
`16B`	when `size = 00, Q = 1`
`4H`	when `size = 01, Q = 0`
`8H`	when `size = 01, Q = 1`
`2S`	when `size = 10, Q = 0`

Chapter C8
SVE Instruction Descriptions

This chapter describes the SVE instructions.

It contains the following sections:

- *About the SVE instructions* on page C8-2944.
- *Alphabetical list of SVE instructions* on page C8-2945.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C8.1 About the SVE instructions

Alphabetical list of SVE instructions on page C8-2945 gives full descriptions of the SVE instructions that are in the following instruction groups:

- Loads and store instructions associated with the SVE registers.
- Data processing instructions with SVE registers.

A64 instruction set encoding on page C4-380 provides an overview of the instruction encodings as part of an instruction class within a functional group.

The SVE instructions include details relating to the *Scalable Matrix Extension* (SME), such as Streaming SVE mode and FEAT_SME. For more information, see, *Arm® Architecture Reference Manual Supplement, The Scalable Matrix Extension (SME), for Armv9-A* (ARM DDI 0616).

Non-Confidential

C8.2 Alphabetical list of SVE instructions

This section lists every section in the SVE category of the A64 instruction set. For details of the format used, see *Structure of the A64 assembler language* on page C1-224.

C8.2.1 ABS

Compute the absolute value of the signed integer in each active element of the source vector, and place the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12	10 9	5 4	0
0 0 0 0	0 1 0 0	size	0 1 0	1 1		0	1 0 1	Pg	Zn	Zd	

Encoding

```
ABS <Zd>.<T>, <Pg>/M, <Zn>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Zd);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(VL) result = Z[d];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        integer element = SInt(Elem[operand, e, esize]);
        element = Abs(element);
        Elem[result, e, esize] = element<esize-1:0>;

Z[d] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.2 ADCLB

Add the even-numbered elements of the first source vector and the 1-bit carry from the least-significant bit of the odd-numbered elements of the second source vector to the even-numbered elements of the destination and accumulator vector. The 1-bit carry output is placed in the corresponding odd-numbered element of the destination vector.

31 30 29 28	27 26 25 24	23	22	21	20 … 16	15 14 13 12	11	10	9 … 5	4 … 0
0 1 0 0	0 1 0 1	0	sz	0	Zm	1 1 0 1	0	0	Zn	Zda
								T		

Encoding

```
ADCLB <Zda>.<T>, <Zn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
integer esize = 32 << UInt(sz);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);
```

Assembler symbols

`<Zda>` Is the name of the third source and destination scalable vector register, encoded in the "Zda" field.

`<T>` Is the size specifier, encoded in the "sz" field. It can have the following values:

- `S` when `sz = 0`
- `D` when `sz = 1`

`<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.

`<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer pairs = VL DIV (esize * 2);
bits(VL) operand = Z[n];
bits(VL) carries = Z[m];
bits(VL) result = Z[da];

for p = 0 to pairs-1
    bits(esize) element1 = Elem[result, 2*p + 0, esize];
    bits(esize) element2 = Elem[operand, 2*p + 0, esize];
    bit carry_in = Elem[carries, 2*p + 1, esize]<0>;

    (res, nzcv) = AddWithCarry(element1, element2, carry_in);
    carry_out = nzcv<1>;

    Elem[result, 2*p + 0, esize] = res;
    Elem[result, 2*p + 1, esize] = ZeroExtend(carry_out);

Z[da] = result;
```

C8.2.3 ADCLT

Add the odd-numbered elements of the first source vector and the 1-bit carry from the least-significant bit of the odd-numbered elements of the second source vector to the even-numbered elements of the destination and accumulator vector. The 1-bit carry output is placed in the corresponding odd-numbered element of the destination vector.

31 30 29 28	27 26 25 24	23	22	21	20 … 16	15 14 13 12	11	10	9 … 5	4 … 0
0 1 0 0	0 1 0 1	0	sz	0	Zm	1 1 0 1	0	1	Zn	Zda
								T		

Encoding

```
ADCLT <Zda>.<T>, <Zn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
integer esize = 32 << UInt(sz);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);
```

Assembler symbols

`<Zda>` Is the name of the third source and destination scalable vector register, encoded in the "Zda" field.

`<T>` Is the size specifier, encoded in the "sz" field. It can have the following values:

- `S` when `sz = 0`
- `D` when `sz = 1`

`<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.

`<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer pairs = VL DIV (esize * 2);
bits(VL) operand = Z[n];
bits(VL) carries = Z[m];
bits(VL) result = Z[da];

for p = 0 to pairs-1
    bits(esize) element1 = Elem[result, 2*p + 0, esize];
    bits(esize) element2 = Elem[operand, 2*p + 1, esize];
    bit carry_in = Elem[carries, 2*p + 1, esize]<0>;

    (res, nzcv) = AddWithCarry(element1, element2, carry_in);
    carry_out = nzcv<1>;

    Elem[result, 2*p + 0, esize] = res;
    Elem[result, 2*p + 1, esize] = ZeroExtend(carry_out);

Z[da] = result;
```

C8.2.4 ADD (immediate)

Add an unsigned immediate to each element of the source vector, and destructively place the results in the corresponding elements of the source vector. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<uimm8>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17 16	15 14	13	12	5 4	0
0 0 1 0	0 1 0 1	size	1 0 0	0 0	0	1 1	sh	imm8	Zdn	

Encoding

```
ADD <Zdn>.<T>, <Zdn>.<T>, #<imm>{, <shift>}
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size:sh == '001' then UNDEFINED;
integer esize = 8 << UInt(size);
integer dn = UInt(Zdn);
integer imm = UInt(imm8);
if sh == '1' then imm = imm << 8;
```

Assembler symbols

`<Zdn>` Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `B` when `size = 00`
- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

`<imm>` Is an unsigned immediate in the range 0 to 255, encoded in the "imm8" field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

- `LSL #0` when `sh = 0`
- `LSL #8` when `sh = 1`

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn];
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    Elem[result, e, esize] = element1 + imm;
```

C8.2.5 ADD (vectors, predicated)

Add active elements of the second source vector to corresponding elements of the first source vector and destructively place the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12 10 9	5 4	0
0 0 0 0	0 1 0 0	size	0 0 0	0 0	0	0	0 0 0	Pg	Zm	Zdn

Encoding

```
ADD <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m] else Zeros();
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    bits(esize) element2 = Elem[operand2, e, esize];
    if ElemP[mask, e, esize] == '1' then
        Elem[result, e, esize] = element1 + element2;
    else
        Elem[result, e, esize] = Elem[operand1, e, esize];

Z[dn] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.6 ADD (vectors, unpredicated)

Add all elements of the second source vector to corresponding elements of the first source vector and place the results in the corresponding elements of the destination vector. This instruction is unpredicated.

31 30 29 28	27 26 25 24	23 22	21	20 16	15 14 13	12 11	10	9 5	4 0
0 0 0 0	0 1 0 0	size	1	Zm	0 0 0	0 0	0	Zn	Zd

Encoding

```
ADD <Zd>.<T>, <Zn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(VL) operand1 = Z[n];
bits(VL) operand2 = Z[m];
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    bits(esize) element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = element1 + element2;

Z[d] = result;
```

```

Assembler symbols

<Zdn> Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

Operation

```
CheckNonStreamingSVEEnabled();
integer segments = VL DIV 128;
bits(VL) operand = Z[dn];
bits(VL) result;

for s = 0 to segments-1
    Elem[result, s, 128] = AESInvMixColumns(Elem[operand, s, 128]);

Z[dn] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C8.2.16 AESMC

The AESMC instruction reads a 16-byte state array from each 128-bit segment of the source register, and performs a single round of the MIXCOLUMNS() transformation on each state array in accordance with the AES standard. Each updated state array is destructively placed in the corresponding segment of the first source vector. This instruction is unpredicated.

ID_AA64ZFR0_EL1.AES indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

SVE2

(FEAT_SVE_AES)

Encoding

```
AESMC <Zdn>.B, <Zdn>.B
```

Decode for this encoding

```
if !HaveSVE() || !HaveSVE2AES() then UNDEFINED;
integer dn = UInt(Zdn);
```

Assembler symbols

<Zdn> Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

Operation

```
CheckNonStreamingSVEEnabled();
integer segments = VL DIV 128;
bits(VL) operand = Z[dn];
bits(VL) result;

for s = 0 to segments-1
    Elem[result, s, 128] = AESMixColumns(Elem[operand, s, 128]);

Z[dn] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C8.2.17 AND (immediate)

Bitwise AND an immediate with each 64-bit element of the source vector, and destructively place the results in the corresponding elements of the source vector. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32 or 64 bits. This instruction is unpredicated.

This instruction is used by the pseudo-instruction BIC (immediate). The pseudo-instruction is never the preferred disassembly.

31 30 29 28	27 26 25 24	23	22	21 20	19 18 17	5 4	0
0 0 0 0	0 1 0 1	1	0	0 0	0	imm13	Zdn

Encoding

```
AND <Zdn>.<T>, <Zdn>.<T>, #<const>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer dn = UInt(Zdn);
bits(64) imm;
(imm, -) = DecodeBitMasks(imm13<12>, imm13<5:0>, imm13<11:6>, TRUE);
```

Assembler symbols

<Zdn> Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "imm13<12>:imm13<5:0>" field. It can have the following values:

S when imm13<12> = 0, imm13<5:0> = 0xxxxx

H when imm13<12> = 0, imm13<5:0> = 10xxxx

B when imm13<12> = 0, imm13<5:0> = 110xxx

B when imm13<12> = 0, imm13<5:0> = 1110xx

B when imm13<12> = 0, imm13<5:0> = 11110x

D when imm13<12> = 1, imm13<5:0> = xxxxxx

The following encodings are reserved:

- imm13<12> = 0, imm13<5:0> = 111110.
- imm13<12> = 0, imm13<5:0> = 111111.

<const> Is a 64, 32, 16 or 8-bit bitmask consisting of replicated 2, 4, 8, 16, 32 or 64 bit fields, each field containing a rotated run of non-zero bits, encoded in the "imm13" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV 64;
bits(VL) operand = Z[dn];
bits(VL) result;

for e = 0 to elements-1
    bits(64) element1 = Elem[operand, e, 64];
    Elem[result, e, 64] = element1 AND imm;
```

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
Z[dn] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.18 AND (predicates)

Bitwise AND active elements of the second source predicate with corresponding elements of the first source predicate and place the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Does not set the condition flags.

This instruction is used by the alias MOV (predicate, predicated, zeroing). See *Alias conditions* for details of when each alias is preferred.

31 30 29 28	27 26 25 24	23	22	21 20	19 16	15 14 13	10 9 8	5 4	3 0
0 0 1 0	0 1 0 1	0	0	0 0	Pm	0 1	Pg	0	Pn	0	Pd
			S						

Encoding

```
AND <Pd>.B, <Pg>/Z, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8;
integer g = UInt(Pg);
integer n = UInt(Pn);
integer m = UInt(Pm);
integer d = UInt(Pd);
boolean setflags = FALSE;
```

Alias conditions

Alias	is preferred when
MOV (predicate, predicated, zeroing)	`S == '0' && Pn == Pm`

Assembler symbols

`<Pd>`	Is the name of the destination scalable predicate register, encoded in the "Pd" field.
`<Pg>`	Is the name of the governing scalable predicate register, encoded in the "Pg" field.
`<Pn>`	Is the name of the first source scalable predicate register, encoded in the "Pn" field.
`<Pm>`	Is the name of the second source scalable predicate register, encoded in the "Pm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(PL) operand1 = P[n];
bits(PL) operand2 = P[m];
bits(PL) result;

for e = 0 to elements-1
    bit element1 = ElemP[operand1, e, esize];
    bit element2 = ElemP[operand2, e, esize];
    if ElemP[mask, e, esize] == '1' then
        ElemP[result, e, esize] = element1 AND element2;
```

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    else
        ElemP[result, e, esize] = '0';

if setflags then
    PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
P[d] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

C8.2.19 AND (vectors, predicated)

Bitwise AND active elements of the second source vector with corresponding elements of the first source vector and destructively place the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12 10 9	5 4	0
0 0 0 0	0 1 0 0	size	0 1 1	0 1		0	0 0 0	Pg	Zm	Zdn

Encoding

```
AND <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m] else Zeros();
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    bits(esize) element2 = Elem[operand2, e, esize];
    if ElemP[mask, e, esize] == '1' then
        Elem[result, e, esize] = element1 AND element2;
    else
        Elem[result, e, esize] = Elem[operand1, e, esize];

Z[dn] = result;
```

C8.2.20 AND (vectors, unpredicated)

Bitwise AND all elements of the second source vector with corresponding elements of the first source vector and place the results in the corresponding elements of the destination vector. This instruction is unpredicated.

31 30 29 28	27 26 25 24	23	22	21	20 … 16	15 14 13 12	11 10	9 … 5	4 … 0
0 0 0 0	0 1 0 0	0	0	1	Zm	0 0 1 1	0 0	Zn	Zd

Encoding

```
AND <Zd>.D, <Zn>.D, <Zm>.D
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
bits(VL) operand1 = Z[n];
bits(VL) operand2 = Z[m];

Z[d] = operand1 AND operand2;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C8.2.21 ANDS

Bitwise AND active elements of the second source predicate with corresponding elements of the first source predicate and place the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

This instruction is used by the alias MOVS (predicated). See *Alias conditions* for details of when each alias is preferred.

31 30 29 28	27 26 25 24	23	22	21 20	19 16	15 14	13 10	9	8 5	4	3 0
0 0 1 0	0 1 0 1	0	1	0 0	Pm	0 1	Pg	0	Pn	0	Pd
			S								

Encoding

```
ANDS <Pd>.B, <Pg>/Z, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8;
integer g = UInt(Pg);
integer n = UInt(Pn);
integer m = UInt(Pm);
integer d = UInt(Pd);
boolean setflags = TRUE;
```

Alias conditions

Alias	is preferred when
MOVS (predicated)	`S == '1' && Pn == Pm`

Assembler symbols

`<Pd>`	Is the name of the destination scalable predicate register, encoded in the "Pd" field.
`<Pg>`	Is the name of the governing scalable predicate register, encoded in the "Pg" field.
`<Pn>`	Is the name of the first source scalable predicate register, encoded in the "Pn" field.
`<Pm>`	Is the name of the second source scalable predicate register, encoded in the "Pm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(PL) operand1 = P[n];
bits(PL) operand2 = P[m];
bits(PL) result;

for e = 0 to elements-1
    bit element1 = ElemP[operand1, e, esize];
    bit element2 = ElemP[operand2, e, esize];
    if ElemP[mask, e, esize] == '1' then
```

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
        ElemP[result, e, esize] = element1 AND element2;
    else
        ElemP[result, e, esize] = '0';

if setflags then
    PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
P[d] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C8.2.22 ANDV

Bitwise AND horizontally across all lanes of a vector, and place the result in the SIMD&FP scalar destination register. Inactive elements in the source vector are treated as all ones.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12 10	9 5	4 0
0 0 0 0	0 1 0 0	size	0 1	1 0	1	0	0 0 1	Pg	Zn	Vd

Encoding

```
ANDV <V><d>, <Pg>, <Zn>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Vd);
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

B when size = 00

H when size = 01

S when size = 10

D when size = 11

<d> Is the number [0-31] of the destination SIMD&FP register, encoded in the "Vd" field.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

B when size = 00

H when size = 01

S when size = 10

D when size = 11

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(esize) result = Ones(esize);

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        result = result AND Elem[operand, e, esize];

V[d] = result;
```

C8.2.25 ASR (vectors)

Shift right, preserving the sign bit, active elements of the first source vector by corresponding elements of the second source vector and destructively place the results in the corresponding elements of the first source vector. The shift amount operand is a vector of unsigned elements in which all bits are significant, and not used modulo the element size. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19	18	17	16	15 14 13 12	10 9	5 4	0
0 0 0 0	0 1 0 0	size	0 1 0	0	0	0	1 0 0	Pg	Zm	Zdn	
				R	L	U					

Encoding

```
ASR <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

B	when size = 00
H	when size = 01
S	when size = 10
D	when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m] else Zeros();
bits(VL) result;

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element1 = Elem[operand1, e, esize];
        bits(esize) element2 = Elem[operand2, e, esize];
        integer shift = Min(UInt(element2), esize);
        Elem[result, e, esize] = ASR(element1, shift);
    else
        Elem[result, e, esize] = Elem[operand1, e, esize];

Z[dn] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.34 BFCVTNT

Convert to BFloat16 from single-precision in each active floating-point element of the source vector, and place the results in the odd-numbered 16-bit elements of the destination vector, leaving the even-numbered elements unchanged. Inactive elements in the destination vector register remain unmodified.

ID_AA64ZFR0_EL1.BF16 indicates whether this instruction is implemented.

C8.2.35 BFDOT (indexed)

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, irrespective of the other control bits in the FPCR, this instruction:

* Performs an unfused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second vector. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.

* Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.

* Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).

* Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.

* Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.

* Generates only the Default NaN, as if FPCR.DN is 1.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, then this instruction:

* Performs a fused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.

* Generates only the default NaN, as if FPCR.DN is 1.

* Follows all other floating-point behaviors that apply to single-precision arithmetic, as controlled by the effective value of the FPCR in the current execution mode, and captured in the FPSR.

The BFloat16 pairs within the second source vector are specified using an immediate index which selects the same BFloat16 pair position within each 128-bit vector segment. The index range is from 0 to 3.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.BF16 indicates whether this instruction is implemented.

C8.2.41 BFMMLA

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, irrespective of the other control bits in the FPCR, this instruction:

* Performs two unfused sums-of-products within each two pairs of adjacent BFloat16 elements while multiplying the 2×4 matrix of BFloat16 values held in each 128-bit segment of the first source vector by the 4×2 matrix of BFloat16 values in the corresponding segment of the second source vector. The intermediate single-precision products are rounded before they are summed and the intermediate sum is rounded before accumulation into the 2×2 single-precision matrix in the corresponding segment of the destination vector. This is equivalent to accumulating two 2-way unfused dot products per destination element.

* Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.

* Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).

* Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.

* Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.

* Generates only the Default NaN, as if FPCR.DN is 1.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, then this instruction:

* Performs two fused sums-of-products within each two pairs of adjacent BFloat16 elements while multiplying the 2×4 matrix of BFloat16 values held in each 128-bit segment of the first source vector by the 4×2 matrix of BFloat16 values in the corresponding segment of the second source vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the 2×2 single-precision matrix in the corresponding segment of the destination vector. This is equivalent to accumulating two 2-way fused dot products per destination element.

* Generates only the default NaN, as if FPCR.DN is 1.

* Follows all other floating-point behaviors that apply to single-precision arithmetic, as controlled by the effective value of the FPCR in the current execution mode, and captured in the FPSR.

This instruction is unpredicated and vector length agnostic.

ID_AA64ZFR0_EL1.BF16 indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

    Elem[result, s, 128] = res;

Z[da] = result;
```

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.42 BGRP

This instruction separates bits in each element of the first source vector by gathering from the bit positions indicated by non-zero bits in the corresponding mask element of the second source vector to the lowest-numbered contiguous bits of the corresponding destination element, and from positions indicated by zero bits to the highest-numbered bits of the destination element, preserving the bit order within each group. This instruction is unpredicated.

ID_AA64ZFR0_EL1.BitPerm indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

SVE2

(FEAT_SVE_BitPerm)

31 30 29 28	27 26 25 24	23 22	21	20 … 16	15 14 13 12	11	10	9 … 5	4 … 0
0 1 0 0	0 1 0 1	size	0	Zm	1 0 1 1	1	0	Zn	Zd

Encoding

```
BGRP <Zd>.<T>, <Zn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() || !HaveSVE2BitPerm() then UNDEFINED;
integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckNonStreamingSVEEnabled();
integer elements = VL DIV esize;
bits(VL) data = Z[n];
bits(VL) mask = Z[m];
bits(VL) result;

for e = 0 to elements - 1
    Elem[result, e, esize] = BitGroup(Elem[data, e, esize], Elem[mask, e, esize]);

Z[d] = result;
```

C8.2.43 BIC (immediate)

Bitwise clear bits using immediate with each 64-bit element of the source vector, and destructively place the results in the corresponding elements of the source vector. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32 or 64 bits. This instruction is unpredicated.

This instruction is a pseudo-instruction of the AND (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of AND (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of AND (immediate) gives the operational pseudocode for this instruction.

31 30 29 28	27 26 25 24	23	22	21 20	19 18 17	5 4	0
0 0 0 0	0 1 0 1	1	0	0 0	0 0	imm13	Zdn

Encoding

```
BIC <Zdn>.<T>, <Zdn>.<T>, #<const>
```

is equivalent to

```
AND <Zdn>.<T>, <Zdn>.<T>, #(-<const> - 1)
```

and is never the preferred disassembly.

Assembler symbols

`<Zdn>` Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

`<T>` Is the size specifier, encoded in the "imm13<12>:imm13<5:0>" field. It can have the following values:

S	when `imm13<12> = 0`, `imm13<5:0> = 0xxxxx`
H	when `imm13<12> = 0`, `imm13<5:0> = 10xxxx`
B	when `imm13<12> = 0`, `imm13<5:0> = 110xxx`
B	when `imm13<12> = 0`, `imm13<5:0> = 1110xx`
B	when `imm13<12> = 0`, `imm13<5:0> = 11110x`
D	when `imm13<12> = 1`, `imm13<5:0> = xxxxxx`

The following encodings are reserved:

- `imm13<12> = 0`, `imm13<5:0> = 111110`.
- `imm13<12> = 0`, `imm13<5:0> = 111111`.

`<const>` Is a 64, 32, 16 or 8-bit bitmask consisting of replicated 2, 4, 8, 16, 32 or 64 bit fields, each field containing a rotated run of non-zero bits, encoded in the "imm13" field.

Operation

The description of AND (immediate) gives the operational pseudocode for this instruction.

C8.2.44 BIC (predicates)

Bitwise AND inverted active elements of the second source predicate with corresponding elements of the first source predicate and place the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Does not set the condition flags.

31 30 29 28	27 26 25 24	23	22	21 20	19 16	15 14	13 10	9	8 5	4	3 0
0 0 1 0	0 1 0 1	0	0	0 0	Pm	0 1	Pg	0	Pn	1	Pd
			S								

Encoding

```
BIC <Pd>.B, <Pg>/Z, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8;
integer g = UInt(Pg);
integer n = UInt(Pn);
integer m = UInt(Pm);
integer d = UInt(Pd);
boolean setflags = FALSE;
```

Assembler symbols

<Pd>	Is the name of the destination scalable predicate register, encoded in the "Pd" field.
<Pg>	Is the name of the governing scalable predicate register, encoded in the "Pg" field.
<Pn>	Is the name of the first source scalable predicate register, encoded in the "Pn" field.
<Pm>	Is the name of the second source scalable predicate register, encoded in the "Pm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(PL) operand1 = P[n];
bits(PL) operand2 = P[m];
bits(PL) result;

for e = 0 to elements-1

C8.2.45 BIC (vectors, predicated)

Bitwise AND inverted active elements of the second source vector with corresponding elements of the first source vector and destructively place the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12 10 9	5 4	0
0 0 0 0	0 1 0 0	size	0 1 1	0 1	1	0	0 0	Pg	Zm	Zdn

Encoding

```
BIC <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m] else Zeros();
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    bits(esize) element2 = Elem[operand2, e, esize];
    if ElemP[mask, e, esize] == '1' then
        Elem[result, e, esize] = element1 AND (NOT element2);
    else
        Elem[result, e, esize] = Elem[operand1, e, esize];

Z[dn] = result;
```

C8.2.58 BSL

Selects bits from the first source vector where the corresponding bit in the third source vector is '1', and from the second source vector where the corresponding bit in the third source vector is '0'. The result is placed destructively in the destination and first source vector. This instruction is unpredicated.

31 30 29 28	27 26 25 24	23	22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0
0 0 0 0	0 1 0 0	0	0	1	Zm	0	0	1	1	1	1	Zk	Zdn

Encoding

```
BSL <Zdn>.D, <Zdn>.D, <Zm>.D, <Zk>.D
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
integer m = UInt(Zm);
integer k = UInt(Zk);
integer dn = UInt(Zdn);
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

<Zk> Is the name of the third source scalable vector register, encoded in the "Zk" field.

Operation

```
CheckSVEEnabled();
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = Z[m];
bits(VL) operand3 = Z[k];

Z[dn] = (operand1 AND operand3) OR (operand2 AND NOT(operand3));
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.61 CADD

Add the real and imaginary components of the integral complex numbers from the first source vector to the complex numbers from the second source vector which have first been rotated by 90 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, equivalent to multiplying the complex numbers in the second source vector by ±J beforehand. Destructively place the results in the corresponding elements of the first source vector. This instruction is unpredicated.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

31 30 29 28	27 26 25 24	23 22	21 20	19 18 17 16	15	14 13 12	11	10	9 5	4 0
0 1 0 0	0 1 0 1	size	0 0	0 0 0	0	1 1 0	1 1	rot	Zm	Zdn

Encoding

```
CADD <Zdn>.<T>, <Zdn>.<T>, <Zm>.<T>, <const>
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer m = UInt(Zm);
integer dn = UInt(Zdn);
boolean sub_i = (rot == '0');
boolean sub_r = (rot == '1');
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

<const> Is the const specifier, encoded in the "rot" field. It can have the following values:

- #90 when rot = 0
- #270 when rot = 1

Operation

```
CheckSVEEnabled();
integer pairs = VL DIV (2 * esize);
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = Z[m];
bits(VL) result;

for p = 0 to pairs-1
    integer acc_r  = SInt(Elem[operand1, 2 * p + 0, esize]);
    integer acc_i  = SInt(Elem[operand1, 2 * p + 1, esize]);
    integer elt2_r = SInt(Elem[operand2, 2 * p + 0, esize]);
```

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.

C8.2.62 CDOT (indexed)

The complex integer dot product instructions delimit the source vectors into pairs of 8-bit or 16-bit signed integer complex numbers. Within each pair, the complex numbers in the first source vector are multiplied by the corresponding complex numbers in the second source vector and the resulting wide real or wide imaginary part of the product is accumulated into a 32-bit or 64-bit destination vector element which overlaps all four of the elements that comprise a pair of complex number values in the first source vector.

As a result each instruction implicitly deinterleaves the real and imaginary components of their complex number inputs, so that the destination vector accumulates 4×wide real sums or 4×wide imaginary sums.

The complex numbers in the second source vector are rotated by 0, 90, 180 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, by performing the following transformations prior to the dot product operations:

* If the rotation is #0, the imaginary parts of the complex numbers in the second source vector are negated. The destination vector therefore accumulates the real parts of a complex dot product.

* If the rotation is #90, the real and imaginary parts of the complex numbers the second source vector are swapped. The destination vector therefore accumulates the imaginary parts of a complex dot product.

* If the rotation is #180, there is no transformation. The destination vector therefore accumulates the real parts of a complex conjugate dot product.

* If the rotation is #270, the real parts of the complex numbers in the second source vector are negated and then swapped with the imaginary parts. The destination vector therefore accumulates the imaginary parts of a complex conjugate dot product.

The indexed form of these instructions select a single pair of complex numbers within each 128-bit segment of the second source vector as the multiplier for all pairs of complex numbers within the corresponding 128-bit segment of the first source vector. The complex number pairs within the second source vector are specified using an immediate index which selects the same complex number pair position within each 128-bit vector segment. The index range is from 0 to one less than the number of complex number pairs per 128-bit segment, encoded in 1 or 2 bits depending on the size of the complex number pair.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

32-bit

Encoding

```
CDOT <Zda>.S, <Zn>.B, <Zm>.B[<imm>], <const>
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
integer esize = 32;
integer index = UInt(i2);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);
integer sel_a = UInt(rot<0>);
```

boolean sub_i = (rot<0> == rot<1>);
```

64-bit

Encoding

```
CDOT <Zda>.D, <Zn>.H, <Zm>.H[<imm>], <const>
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
integer esize = 64;
integer index = UInt(i1);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);
integer sel_a = UInt(rot<0>);
integer sel_b = UInt(NOT(rot<0>));
boolean sub_i = (rot<0> == rot<1>);
```

Assembler symbols

`<Zda>` Is the name of the third source and destination scalable vector register, encoded in the "Zda" field.

`<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.

`<Zm>` For the 32-bit variant: is the name of the second source scalable vector register Z0-Z7, encoded in the "Zm" field.

For the 64-bit variant: is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.

`<imm>` For the 32-bit variant: is the immediate index of a quadtuplet of four 8-bit elements within each 128-bit vector segment, in the range 0 to 3, encoded in the "i2" field.

For the 64-bit variant: is the immediate index of a quadtuplet of four 16-bit elements within each 128-bit vector segment, in the range 0 to 1, encoded in the "i1" field.

`<const>` Is the const specifier, encoded in the "rot" field. It can have the following values:

`#0`	when `rot = 00`
`#90`	when `rot = 01`
`#180`	when `rot = 10`
`#270`	when `rot = 11`

Operation for all encodings

```
CheckSVEEnabled();
integer elements = VL DIV esize;
integer eltspersegment = 128 DIV esize;
bits(VL) operand1 = Z[n];
bits(VL) operand2 = Z[m];
bits(VL) operand3 = Z[da];
```

```
bits(VL) result;

for e = 0 to elements-1
    integer segmentbase = e - (e MOD eltspersegment);
    integer s = segmentbase + index;
    bits(esize) res = Elem[operand3, e, esize];
    for i = 0 to 1
        integer elt1_r = SInt(Elem[operand1, 4 * e + 2 * i + 0, esize DIV 4]);
        integer elt1_i = SInt(Elem[operand1, 4 * e + 2 * i + 1, esize DIV 4]);
        integer elt2_a = SInt(Elem[operand2, 4 * s + 2 * i + sel_a, esize DIV 4]);
        integer elt2_b = SInt(Elem[operand2, 4 * s + 2 * i + sel_b, esize DIV 4]);
        if sub_i then
            res = res + (elt1_r * elt2_a) - (elt1_i * elt2_b);
        else
            res = res + (elt1_r * elt2_a) + (elt1_i * elt2_b);
    Elem[result, e, esize] = res;

Z[da] = result;
```

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.72 CMLA (indexed)

Multiply the duplicated real components for rotations 0 and 180, or imaginary components for rotations 90 and 270, of the integral numbers in each 128-bit segment of the first source vector by the specified complex number in the corresponding the second source vector segment rotated by 0, 90, 180 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation.

Then add the products to the corresponding components of the complex numbers in the addend vector. Destructively place the results in the corresponding elements of the addend vector. This instruction is unpredicated.

These transformations permit the creation of a variety of multiply-add and multiply-subtract operations on complex numbers by combining two of these instructions with the same vector operands but with rotations that are 90 degrees apart.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

16-bit

Encoding

```
CMLA <Zda>.H, <Zn>.H, <Zm>.H[<imm>], <const>
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;

```

Assembler symbols

`<Zda>` Is the name of the third source and destination scalable vector register, encoded in the "Zda" field.

`<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.

`<Zm>` For the 16-bit variant: is the name of the second source scalable vector register Z0-Z7, encoded in the "Zm" field.

For the 32-bit variant: is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.

`<imm>` For the 16-bit variant: is the element index, in the range 0 to 3, encoded in the "i2" field.

For the 32-bit variant: is the element index, in the range 0 to 1, encoded in the "i1" field.

`<const>` Is the const specifier, encoded in the "rot" field. It can have the following values:

`#0`	when `rot = 00`
`#90`	when `rot = 01`
`#180`	when `rot = 10`
`#270`	when `rot = 11`

Operation for all encodings

```
CheckSVEEnabled();

C8.2.74 CMP<cc> (immediate)

Compare active integer elements in the source vector with an immediate, and place the boolean results of the specified comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

The <cc> symbol specifies one of the standard ARM condition codes: EQ, GE, GT, HI, HS, LE, LO, LS, LT or NE.

B	when size = 00
H	when size = 01
S	when size = 10
D	when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

<imm> For the equal, greater than, greater than or equal, less than, less than or equal and not equal variant: is the signed immediate operand, in the range -16 to 15, encoded in the "imm5" field.

For the higher, higher or same, lower and lower or same variant: is the unsigned immediate operand, in the range 0 to 127, encoded in the "imm7" field.

Operation for all encodings

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(PL) result;

for e = 0 to elements-1
    integer element1 = Int(Elem[operand1, e, esize], unsigned);
    if ElemP[mask, e, esize] == '1' then
        boolean cond;
        case op of
            when Cmp_EQ cond = element1 == imm;
            when Cmp_NE cond = element1 != imm;
            when Cmp_GE cond = element1 >= imm;
            when Cmp_LT cond = element1 <  imm;
            when Cmp_GT cond = element1 >  imm;
            when Cmp_LE cond = element1 <= imm;
        ElemP[result, e, esize] = if cond then '1' else '0';
    else
        ElemP[result, e, esize] = '0';

PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
P[d] = result;
```

C8.2.75 CMP<cc> (vectors)

Compare active integer elements in the first source vector with corresponding elements in the second source vector, and place the boolean results of the specified comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

The <cc> symbol specifies one of the standard ARM condition codes: EQ, GE, GT, HI, HS or NE.

This instruction is used by the pseudo-instructions CMPLE (vectors), CMPLO (vectors), CMPLS (vectors), and CMPLT (vectors). The pseudo-instruction is never the preferred disassembly.

C8.2.77 CMPLE (vectors)

Compare active signed integer elements in the first source vector being less than or equal to corresponding signed elements in the second source vector, and place the boolean results of the comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

This instruction is a pseudo-instruction of the CMP<cc> (vectors) instruction. This means that:

- The encodings in this description are named to match the encodings of CMP<cc> (vectors).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CMP<cc> (vectors) gives the operational pseudocode for this instruction.

31 30 29 28	27 26 25 24	23 22	21	20 16	15	14	13	12 10	9 5	4	3 0
0 0 1 0	0 1 0 0	size	0	Zm	1	0	0	Pg	Zn	0	Pd
										ne	

Encoding

```
CMPLE <Pd>.<T>, <Pg>/Z, <Zm>.<T>, <Zn>.<T>
```

is equivalent to

```
CMPGE   <Pd>.<T>, <Pg>/Z, <Zn>.<T>, <Zm>.<T>
```

and is never the preferred disassembly.

Assembler symbols

`<Pd>` Is the name of the destination scalable predicate register, encoded in the "Pd" field.

`<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

`<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `B` when `size = 00`
- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

`<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

Operation

The description of CMP<cc> (vectors) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

C8.2.78 CMPLO (vectors)

Compare active unsigned integer elements in the first source vector being lower than corresponding unsigned elements in the second source vector, and place the boolean results of the comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

This instruction is a pseudo-instruction of the CMP<cc> (vectors) instruction. This means that:

- The encodings in this description are named to match the encodings of CMP<cc> (vectors).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CMP<cc> (vectors) gives the operational pseudocode for this instruction.

31 30 29 28	27 26 25 24	23 22	21	20 16	15	14	13	12 10	9 5	4	3 0
0 0 1 0	0 1 0 0	size	0	Zm	0	0	0	Pg	Zn	1 (ne)	Pd

Encoding

```
CMPLO <Pd>.<T>, <Pg>/Z, <Zm>.<T>, <Zn>.<T>
```

is equivalent to

```
CMPHI   <Pd>.<T>, <Pg>/Z, <Zn>.<T>, <Zm>.<T>
```

and is never the preferred disassembly.

Assembler symbols

`<Pd>` Is the name of the destination scalable predicate register, encoded in the "Pd" field.

`<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

`<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `B` when `size = 00`
- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

`<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

Operation

The description of CMP<cc> (vectors) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the predicate register or NZCV condition flags written by this instruction might be significantly delayed.

C8.2.81 CNOT

Logically invert the boolean value in each active element of the source vector, and place the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified.

Boolean TRUE is any non-zero value in a source, and one in a result element. Boolean FALSE is always zero.

31 30 29 28	27 26 25 24	23 22	21 20	19	18 17 16	15 14 13 12	10 9	5 4	0
0 0 0 0	0 1 0 0	size	0 1 1	0	1	1 0 1	Pg	Zn	Zd

Encoding

```
CNOT <Zd>.<T>, <Pg>/M, <Zn>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Zd);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(VL) result = Z[d];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element = Elem[operand, e, esize];
        Elem[result, e, esize] = ZeroExtend(IsZeroBit(element), esize);

Z[d] = result;
```

C8.2.83 CNTB, CNTD, CNTH, CNTW

Determines the number of active elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then places the result in the scalar destination.

The named predicate constraint limits the number of active elements in a single predicate to:

* A fixed number (`VL1` to `VL256`)

* The largest power of two (`POW2`)

* The largest multiple of three or four (`MUL3` or `MUL4`)

* All available, implicitly a multiple of two (`ALL`).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

Byte

Encoding

```
CNTB <Xd>{, <pattern>{, MUL #<imm>}}
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8;
integer d = UInt(Rd);
bits(5) pat = pattern;
integer imm = UInt(imm4) + 1;
```

Doubleword

Encoding

```
CNTD <Xd>{, <pattern>{, MUL #<imm>}}
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 64;
integer d = UInt(Rd);
bits(5) pat = pattern;
integer imm = UInt(imm4) + 1;
```

Halfword

Encoding

```
CNTH <Xd>{, <pattern>{, MUL #<imm>}}
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 16;
integer d = UInt(Rd);
bits(5) pat = pattern;
integer imm = UInt(imm4) + 1;
```

Word

Encoding

```
CNTW <Xd>{, <pattern>{, MUL #<imm>}}
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 32;
integer d = UInt(Rd);
bits(5) pat = pattern;
integer imm = UInt(imm4) + 1;
```

Assembler symbols

`<Xd>` Is the 64-bit name of the destination general-purpose register, encoded in the "Rd" field.

`<pattern>` Is the optional pattern specifier, defaulting to ALL, encoded in the "pattern" field. It can have the following values:

`POW2`	when `pattern = 00000`
`VL1`	when `pattern = 00001`
`VL2`	when `pattern = 00010`
`VL3`	when `pattern = 00011`
`VL4`	when `pattern = 00100`
`VL5`	when `pattern = 00101`
`VL6`	when `pattern = 00110`
`VL7`	when `pattern = 00111`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.

VL8	when pattern = 01000
VL16	when pattern = 01001
VL32	when pattern = 01010
VL64	when pattern = 01011
VL128	when pattern = 01100
VL256	when pattern = 01101
#uimm5	when pattern = 0111x
#uimm5	when pattern = 101x1
#uimm5	when pattern = 10110
#uimm5	when pattern = 1x0x1
#uimm5	when pattern = 1x010
#uimm5	when pattern = 1xx00
MUL4	when pattern = 11101
MUL3	when pattern = 11110
ALL	when pattern = 11111

<imm> Is the immediate multiplier, in the range 1 to 16, defaulting to 1, encoded in the "imm4" field.

Operation for all encodings

```
CheckSVEEnabled();
integer count = DecodePredCount(pat, esize);

X[d] = (count * imm)<63:0>;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C8.2.84 CNTP

Counts the number of active and true elements in the source predicate and places the scalar result in the destination general-purpose register. Inactive predicate elements are not counted.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14	13 10	9	8 5	4 0
0 0 1 0	0 1 0 1	size	1 0 0	0 0	0	1 0	Pg		0	Pn	Rd

Encoding

```
CNTP <Xd>, <Pg>, <Pn>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Pn);
integer d = UInt(Rd);
```

Assembler symbols

<Xd> Is the 64-bit name of the destination general-purpose register, encoded in the "Rd" field.

<Pg> Is the name of the governing scalable predicate register, encoded in the "Pg" field.

<Pn> Is the name of the source scalable predicate register, encoded in the "Pn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

B	when size = 00
H	when size = 01
S	when size = 10
D	when size = 11

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(PL) operand = P[n];
bits(64) sum = Zeros();

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' && ElemP[operand, e, esize] == '1' then
        sum = sum + 1;
X[d] = sum;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.

C8.2.85 COMPACT

Read the active elements from the source vector and pack them into the lowest-numbered elements of the destination vector. Then set any remaining elements of the destination vector to zero.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

31 30 29 28	27 26 25 24	23 22	21 20	19 18 17 16	15 14 13 12	10 9	5 4	0
0 0 0 0	0 1 0 1	size	1 0	0 0 0 1	1 0 0	Pg	Zn	Zd

Encoding

```
COMPACT <Zd>.<T>, <Pg>, <Zn>.<T>
```

Decode for this encoding

```
if !HaveSVE() then UNDEFINED;
if size == '0x' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Zd);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size<0>" field. It can have the following values:

S when size<0> = 0

D when size<0> = 1

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation

```
CheckNonStreamingSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(VL) result = Zeros();
integer x = 0;

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element = Elem[operand1, e, esize];
        Elem[result, x, esize] = element;
        x = x + 1;

Z[d] = result;
```

C8.2.86 CPY (immediate, merging)

Copy a signed integer immediate to each active element in the destination vector. Inactive elements in the destination vector register remain unmodified.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<simm8>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

This instruction is used by the pseudo-instructions FMOV (zero, predicated) and MOV (immediate, predicated, merging). The alias is always the preferred disassembly.

31 30 29 28	27 26 25 24	23 22	21 20	19 16	15	14	13	12	5 4	0
0 0 0 0	0 1 0 1	size	0 1	Pg	0	1	sh	imm8		Zd
						M				

Encoding

```
CPY <Zd>.<T>, <Pg>/M, #<imm>{, <shift>}
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size:sh == '001' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer d = UInt(Zd);
boolean merging = TRUE;
integer imm = SInt(imm8);
if sh == '1' then imm = imm << 8;
```

Alias conditions

Alias or pseudo-instruction	is preferred when
FMOV (zero, predicated)	Never
MOV (immediate, predicated, merging)	Unconditionally

Assembler symbols

`<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `B` when `size = 00`
- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

`<Pg>` Is the name of the governing scalable predicate register, encoded in the "Pg" field.

`<imm>` Is a signed immediate in the range -128 to 127, encoded in the "imm8" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

`LSL #0` when `sh = 0`

`LSL #8` when `sh = 1`

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) dest = Z[d];
bits(VL) result;

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        Elem[result, e, esize] = imm<esize-1:0>;
    elsif merging then
        Elem[result, e, esize] = Elem[dest, e, esize];
    else
        Elem[result, e, esize] = Zeros();

Z[d] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.87 CPY (immediate, zeroing)

Copy a signed integer immediate to each active element in the destination vector. Inactive elements in the destination vector register are set to zero.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<simm8>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

This instruction is used by the alias MOV (immediate, predicated, zeroing). The alias is always the preferred disassembly.

31 30 29 28	27 26 25 24	23 22	21 20	19 16	15	14	13	12 5	4 0
0 0 0 0	0 1 0 1	size	0 1	Pg	0	0 (M)	sh	imm8	Zd

Encoding

```
CPY <Zd>.<T>, <Pg>/Z, #<imm>{, <shift>}
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size:sh == '001' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer d = UInt(Zd);
boolean merging = FALSE;
integer imm = SInt(imm8);
if sh == '1' then imm = imm << 8;
```

Assembler symbols

`<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `B` when `size = 00`
- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

`<Pg>` Is the name of the governing scalable predicate register, encoded in the "Pg" field.

`<imm>` Is a signed immediate in the range -128 to 127, encoded in the "imm8" field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

- `LSL #0` when `sh = 0`
- `LSL #8` when `sh = 1`

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) dest = Z[d];
bits(VL) result;

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        Elem[result, e, esize] = imm<esize-1:0>;
    elsif merging then
        Elem[result, e, esize] = Elem[dest, e, esize];
    else
        Elem[result, e, esize] = Zeros();

Z[d] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

C8.2.90 CTERMEQ, CTERMNE

Detect termination conditions in serialized vector loops. Tests whether the comparison between the scalar source operands holds true and if not tests the state of the !LAST condition flag (C) which indicates whether the previous flag-setting predicate instruction selected the last element of the vector partition.

The Z and C condition flags are preserved by this instruction. The N and V condition flags are set as a pair to generate one of the following conditions for a subsequent conditional instruction:

* GE (N=0 & V=0): continue loop (compare failed and last element not selected);

* LT (N=0 & V=1): terminate loop (last element selected);

* LT (N=1 & V=0): terminate loop (compare succeeded);

The scalar source operands are 32-bit or 64-bit general-purpose registers of the same size.

C8.2.91 DECB, DECD, DECH, DECW (scalar)

Determines the number of active elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement the scalar destination.

The named predicate constraint limits the number of active elements in a single predicate to:

* A fixed number (`VL1` to `VL256`)

* The largest power of two (`POW2`)

* The largest multiple of three or four (`MUL3` or `MUL4`)

* All available, implicitly a multiple of two (`ALL`).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

C8.2.93 DECP (scalar)

Counts the number of true elements in the source predicate and then uses the result to decrement the scalar destination.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13 12	11 10	9 8	5 4	0
0 0 1 0	0 1 0 1	size	1 0	1 1	0	1	1 0 0 0	1 0	0	Pm	Rdn
						D					

Encoding

```
DECP <Xdn>, <Pm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer m = UInt(Pm);
integer dn = UInt(Rdn);
```

Assembler symbols

<Xdn> Is the 64-bit name of the source and destination general-purpose register, encoded in the "Rdn" field.

<Pm> Is the name of the source scalable predicate register, encoded in the "Pm" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

B when size = 00

H when size = 01

S when size = 10

D when size = 11

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(64) operand1 = X[dn];
bits(PL) operand2 = P[m];
integer count = 0;

for e = 0 to elements-1
    if ElemP[operand2, e, esize] == '1' then
        count = count + 1;

X[dn] = operand1 - count;
```

Operational information

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the general-purpose register written by this instruction might be significantly delayed.

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer m = UInt(Pm);
integer dn = UInt(Zdn);
```

Assembler symbols

<Zdn> Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10
- D when size = 11

The encoding size = 00 is reserved.

<Pm> Is the name of the source scalable predicate register, encoded in the "Pm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn];
bits(PL) operand2 = P[m];
bits(VL) result;
integer count = 0;

for e = 0 to elements-1
    if ElemP[operand2, e, esize] == '1' then
        count = count + 1;

for e = 0 to elements-1
    Elem[result, e, esize] = Elem[operand1, e, esize] - count;

Z[dn] = result;
```

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

Non-Confidential

C8.2.95 DUP (immediate)

Unconditionally broadcast the signed integer immediate into each element of the destination vector. This instruction is unpredicated.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<simm8>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

This instruction is used by the pseudo-instructions FMOV (zero, unpredicated) and MOV (immediate, unpredicated). The alias is always the preferred disassembly.

31 30 29 28	27 26 25 24	23 22	21 20	19	18	17	16	15 14	13	12	5 4	0
0 0 1 0	0 1 0 1	size	1 1 1	0	0	0	1	1	sh	imm8		Zd

Encoding

```
DUP <Zd>.<T>, #<imm>{, <shift>}
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size:sh == '001' then UNDEFINED;
integer esize = 8 << UInt(size);
integer d = UInt(Zd);
integer imm = SInt(imm8);
if sh == '1' then imm = imm << 8;
```

Alias conditions

Alias or pseudo-instruction	is preferred when
FMOV (zero, unpredicated)	Never
MOV (immediate, unpredicated)	Unconditionally

Assembler symbols

`<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `B` when `size = 00`
- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

`<imm>` Is a signed immediate in the range -128 to 127, encoded in the "imm8" field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

- `LSL #0` when `sh = 0`

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

LSL #8 when sh = 1

Operation

```
CheckSVEEnabled();
bits(VL) result = Replicate(imm<esize-1:0>);
Z[d] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Non-Confidential

C8.2.96 DUP (indexed)

Unconditionally broadcast the indexed source vector element into each element of the destination vector. This instruction is unpredicated.

The immediate element index is in the range of 0 to 63 (bytes), 31 (halfwords), 15 (words), 7 (doublewords) or 3 (quadwords). Selecting an element beyond the accessible vector length causes the destination vector to be set to zero.

This instruction is used by the alias MOV (SIMD&FP scalar, unpredicated). See *Alias conditions* for details of when each alias is preferred.

31 30 29 28	27 26 25 24	23 22 21 20	16	15 14 13 12	11 10	9 5	4 0
0 0 0 0	0 1 0 1	imm2 1	tsz	0 0 1 0	0 0	Zn	Zd

Encoding

```
DUP <Zd>.<T>, <Zn>.<T>[<imm>]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
bits(7) imm = imm2:tsz;
integer esize;
integer index;
case tsz of
    when '00000' UNDEFINED;
    when '10000' esize = 128; index = UInt(imm<6:5>);
    when 'x1000' esize = 64;  index = UInt(imm<6:4>);
    when 'xx100' esize = 32;  index = UInt(imm<6:3>);
    when 'xxx10' esize = 16;  index = UInt(imm<6:2>);
    when 'xxxx1' esize = 8;   index = UInt(imm<6:1>);
integer n = UInt(Zn);
integer d = UInt(Zd);
```

Alias conditions

Alias	is preferred when
MOV (SIMD&FP scalar, unpredicated)	`BitCount(imm2:tsz) == 1`
MOV (SIMD&FP scalar, unpredicated)	`BitCount(imm2:tsz) > 1`

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "tsz" field. It can have the following values:

- B when `tsz = xxxx1`
- H when `tsz = xxx10`
- S when `tsz = xx100`
- D when `tsz = x1000`
- Q when `tsz = 10000`

The encoding `tsz = 00000` is reserved.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

<imm> Is the immediate index, in the range 0 to one less than the number of elements in 512 bits, encoded in "imm2:tsz".

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(VL) operand1 = Z[n];
bits(VL) result;
bits(esize) element;

if index >= elements then
    element = Zeros();
else
    element = Elem[operand1, index, esize];
result = Replicate(element);

Z[d] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C8.2.97 DUP (scalar)

Unconditionally broadcast the general-purpose scalar source register into each element of the destination vector. This instruction is unpredicated.

This instruction is used by the alias MOV (scalar, unpredicated). The alias is always the preferred disassembly.

31 30 29 28	27 26 25 24	23 22	21 20	19 18 17 16	15 14 13 12	11 10	9 5	4 0
0 0 0 0	0 1 0 1	size	1 0	0 0 0 0	0 0 1 1	1 0	Rn	Zd

Encoding

```
DUP <Zd>.<T>, <R><n|SP>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer n = UInt(Rn);
integer d = UInt(Zd);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<R> Is a width specifier, encoded in the "size" field. It can have the following values:

- W when size = 01
- W when size = x0
- X when size = 11

<n|SP> Is the number [0-30] of the general-purpose source register or the name SP (31), encoded in the "Rn" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(64) operand;
if n == 31 then
    operand = SP[];
else
    operand = X[n];
bits(VL) result;

for e = 0 to elements-1
    Elem[result, e, esize] = operand<esize-1:0>;

Z[d] = result;
```

C8.2.98 DUPM

Unconditionally broadcast the logical bitmask immediate into each element of the destination vector. This instruction is unpredicated. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32 or 64 bits.

This instruction is used by the alias MOV. See *Alias conditions* for details of when each alias is preferred.

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17	5 4	0
0 0 0 0	0 1 0 1	1 1 0 0	0 0	imm13	Zd

Encoding

```
DUPM <Zd>.<T>, #<const>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 64;
integer d = UInt(Zd);
bits(esize) imm;
(imm, -) = DecodeBitMasks(imm13<12>, imm13<5:0>, imm13<11:6>, TRUE);
```

Alias conditions

Alias	is preferred when
MOV	`SVEMoveMaskPreferred(imm13)`

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "imm13<12>:imm13<5:0>" field. It can have the following values:

S when `imm13<12> = 0, imm13<5:0> = 0xxxxx`

H when `imm13<12> = 0, imm13<5:0> = 10xxxx`

B when `imm13<12> = 0, imm13<5:0> = 110xxx`

B when `imm13<12> = 0, imm13<5:0> = 1110xx`

B when `imm13<12> = 0, imm13<5:0> = 11110x`

D when `imm13<12> = 1, imm13<5:0> = xxxxxx`

The following encodings are reserved:

- `imm13<12> = 0, imm13<5:0> = 111110`.
- `imm13<12> = 0, imm13<5:0> = 111111`.

<const> Is a 64, 32, 16 or 8-bit bitmask consisting of replicated 2, 4, 8, 16, 32 or 64 bit fields, each field containing a rotated run of non-zero bits, encoded in the "imm13" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.

C8.2.99 EON

Bitwise exclusive OR an inverted immediate with each 64-bit element of the source vector, and destructively place the results in the corresponding elements of the source vector. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32 or 64 bits. This instruction is unpredicated.

This instruction is a pseudo-instruction of the EOR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of EOR (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of EOR (immediate) gives the operational pseudocode for this instruction.

31 30 29 28	27 26 25 24	23	22	21 20	19 18 17	5 4	0
0 0 0 0	0 1 0 1	0	1	0 0	0 0	imm13	Zdn

Encoding

```
EON <Zdn>.<T>, <Zdn>.<T>, #<const>
```

is equivalent to

```
EOR <Zdn>.<T>, <Zdn>.<T>, #(-<const> - 1)
```

and is never the preferred disassembly.

Assembler symbols

`<Zdn>` Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

`<T>` Is the size specifier, encoded in the "imm13<12>:imm13<5:0>" field. It can have the following values:

S	when `imm13<12> = 0`, `imm13<5:0> = 0xxxxx`
H	when `imm13<12> = 0`, `imm13<5:0> = 10xxxx`
B	when `imm13<12> = 0`, `imm13<5:0> = 110xxx`
B	when `imm13<12> = 0`, `imm13<5:0> = 1110xx`
B	when `imm13<12> = 0`, `imm13<5:0> = 11110x`
D	when `imm13<12> = 1`, `imm13<5:0> = xxxxxx`

The following encodings are reserved:

- `imm13<12> = 0`, `imm13<5:0> = 111110`.
- `imm13<12> = 0`, `imm13<5:0> = 111111`.

`<const>` Is a 64, 32, 16 or 8-bit bitmask consisting of replicated 2, 4, 8, 16, 32 or 64 bit fields, each field containing a rotated run of non-zero bits, encoded in the "imm13" field.

Operation

The description of EOR (immediate) gives the operational pseudocode for this instruction.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.100 EOR (immediate)

Bitwise exclusive OR an immediate with each 64-bit element of the source vector, and destructively place the results in the corresponding elements of the source vector. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32 or 64 bits. This instruction is unpredicated.

This instruction is used by the pseudo-instruction EON. The pseudo-instruction is never the preferred disassembly.

31 30 29 28	27 26 25 24	23	22	21 20	19 18 17	5 4	0
0 0 0 0	0 1 0 1	0	1	0 0	0 0	imm13	Zdn

Encoding

```
EOR <Zdn>.<T>, <Zdn>.<T>, #<const>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer dn = UInt(Zdn);
bits(64) imm;
(imm, -) = DecodeBitMasks(imm13<12>, imm13<5:0>, imm13<11:6>, TRUE);
```

Assembler symbols

<Zdn> Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "imm13<12>:imm13<5:0>" field. It can have the following values:

S when imm13<12> = 0, imm13<5:0> = 0xxxxx

H when imm13<12> = 0, imm13<5:0> = 10xxxx

B when imm13<12> = 0, imm13<5:0> = 110xxx

B when imm13<12> = 0, imm13<5:0> = 1110xx

B when imm13<12> = 0, imm13<5:0> = 11110x

D when imm13<12> = 1, imm13<5:0> = xxxxxx

The following encodings are reserved:

- imm13<12> = 0, imm13<5:0> = 111110.
- imm13<12> = 0, imm13<5:0> = 111111.

<const> Is a 64, 32, 16 or 8-bit bitmask consisting of replicated 2, 4, 8, 16, 32 or 64 bit fields, each field containing a rotated run of non-zero bits, encoded in the "imm13" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV 64;
bits(VL) operand = Z[dn];
bits(VL) result;

for e = 0 to elements-1
    bits(64) element1 = Elem[operand, e, 64];
    Elem[result, e, 64] = element1 EOR imm;

Z[dn] = result;
```

C8.2.101 EOR (predicates)

Bitwise exclusive OR active elements of the second source predicate with corresponding elements of the first source predicate and place the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Does not set the condition flags.

This instruction is used by the alias NOT (predicate). See *Alias conditions* for details of when each alias is preferred.

31 30 29 28	27 26 25 24	23	22	21 20	19 16	15 14	13 10	9	8 5	4	3 0
0 0 1 0	0 1 0 1	0	0	0 0	Pm	0 1	Pg	1	Pn	0	Pd
			S								

Encoding

```
EOR <Pd>.B, <Pg>/Z, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8;
integer g = UInt(Pg);
integer n = UInt(Pn);
integer m = UInt(Pm);
integer d = UInt(Pd);
boolean setflags = FALSE;
```

Alias conditions

Alias	is preferred when
NOT (predicate)	`Pm == Pg`

Assembler symbols

`<Pd>`	Is the name of the destination scalable predicate register, encoded in the "Pd" field.
`<Pg>`	Is the name of the governing scalable predicate register, encoded in the "Pg" field.
`<Pn>`	Is the name of the first source scalable predicate register, encoded in the "Pn" field.
`<Pm>`	Is the name of the second source scalable predicate register, encoded in the "Pm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(PL) operand1 = P[n];
bits(PL) operand2 = P[m];
bits(PL) result;

for e = 0 to elements-1
    bit element1 = ElemP[operand1, e, esize];
    bit element2 = ElemP[operand2, e, esize];
    if ElemP[mask, e, esize] == '1' then
        ElemP[result, e, esize] = element1 EOR element2;
    else
        ElemP[result, e, esize] = '0';
```

C8.2.102 EOR (vectors, predicated)

Bitwise exclusive OR active elements of the second source vector with corresponding elements of the first source vector and destructively place the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12 10 9	5 4	0
0 0 0 0	0 1 0 0	size	0 1 1	0 0	1	0	0 0	Pg	Zm	Zdn

Encoding

```
EOR <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m] else Zeros();
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    bits(esize) element2 = Elem[operand2, e, esize];
    if ElemP[mask, e, esize] == '1' then
        Elem[result, e, esize] = element1 EOR element2;
    else
        Elem[result, e, esize] = Elem[operand1, e, esize];

Z[dn] = result;
```

C8.2.103 EOR (vectors, unpredicated)

Bitwise exclusive OR all elements of the second source vector with corresponding elements of the first source vector and place the results in the corresponding elements of the destination vector. This instruction is unpredicated.

31 30 29 28	27 26 25 24	23	22	21	20 … 16	15 14 13 12	11 10	9 … 5	4 … 0
0 0 0 0	0 1 0 0	1	0	1	Zm	0 0 1 1	0 0	Zn	Zd

Encoding

```
EOR <Zd>.D, <Zn>.D, <Zm>.D
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
```

Assembler symbols

<Zd>	Is the name of the destination scalable vector register, encoded in the "Zd" field.
<Zn>	Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Zm>	Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
bits(VL) operand1 = Z[n];
bits(VL) operand2 = Z[m];

Z[d] = operand1 EOR operand2;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

C8.2.104 EOR3

Bitwise exclusive OR the corresponding elements of all three source vectors, and destructively place the results in the corresponding elements of the destination and first source vector. This instruction is unpredicated.

31 30 29 28	27 26 25 24	23	22	21	20 … 16	15	14	13	12	11	10	9 … 5	4 … 0
0 0 0 0	0 1 0 0	0	0	1	Zm	0	0	1	1	1	0	Zk	Zdn

Encoding

```
EOR3 <Zdn>.D, <Zdn>.D, <Zm>.D, <Zk>.D
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
integer m = UInt(Zm);
integer k = UInt(Zk);
integer dn = UInt(Zdn);
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

<Zk> Is the name of the third source scalable vector register, encoded in the "Zk" field.

Operation

```
CheckSVEEnabled();
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = Z[m];
bits(VL) operand3 = Z[k];

Z[dn] = operand1 EOR operand2 EOR operand3;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.105 EORBT

Interleaving exclusive OR between the even-numbered elements of the first source vector register and the odd-numbered elements of the second source vector register, placing the result in the even-numbered elements of the destination vector, leaving the odd-numbered elements unchanged. This instruction is unpredicated.

31 30 29 28	27 26 25 24	23 22 21 20	16	15 14 13 12	11 10	9 5	4 0
0 1 0 0	0 1 0 1	size	0	Zm	1 0 0 1 0	0 (tb)	Zn	Zd

Encoding

```
EORBT <Zd>.<T>, <Zn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
integer sel1 = 0;
integer sel2 = 1;
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV (2 * esize);
bits(VL) operand1 = Z[n];
bits(VL) operand2 = Z[m];
bits(VL) result = Z[d];

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, 2*e + sel1, esize];
    bits(esize) element2 = Elem[operand2, 2*e + sel2, esize];
    Elem[result, 2*e + sel1, esize] = element1 EOR element2;

Z[d] = result;
```

C8.2.106 EORS

Bitwise exclusive OR active elements of the second source predicate with corresponding elements of the first source predicate and place the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

This instruction is used by the alias NOTS. See *Alias conditions* for details of when each alias is preferred.

31 30 29 28	27 26 25 24	23	22	21 20	19 16	15 14 13	10 9	8 5	4	3 0
0 0 1 0	0 1 0 1	0	1	0 0	Pm	0 1	Pg	1	Pn	0	Pd
			S							

Encoding

```
EORS <Pd>.B, <Pg>/Z, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8;
integer g = UInt(Pg);
integer n = UInt(Pn);
integer m = UInt(Pm);
integer d = UInt(Pd);
boolean setflags = TRUE;
```

Alias conditions

Alias	is preferred when
NOTS	`Pm == Pg`

Assembler symbols

`<Pd>`	Is the name of the destination scalable predicate register, encoded in the "Pd" field.
`<Pg>`	Is the name of the governing scalable predicate register, encoded in the "Pg" field.
`<Pn>`	Is the name of the first source scalable predicate register, encoded in the "Pn" field.
`<Pm>`	Is the name of the second source scalable predicate register, encoded in the "Pm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(PL) operand1 = P[n];
bits(PL) operand2 = P[m];
bits(PL) result;

for e = 0 to elements-1
    bit element1 = ElemP[operand1, e, esize];
    bit element2 = ElemP[operand2, e, esize];
    if ElemP[mask, e, esize] == '1' then
        ElemP[result, e, esize] = element1 EOR element2;
```

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    else
        ElemP[result, e, esize] = '0';

if setflags then
    PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
P[d] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.

C8.2.107 EORTB

Interleaving exclusive OR between the odd-numbered elements of the first source vector register and the even-numbered elements of the second source vector register, placing the result in the odd-numbered elements of the destination vector, leaving the even-numbered elements unchanged. This instruction is unpredicated.

31 30 29 28	27 26 25 24	23 22 21 20	16	15 14 13 12	11 10	9 5	4 0
0 1 0 0	0 1 0 1	size	0	Zm	1 0 0 1 0	1 (tb)	Zn	Zd

Encoding

```
EORTB <Zd>.<T>, <Zn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
integer sel1 = 1;
integer sel2 = 0;
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV (2 * esize);
bits(VL) operand1 = Z[n];
bits(VL) operand2 = Z[m];
bits(VL) result = Z[d];

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, 2*e + sel1, esize];
    bits(esize) element2 = Elem[operand2, 2*e + sel2, esize];
    Elem[result, 2*e + sel1, esize] = element1 EOR element2;

Z[d] = result;
```

C8.2.108 EORV

Bitwise exclusive OR horizontally across all lanes of a vector, and place the result in the SIMD&FP scalar destination register. Inactive elements in the source vector are treated as zero.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12 10	9 5	4 0
0 0 0 0	0 1 0 0	size	0 1	1 0	0	1	0 0 1	Pg	Zn	Vd

Encoding

```
EORV <V><d>, <Pg>, <Zn>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Vd);
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<d> Is the number [0-31] of the destination SIMD&FP register, encoded in the "Vd" field.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(esize) result = Zeros(esize);

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        result = result EOR Elem[operand, e, esize];

V[d] = result;
```

C8.2.109 EXT

Copy the indexed byte up to the last byte of the first source vector to the bottom of the result vector, then fill the remainder of the result starting from the first byte of the second source vector. The result is placed destructively in the destination and first source vector, or constructively in the destination vector. This instruction is unpredicated.

An index that is greater than or equal to the vector length in bytes is treated as zero, resulting in the first source vector being copied to the result unchanged.

The Destructive encoding of this instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE: The MOVPRFX instruction must be unpredicated. The MOVPRFX instruction must specify the same destination register as this instruction. The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

Constructive

31 30 29 28	27 26 25 24	23 22 21 20	16	15 14 13 12	10 9	5 4	0
0 0 0 0	0 1 0 1	0 1 1	imm8h	0 0 0	imm8l	Zn	Zd

Encoding

```
EXT <Zd>.B, { <Zn1>.B, <Zn2>.B }, #<imm>
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
integer esize = 8;
integer dst = UInt(Zd);
integer s1 = UInt(Zn);
integer s2 = (s1 + 1) MOD 32;
integer position = UInt(imm8h:imm8l);
```

Destructive

31 30 29 28	27 26 25 24	23 22 21 20	16	15 14 13 12	10 9	5 4	0
0 0 0 0	0 1 0 1	0 0 1	imm8h	0 0 0	imm8l	Zm	Zdn

Encoding

```
EXT <Zdn>.B, <Zdn>.B, <Zm>.B, #<imm>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8;
integer dst = UInt(Zdn);
integer s1 = dst;
integer s2 = UInt(Zm);
integer position = UInt(imm8h:imm8l);
```

Assembler symbols

`<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.

`<Zn1>` Is the name of the first scalable vector register of a multi-vector sequence, encoded in the "Zn" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Zn2> Is the name of the second scalable vector register of a multi-vector sequence, encoded in the "Zn" field.

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

<imm> Is the unsigned immediate operand, in the range 0 to 255, encoded in the "imm8h:imm8l" fields.

Operation for all encodings

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(VL) operand1 = Z[s1];
bits(VL) operand2 = Z[s2];
bits(VL) result;

if position >= elements then
    position = 0;

position = position << 3;
bits(VL*2) concat = operand2 : operand1;
result = concat<(position+VL)-1:position>;

Z[dst] = result;
```

Operational information

C8.2.110 FABD

Compute the absolute difference of active floating-point elements of the second source vector and corresponding floating-point elements of the first source vector and destructively place the result in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19 18 17	16	15 14 13	12	10 9	5 4	0
0 1 1 0	0 1 0 1	size	0 0	1 0 0	0	1 0 0	Pg	Zm	Zdn	

Encoding

```
FABD <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10
- D when size = 11

The encoding size = 00 is reserved.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m] else Zeros();
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element2 = Elem[operand2, e, esize];
        Elem[result, e, esize] = FPAbs(FPSub(element1, element2, FPCR[]));
    else
        Elem[result, e, esize] = element1;

Z[dn] = result;
```

C8.2.111 FABS

Take the absolute value of each active floating-point element of the source vector, and place the results in the corresponding elements of the destination vector. This clears the sign bit and cannot signal a floating-point exception. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12 10 9	5 4	0
0 0 0 0	0 1 0 0	size	0 1 1	1 0	0	1	0 1	Pg	Zn	Zd

Encoding

```
FABS <Zd>.<T>, <Pg>/M, <Zn>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Zd);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

H when size = 01

S when size = 10

D when size = 11

The encoding size = 00 is reserved.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(VL) result = Z[d];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element = Elem[operand, e, esize];
        Elem[result, e, esize] = FPAbs(element);

Z[d] = result;
```

C8.2.112 FAC<cc>

Compare active absolute values of floating-point elements in the first source vector with corresponding absolute values of elements in the second source vector, and place the boolean results of the specified comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Does not set the condition flags.

The <cc> symbol specifies one of the standard ARM condition codes: GE, GT, LE, or LT.

This instruction is used by the pseudo-instructions FACLE and FACLT. The pseudo-instruction is never the preferred disassembly.

C8.2.118 FADDA

Floating-point add a SIMD&FP scalar source and all active lanes of the vector source and place the result destructively in the SIMD&FP scalar source register. Vector elements are processed strictly in order from low to high, with the scalar source providing the initial value. Inactive elements in the source vector are ignored.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13 12	10 9	5 4	0

C8.2.121 FCADD

Add the real and imaginary components of the active floating-point complex numbers from the first source vector to the complex numbers from the second source vector which have first been rotated by 90 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, equivalent to multiplying the complex numbers in the second source vector by ±J beforehand. Destructively place the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

31 30 29 28	27 26 25 24	23 22	21 20	19 18 17 16	15	14 13 12	10 9	5 4	0

C8.2.122 FCM<cc> (vectors)

Compare active floating-point elements in the first source vector with corresponding elements in the second source vector, and place the boolean results of the specified comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Does not set the condition flags.

The <cc> symbol specifies one of the standard ARM condition codes: `EQ`, `GE`, `GT`, or `NE`, with the addition of `UO` for an unordered comparison.

This instruction is used by the pseudo-instructions FCMLE (vectors) and FCMLT (vectors). The pseudo-instruction is never the preferred disassembly.

C8.2.124 FCMLA (indexed)

Multiply the duplicated real components for rotations 0 and 180, or imaginary components for rotations 90 and 270, of the floating-point complex numbers in each 128-bit segment of the first source vector by the specified complex number in the corresponding the second source vector segment rotated by 0, 90, 180 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation.

Then destructively add the products to the corresponding components of the complex numbers in the addend and destination vector, without intermediate rounding.

These transformations permit the creation of a variety of multiply-add and multiply-subtract operations on complex numbers by combining two of these instructions with the same vector operands but with rotations that are 90 degrees apart.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

The complex numbers within the second source vector are specified using an immediate index which selects the same complex number position within each 128-bit vector segment. The index range is from 0 to one less than the number of complex numbers per 128-bit segment, encoded in 1 to 2 bits depending on the size of the complex number. This instruction is unpredicated.

Half-precision

Encoding

```
FCMLA <Zda>.H, <Zn>.H, <Zm>.H[<imm>], <const>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;

C8.2.126 FCMLE (vectors)

Compare active floating-point elements in the first source vector being less than or equal to corresponding elements in the second source vector, and place the boolean results of the comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Does not set the condition flags.

This instruction is a pseudo-instruction of the FCM<cc> (vectors) instruction. This means that:

- The encodings in this description are named to match the encodings of FCM<cc> (vectors).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of FCM<cc> (vectors) gives the operational pseudocode for this instruction.

Encoding

```
FCMLE <Pd>.<T>, <Pg>/Z, <Zm>.<T>, <Zn>.<T>
```

is equivalent to

```
FCMGE   <Pd>.<T>, <Pg>/Z, <Zn>.<T>, <Zm>.<T>
```

and is never the preferred disassembly.

Assembler symbols

`<Pd>` Is the name of the destination scalable predicate register, encoded in the "Pd" field.

`<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

`<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

The encoding `size = 00` is reserved.

`<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

Operation

The description of FCM<cc> (vectors) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the predicate register written by this instruction might be significantly delayed.

C8.2.127 FCMLT (vectors)

Compare active floating-point elements in the first source vector being less than corresponding elements in the second source vector, and place the boolean results of the comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Does not set the condition flags.

This instruction is a pseudo-instruction of the FCM<cc> (vectors) instruction. This means that:

- The encodings in this description are named to match the encodings of FCM<cc> (vectors).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of FCM<cc> (vectors) gives the operational pseudocode for this instruction.

Encoding

```
FCMLT <Pd>.<T>, <Pg>/Z, <Zm>.<T>, <Zn>.<T>
```

is equivalent to

```
FCMGT   <Pd>.<T>, <Pg>/Z, <Zn>.<T>, <Zm>.<T>
```

and is never the preferred disassembly.

Assembler symbols

`<Pd>` Is the name of the destination scalable predicate register, encoded in the "Pd" field.

`<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

`<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

The encoding `size = 00` is reserved.

`<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

Operation

The description of FCM<cc> (vectors) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the predicate register written by this instruction might be significantly delayed.

C8.2.128 FCPY

Copy a floating-point immediate into each active element in the destination vector. Inactive elements in the destination vector register remain unmodified.

This instruction is used by the alias FMOV (immediate, predicated). The alias is always the preferred disassembly.

31 30 29 28	27 26 25 24	23 22	21 20	19 16	15 14 13	12 5	4 0
0 0 0 0	0 1 0 1	size	0 1	Pg	1 1 0	imm8	Zd

Encoding

```
FCPY <Zd>.<T>, <Pg>/M, #<const>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer d = UInt(Zd);
bits(esize) imm = VFPExpandImm(imm8);
```

Assembler symbols

`<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

The encoding `size = 00` is reserved.

`<Pg>` Is the name of the governing scalable predicate register, encoded in the "Pg" field.

`<const>` Is a floating-point immediate value expressable as ±n÷16×2^r, where n and r are integers such that $16 \le n \le 31$ and $-3 \le r \le 4$, i.e. a normalized binary floating-point encoding with 1 sign bit, 3-bit exponent, and 4-bit fractional part, encoded in the "imm8" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) result = Z[d];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        Elem[result, e, esize] = imm;

Z[d] = result;
```

C8.2.129 FCVT

Convert the size and precision of each active floating-point element of the source vector, and place the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified.

Since the input and result types have a different size the smaller type is held unpacked in the least significant bits of elements of the larger size. When the input is the smaller type the upper bits of each source element are ignored. When the result is the smaller type the results are zero-extended to fill each destination element.

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation for all encodings

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand  = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(VL) result = Z[d];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element = Elem[operand, e, esize];
        bits(d_esize) res = FPToFixed(element<s_esize-1:0>, 0, unsigned, FPCR[], rounding);
        Elem[result, e, esize] = Extend(res, unsigned);

Z[d] = result;
```

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.139 FEXPA

The FEXPA instruction accelerates the polynomial series calculation of the EXP(X) function.

The double-precision variant copies the low 52 bits of an entry from a hard-wired table of 64-bit coefficients, indexed by the low 6 bits of each element of the source vector, and prepends to that the next 11 bits of the source element (src<16:6>), setting the sign bit to zero.

The single-precision variant copies the low 23 bits of an entry from hard-wired table of 32-bit coefficients, indexed by the low 6 bits of each element of the source vector, and prepends to that the next 8 bits of the source element (src<13:6>), setting the sign bit to zero.

The half-precision variant copies the low 10 bits of an entry from hard-wired table of 16-bit coefficients, indexed by the low 5 bits of each element of the source vector, and prepends to that the next 5 bits of the source element (src<9:5>), setting the sign bit to zero.

A coefficient table entry with index M holds the floating-point value $2^{(m/64)}$, or for the half-precision variant $2^{(m/32)}$. This instruction is unpredicated.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

C8.2.140 FLOGB

This instruction returns the signed integer base 2 logarithm of each floating-point input element |X| after normalization.

This is the unbiased exponent of X used in the representation of the floating-point value, such that, for positive X, X = significand × $2^{exponent}$.

The integer results are placed in elements of the destination vector which have the same width (ESIZE) as the floating-point input elements:

* If X is normal, the result is the base 2 logarithm of X.

* If X is subnormal, the result corresponds to the normalized representation.

* If X is infinite, the result is $2^{(esize-1)}$-1.

* If X is ±0.0 or NaN, the result is -$2^{(esize-1)}$.

Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23	22	21 20	19 18 17 16	15	14 13 12	10 9	5 4	0

C8.2.147 FMAXNMV

Floating-point maximum number horizontally over all lanes of a vector using a recursive pairwise reduction, and place the result in the SIMD&FP scalar destination register. Inactive elements in the source vector are treated as the default NaN.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12 10 9	5 4	0
0 1 1 0	0 1 0 1	size	0 0 0	1 0	0	0	0 0 1	Pg	Zn	Vd

Encoding

```
FMAXNMV <V><d>, <Pg>, <Zn>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Vd);
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

- H when `size = 01`
- S when `size = 10`
- D when `size = 11`

The encoding `size = 00` is reserved.

<d> Is the number [0-31] of the destination SIMD&FP register, encoded in the "Vd" field.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when `size = 01`
- S when `size = 10`
- D when `size = 11`

The encoding `size = 00` is reserved.

Operation

```
CheckSVEEnabled();
bits(PL) mask = P[g];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(esize) identity = FPDefaultNaN();

C8.2.153 FMINNM (vectors)

Determine the minimum number value of active floating-point elements of the second source vector and corresponding floating-point elements of the first source vector and destructively place the results in the corresponding elements of the first source vector. If one element value is numeric and the other is a quiet NaN, then the result is the numeric value. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19 18 17	16	15 14 13	12 10 9	5 4	0
0 1 1 0	0 1 0 1	size	0 0	0 1 0	1	1 0 0	Pg	Zm	Zdn

Encoding

```
FMINNM <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10
- D when size = 11

The encoding size = 00 is reserved.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m] else Zeros();
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element2 = Elem[operand2, e, esize];
        Elem[result, e, esize] = FPMinNum(element1, element2, FPCR[]);
    else
        Elem[result, e, esize] = element1;

Z[dn] = result;

C8.2.155 FMINNMV

Floating-point minimum number horizontally over all lanes of a vector using a recursive pairwise reduction, and place the result in the SIMD&FP scalar destination register. Inactive elements in the source vector are treated as the default NaN.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12	10 9	5 4	0
0 1 1 0	0 1 0 1	size	0 0 0	1 0	1	0	0 1	Pg	Zn	Vd	

Encoding

```
FMINNMV <V><d>, <Pg>, <Zn>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Vd);
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

- H when `size = 01`
- S when `size = 10`
- D when `size = 11`

The encoding `size = 00` is reserved.

<d> Is the number [0-31] of the destination SIMD&FP register, encoded in the "Vd" field.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when `size = 01`
- S when `size = 10`
- D when `size = 11`

The encoding `size = 00` is reserved.

Operation

```
CheckSVEEnabled();
bits(PL) mask = P[g];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(esize) identity = FPDefaultNaN();

V[d] = ReducePredicated(ReduceOp_FMINNUM, operand, mask, identity);

C8.2.158 FMLA (indexed)

Multiply all floating-point elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The products are then destructively added without intermediate rounding to the corresponding elements of the addend and destination vector.

The elements within the second source vector are specified using an immediate index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 3 bits depending on the size of the element. This instruction is unpredicated.

Half-precision

Encoding

```
FMLA <Zda>.H, <Zn>.H, <Zm>.H[<imm>]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 16;
integer index = UInt(i3h:i3l);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);
boolean op1_neg = FALSE;
boolean op3_neg = FALSE;
```

Single-precision

Encoding

```
FMLA <Zda>.S, <Zn>.S, <Zm>.S[<imm>]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 32;
integer index = UInt(i2);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);
boolean op1_neg = FALSE;
boolean op3_neg = FALSE;
```

C8.2.164 FMLS (indexed)

Multiply all floating-point elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The products are then destructively subtracted without intermediate rounding from the corresponding elements of the addend and destination vector.

The elements within the second source vector are specified using an immediate index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 3 bits depending on the size of the element. This instruction is unpredicated.

Half-precision

Encoding

```
FMLS <Zda>.H, <Zn>.H, <Zm>.H[<imm>]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;

integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);
boolean op1_neg = TRUE;
boolean op3_neg = FALSE;
```

Assembler symbols

`<Zda>` Is the name of the third source and destination scalable vector register, encoded in the "Zda" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

The encoding `size = 00` is reserved.

`<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

`<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.

`<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m] else Zeros();
bits(VL) operand3 = Z[da];
bits(VL) result;

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element1 = Elem[operand1, e, esize];
        bits(esize) element2 = Elem[operand2, e, esize];
        bits(esize) element3 = Elem[operand3, e, esize];
```

C8.2.170 FMMLA

The floating-point matrix multiply-accumulate instruction supports single-precision and double-precision data types in a 2×2 matrix contained in segments of 128 or 256 bits, respectively. It multiplies the 2×2 matrix in each segment of the first source vector by the 2×2 matrix in the corresponding segment of the second source vector. The resulting 2×2 matrix product is then destructively added to the matrix accumulator held in the corresponding segment of the addend and destination vector. This is equivalent to performing a 2-way dot product per destination element. This instruction is unpredicated. The single-precision variant is vector length agnostic. The double-precision variant requires that the current vector length is at least 256 bits, and if the current vector length is not an integer multiple of 256 bits then the trailing bits are set to zero.

ID_AA64ZFR0_EL1.F32MM indicates whether the single-precision variant is implemented.

ID_AA64ZFR0_EL1.F64MM indicates whether the double-precision variant is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

C8.2.171 FMOV (immediate, predicated)

Move a floating-point immediate into each active element in the destination vector. Inactive elements in the destination vector register remain unmodified.

This instruction is an alias of the FCPY instruction. This means that:

- The encodings in this description are named to match the encodings of FCPY.
- The description of FCPY gives the operational pseudocode for this instruction.

31 30 29 28	27 26 25 24	23 22	21 20	19 16	15 14 13	12 5	4 0
0 0 0 0	0 1 0 1	size	0 1	Pg	1 1 0	imm8	Zd

Encoding

```
FMOV <Zd>.<T>, <Pg>/M, #<const>
```

is equivalent to

```
FCPY    <Zd>.<T>, <Pg>/M, #<const>
```

and is always the preferred disassembly.

Assembler symbols

`<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- `H` when `size = 01`
- `S` when `size = 10`
- `D` when `size = 11`

The encoding `size = 00` is reserved.

`<Pg>` Is the name of the governing scalable predicate register, encoded in the "Pg" field.

`<const>` Is a floating-point immediate value expressable as ±n÷16×2^r, where n and r are integers such that 16 ≤ n ≤ 31 and -3 ≤ r ≤ 4, i.e. a normalized binary floating-point encoding with 1 sign bit, 3-bit exponent, and 4-bit fractional part, encoded in the "imm8" field.

Operation

The description of FCPY gives the operational pseudocode for this instruction.

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.176 FMUL (immediate)

Multiply by an immediate each active floating-point element of the source vector, and destructively place the results in the corresponding elements of the source vector. The immediate may take the value +0.5 or +2.0 only. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13	12	10 9 8	7 6	5	4 0
0 1 1 0	0 1 0 1	size	0 1 1	0 1	0	1 0 0	Pg		0 0 0	0	i1	Zdn

Encoding

```
FMUL <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <const>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
bits(esize) imm = if i1 == '0' then FPPointFive('0') else FPTwo('0');
```

Assembler symbols

<Zdn> Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

H when size = 01

S when size = 10

D when size = 11

The encoding size = 00 is reserved.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<const> Is the floating-point immediate value, encoded in the "i1" field. It can have the following values:

#0.5 when i1 = 0

#2.0 when i1 = 1

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = Z[dn];
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];

C8.2.177 FMUL (indexed)

Multiply all floating-point elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The results are placed in the corresponding elements of the destination vector.

The elements within the second source vector are specified using an immediate index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 3 bits depending on the size of the element. This instruction is unpredicated.

Half-precision

Encoding

```
FMUL <Zd>.H, <Zn>.H, <Zm>.H[<imm>]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 16;
integer index = UInt(i3h:i3l);

C8.2.180 FMULX

Multiply active floating-point elements of the first source vector by corresponding floating-point elements of the second source vector except that ∞×0.0 gives 2.0 instead of NaN, and destructively place the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

The instruction can be used with FRECPX to safely convert arbitrary elements in mathematical vector space to UNIT VECTORS or DIRECTION VECTORS with length 1.

31 30 29 28	27 26 25 24	23 22	21 20	19 18 17	16	15 14 13 12	10 9	5 4	0
0 1 1 0	0 1 0 1	size	0 0	1 0 1	0	1 0 0	Pg	Zm	Zdn

Encoding

```
FMULX <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);
```

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10
- D when size = 11

The encoding size = 00 is reserved.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand1 = Z[dn];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m] else Zeros();
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element2 = Elem[operand2, e, esize];
        Elem[result, e, esize] = FPMulX(element1, element2, FPCR[]);
    else
        Elem[result, e, esize] = element1;

C8.2.181 FNEG

Negate each active floating-point element of the source vector, and place the results in the corresponding elements of the destination vector. This inverts the sign bit and cannot signal a floating-point exception. Inactive elements in the destination vector register remain unmodified.

31 30 29 28	27 26 25 24	23 22	21 20	19 18 17	16	15 14 13	12	10 9	5 4	0
0 0 0 0	0 1 0 0	size	0 1 1	1 0	1	1 0 1	Pg	Zn	Zd	

Encoding

```
FNEG <Zd>.<T>, <Pg>/M, <Zn>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Zd);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10
- D when size = 11

The encoding size = 00 is reserved.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(VL) result = Z[d];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element = Elem[operand, e, esize];
        Elem[result, e, esize] = FPNeg(element);

Z[d] = result;
```

C8.2.189 FRINT<r>

Round to an integral floating-point value with the specified rounding option from each active floating-point element of the source vector, and place the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified.

The <r> symbol specifies one of the following rounding options: `N` (to nearest, with ties to even), `A` (to nearest, with ties away from zero), `M` (toward minus Infinity), `P` (toward plus Infinity), `Z` (toward zero), `I` (current FPCR rounding mode), or `X` (current FPCR rounding mode, signalling inexact).

Current mode

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10
- D when size = 11

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The encoding `size = 00` is reserved.

`<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

`<Zn>` Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation for all encodings

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n] else Zeros();
bits(VL) result = Z[d];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element = Elem[operand, e, esize];
        Elem[result, e, esize] = FPRoundInt(element, FPCR[], rounding, exact);

Z[d] = result;
```

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.191 FRSQRTS

Multiply corresponding floating-point elements of the first and second source vectors, subtract the products from 3.0 and divide the results by 2.0 without any intermediate rounding and place the results in the corresponding elements of the destination vector. This instruction is unpredicated.

This instruction can be used to perform a single Newton-Raphson iteration for calculating the reciprocal square root of a vector of floating-point values.

31 30 29 28	27 26 25 24	23 22	21	20 … 16	15 14 13	12	11	10	9 … 5	4 … 0
0 1 1 0	0 1 0 1	size	0	Zm	0 0 0	1	1	1	Zn	Zd

Encoding

```
FRSQRTS <Zd>.<T>, <Zn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10
- D when size = 11

The encoding size = 00 is reserved.

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(VL) operand1 = Z[n];
bits(VL) operand2 = Z[m];
bits(VL) result;

for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    bits(esize) element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = FPRSqrtStepFused(element1, element2);

Z[d] = result;

C8.2.199 FTMAD

The FTMAD instruction calculates the series terms for either SIN(X) or COS(X), where the argument X has been adjusted to be in the range $-\pi/4 < X \leq \pi/4$.

To calculate the series terms of SIN(X) and COS(X) the initial source operands of FTMAD should be zero in the first source vector and X^2 in the second source vector. The FTMAD instruction is then executed eight times to calculate the sum of eight series terms, which gives a result of sufficient precision.

The FTMAD instruction multiplies each element of the first source vector by the absolute value of the corresponding element of the second source vector and performs a fused addition of each product with a value obtained from a table of hard-wired coefficients, and places the results destructively in the first source vector.

The coefficients are different for SIN(X) and COS(X), and are selected by a combination of the sign bit in the second source element and an immediate index in the range 0 to 7.

This instruction is unpredicated.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

31 30 29 28	27 26 25 24	23 22	21 20	19 18 16	15 14 13 12	11 10	9 5	4 0

C8.2.200 FTSMUL

The FTSMUL instruction calculates the initial value for the FTMAD instruction. The instruction squares each element in the first source vector and then sets the sign bit to a copy of bit 0 of the corresponding element in the second source register, and places the results in the destination vector. This instruction is unpredicated.

To compute SIN(X) or COS(X) the instruction is executed with elements of the first source vector set to X, adjusted to be in the range $-\pi/4 < X \leq \pi/4$.

The elements of the second source vector hold the corresponding value of the quadrant Q number as an integer not a floating-point value. The value Q satisfies the relationship $(2q-1) \times \pi/4 < X \leq (2q+1) \times \pi/4$.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

C8.2.201 FTSSEL

The FTSSEL instruction selects the coefficient for the final multiplication in the polynomial series approximation. The instruction places the value 1.0 or a copy of the first source vector element in the destination element, depending on bit 0 of the quadrant number Q held in the corresponding element of the second source vector. The sign bit of the destination element is copied from bit 1 of the corresponding value of Q. This instruction is unpredicated.

To compute SIN(X) or COS(X) the instruction is executed with elements of the first source vector set to X, adjusted to be in the range $-\pi/4 < X \leq \pi/4$.

The elements of the second source vector hold the corresponding value of the quadrant Q number as an integer not a floating-point value. The value Q satisfies the relationship $(2q-1) \times \pi/4 < X \leq (2q+1) \times \pi/4$.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

31 30 29 28	27 26 25 24	23 22	21	20 … 16	15 14 13 12	11	10	9 … 5	4 … 0

C8.2.204 INCB, INCD, INCH, INCW (scalar)

Determines the number of active elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment the scalar destination.

The named predicate constraint limits the number of active elements in a single predicate to:

* A fixed number (`VL1` to `VL256`)

* The largest power of two (`POW2`)

* The largest multiple of three or four (`MUL3` or `MUL4`)

* All available, implicitly a multiple of two (`ALL`).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.206 INCP (scalar)

Counts the number of true elements in the source predicate and then uses the result to increment the scalar destination.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13 12	11 10	9	8	5 4	0
0 0 1 0	0 1 0 1	size	1 0	1 1	0	0	1 0 0 0	1 0	0		Pm	Rdn
						D						

Encoding

```
INCP <Xdn>, <Pm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer m = UInt(Pm);
integer dn = UInt(Rdn);
```

Assembler symbols

<Xdn> Is the 64-bit name of the source and destination general-purpose register, encoded in the "Rdn" field.

<Pm> Is the name of the source scalable predicate register, encoded in the "Pm" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

B	when size = 00
H	when size = 01
S	when size = 10
D	when size = 11

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(64) operand1 = X[dn];
bits(PL) operand2 = P[m];
integer count = 0;

for e = 0 to elements-1
    if ElemP[operand2, e, esize] == '1' then
        count = count + 1;

X[dn] = operand1 + count;
```

Operational information

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the general-purpose register written by this instruction might be significantly delayed.

C8.2.207 INCP (vector)

Counts the number of true elements in the source predicate and then uses the result to increment all destination vector elements.

The predicate size specifier may be omitted in assembler source code, but this is deprecated and will be prohibited in a future release of the architecture.

31 30 29 28	27 26 25 24	23 22	21 20	19 18	17	16	15 14 13 12	11 10	9	8	5 4	0
0 0 1 0	0 1 0 1	size	1 0	1 1	0	0	1 0 0 0	0	0	Pm	Zdn	
						D						

Encoding

```
INCP <Zdn>.<T>, <Pm>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
integer esize = 8 << UInt(size);
integer m = UInt(Pm);
integer dn = UInt(Zdn);
```

Assembler symbols

<Zdn> Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10
- D when size = 11

The encoding size = 00 is reserved.

<Pm> Is the name of the source scalable predicate register, encoded in the "Pm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn];
bits(PL) operand2 = P[m];
bits(VL) result;
integer count = 0;

for e = 0 to elements-1
    if ElemP[operand2, e, esize] == '1' then
        count = count + 1;

for e = 0 to elements-1
    Elem[result, e, esize] = Elem[operand1, e, esize] + count;

Z[dn] = result;
```

C8.2.208 INDEX (immediate, scalar)

Populates the destination vector by setting the first element to the first signed immediate integer operand and monotonically incrementing the value by the second signed scalar integer operand for each subsequent element. The scalar source operand is a general-purpose register in which only the least significant bits corresponding to the vector element size are used and any remaining bits are ignored. This instruction is unpredicated.

31 30 29 28	27 26 25 24	23 22	21	20 16	15 14 13 12	11 10	9 5	4 0
0 0 0 0	0 1 0 0	size	1	Rm	0 1 0 0	1 0	imm5	Zd

Encoding

```
INDEX <Zd>.<T>, #<imm>, <R><m>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer m = UInt(Rm);
integer d = UInt(Zd);
integer imm = SInt(imm5);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<imm> Is the signed immediate operand, in the range -16 to 15, encoded in the "imm5" field.

<R> Is a width specifier, encoded in the "size" field. It can have the following values:

- W when size = 01
- W when size = x0
- X when size = 11

<m> Is the number [0-30] of the source general-purpose register or the name ZR (31), encoded in the "Rm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(esize) operand2 = X[m];
integer element2 = SInt(operand2);
bits(VL) result;

for e = 0 to elements-1
    integer index = imm + e * element2;
    Elem[result, e, esize] = index<esize-1:0>;
```

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer rsize = if esize < 64 then 32 else 64;
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Rd);
boolean isBefore = TRUE;
```

Assembler symbols

<R> Is a width specifier, encoded in the "size" field. It can have the following values:

- W when size = 01
- W when size = x0
- X when size = 11

<d> Is the number [0-30] of the destination general-purpose register or the name ZR (31), encoded in the "Rd" field.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) operand = Z[n];
bits(rsize) result;
integer last = LastActiveElement(mask, esize);

if isBefore then
    if last < 0 then last = elements - 1;
else
```

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    last = last + 1;
    if last >= elements then last = 0;
result = ZeroExtend(Elem[operand, last, esize]);

X[d] = result;
```

Operational information

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the general-purpose register written by this instruction might be significantly delayed.

C8.2.217 LASTB (SIMD&FP scalar)

If there is an active element then extract the last active element from the final source vector register. If there are no active elements, extract the highest-numbered element. Then place the extracted element in the destination SIMD&FP register.

31 30 29 28	27 26 25 24	23 22	21 20	19 18 17 16	15	14 13 12	10 9	5 4	0
0 0 0 0	0 1 0 1	size	1 0	0 0 1	1 (B)	1 0 0	Pg	Zn	Vd

Encoding

```
LASTB <V><d>, <Pg>, <Zn>.<T>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Vd);
boolean isBefore = TRUE;
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<d> Is the number [0-31] of the destination SIMD&FP register, encoded in the "Vd" field.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

Operation

```
CheckSVEEnabled();

C8.2.218 LD1B (scalar plus immediate)

Contiguous load of unsigned bytes to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

8-bit element

Encoding

```
LD1B { <Zt>.B }, <Pg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
integer esize = 8;
integer msize = 8;
boolean unsigned = TRUE;
integer offset = SInt(imm4);
```

16-bit element

Encoding

C8.2.225 LD1D (vector plus immediate)

Gather load of doublewords to active elements of a vector register from memory addresses generated by a vector base plus immediate index. The index is a multiple of 8 in the range 0 to 248. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

Encoding

```
LD1D { <Zt>.D }, <Pg>/Z, [<Zn>.D{, #<imm>}]
```

Decode for this encoding

```
if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Zn);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 64;
boolean unsigned = TRUE;
integer offset = UInt(imm5);
```

Assembler symbols

<Zt>	Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
<Pg>	Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Zn>	Is the name of the base scalable vector register, encoded in the "Zn" field.
<imm>	Is the optional unsigned immediate byte offset, a multiple of 8 in the range 0 to 248, defaulting to 0, encoded in the "imm5" field.

Operation

```
CheckNonStreamingSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) base;
bits(VL) result;
bits(msize) data;
constant integer mbytes = msize DIV 8;

if HaveMTEExt() then SetTagCheckedInstruction(TRUE);

if AnyActiveElement(mask, esize) then
    base = Z[n];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(64) addr = ZeroExtend(Elem[base, e, esize], 64) + offset * mbytes;
```

C8.2.231 LD1RD

Load a single doubleword from a memory address generated by a 64-bit scalar base address plus an immediate offset which is a multiple of 8 in the range 0 to 504.

Broadcast the loaded data into all active elements of the destination vector, setting the inactive elements to zero. If all elements are inactive then the instruction will not perform a read from Device memory or cause a data abort.

Encoding

```
LD1RD { <Zt>.D }, <Pg>/Z, [<Xn|SP>{, #<imm>}]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 64;
boolean unsigned = TRUE;
integer offset = UInt(imm6);
```

Assembler symbols

`<Zt>`	Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
`<Pg>`	Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<imm>`	Is the optional unsigned immediate byte offset, a multiple of 8 in the range 0 to 504, defaulting to 0, encoded in the "imm6" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(64) base;
bits(PL) mask = P[g];
bits(VL) result;
bits(msize) data;
constant integer mbytes = msize DIV 8;

if HaveMTEExt() then SetTagCheckedInstruction(n != 31);

if !AnyActiveElement(mask, esize) then
    if n == 31 && ConstrainUnpredictableBool() then
        CheckSPAlignment();
else
    if n == 31 then CheckSPAlignment();
    base = if n == 31 then SP[] else X[n];
    bits(64) addr = base + offset * mbytes;
    data = Mem[addr, mbytes, AccType_SVE];
```

C8.2.232 LD1RH

Load a single unsigned halfword from a memory address generated by a 64-bit scalar base address plus an immediate offset which is a multiple of 2 in the range 0 to 126.

Broadcast the loaded data into all active elements of the destination vector, setting the inactive elements to zero. If all elements are inactive then the instruction will not perform a read from Device memory or cause a data abort.

16-bit element

Encoding

```
LD1RH { <Zt>.H }, <Pg>/Z, [<Xn|SP>{, #<imm>}]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
integer esize = 16;
integer msize = 16;
boolean unsigned = TRUE;
integer offset = UInt(imm6);
```

32-bit element

Encoding

```
LD1RH { <Zt>.S }, <Pg>/Z, [<Xn|SP>{, #<imm>}]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
integer esize = 32;
integer msize = 16;
boolean unsigned = TRUE;
integer offset = UInt(imm6);

C8.2.233 LD1ROB (scalar plus immediate)

Load thirty-two contiguous bytes to elements of a 256-bit (octaword) vector from the memory address generated by a 64-bit scalar base address and immediate index that is a multiple of 32 in the range -256 to +224 added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero.

The resulting 256-bit vector is then replicated to fill the destination vector. The instruction requires that the current vector length is at least 256 bits, and if the current vector length is not an integer multiple of 256 bits then the trailing bits in the destination vector are set to zero.

Only the first thirty-two predicate elements are used and higher numbered predicate elements are ignored.

ID_AA64ZFR0_EL1.F64MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

C8.2.240 LD1ROW (scalar plus scalar)

Load eight contiguous words to elements of a 256-bit (octaword) vector from the memory address generated by a 64-bit scalar base address and scalar index which is multiplied by 4 and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero.

The resulting 256-bit vector is then replicated to fill the destination vector. The instruction requires that the current vector length is at least 256 bits, and if the current vector length is not an integer multiple of 256 bits then the trailing bits in the destination vector are set to zero.

Only the first eight predicate elements are used and higher numbered predicate elements are ignored.

ID_AA64ZFR0_EL1.F64MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

SVE

C8.2.255 LD1SB (scalar plus vector)

Gather load of signed bytes to active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally sign or zero-extended from 32 to 64 bits. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

32-bit unpacked unscaled offset

Encoding

```
LD1SB { <Zt>.D }, <Pg>/Z, [<Xn|SP>, <Zm>.D, <mod>]
```

Decode for this encoding

```
if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer m = UInt(Zm);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 8;
integer offs_size = 32;
boolean unsigned = FALSE;
boolean offs_unsigned = xs == '0';
integer scale = 0;
```

32-bit unscaled offset

Encoding

```
LD1SB { <Zt>.S }, <Pg>/Z, [<Xn|SP>, <Zm>.S, <mod>]
```

Decode for this encoding

```
if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer m = UInt(Zm);
integer g = UInt(Pg);
integer esize = 32;
integer msize = 8;
integer offs_size = 32;
boolean unsigned = FALSE;
boolean offs_unsigned = xs == '0';
integer scale = 0;
```

C8.2.258 LD1SH (scalar plus scalar)

Contiguous load of signed halfwords to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index which is multiplied by 2 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

32-bit element

Encoding

```
LD1SH { <Zt>.S }, <Pg>/Z, [<Xn|SP>, <Xm>, LSL #1]
```

Decode for this encoding

```

C8.2.265 LD1W (scalar plus immediate)

Contiguous load of unsigned words to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

32-bit element

Encoding

```
LD1W { <Zt>.S }, <Pg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
integer esize = 32;
integer msize = 32;
boolean unsigned = TRUE;
integer offset = SInt(imm4);
```

64-bit element

Encoding

```
LD1W { <Zt>.D }, <Pg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 32;
boolean unsigned = TRUE;
integer offset = SInt(imm4);
```

Assembler symbols

`<Zt>` Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.

`<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

C8.2.267 LD1W (scalar plus vector)

Gather load of unsigned words to active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign or zero-extended from 32 to 64 bits and then optionally multiplied by 4. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

32-bit scaled offset

31 30 29 28	27 26 25 24	23	22	21	20 … 16	15	14	13	12 … 10	9 … 5	4 … 0
1 0 0 0	0 1 0 1	0	xs	1	Zm	0	1	0	Pg	Rn	Zt
							U	ff			

Encoding

C8.2.272 LD2D (scalar plus scalar)

Contiguous load two-doubleword structures, each to the same element number in two vector registers from the memory address generated by a 64-bit scalar base and a 64-bit scalar index register scaled by the element size (LSL option) and added to the base address. After each structure access the index value is incremented by two. The index register is not updated by the instruction.

Each predicate element applies to the same element number in each of the two vector registers, or equivalently to the two consecutive doublewords in memory which make up each structure. Inactive elements will not cause a read from Device memory or signal a fault, and the corresponding element is set to zero in each of the two destination vector registers.

Encoding

```
LD2D { <Zt1>.D, <Zt2>.D }, <Pg>/Z, [<Xn|SP>, <Xm>, LSL #3]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;

C8.2.281 LD3H (scalar plus immediate)

Contiguous load three-halfword structures, each to the same element number in three vector registers from the memory address generated by a 64-bit scalar base and an immediate index which is a multiple of 3 in the range -24 to 21 that is multiplied by the vector's in-memory size, irrespective of predication,

Each predicate element applies to the same element number in each of the three vector registers, or equivalently to the three consecutive halfwords in memory which make up each structure. Inactive elements will not cause a read from Device memory or signal a fault, and the corresponding element is set to zero in each of the three destination vector registers.

Encoding

```
LD3H { <Zt1>.H, <Zt2>.H, <Zt3>.H }, <Pg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
integer esize = 16;
integer offset = SInt(imm4);
integer nreg = 3;
```

Assembler symbols

`<Zt1>`	Is the name of the first scalable vector register to be transferred, encoded in the "Zt" field.
`<Zt2>`	Is the name of the second scalable vector register to be transferred, encoded as "Zt" plus 1 modulo 32.
`<Zt3>`	Is the name of the third scalable vector register to be transferred, encoded as "Zt" plus 2 modulo 32.
`<Pg>`	Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<imm>`	Is the optional signed immediate vector offset, a multiple of 3 in the range -24 to 21, defaulting to 0, encoded in the "imm4" field.

Operation

```
CheckSVEEnabled();

C8.2.289 LD4H (scalar plus immediate)

Contiguous load four-halfword structures, each to the same element number in four vector registers from the memory address generated by a 64-bit scalar base and an immediate index which is a multiple of 4 in the range -32 to 28 that is multiplied by the vector's in-memory size, irrespective of predication,

Each predicate element applies to the same element number in each of the four vector registers, or equivalently to the four consecutive halfwords in memory which make up each structure. Inactive elements will not cause a read from Device memory or signal a fault, and the corresponding element is set to zero in each of the four destination vector registers.

Encoding

```
LD4H { <Zt1>.H, <Zt2>.H, <Zt3>.H, <Zt4>.H }, <Pg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
integer esize = 16;
integer offset = SInt(imm4);
integer nreg = 4;
```

Assembler symbols

`<Zt1>`	Is the name of the first scalable vector register to be transferred, encoded in the "Zt" field.
`<Zt2>`	Is the name of the second scalable vector register to be transferred, encoded as "Zt" plus 1 modulo 32.
`<Zt3>`	Is the name of the third scalable vector register to be transferred, encoded as "Zt" plus 2 modulo 32.
`<Zt4>`	Is the name of the fourth scalable vector register to be transferred, encoded as "Zt" plus 3 modulo 32.
`<Pg>`	Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<imm>`	Is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the "imm4" field.

Operation

```
CheckSVEEnabled();

C8.2.295 LDFF1B (vector plus immediate)

Gather load with first-faulting behavior of unsigned bytes to active elements of a vector register from memory addresses generated by a vector base plus immediate index. The index is in the range 0 to 31. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

32-bit element

Encoding

```
LDFF1B { <Zt>.S }, <Pg>/Z, [<Zn>.S{, #<imm>}]
```

Decode for this encoding

```
if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Zn);
integer g = UInt(Pg);
integer esize = 32;
integer msize = 8;
boolean unsigned = TRUE;
integer offset = UInt(imm5);
```

64-bit element

Encoding

```
LDFF1B { <Zt>.D }, <Pg>/Z, [<Zn>.D{, #<imm>}]
```

Decode for this encoding

```
if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Zn);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 8;
boolean unsigned = TRUE;
integer offset = UInt(imm5);
```

Assembler symbols

<Zt> Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the base scalable vector register, encoded in the "Zn" field.

<imm> Is the optional unsigned immediate byte offset, in the range 0 to 31, defaulting to 0, encoded in the "imm5" field.

Operation for all encodings

```
CheckNonStreamingSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) base;
bits(VL) result;
bits(VL) orig = Z[t];
bits(msize) data;
constant integer mbytes = msize DIV 8;

C8.2.301 LDFF1H (vector plus immediate)

Gather load with first-faulting behavior of unsigned halfwords to active elements of a vector register from memory addresses generated by a vector base plus immediate index. The index is a multiple of 2 in the range 0 to 62. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

C8.2.306 LDFF1SH (scalar plus vector)

Gather load with first-faulting behavior of signed halfwords to active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign or zero-extended from 32 to 64 bits and then optionally multiplied by 2. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

32-bit scaled offset

31	30	29	28	27	26	25	24	23	22	21	20–16	15	14	13	12–10	9–5	4–0
1	0	0	0	0	1	0	0	1	xs	1	Zm	0	0	1	Pg	Rn	Zt
													U	ff			

Encoding

```
LDFF1SH { <Zt>.S }, <Pg>/Z, [<Xn|SP>, <Zm>.S, <mod> #1]
```

Decode for this encoding

```
if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer m = UInt(Zm);
integer g = UInt(Pg);
integer esize = 32;
integer msize = 16;
integer offs_size = 32;
boolean unsigned = FALSE;
boolean offs_unsigned = xs == '0';
integer scale = 1;
```

C8.2.308 LDFF1SW (scalar plus scalar)

Contiguous load with first-faulting behavior of signed words to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index which is multiplied by 4 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

Encoding

```
LDFF1SW { <Zt>.D }, <Pg>/Z, [<Xn|SP>{, <Xm>, LSL #2}]
```

Decode for this encoding

```
if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 32;
boolean unsigned = FALSE;
```

Assembler symbols

`<Zt>`	Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.

C8.2.310 LDFF1SW (vector plus immediate)

Gather load with first-faulting behavior of signed words to active elements of a vector register from memory addresses generated by a vector base plus immediate index. The index is a multiple of 4 in the range 0 to 124. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

Encoding

```
LDFF1SW { <Zt>.D }, <Pg>/Z, [<Zn>.D{, #<imm>}]
```

Decode for this encoding

```
if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Zn);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 32;
boolean unsigned = FALSE;
integer offset = UInt(imm5);
```

Assembler symbols

<Zt>	Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
<Pg>	Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Zn>	Is the name of the base scalable vector register, encoded in the "Zn" field.
<imm>	Is the optional unsigned immediate byte offset, a multiple of 4 in the range 0 to 124, defaulting to 0, encoded in the "imm5" field.

Operation

```
CheckNonStreamingSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) base;
bits(VL) result;
bits(VL) orig = Z[t];
bits(msize) data;
constant integer mbytes = msize DIV 8;
boolean first = TRUE;
boolean fault = FALSE;
boolean faulted = FALSE;
boolean unknown = FALSE;

if HaveMTEExt() then SetTagCheckedInstruction(TRUE);
```

C8.2.312 LDFF1W (scalar plus vector)

Gather load with first-faulting behavior of unsigned words to active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign or zero-extended from 32 to 64 bits and then optionally multiplied by 4. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

C8.2.315 LDNF1D

Contiguous load with non-faulting behavior of doublewords to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

Encoding

```
LDNF1D { <Zt>.D }, <Pg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]
```

Decode for this encoding

```
if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 64;
boolean unsigned = TRUE;
integer offset = SInt(imm4);
```

Assembler symbols

<Zt>	Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
<Pg>	Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	Is the optional signed immediate vector offset, in the range -8 to 7, defaulting to 0, encoded in the "imm4" field.

Operation

```
CheckNonStreamingSVEEnabled();
integer elements = VL DIV esize;
bits(64) base;
bits(PL) mask = P[g];
bits(VL) result;
bits(VL) orig = Z[t];
bits(msize) data;
constant integer mbytes = msize DIV 8;
boolean fault = FALSE;
boolean faulted = FALSE;
boolean unknown = FALSE;

if HaveMTEExt() then SetTagCheckedInstruction(n != 31);

if !AnyActiveElement(mask, esize) then

C8.2.322 LDNT1B (scalar plus scalar)

Contiguous load non-temporal of bytes to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

Encoding

```
LDNT1B { <Zt>.B }, <Pg>/Z, [<Xn|SP>, <Xm>]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if Rm == '11111' then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer g = UInt(Pg);
integer esize = 8;
```

Assembler symbols

<Zt>	Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
<Pg>	Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the general-purpose offset register, encoded in the "Rm" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(64) base;
bits(64) offset;
bits(PL) mask = P[g];
bits(VL) result;
constant integer mbytes = esize DIV 8;

if HaveMTEExt() then SetTagCheckedInstruction(TRUE);

if !AnyActiveElement(mask, esize) then
    if n == 31 && ConstrainUnpredictableBool() then
        CheckSPAlignment();
else
    if n == 31 then CheckSPAlignment();
    base = if n == 31 then SP[] else X[n];
    offset = X[m];

for e = 0 to elements-1

C8.2.323 LDNT1B (vector plus scalar)

Gather load non-temporal of unsigned bytes to active elements of a vector register from memory addresses generated by a vector base plus a 64-bit unscaled scalar register offset. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

32-bit unscaled offset

Encoding

```
LDNT1B { <Zt>.S }, <Pg>/Z, [<Zn>.S{, <Xm>}]
```

Decode for this encoding

```
if !HaveSVE2() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Zn);
integer m = UInt(Rm);
integer g = UInt(Pg);
integer esize = 32;
integer msize = 8;
boolean unsigned = TRUE;
```

64-bit unscaled offset

Encoding

```
LDNT1B { <Zt>.D }, <Pg>/Z, [<Zn>.D{, <Xm>}]
```

Decode for this encoding

```
if !HaveSVE2() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Zn);
integer m = UInt(Rm);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 8;
boolean unsigned = TRUE;
```

C8.2.331 LDNT1SH

Gather load non-temporal of signed halfwords to active elements of a vector register from memory addresses generated by a vector base plus a 64-bit unscaled scalar register offset. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

32-bit unscaled offset

Encoding

```
LDNT1SH { <Zt>.S }, <Pg>/Z, [<Zn>.S{, <Xm>}]
```

Decode for this encoding

```
if !HaveSVE2() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Zn);
integer m = UInt(Rm);
integer g = UInt(Pg);
integer esize = 32;
integer msize = 16;
boolean unsigned = FALSE;
```

64-bit unscaled offset

Encoding

```
LDNT1SH { <Zt>.D }, <Pg>/Z, [<Zn>.D{, <Xm>}]
```

Decode for this encoding

```
if !HaveSVE2() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Zn);
integer m = UInt(Rm);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 16;
boolean unsigned = FALSE;
```

Assembler symbols

`<Zt>`	Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
`<Pg>`	Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
`<Zn>`	Is the name of the base scalable vector register, encoded in the "Zn" field.
`<Xm>`	Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the "Rm" field.

Operation for all encodings

```
CheckNonStreamingSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) base;
bits(64) offset;
bits(VL) result;
bits(msize) data;
constant integer mbytes = msize DIV 8;

if HaveMTEExt() then SetTagCheckedInstruction(TRUE);

if AnyActiveElement(mask, esize) then
    base = Z[n];
    offset = X[m];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(64) addr = ZeroExtend(Elem[base, e, esize], 64) + offset;
        data = Mem[addr, mbytes, AccType_SVESTREAM];
        Elem[result, e, esize] = Extend(data, esize, unsigned);
    else
        Elem[result, e, esize] = Zeros();

Z[t] = result;
```

C8.2.332 LDNT1SW

Gather load non-temporal of signed words to active elements of a vector register from memory addresses generated by a vector base plus a 64-bit unscaled scalar register offset. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

Encoding

```
LDNT1SW { <Zt>.D }, <Pg>/Z, [<Zn>.D{, <Xm>}]
```

Decode for this encoding

```
if !HaveSVE2() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Zn);
integer m = UInt(Rm);
integer g = UInt(Pg);
integer esize = 64;
integer msize = 32;
boolean unsigned = FALSE;
```

Assembler symbols

<Zt>	Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
<Pg>	Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Zn>	Is the name of the base scalable vector register, encoded in the "Zn" field.
<Xm>	Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the "Rm" field.

Operation

```
CheckNonStreamingSVEEnabled();
integer elements = VL DIV esize;
bits(PL) mask = P[g];
bits(VL) base;
bits(64) offset;
bits(VL) result;
bits(msize) data;
constant integer mbytes = msize DIV 8;

if HaveMTEExt() then SetTagCheckedInstruction(TRUE);

if AnyActiveElement(mask, esize) then
    base = Z[n];
    offset = X[m];
```

C8.2.333 LDNT1W (scalar plus immediate)

Contiguous load non-temporal of words to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

Encoding

```
LDNT1W { <Zt>.S }, <Pg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
integer esize = 32;
integer offset = SInt(imm4);
```

Assembler symbols

`<Zt>`	Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
`<Pg>`	Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<imm>`	Is the optional signed immediate vector offset, in the range -8 to 7, defaulting to 0, encoded in the "imm4" field.

Operation

```
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(64) base;
bits(PL) mask = P[g];
bits(VL) result;
constant integer mbytes = esize DIV 8;

if HaveMTEExt() then SetTagCheckedInstruction(n != 31);

if !AnyActiveElement(mask, esize) then
    if n == 31 && ConstrainUnpredictableBool() then
        CheckSPAlignment();
else
    if n == 31 then CheckSPAlignment();
    base = if n == 31 then SP[] else X[n];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
```
