Release information

The following releases of this document have been made.

Date	Version	Changes
30/Sep/2026	M.d	• Updated Non-Confidential Armv9.6 EAC release, incorporating FEAT_TRAPFPE
30/Jun/2026	M.c	• Updated Non-Confidential Armv9.6 EAC release, incorporating FEAT_HINTE
06/Apr/2026	M.b	• Updated Non-Confidential Armv9.6 EAC release, incorporating ASL1 and withdrawing FEAT_SEBEP
17/Dec/2025	M.a.a	• Non-Confidential Armv9.6 EAC release with event links fix. No other content changes.
01/Dec/2025	M.a	• Initial Non-Confidential Armv9.6 EAC release
30/Apr/2025	L.b	• Updated Non-Confidential Armv9.5 EAC release with the MPAM PE content rewritten as rules
30/Nov/2024	L.a	• Initial Non-Confidential Armv9.5 EAC release and separation of the RAS System Architecture into Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture (ARM IHI 0100)
20/Mar/2024	K.a	• Initial Non-Confidential Armv8.9 and Armv9.4 EAC release, incorporating MPAM and SME
21/Apr/2023	J.a	• Updated Non-Confidential Armv8.8 and Armv9.3 EAC release incorporating MEC, RAS, and RME
19/Aug/2022	I.a	• Updated Non-Confidential Armv8.8 and Armv9.3 EAC release incorporating BRBE, ETE, and TRBE
04/Feb/2022	H.a	• Initial Non-Confidential Armv8.8 and Armv9.3 EAC release, incorporating SVE
22/Jul/2021	G.b	• Updated Non-Confidential Armv8.7 EAC release
22/Jan/2021	G.a	• Initial Non-Confidential Armv8.7 EAC release
17/Jul/2020	F.c	• Initial Non-Confidential Armv8.6 EAC release
31/Mar/2020	F.b	• Non-Confidential Armv8.5 EAC, initial Armv8.6 Beta release
20/Feb/2020	F.a	• Initial Non-Confidential Armv8.6 Beta release
05/Jul/2019	E.a	• Initial Non-Confidential Armv8.5 EAC release
29/Apr/2019	D.b	• Updated Non-Confidential Armv8.4 EAC release incorporating accessibility changes
31/Oct/2018	D.a	• Initial Non-Confidential Armv8.4 EAC release
20/Dec/2017	C.a	• Initial Non-Confidential Armv8.3 EAC release
26/Sep/2017	B.b	• Initial Non-Confidential Armv8.2 EAC release, incorporating SPE
31/Mar/2017	B.a	• Initial Non-Confidential Armv8.1 EAC, v8.2 Beta release
30/Sep/2016	A.k	• Updated Non-Confidential EAC release
03/Jun/2016	A.j	• Non-Confidential EAC release
28/Jan/2016	A.i	• Ninth Non-Confidential Beta release
30/Sep/2015	A.h	• Eighth Non-Confidential Beta release
10/Jul/2015	A.g	• Seventh Non-Confidential Beta release
25/Mar/2015	A.f	• Sixth Non-Confidential Beta release
17/Dec/2014	A.e	• Fifth Non-Confidential Beta release
09/Oct/2014	A.d	• Fourth Non-Confidential Beta release
18/Jul/2014	A.c	• Third Non-Confidential Beta release
24/Dec/2013	A.b	• Second Non-Confidential Beta release
04/Sep/2013	A.a	• Non-Confidential Beta release
12/Jun/2013	A.a-2	• Second confidential Beta draft of first issue, limited circulation
30/Apr/2013	A.a-1	• Confidential Beta draft of first issue, limited circulation

This document is protected by copyright and other related rights and the use or implementation of the information contained in this document may be protected by one or more patents or pending patent applications. No part of this document may be reproduced in any form by any means without the express prior written permission of Arm Limited ("Arm"). **No license, express or implied, by estoppel or otherwise to any intellectual property rights is granted by this document unless specifically stated.**

Your access to the information in this document is conditional upon your acceptance that you will not use or permit others to use the information for the purposes of determining whether the subject matter of this document infringes any third party patents.

The content of this document is informational only. Any solutions presented herein are subject to changing conditions, information, scope, and data. This document was produced using reasonable efforts based on information available as of the date of issue of this document. The scope of information in this document may exceed that which Arm is required to provide, and such additional information is merely intended to further assist the recipient and does not represent Arm's view of the scope of its obligations. You acknowledge and agree that you possess the necessary expertise in system security and functional safety and that you shall be solely responsible for compliance with all legal, regulatory, safety and security related requirements concerning your products, notwithstanding any information or support that may be provided by Arm herein. In addition, you are responsible for any applications which are used in conjunction with any Arm technology described in this document, and to minimize risks, adequate design and operating safeguards should be provided for by you.

This document may include technical inaccuracies or typographical errors. THIS DOCUMENT IS PROVIDED "AS IS". ARM PROVIDES NO REPRESENTATIONS AND NO WARRANTIES, EXPRESS, IMPLIED OR STATUTORY, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTABILITY, SATISFACTORY QUALITY, NON-INFRINGEMENT OR FITNESS FOR A PARTICULAR PURPOSE WITH RESPECT TO THE DOCUMENT. For the avoidance of doubt, Arm makes no representation with respect to, and has undertaken no analysis to identify or understand the scope and content of, any patents, copyrights, trade secrets, trademarks, or other rights.

TO THE EXTENT NOT PROHIBITED BY LAW, IN NO EVENT WILL ARM BE LIABLE FOR ANY DAMAGES, INCLUDING WITHOUT LIMITATION ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL, PUNITIVE, OR CONSEQUENTIAL DAMAGES, HOWEVER CAUSED AND REGARDLESS OF THE THEORY OF LIABILITY, ARISING OUT OF ANY USE OF THIS DOCUMENT, EVEN IF ARM HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Reference by Arm to any third party's products or services within this document is not an express or implied approval or endorsement of the use thereof.

This document consists solely of commercial items. You shall be responsible for ensuring that any permitted use, duplication, or disclosure of this document complies fully with any relevant export laws and regulations to assure that this document or any portion thereof is not exported, directly or indirectly, in violation of such export laws. Use of the word "partner" in reference to Arm's customers is not intended to create or refer to any partnership relationship with any other company. Arm may make changes to this document at any time and without notice.

This document may be translated into other languages for convenience, and you agree that if there is any conflict between the English version of this document and any translation, the terms of the English version of this document shall prevail.

The validity, construction and performance of this notice shall be governed by English Law.

Non-Confidential

Product Status

The information in this document is final, that is for a developed product.

The information in this Manual is at EAC quality, which means that all features of the specification are described in the Manual.

Arm® Architecture Reference Manual for A-profile architecture

Preface

About this Manual 23

Using this Manual 27

Conventions 34

Additional reading 37

Feedback 38

Part A — **Arm Architecture Introduction and Overview**

Chapter A1 — **Introduction to the Arm Architecture**

A1.1 About the Arm architecture 41

A1.2 Architecture profiles 43

A1.3 Arm architectural concepts 44

A1.4 Supported data types 47

A1.5 Floating-point support 63

A1.6 The Arm memory model 81

A1.7 Reliability, Availability, and Serviceability 82

Chapter A2 — **A-profile Architecture Extensions**

A2.1 About the A-profile architecture extensions 86

A2.2 Armv8-A architecture extensions 87

A2.3 Armv9-A architecture extensions 164

Part B — **The AArch64 Application Level Architecture**

Chapter B1 — **The AArch64 Application Level Programmers' Model**

B1.1 About the Application level programmers' model 205

B1.2 Registers in AArch64 Execution state 206

B1.3 Process state, PSTATE 210

B1.4 The Scalable Vector Extension and Scalable Matrix Extension 213

B1.5 Software control features and EL0 242

Chapter B2 — **The AArch64 Application Level Memory Model**

B2.1 About the Arm memory model 248

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B2.2 Atomicity in the Arm architecture 250
B2.3 Ordering requirements defined by the formal concurrency model 255
B2.4 Additional ordering requirements outside of the scope of the formal concurrency model 287
B2.5 Restrictions on the effects of speculation 292
B2.6 Memory barriers 299
B2.7 Caches and memory hierarchy 307
B2.8 Alignment support 312
B2.9 Endian support 315
B2.10 Memory types and attributes 319
B2.11 Mismatched memory attributes 331
B2.12 Synchronization and semaphores 334

Part C The AArch64 Instruction Set

Chapter C1 The A64 Instruction Set

C1.1 About the A64 instruction set 347
C1.2 Structure of the A64 assembler language 348
C1.3 Address generation 355
C1.4 Instruction aliases 358

Chapter C2 About the A64 Instruction Descriptions

C2.1 Understanding the A64 instruction descriptions 360
C2.2 General information about the A64 instruction descriptions 363

Chapter C3 A64 Instruction Set Overview

C3.1 Branches, Exception generating, and System instructions 367
C3.2 Loads and stores 381
C3.3 Loads and stores - SVE, SVE2 421
C3.4 Loads and stores - SME, SME2, SVE2p1 432
C3.5 Data processing - immediate 438
C3.6 Data Processing - MTE 443
C3.7 Data processing - register 444
C3.8 Data processing - SIMD and floating-point 453
C3.9 Data processing - SVE 483
C3.10 Data processing - SVE2 508
C3.11 Data processing - SME, SME2 535

Chapter C4 A64 Instruction Set Encoding

C4.1 A64 instruction set encoding 558

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Chapter C5 **The A64 System Instruction Class**

C5.1 The System instruction class encoding space 928
C5.2 Special-purpose registers 949
C5.3 A64 System instructions for cache maintenance 1083
C5.4 A64 System instructions for address translation 1170
C5.5 A64 System instructions for TLB maintenance 1202
C5.6 A64 System instructions for prediction restriction 1755
C5.7 A64 System instructions for the Branch Record Buffer Extension 1772
C5.8 A64 System instructions for the Trace Extension 1777
C5.9 A64 System instructions for the Guarded Control Stack 1779
C5.10 A64 System instructions introduced by FEAT_RME_GPC3 1793
C5.11 A64 IMPLEMENTATION DEFINED System instructions 1796

Chapter C6 **A64 Base Instruction Descriptions**

C6.1 About the A64 base instructions 1801
C6.2 Alphabetical list of A64 base instructions 1804

Chapter C7 **A64 Advanced SIMD and Floating-point Instruction Descriptions**

C7.1 About the A64 Advanced SIMD and floating-point instructions 2937
C7.2 Alphabetical list of A64 Advanced SIMD and floating-point instructions 2940

Chapter C8 **SVE Instruction Descriptions**

C8.1 About the SVE instructions 4112
C8.2 Alphabetical list of SVE instructions 4113

Chapter C9 **SME Instruction Descriptions**

C9.1 About the SME instructions 6234
C9.2 Alphabetical list of SME instructions 6235

Part D **The AArch64 System Level Architecture**

Chapter D1 **The AArch64 System Level Programmers' Model**

D1.1 Exception levels 7205
D1.2 Registers for instruction processing and exception handling 7210
D1.3 System register locking 7212
D1.4 Exceptions 7214
D1.5 Process state, PSTATE 7260
D1.6 Resets and power domains 7263
D1.7 Mechanisms for entering a low-power state 7266
D1.8 Self-hosted debug 7271

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.9 Event monitors 7272
D1.10 Interprocessing 7273
D1.11 Check Feature 7280

Chapter D2 AArch64 Self-hosted Debug

D2.1 About self-hosted debug 7282
D2.2 Routing debug exceptions 7286
D2.3 The debug exception enable controls 7288
D2.4 The effect of powerdown on debug exceptions 7290
D2.5 Summary of the routing and enabling of debug exceptions 7291
D2.6 Pseudocode description of debug exceptions 7293
D2.7 Breakpoint Instruction exceptions 7294
D2.8 Breakpoint exceptions 7296
D2.9 Watchpoint exceptions 7318
D2.10 Vector Catch exceptions 7336
D2.11 Software Step exceptions 7337
D2.12 Synchronization and debug exceptions 7350

Chapter D3 AArch64 Self-hosted Trace

D3.1 About self-hosted trace 7352
D3.2 Prohibited regions in self-hosted trace 7353
D3.3 Self-hosted trace timestamps 7355
D3.4 Synchronization in self-hosted trace 7356

Chapter D4 The Embedded Trace Extension

D4.1 About the Embedded Trace Extension 7358
D4.2 Programmers' model 7365
D4.3 Trace elements 7369
D4.4 Instruction and exception classification 7384
D4.5 About the ETE trace unit 7393
D4.6 Resource operation 7433

Chapter D5 ETE Protocol Descriptions

D5.1 About the ETE protocol 7463
D5.2 Summary list of ETE packets 7465
D5.3 Alphabetical list of ETE packets 7468

Chapter D6 The Trace Buffer Extension

D6.1 About the Trace Buffer Extension 7590
D6.2 The trace buffer 7593

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D6.3 Trace buffer Self-hosted mode 7598
D6.4 Trace buffer External mode 7606
D6.5 Trace buffer management 7611
D6.6 Synchronization and the Trace Buffer Unit 7625
D6.7 Trace synchronization and memory barriers 7629
D6.8 Trace of Speculative execution 7630
D6.9 Trace in Debug state 7631
D6.10 Synchronization litmus tests 7632
D6.11 UNPREDICTABLE behavior 7636

Chapter D7 The AArch64 System Level Memory Model

D7.1 About the memory system architecture 7639
D7.2 Address space 7640
D7.3 Mixed-endian support in AArch64 7641
D7.4 Memory Encryption Contexts 7642
D7.5 Cache support 7644
D7.6 External aborts 7674
D7.7 Memory barrier instructions 7676
D7.8 Pseudocode description of general memory System instructions 7677

Chapter D8 The AArch64 Virtual Memory System Architecture

D8.1 Address translation 7681
D8.2 Translation process 7697
D8.3 Translation table descriptor formats 7735
D8.4 Memory access control 7755
D8.5 Hardware updates to the translation tables 7781
D8.6 Memory region attributes 7796
D8.7 Other descriptor fields 7805
D8.8 Address tagging 7810
D8.9 Logical Address Tagging 7811
D8.10 Pointer authentication 7813
D8.11 Checked Pointer Arithmetic 7819
D8.12 Memory Encryption Contexts extension 7821
D8.13 Virtualization Host Extensions 7824
D8.14 Nested virtualization 7831
D8.15 Memory aborts 7839
D8.16 Translation Lookaside Buffers 7852
D8.17 TLB maintenance 7857

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D8.18 Caches 7876

D8.19 Pseudocode description of VMSA address translation 7878

Chapter D9 The Granule Protection Check Mechanism

D9.1 GPC behavior overview 7881

D9.2 GPC bypass windows 7882

D9.3 Granular Data Isolation 7883

D9.4 GPC faults 7884

D9.5 GPT caching and invalidation 7886

D9.6 GPT formats 7888

D9.7 GPT lookup process 7893

D9.8 Explicit PAS control 7895

Chapter D10 The Memory Tagging Extension

D10.1 Introduction 7897

D10.2 Allocation Tags 7898

D10.3 Memory region tagging types 7899

D10.4 Tag checking 7901

D10.5 Allocation Tag Access controls 7903

D10.6 Physical Tag locations 7904

D10.7 Tag Check Faults 7906

Chapter D11 The Guarded Control Stack

D11.1 Introduction 7909

D11.2 The Guarded Control Stack 7910

D11.3 Procedure returns 7912

D11.4 Exception returns 7914

D11.5 Stage 1 permission model 7917

D11.6 Stage 2 Permission model 7919

D11.7 Guarded Control Stack switching 7920

D11.8 GCS record for software use 7922

D11.9 Guarded Control Stack exceptions 7923

D11.10 Guarded Control Stack data accesses 7924

D11.11 Detecting when FEAT_GCS is enabled 7930

Chapter D12 The Generic Timer in AArch64 state

D12.1 About the Generic Timer 7932

D12.2 The AArch64 view of the Generic Timer 7937

Chapter D13 The Performance Monitors Extension

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D13.1 About the Performance Monitors 7946
D13.2 Accuracy of the Performance Monitors 7950
D13.3 Behavior on overflow 7952
D13.4 Attributability 7957
D13.5 Controlling the PMU counters 7958
D13.6 Multithreaded implementations 7964
D13.7 Event filtering 7965
D13.8 Event threshold and edge counting 7967
D13.9 PMU snapshots 7972
D13.10 Performance Monitors and Debug state 7976
D13.11 Counter access 7977
D13.12 Performance Monitors Extension registers 7979

Chapter D14 PMU Event Descriptions

D14.1 Definitions 7981
D14.2 The PMU event number space and common events 7993
D14.3 Common event numbers 8046
D14.4 Cycle event counting 8248
D14.5 Meaningful combinations of common events 8250
D14.6 Required events 8256
D14.7 IMPLEMENTATION DEFINED event numbers 8258

Chapter D15 The System Performance Monitors Extension

D15.1 About the System Performance Monitors 8260
D15.2 System PMU configuration 8261
D15.3 Accessing System PMUs 8263
D15.4 Generating System PMU overflow interrupt requests 8265

Chapter D16 The Activity Monitors Extension

D16.1 About the Activity Monitors Extension 8267
D16.2 Properties and behavior of the activity monitors 8268
D16.3 AMU events and event numbers 8270

Chapter D17 The Statistical Profiling Extension

D17.1 About the Statistical Profiling Extension 8272
D17.2 Defining the sample population 8274
D17.3 Controlling when an operation is sampled 8275
D17.4 Enabling profiling 8278
D17.5 Filtering sample records 8280
D17.6 The profiling data 8283

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.7 The Profiling Buffer 8297
D17.8 Profiling Buffer management 8304
D17.9 Synchronization and Statistical Profiling 8315

Chapter D18 Statistical Profiling Extension Sample Record Specification

D18.1 About the Statistical Profiling Extension sample records 8318
D18.2 Alphabetical list of Statistical Profiling Extension packets 8321

Chapter D19 The Branch Record Buffer Extension

D19.1 About the Branch Record Buffer Extension 8367
D19.2 Branch record filtering 8372
D19.3 Branch record buffer operation 8376
D19.4 Branch record buffer 8379
D19.5 Programmers' model 8381

Chapter D20 RAS PE Architecture

D20.1 About the RAS Extension 8384
D20.2 PE error handling 8385
D20.3 Generating error exceptions 8390
D20.4 Taking error exceptions 8391
D20.5 Error synchronization event 8400
D20.6 Virtual SError exceptions and delegated SError exceptions 8406
D20.7 Error records in the PE 8407

Chapter D21 MPAM PE Architecture

D21.1 About MPAM 8412
D21.2 PARTID spaces 8416
D21.3 Partition Identifiers (PARTIDs) 8420
D21.4 Performance Monitoring Groups (PMGs) 8423
D21.5 Effect of the MPAM3_EL3.{SDEFLT, FORCE_NS} controls on PE Secure state execution 8424
D21.6 Effect of access type on MPAM information 8426
D21.7 Virtualization support 8428
D21.8 PE-side Maximum bandwidth limit injection control 8431
D21.9 MPAM errors 8432
D21.10 Synchronization of MPAM System register changes 8433

Chapter D22 The Scalable Matrix Extension

D22.1 Overview 8435
D22.2 SME traps and exceptions 8436
D22.3 Validity of SME and SVE state 8437

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D22.4 Streaming execution priority 8438
D22.5 Floating-point behaviors in Streaming SVE mode 8440
D22.6 Floating-point behaviors for instructions that target the SME ZA array 8441
D22.7 Security and power considerations 8442

Chapter D23 AArch64 System Register Encoding

D23.1 The System register encoding space 8444
D23.2 Moves to and from debug and trace System registers 8445
D23.3 Moves to and from non-debug System registers, Special-purpose registers 8450

Chapter D24 AArch64 System Register Descriptions

D24.1 About the AArch64 System registers 8468
D24.2 General system control registers 8478
D24.3 Debug System registers 10155
D24.4 Trace registers 10321
D24.5 Performance Monitors registers 10665
D24.6 Activity Monitors registers 10900
D24.7 Statistical Profiling Extension registers 10945
D24.8 Branch Record Buffer Extension registers 11095
D24.9 RAS registers 11148
D24.10 Generic Timer registers 11208
D24.11 Guarded Control Stack registers 11340
D24.12 MPAM registers 11372

Part E The AArch32 Application Level Architecture

Chapter E1 The AArch32 Application Level Programmers' Model

E1.1 About the Application level programmers' model 11475
E1.2 The Application level programmers' model in AArch32 state 11476
E1.3 Advanced SIMD and floating-point instructions 11489
E1.4 About the AArch32 System register interface 11507
E1.5 Exceptions 11508

Chapter E2 The AArch32 Application Level Memory Model

E2.1 About the Arm memory model 11510
E2.2 Atomicity in the Arm architecture 11512
E2.3 Definition of the memory model 11516
E2.4 Ordering of translation table walks 11526
E2.5 Caches and memory hierarchy 11527
E2.6 Alignment support 11532

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E2.7 Endian support 11534
E2.8 Memory types and attributes 11538
E2.9 Mismatched memory attributes 11548
E2.10 Synchronization and semaphores 11551

Part F The AArch32 Instruction Sets

Chapter F1 About the T32 and A32 Instruction Descriptions

F1.1 Format of instruction descriptions 11563
F1.2 Standard assembler syntax fields 11568
F1.3 Conditional execution 11569
F1.4 Shifts applied to a register 11571
F1.5 Memory accesses 11573
F1.6 Encoding of lists of general-purpose registers and the PC 11574
F1.7 General information about the T32 and A32 instruction descriptions 11575
F1.8 Additional pseudocode support for instruction descriptions 11589
F1.9 Additional information about Advanced SIMD and floating-point instructions 11590

Chapter F2 The AArch32 Instruction Sets Overview

F2.1 Support for instructions in different versions of the Arm architecture 11597
F2.2 Unified Assembler Language 11598
F2.3 Branch instructions 11600
F2.4 Data-processing instructions 11601
F2.5 PSTATE and banked register access instructions 11609
F2.6 Load/store instructions 11610
F2.7 Load/store multiple instructions 11613
F2.8 Miscellaneous instructions 11614
F2.9 Exception-generating and exception-handling instructions 11615
F2.10 System register access instructions 11617
F2.11 Advanced SIMD and floating-point load/store instructions 11618
F2.12 Advanced SIMD and floating-point register transfer instructions 11620
F2.13 Advanced SIMD data-processing instructions 11621
F2.14 Floating-point data-processing instructions 11632

Chapter F3 T32 Instruction Set Encoding

F3.1 T32 instruction set encoding 11635
F3.2 About the T32 Advanced SIMD and floating-point instructions and their encoding 11713

Chapter F4 A32 Instruction Set Encoding

F4.1 A32 instruction set encoding 11715

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F4.2 About the A32 Advanced SIMD and floating-point instructions and their encoding 11783

Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions

F5.1 Alphabetical list of T32 and A32 base instruction set instructions 11785

F5.2 Encoding and use of banked register transfer instructions 12564

Chapter F6 T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions

F6.1 Alphabetical list of Advanced SIMD and floating-point instructions 12569

Part G The AArch32 System Level Architecture

Chapter G1 The AArch32 System Level Programmers' Model

G1.1 About the AArch32 System level programmers' model 13428

G1.2 Exception levels 13429

G1.3 Exception terminology 13430

G1.4 Execution state 13432

G1.5 Instruction Set state 13434

G1.6 Security state 13435

G1.7 Security state, Exception levels, and AArch32 execution privilege 13438

G1.8 Virtualization 13440

G1.9 AArch32 state PE modes 13442

G1.10 AArch32 general-purpose registers, the PC, and the Special-purpose registers 13448

G1.11 Process state, PSTATE 13451

G1.12 Instruction set states 13457

G1.13 Handling exceptions that are taken to an Exception level using AArch32 13459

G1.14 Routing of aborts taken to AArch32 state 13477

G1.15 Exception return to an Exception level using AArch32 13479

G1.16 Asynchronous exception behavior for exceptions taken from AArch32 state 13483

G1.17 AArch32 state exception descriptions 13491

G1.18 Reset into AArch32 state 13512

G1.19 Mechanisms for entering a low-power state 13514

G1.20 The AArch32 System register interface 13519

G1.21 Advanced SIMD and floating-point support 13522

G1.22 Configurable instruction controls 13526

Chapter G2 AArch32 Self-hosted Debug

G2.1 About self-hosted debug 13532

G2.2 Routing debug exceptions 13536

G2.3 The debug exception enable controls 13538

G2.4 The effect of powerdown on debug exceptions 13540

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

G2.5 Summary of permitted routing and enabling of debug exceptions 13541
G2.6 Pseudocode description of debug exceptions 13543
G2.7 Breakpoint Instruction exceptions 13544
G2.8 Breakpoint exceptions 13547
G2.9 Watchpoint exceptions 13571
G2.10 Vector Catch exceptions 13584
G2.11 Synchronization and debug exceptions 13592

Chapter G3 AArch32 Self-hosted Trace

G3.1 About self-hosted trace 13595
G3.2 Prohibited regions in self-hosted trace 13596
G3.3 Self-hosted trace timestamps 13597
G3.4 Synchronization in self-hosted trace 13598

Chapter G4 The AArch32 System Level Memory Model

G4.1 About the memory system architecture 13600
G4.2 Address space 13601
G4.3 Mixed-endian support in AArch32 13602
G4.4 AArch32 cache and branch predictor support 13603
G4.5 System register support for IMPLEMENTATION DEFINED memory features 13627
G4.6 External aborts 13628
G4.7 Memory barrier instructions 13630
G4.8 Pseudocode description of general memory System instructions 13631

Chapter G5 The AArch32 Virtual Memory System Architecture

G5.1 About VMSAv8-32 13635
G5.2 The effects of disabling address translation stages on VMSAv8-32 behavior 13643
G5.3 Translation tables 13647
G5.4 The VMSAv8-32 Short-descriptor translation table format 13652
G5.5 The VMSAv8-32 Long-descriptor translation table format 13661
G5.6 Memory access control 13680
G5.7 Memory region attributes 13691
G5.8 Translation Lookaside Buffers 13703
G5.9 TLB maintenance requirements 13707
G5.10 Caches in VMSAv8-32 13721
G5.11 VMSAv8-32 memory aborts 13724
G5.12 Exception reporting in a VMSAv8-32 implementation 13736
G5.13 Address translation instructions 13754
G5.14 Pseudocode description of VMSAv8-32 memory system operations 13760

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

G5.15 About the System registers for VMSAv8-32 13763
G5.16 Functional grouping of VMSAv8-32 System registers 13768

Chapter G6 The Generic Timer in AArch32 state

G6.1 About the Generic Timer in AArch32 state 13770
G6.2 The AArch32 view of the Generic Timer 13775

Chapter G7 AArch32 System Register Encoding

G7.1 The AArch32 System register encoding space 13784
G7.2 Organization of registers in the (`coproc` == `0b1110`) encoding space 13785
G7.3 Organization of registers in the (`coproc` == `0b1111`) encoding space 13788

Chapter G8 AArch32 System Register Descriptions

G8.1 About the AArch32 System registers 13802
G8.2 General system control registers 13817
G8.3 Debug System registers 14428
G8.4 Performance Monitors registers 14587
G8.5 Activity Monitors registers 14691
G8.6 RAS registers 14733
G8.7 Generic Timer registers 14810

Part H External Debug

Chapter H1 About External Debug

H1.1 Introduction to external debug 14910
H1.2 External debug 14912
H1.3 Required debug authentication 14913

Chapter H2 Debug State

H2.1 About Debug state 14916
H2.2 Halting the PE on debug events 14917
H2.3 Entering Debug state 14924
H2.4 Behavior in Debug state 14927
H2.5 Exiting Debug state 14961

Chapter H3 Halting Debug Events

H3.1 Introduction to Halting debug events 14964
H3.2 Halting Step debug events 14966
H3.3 Halt Instruction debug event 14976
H3.4 Exception Catch debug event 14977
H3.5 External Debug Request debug event 14981

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H3.6 OS Unlock Catch debug event 14983
H3.7 Reset Catch debug events 14984
H3.8 Software Access debug event 14985
H3.9 Synchronization and Halting debug events 14986

Chapter H4 The Debug Communication Channel and Instruction Transfer Register

H4.1 Introduction 14989
H4.2 DCC and ITR registers 14990
H4.3 DCC and ITR access modes 14994
H4.4 Flow control of the DCC and ITR registers 14998
H4.5 Synchronization of DCC and ITR accesses 15001
H4.6 Interrupt-driven use of the DCC 15006
H4.7 Pseudocode description of the operation of the DCC and ITR registers 15007

Chapter H5 The Embedded Cross-Trigger Interface

H5.1 About the Embedded Cross-Trigger 15009
H5.2 Basic operation on the ECT 15011
H5.3 Cross-triggers on a PE in an Arm A-profile implementation 15015
H5.4 Description and allocation of CTI triggers 15016
H5.5 CTI registers programmers' model 15020
H5.6 Examples 15021

Chapter H6 Debug Reset and Powerdown Support

H6.1 About Debug over powerdown 15025
H6.2 Power domains and debug 15026
H6.3 Core power domain power states 15027
H6.4 Powerup request mechanism 15029
H6.5 Emulating low-power states 15030
H6.6 Debug OS Save and Restore sequences 15032
H6.7 Reset and debug 15038

Chapter H7 The PC Sample-based Profiling Extension

H7.1 About the PC Sample-based Profiling Extension 15041

Chapter H8 About the External Debug Registers

H8.1 Relationship between external debug and System registers 15046
H8.2 Endianness and supported access sizes 15047
H8.3 Synchronization of changes to the external debug registers 15048
H8.4 Memory-mapped accesses to the external debug interface 15052
H8.5 External debug interface register access permissions 15054

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H8.6 External debug interface registers 15058
H8.7 Cross-trigger interface registers 15064
H8.8 External debug register resets 15066

Chapter H9 External Debug Register Descriptions

H9.1 About the external debug registers 15070
H9.2 External debug registers 15071
H9.3 External trace registers 15235
H9.4 External Trace Buffer registers 15428
H9.5 Cross-Trigger Interface registers 15498

Part I Memory-mapped Components of the Arm Architecture

Chapter I1 Requirements for Memory-mapped Components

I1.1 Supported access sizes and Endianness 15567
I1.2 Synchronization of memory-mapped registers 15569
I1.3 Access requirements for reserved and unallocated registers 15571

Chapter I2 System Level Implementation of the Generic Timer

I2.1 About the Generic Timer specification 15573
I2.2 Memory-mapped counter module 15575
I2.3 Memory-mapped timer components 15579

Chapter I3 Recommended External Interface to the Performance Monitors

I3.1 About the external interface to the Performance Monitors registers 15584

Chapter I4 Recommended External Interface to the Activity Monitors

I4.1 About the external interface to the Activity Monitors Extension registers 15592

Chapter I5 External System Control Register Descriptions

I5.1 About the external system control register descriptions 15595
I5.2 External Performance Monitors registers summary 15597
I5.3 Performance Monitors external register descriptions 15602
I5.4 External Activity Monitors Extension registers summary 15777
I5.5 Activity Monitors external register descriptions 15780
I5.6 Generic Timer memory-mapped registers overview 15855
I5.7 Generic Timer memory-mapped register descriptions 15856

Part J Architectural Pseudocode

Chapter J1 A-profile Architecture Pseudocode

J1.1 Standard library 15909

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

J1.2 Pseudocode for AArch64 operation 15911
J1.3 Pseudocode for AArch32 operation 16313
J1.4 Shared pseudocode 16433

Part K Appendixes

Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors

K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors 16792
K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors 16813

Appendix K2 Recommendations for Reporting Memory Attributes on an Interconnect

K2.1 Arm recommendations for reporting memory attributes on an interconnect 16834

Appendix K3 ETE Recommended Configurations

K3.1 Configurations 16836

Appendix K4 Stages of Execution

K4.1 Stages of execution 16838

Appendix K5 Recommended External Debug Interface

K5.1 About the recommended external debug interface 16840
K5.2 PMUEVENT bus 16844
K5.3 Recommended authentication interface 16845
K5.4 Management registers and CoreSight compliance 16847

Appendix K6 Additional Information for Implementations of the Generic Timer

K6.1 Providing a complete set of features in a system level implementation 16860
K6.2 Gray count scheme for timer distribution scheme 16862

Appendix K7 Legacy Instruction Syntax for AArch32 Instruction Sets

K7.1 Legacy Instruction Syntax 16864

Appendix K8 Address Translation Examples

K8.1 AArch64 Address translation examples 16871
K8.2 AArch32 Address translation examples 16885

Appendix K9 Recommended Upload and Download Processes for External Debug

K9.1 Using Memory access mode in AArch64 state 16895

Appendix K10 Software Usage Examples

K10.1 Use of the Advanced SIMD complex number instructions 16900
K10.2 Use of the Armv8.2 extensions to the Cryptographic Extension 16902
K10.3 SVE and SVE2 Programming Examples 16909

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K10.4 Use of the FEAT_PCDPHINT STSHH and PRFM IR hint instructions 16910
K10.5 Use of the Embedded Trace and Trace Buffer Extensions 16912
K10.6 Use of the GCS Extension 16979
K10.7 Use of the RAS Extension 16989
K10.8 Example OS Save and Restore sequences 16990
K10.9 RME example software flows 16993
K10.10 MEC example software flows 16997

Appendix K11 Barrier Litmus Tests

K11.1 Introduction 17003
K11.2 Load-Acquire, Store-Release and barriers 17006
K11.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers 17009
K11.4 Using a mailbox to send an interrupt 17014
K11.5 Cache and TLB maintenance instructions and barriers 17015

Appendix K12 Random Number Generation

K12.1 Properties of the generated random number 17028

Appendix K13 Arm Pseudocode Definition

K13.1 About the Arm pseudocode 17030
K13.2 Pseudocode for instruction descriptions 17031

Appendix K14 Registers Index

K14.1 Introduction and register disambiguation 17033
K14.2 Alphabetical index of AArch64 registers and System instructions 17044
K14.3 Functional index of AArch64 registers and System instructions 17064
K14.4 Alphabetical index of AArch32 registers and System instructions 17084
K14.5 Functional index of AArch32 registers and System instructions 17093
K14.6 Alphabetical index of memory-mapped registers 17103
K14.7 Functional index of memory-mapped registers 17116

Preface

This preface introduces the *Arm Architecture Reference Manual, for A-profile architecture*. It contains the following sections:

- About this Manual
- Using this Manual
- Conventions
- Additional reading
- Feedback

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

About this Manual

This Manual describes the Arm® A-profile architecture versions Armv8-A and Armv9-A.

This Manual is also available in HTML on the Arm Support website, at https://support.arm.com/documentation/ddi0487/md. The HTML version is currently an early-access preview, provided for convenience only. In the event of any difference between this PDF and the HTML version, this PDF is the authoritative reference.

Download this PDF from https://support.arm.com/documentation/ddi0487/md.

The Architecture Speaks chatbot, available at https://developer.arm.com/architecture/the-architecture-speaks, aims to answer questions about the *Arm® Architecture Reference Manual for A-profile architecture*, and point users to sources within it that justify the answers.

Known limitations of this release

Validation of this release has identified the following issues that Arm will address in future issues:

- The A64 Instruction Set Encoding is not yet included in the HTML version. It is currently only available in the PDF version.
- The pseudocode in Architectural Pseudocode conforms to the definitions of ASL1, which is described in *Arm® Architecture Specification Language (ASL) Reference* (ARM DDI 0626). Other content in this Manual will be updated to align with ASL1 in future releases.
- Some diagrams in the register descriptions chapter have long field names that split over several lines.

For a monthly updated list of known issues in this release, see the Arm® Architecture Reference Manual for A-profile architecture, Known Issues.

For release notes corresponding to the most recent Register and Instruction XML release, see https://support.arm.com/Architectures/A-Profile%20Architecture#Downloads.

Corresponding Collateral

The following packages provide additional information, including machine-readable data, that is aligned to this release:

Name	Architecture version	Architecture quality	Package version	Package format	Description & Links
Machine-Readable Descriptions for Features, Registers, and Instructions.	up to Armv9.6	EAC	2026-09	XML & HTML	The following packages provide machine-readable descriptions for Armv8.9-A and Armv9.6-A content: • Features • Registers • Instructions (A64) • Instructions (A32/T32)
Architecture Specification Language (ASL) Definition	N/A	N/A	00eac1	PDF	*Architecture Specification Language* (ASL) is used to specify System registers and instruction descriptions in the *Arm® Architecture Reference Manual for A-profile architecture* and in the other collateral listed in this table. The following PDFs provide information on ASL: • ASL Reference (DDI 0626) version 00eac1, the formal language definition for ASL. • ASL Reader's Guide (111069) version A.a, an informal guide to reading ASL code. See Architecture Specification Language.

Non-Confidential

Name	Architecture version	Architecture quality	Package version	Package format	Description & Links
Architecture Specification Language (ASL) Ecosystem	N/A	N/A	00eac1	Source files & tools	*ASLRef* is the reference definition ecosystem for ASL, and is available in a publicly accessible repository that contains all of: • Source code for Arm's reference implementation of ASL. • Tests that illustrate the ASL language, including those that also appear in ASL Reference (DDI 0626), the formal language definition for ASL. • The source files used to produce ASL Reference (DDI 0626). The ASLRef version corresponding to this release is *ASLRef EAC1 release*.
cat Language Definition	N/A	N/A	Latest	PDF	*cat* is a domain specific language used to specify the Arm memory model. The following PDF provides information on cat: • Syntax and semantics of the weak consistency model specification language cat.
cat file (Machine-Readable, Executable and Formal Concurrency Model Description).	N/A	EAC	Latest	Source files	*cat file* (Machine-Readable, Executable, and Formal Concurrency Model Description). • aarch64.cat contains the definitions and ordering rules that correspond to the section Ordering requirements defined by the formal concurrency model. The herdtools7 version corresponding to this release is *ArmARM-M.d-concurrency*.
Concurrency Model Ecosystem	N/A	EAC	Latest	Source files & tools	*herdtools7* is a tool suite used to develop, simulate, and test the Arm Concurrency Model, among others. It is available in a publicly accessible repository that contains all of: • The source code for herd7, the concurrency model simulation tool. • The source code for litmus7, a tool that generates hardware-executable binaries from litmus tests. • The source code for diy7/diyone7, tools that generate litmus tests. • A collection of litmus tests illustrating the ordering requirements defined in the section Ordering requirements defined by the formal concurrency model. The herdtools7 version corresponding to this release is *ArmARM-M.d-concurrency*. See also: • herd7 Tool.

Architecture description

The Arm® A-profile architecture describes the operation of an Armv8-A and an Armv9-A *Processing element* (PE). This Manual includes descriptions of:

- The two Execution states, AArch64 and AArch32.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction sets:
  - In AArch32 state, the T32 and A32 instruction sets, which are compatible with earlier versions of the Arm architecture.
  - In AArch64 state, the A64 instruction set.
- The states that determine how a PE operates, including the current Exception level and Security state, and in AArch32 state the PE mode.
- The Exception model.
- The interprocessing model, that supports transitioning between AArch64 state and AArch32 state.
- The memory model, that defines memory ordering and memory management. This Manual covers the Arm A architecture profile, both Armv8-A and Armv9-A, that defines a *Virtual Memory System Architecture* (VMSA).
- The programmers' model, and its interfaces to System registers that control most PE and memory system features, and provide status information.
- The Advanced SIMD and floating-point instructions, which provide high-performance:
  - Single-precision, half-precision, and double-precision floating-point operations.
  - Conversions between double-precision, single-precision, and half-precision floating-point values.
  - Integer, single-precision floating-point, and half-precision floating-point vector operations in all instruction sets.
  - Double-precision floating-point vector operations in the A64 instruction set.
- The security model, which provides up to four Security states to support Secure applications and confidential computing.
- The virtualization model.
- The Debug architecture, which provides software access to debug features.

This Manual gives the assembler syntax for the instructions it describes, meaning that it describes instructions in textual form. However, this Manual is not a tutorial for Arm assembler language, nor does it describe Arm assembler language, except at a basic level. To make effective use of Arm assembler language, read the documentation supplied with the assembler being used.

This Manual is organized into parts:

Part A Provides an introduction to the Arm architecture, and an overview of the AArch64 and AArch32 Execution states.

Part B Describes the application level view of the AArch64 Execution state, meaning the view from EL0. It describes the application level view of the programmers' model and the memory model.

Part C Describes the A64 instruction set, which is available in the AArch64 Execution state. The descriptions for each instruction also include the precise effects of each instruction when executed at EL0, described as *unprivileged* execution, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate Arm machine code.

Part D Describes the system level view of the AArch64 Execution state. It includes details of the System registers, most of which are not accessible from EL0, and the system level view of the programmers' model and the memory model. This part includes the description of self-hosted debug.

Part E Describes the application level view of the AArch32 Execution state, meaning the view from the EL0. It describes the application level view of the programmers' model and the memory model.

Note

In AArch32 state, execution at EL0 is execution in User mode.

Part F Describes the T32 and A32 instruction sets, which are available in the AArch32 Execution state. These instruction sets are backwards-compatible with earlier versions of the Arm architecture. This part describes the precise effects of each instruction when executed in User mode, described as *unprivileged* execution or execution at EL0, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate Arm machine code.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

User mode is the only mode where software execution is unprivileged.

Part G Describes the system level view of the AArch32 Execution state, which is generally compatible with earlier versions of the Arm architecture. This part includes details of the System registers, most of which are not accessible from EL0, and the instruction interface to those registers. It also describes the system level view of the programmers' model and the memory model.

Part H Describes the Debug architecture for external debug. This provides configuration, breakpoint and watchpoint support, and a *Debug Communications Channel* (DCC) to a debug host.

Part I Describes additional features of the architecture that are not closely coupled to a PE, and therefore are accessed through memory-mapped interfaces. Some of these features are OPTIONAL.

Part J Provides pseudocode that describes various features of the Arm architecture.

Part K, Appendixes

Provide additional information. Some appendixes give information that is not part of the A-profile architectural requirements. The cover page of each appendix indicates its status.

Glossary Defines terms used in this Manual that have a specialized meaning.

Note

Terms that are generally well understood in the microelectronics industry are not included in the Glossary.

Using this Manual

The information in this Manual is organized into parts, as described in this section.

Part A, Introduction and Architecture Overview

Part A gives an overview of the Armv8-A and Armv9-A architecture profiles, including its relationship to the other Arm PE architectures. It introduces the terminology used to describe the architecture, and gives an overview of the Executions states, AArch64 and AArch32.

It contains the following chapters:

Introduction to the Arm Architecture

Read this for an introduction to the Arm architecture.

A-profile Architecture Extensions

Read this for an introduction to the A-profile architecture extensions and features.

Part B, The AArch64 Application Level Architecture

Part B describes the AArch64 state application level view of the architecture. It contains the following chapters:

The AArch64 Application Level Programmers' Model

Read this for an application level description of the programmers' model for software executing in AArch64 state. It describes execution at EL0 when EL0 is using AArch64 state.

The AArch64 Application Level Memory Model

Read this for an application level description of the memory model for software executing in AArch64 state. It describes the memory model for execution in EL0 when EL0 is using AArch64 state. It includes information about Arm memory types, attributes, and memory access controls.

Part C, The A64 Instruction Set

Part C describes the A64 instruction set, which is used in AArch64 state. It contains the following chapters:

The A64 Instruction Set

Read this for a description of the A64 instruction set and common instruction operation details.

About the A64 Instruction Descriptions

Read this to understand the format of the A64 instruction descriptions.

A64 Instruction Set Overview

Read this for an overview of the A64 instructions.

A64 Instruction Set Encoding

Read this for a description of the A64 instruction set encoding.

The A64 System Instruction Class

Read this for a description of the AArch64 System instructions and register descriptions, and the System instruction class encoding space.

A64 Base Instruction Descriptions

Read this for information on key aspects of the A64 base instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A64 Advanced SIMD and Floating-point Instruction Descriptions

Read this for information on key aspects of the A64 Advanced SIMD and floating-point instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

SVE Instruction Descriptions

Read this for information on key aspects of the SVE instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

SME Instruction Descriptions

Read this for information on key aspects of the SME instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Part D, The AArch64 System Level Architecture

Part D describes the AArch64 state system level view of the architecture. It contains the following chapters:

The AArch64 System Level Programmers' Model

Read this for a description of the AArch64 state system level view of the programmers' model.

AArch64 Self-hosted Debug

Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

AArch64 Self-hosted Trace

Read this for an introduction to, and a description of, self-hosted trace in AArch64 state.

The Embedded Trace Extension

Read this for a description of the Embedded Trace Extension.

ETE Protocol Descriptions

Read this for a description of the ETE packets, which are listed in alphabetical order.

The Trace Buffer Extension

Read this for a description of the Trace Buffer Extension.

The AArch64 System Level Memory Model

Read this for a description of the AArch64 state system level view of the general features of the memory system.

The AArch64 Virtual Memory System Architecture

Read this for a system level view of the AArch64 *Virtual Memory System Architecture* (VMSA), the memory system architecture of an A-profile architecture implementation executing in AArch64 state.

The Granule Protection Check Mechanism

Read this for a description of the granule protection check mechanism, a feature that is added as part of the OPTIONAL Realm Management Extension.

The Memory Tagging Extension

Read this for a description of the Memory Tagging Extension.

The Guarded Control Stack

Read this for a description of the Guarded Control Stack extension.

The Generic Timer in AArch64 state

Read this for a description of the AArch64 view of the Arm Generic Timer.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The Performance Monitors Extension

Read this for a description of the Arm Performance Monitors, an optional non-invasive debug component.

The System Performance Monitors Extension

Read this for a description of the System Performance Monitors, an optional non-invasive debug component.

The Activity Monitors Extension

Read this for a description of the Arm Activity Monitors.

The Statistical Profiling Extension

Read this for a description of the Statistical Profiling Extension, an optional AArch64 state non-invasive debug component.

Statistical Profiling Extension Sample Record Specification

Read this for a description of the sample records generated by the Statistical Profiling Extension.

The Branch Record Buffer Extension

Read this for a description of the Branch Record Buffer Extension.

RAS PE Architecture

Read this for a description of the RAS Extension PE architecture.

MPAM PE Architecture

Read this for a description of the MPAM Extension PE architecture.

The Scalable Matrix Extension

Read this for a description of the Scalable Matrix Extension.

AArch64 System Register Encoding

Read this for a description of the encoding of the AArch64 System registers, and the other uses of the AArch64 System registers encoding space.

AArch64 System Register Descriptions

Read this for an introduction to, and description of, each of the AArch64 System registers.

Part E, The AArch32 Application Level Architecture

Part E describes the AArch32 state application level view of the architecture. It contains the following chapters:

The AArch32 Application Level Programmers' Model

Read this for an application level description of the programmers' model for software executing in AArch32 state. It describes execution at EL0 when EL0 is using AArch32 state.

The AArch32 Application Level Memory Model

Read this for an application level description of the memory model for software executing in AArch32 state. It describes the memory model for execution in EL0 when EL0 is using AArch32 state. It includes information about Arm memory types, attributes, and memory access controls.

Part F, The AArch32 Instruction Sets

Part F describes the T32 and A32 instruction sets, which are used in AArch32 state. It contains the following chapters:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

About the T32 and A32 Instruction Descriptions

Read this to understand the format of the T32 and A32 instruction descriptions.

The AArch32 Instruction Sets Overview

Read this for an overview of the T32 and A32 instruction sets.

T32 Instruction Set Encoding

Read this for a description of the T32 instruction set encoding. This includes the T32 encoding of the Advanced SIMD and floating-point instructions.

A32 Instruction Set Encoding

Read this for a description of the A32 instruction set encoding. This includes the A32 encoding of the Advanced SIMD and floating-point instructions.

T32 and A32 Base Instruction Set Instruction Descriptions

Read this for a description of each of the T32 and A32 base instructions.

T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions

Read this for a description of each of the T32 and A32 Advanced SIMD and floating-point instructions.

Part G, The AArch32 System Level Architecture

Part G describes the AArch32 state system level view of the architecture. It contains the following chapters:

The AArch32 System Level Programmers' Model

Read this for a description of the AArch32 state system level view of the programmers' model for execution in an Exception level that is using AArch32.

AArch32 Self-hosted Debug

Read this for an introduction to, and a description of, self-hosted debug in AArch32 state.

AArch32 Self-hosted Trace

Read this for an introduction to, and a description of, self-hosted trace in AArch32 state.

The AArch32 System Level Memory Model

Read this for a system level view of the general features of the memory system.

The AArch32 Virtual Memory System Architecture

Read this for a description of the AArch32 Virtual Memory System Architecture (VMSA).

The Generic Timer in AArch32 state

Read this for a description of the AArch32 view of an implementation of the Arm Generic Timer.

AArch32 System Register Encoding

Read this for a description of the encoding of the AArch32 System registers, including the System instructions that are part of the AArch32 System registers encoding space.

AArch32 System Register Descriptions

Read this for a description of each of the AArch32 System registers.

Part H, External Debug

Part H describes the architecture for external debug. It contains the following chapters:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

About External Debug

Read this for an introduction to external debug, and a definition of the scope of this part of the Manual.

Debug State

Read this for a description of Debug state, which the PE might enter as the result of a Halting debug event.

Halting Debug Events

Read this for a description of the external debug events referred to as Halting debug events.

The Debug Communication Channel and Instruction Transfer Register

Read this for a description of the communication between a debugger and the PE debug logic using the Debug Communications Channel and the Instruction Transfer register.

The Embedded Cross-Trigger Interface

Read this for a description of the Embedded Cross-Trigger Interface.

Debug Reset and Powerdown Support

Read this for a description of reset and powerdown support in the Debug architecture.

The PC Sample-based Profiling Extension

Read this for a description of the PC Sample-based Profiling Extension that is an OPTIONAL extension to an Armv8 or Armv9 implementation.

About the External Debug Registers

Read this for some additional information about the external debug registers.

External Debug Register Descriptions

Read this for a description of each external debug register.

Part I, Memory-mapped Components of the Arm architecture

Part I describes the memory-mapped components in the architecture. It contains the following chapters:

Requirements for Memory-mapped Components

Read this for descriptions of some general requirements for memory-mapped components within a system that complies with the Arm architecture.

System Level Implementation of the Generic Timer

Read this for a definition of a system level implementation of the Generic Timer.

Recommended External Interface to the Performance Monitors

Read this for a description of the recommended memory-mapped and external debug interfaces to the Performance Monitors.

Recommended External Interface to the Activity Monitors

Read this for a description of the recommended memory-mapped interface to the Activity Monitors.

External System Control Register Descriptions

Read this for a description of each memory-mapped system control register.

Part J, Architectural Pseudocode

Part J contains pseudocode that describes various features of the Arm architecture. It contains the following chapter:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A-profile Architecture Pseudocode

Read this for the pseudocode definitions that describe various features of the Arm architecture, for operation in AArch64 state and in AArch32 state.

Part K, Appendixes

Note

Some of the descriptions in the following appendixes are not part of the Arm architecture specification. They are included here as supplementary information, for the convenience of developers and users who might require this information.

This Manual contains the following appendixes:

Architectural Constraints on UNPREDICTABLE Behaviors

Read this for a description of the architecturally-required constraints on UNPREDICTABLE behaviors in the Arm architecture, including AArch32 behaviors that were UNPREDICTABLE in previous versions of the architecture.

Recommendations for Reporting Memory Attributes on an Interconnect

Read this for the Arm recommendations about how the architectural memory attributes are reported on an interconnect.

ETE Recommended Configurations

Read this for a description of the ETE recommended configurations.

Stages of Execution

Read this for a description of the stages of execution.

Recommended External Debug Interface

Read this for a description of the recommended external debug interface.

Additional Information for Implementations of the Generic Timer

Read this for additional information about implementations of the Arm Generic Timer. This information does not form part of the architectural definition of the Generic Timer.

Legacy Instruction Syntax for AArch32 Instruction Sets

Read this for information about the pre-UAL syntax of the AArch32 instruction sets, which are valid for the A32 instruction set.

Address Translation Examples

Read this for examples of translation table lookups using the translation regimes described in The AArch64 Virtual Memory System Architecture and The AArch32 Virtual Memory System Architecture.

Recommended Upload and Download Processes for External Debug

Read this for information about implementing and using the Arm architecture.

Software Usage Examples

Read this for software examples that help understanding of some aspects of the Arm architecture.

Barrier Litmus Tests

Read this for examples of the use of barrier instructions provided by the Arm architecture.

Random Number Generation

Read this for information on the generation of random numbers using FEAT_RNG.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Arm Pseudocode Definition

Read this for definitions of the Arm pseudocode.

Registers Index

Read this for an alphabetic and functional index of AArch32 and AArch64 registers, and memory-mapped registers.

Glossary

Defines terms used in this Manual that have a specialized meaning.

Note

Terms that are well understood in the microelectronics industry are not included in the Glossary.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Conventions

The following sections describe conventions that this book can use:

- Typographic conventions
- Rules-based writing
- Signals
- Numbers
- Pseudocode descriptions
- Assembler syntax descriptions

Typographic conventions

The typographical conventions are:

italic Introduces special terminology, and denotes citations.

bold Denotes signal names, and is used for terms in descriptive lists, where appropriate.

`monospace` Used for assembler syntax descriptions, pseudocode, and source code examples.

Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

SMALL CAPITALS

Used in body text for a few terms that have specific technical meanings, and are defined in the Glossary.

Colored text Indicates a link. This can be:

- A URL, for example https://support.arm.com.
- A link, to a chapter or appendix, or to a glossary entry, or to the section of the Manual that defines the colored term, for example Simple sequential execution or SCTLR.

{ and } Braces, { and }, have two distinct uses:

Optional items

In syntax descriptions braces enclose optional items. In the following example they indicate that the `<shift>`parameter is optional:

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

Similarly, they can be used in generalized field descriptions, for example TCR_ELx.{I}PS refers to a field in the TCR_ELx registers that is called either IPS or PS.

Sets of items

Braces can be used to enclose sets. For example, HCR_EL2.{E2H, TGE} refers to a set of two register fields, HCR_EL2.E2H and HCR_EL2.TGE.

Notes Notes are formatted as:

Note

This is a Note.

In this Manual, Notes are used only to provide additional information, usually to help understanding of the text. While a Note might repeat architectural information given elsewhere in the Manual, a Note never provides any part of the definition of the architecture.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Rules-based writing

Some sections of this Manual use rules-based writing. Rules-based writing consists of a set of individual content items. A content item is classified as one of the following:

- Rule.
- Information.
- Software usage.
- Declaration.

Rules are normative statements. An implementation that is compliant with this specification must conform to all Rules in this Manual that apply to that implementation.

Rules must not be read in isolation. Where a particular feature is specified by multiple Rules, these are generally grouped into sections and subsections that provide context. Where appropriate, these sections begin with a short introduction.

Arm strongly recommends that implementers read all chapters and sections of this Manual to ensure that an implementation is compliant.

Content items other than Rules are informative statements. These are provided as an aid to understanding this Manual.

Content item identifiers

A content item may have an associated identifier which is unique among content items in this Manual. After content reaches beta status, a given content item has the same identifier across subsequent versions of this Manual.

Content item rendering

In this Manual, a content item is rendered with a token of the following format in the left margin: L_{iiiii}. L is a label that indicates the content class of the content item. iiiii is the identifier of the content item.

Content item classes

Each of the content item classes has a different function in this Manual.

Rule

A Rule is a statement that describes the behavior of a compliant implementation.

A Rule explains what happens in a particular situation.

A Rule does not define concepts or terminology.

A Rule is rendered with the label R.

Information

An Information statement provides information and guidance as an aid to understanding the Manual.

An Information statement is rendered with the label I.

Software usage

A Software usage statement provides guidance on how software can make use of the features defined by the specification.

A Software usage statement is rendered with the label S.

Declaration

A Declaration statement introduces concepts or terminology.

A Declaration does not describe behavior.

A Declaration is rendered with the label D.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Signals

In general this specification does not define hardware signals, but it does include some signal examples and recommendations. The signal conventions are:

Signal level The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:

- HIGH for active-HIGH signals.
- LOW for active-LOW signals.

Lowercase n At the start or end of a signal name denotes an active-LOW signal.

Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a `monospace` font, for example `0xFFFF_0000`. To improve readability, long numbers can be written with an underscore separator between every four characters, for example `0xFFFF_0000_0000_0000`. Ignore any underscores when interpreting the value of a number.

Pseudocode descriptions

This Manual uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in `monospace` font, and is described in Arm Pseudocode Definition.

Assembler syntax descriptions

This Manual contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a `monospace` font, and use the conventions described in Structure of the A64 assembler language, and Arm Pseudocode Definition.

Feedback

Arm welcomes feedback on its documentation.

Feedback on this Manual

If you have any comments or queries about this Manual, create a ticket at https://support.arm.com/support-cases.

As part of the ticket, include:

- The title, Arm® Architecture Reference Manual for A-profile architecture.
- The number, ARM DDI 0487 M.d.
- The section name to which your comments refer.
- The page number(s) to which your comments refer.
- The rule identifier(s) to which your comments refer, if applicable.
- A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

Note

Arm tests PDFs only in Adobe Acrobat and Acrobat Reader, and cannot guarantee the appearance or behavior of any document when viewed with any other PDF reader. Search performance may be significantly improved by increasing the Fast Find Maximum Cache Size under Search in Preferences.
If using Google Chrome™ or Microsoft Edge™, load time is significantly improved since the April 2025 release of these browsers.
Users may find, on some systems, that PDF viewers such as Okular or Foxit™ give good performance.

Inclusive terminology commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive. Arm strives to lead the industry and create change.

Previous issues of this document included language that can be offensive. We have replaced this language. To report offensive language in this document, email `terms@arm.com`.

Part A
Arm Architecture Introduction and Overview

Chapter A1
Introduction to the Arm Architecture

This chapter introduces the Arm architecture. It contains the following sections:

- About the Arm architecture
- Architecture profiles
- Arm architectural concepts
- Supported data types
- Floating-point support
- The Arm memory model
- Reliability, Availability, and Serviceability

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.1 About the Arm architecture

The Arm architecture described in this Architecture Reference Manual defines the behavior of an abstract machine, referred to as a *processing element*, often abbreviated to *PE*. Implementations compliant with the Arm architecture must conform to the described behavior of the processing element. It is not intended to describe how to build an implementation of the PE, nor to limit the scope of such implementations beyond the defined behaviors.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with the Arm architecture must be the same as a simple sequential execution of the program on the processing element. The programmer-visible behavior does not include a specified execution time for any instruction but requires each instruction to execute in finite time, as long as another observer is not continually modifying any Location associated with a Memory Effect, other than an Explicit Memory Effect, that is architecturally required for execution of the instruction. In cases where another observer is continually modifying a Location associated with a Memory Effect, other than an Explicit Memory Effect, at least one of the observers must make forward progress in finite time. Unless otherwise specified, the architecturally defined effects of each instruction also complete in finite time.

The Arm Architecture Reference Manual also describes rules for software to use the PE.

The Arm architecture includes definitions of:

- An associated debug architecture, see:
  - AArch64 Self-hosted Debug.
  - AArch32 Self-hosted Debug.
  - External Debug.
- Associated trace architectures that define trace units that implementers can implement with the associated processor hardware. For more information, see:
  - The *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4* (ARM IHI 0064).
  - AArch64 Self-hosted Trace.
  - The Embedded Trace Extension.
  - The Trace Buffer Extension.
  - AArch32 Self-hosted Trace.

Arm also provides system architecture specifications for systems aimed at particular product categories, such as servers, or personal computers, *Arm® Server Base System Architecture* (ARM DEN 0029) and *Arm® Base System Architecture* (ARM DEN 0094). These specifications build on the architecture specification in this Manual, restricting, as defined in those specifications, some of the optional and IMPLEMENTATION DEFINED features defined in this specification, as well as specifying additional features applicable at the system level.

The Arm architecture is a *Reduced Instruction Set Computer* (RISC) architecture with the following RISC architecture features:

- A large uniform register file.
- A *load/store* architecture, where data-processing operations only operate on register contents, not directly on memory contents.
- Simple addressing modes, with all load/store addresses determined from register contents and instruction fields only.

The architecture defines the interaction of the PE with memory, including caches, and includes a memory translation system. It also describes how multiple PEs interact with each other and with other observers in a system.

This document defines versions 8 and 9 of the A-profile architecture.

See Architecture profiles for more information.

The Arm architecture supports implementations across a wide range of performance points. Implementation size, performance, and very low power consumption are key attributes of the Arm architecture.

An important feature of the Arm architecture is backward compatibility, combined with the freedom for optimal implementation in a wide range of standard and more specialized use cases.

The Arm architecture supports:

- A 64-bit Execution state, AArch64.
- A 32-bit Execution state, AArch32, that is compatible with previous versions of the Arm architecture.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Features that are optional are explicitly defined as such in this Manual.

Note

The presence of an ID register field for a feature does not imply that the feature is optional.

Both Execution states support floating-point instructions:

- AArch32 state provides:
  - SIMD instructions in the base instruction sets that operate on the 32-bit general-purpose registers.
  - Advanced SIMD instructions that operate on registers in the *SIMD and floating-point register* (SIMD&FP register) file.
  - Scalar floating-point instructions that operate on registers in the SIMD&FP register file.
- AArch64 state provides:
  - Advanced SIMD instructions that operate on registers in the SIMD&FP register file.
  - Scalar floating-point instructions that operate on registers in the SIMD&FP register file.

    Note

    The A64 instruction set does not include SIMD instructions that operate on the general-purpose registers, therefore, some AArch64 instructions descriptions use SIMD as a synonym for Advanced SIMD.

  - SVE instructions that operate on registers in the SVE register files.
  - SME instructions that operate on registers in the SVE register files and ZA storage.

Note

See Conventions for information about conventions used in this Manual, including the use of SMALL CAPITALS for particular terms that have Arm-specific meanings that are defined in the Glossary.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.2 Architecture profiles

The Arm architecture has evolved significantly since its introduction, and Arm continues to develop it. Nine major versions of the architecture have been defined to date, denoted by the version numbers 1 to 9. Of these, the first three versions are now obsolete.

The generic names AArch64 and AArch32 describe the 64-bit and 32-bit Execution states:

AArch64 Is the 64-bit Execution state, meaning addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

AArch32 Is the 32-bit Execution state, meaning addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

Note

The *Base instruction set* comprises the supported instructions other than the floating-point instructions.

See sections Execution state and The instruction sets for more information.

Arm defines three architecture profiles:

A Application profile, described in this Manual:

- Supports a *Virtual Memory System Architecture* (VMSA) based on a *Memory Management Unit* (MMU).
- Supports the A64, A32, and T32 instruction sets.

R Real-time profile:

- Supports a *Protected Memory System Architecture* (PMSA) based on a *Memory Protection Unit* (MPU).
- Supports an optional VMSA based on an MMU in the R-profile AArch64 architecture.
- Supports the A64 instruction set if the R-profile AArch64 architecture is implemented, or the A32 and T32 instruction sets if the R-profile AArch32 architecture is implemented.

M Microcontroller profile:

- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
- Supports a PMSA based on an MPU.
- Supports a variant of the T32 instruction set.

This Manual describes only Armv8-A and Armv9-A. For information about the R and M architecture profiles, and earlier Arm architecture versions, see:

- The *Arm® Architecture Reference Manual, for Armv8-R AArch64 architecture profile*.
- The *Arm® Architecture Reference Manual, for Armv8-R AArch32 architecture profile*.
- The *ARM® Architecture Reference Manual ARMv7-A and ARMv7-R edition*.
- The *Armv8-M Architecture Reference Manual*.
- The *Armv7-M Architecture Reference Manual*.
- The *Armv6-M Architecture Reference Manual*.

Non-Confidential

A1.3 Arm architectural concepts

This section introduces architectural concepts and the associated terminology.

The following subsections describe key architectural concepts. Each section introduces the corresponding terms that are used to describe the architecture:

- Execution state
- The instruction sets
- System registers
- Arm Debug

A1.3.1 Execution state

The Execution state defines the PE execution environment, including:

- The supported register widths.
- The supported instruction sets.
- Significant aspects of:
  - The Exception model.
  - The *Virtual Memory System Architecture* (VMSA).
  - The programmers' model.

The Execution states are:

AArch64 The 64-bit Execution state. This Execution state:

- Provides 31 64-bit general-purpose registers, of which X30 is used as the procedure link register.
- Provides a 64-bit *Program Counter* (PC), *stack pointers* (SPs), and *Exception Link Registers* (ELRs).
- Provides 32 128-bit registers for Advanced SIMD vector and scalar floating-point support.
- Provides a single instruction set, A64. For more information, see The instruction sets.
- Defines the Armv8 Exception model, with up to four Exception levels, EL0 - EL3, that provide an *execution privilege* hierarchy, see Exception levels.
- Provides support for 64-bit *virtual addressing*. For more information, including the limits on address ranges, see The AArch64 Virtual Memory System Architecture.
- Defines a number of *Process state* (PSTATE) elements that hold PE state. The A64 instruction set includes instructions that operate directly on various PSTATE elements.
- Names each System register using a suffix that indicates the lowest Exception level at which the register can be accessed.

AArch32 The 32-bit Execution state. This Execution state:

- Provides 13 32-bit general-purpose registers, and a 32-bit PC, SP, and *Link Register* (LR). The LR is used as both an ELR and a procedure link register.
  Some of these registers have multiple *banked* instances for use in different PE *modes*.
- Provides a single ELR, for exception returns from Hyp mode.
- Provides 32 64-bit registers for Advanced SIMD vector and scalar floating-point support.
- Provides two instruction sets, T32 and A32. For more information, see The instruction sets.
- Supports the Armv7-A Exception model, based on *PE modes*, and maps this onto the Armv8 Exception model, that is based on the Exception levels.
- Provides support for 32-bit virtual addressing.
- Defines a number of *Process state* (PSTATE) elements that hold PE state. The T32 and A32 instruction sets include instructions that operate directly on various PSTATE elements, and instructions that access PSTATE by using the *Application Program Status Register* (APSR) or the *Current Program Status Register* (CPSR).

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Later subsections give more information about the different properties of the Execution states.

Transferring control between the AArch64 and AArch32 Execution states is known as *interprocessing*. The PE can move between Execution states only on a change of Exception level, and subject to the rules given in Interprocessing. This means different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.

A1.3.2 The instruction sets

The possible instruction sets depend on the Execution state:

AArch64 AArch64 state supports a single instruction set, called A64. This is a fixed-length instruction set that uses 32-bit instruction encodings.

For information on the A64 instruction set, see A64 Instruction Set Overview.

If FEAT_SVE is implemented, the A64 instruction set supports scalable vector instructions. See About the SVE instructions.

If FEAT_SME is implemented, the A64 instruction set supports scalable matrix instructions. See About the SME instructions.

AArch32 AArch32 state supports the following instruction sets:

A32 This is a fixed-length instruction set that uses 32-bit instruction encodings.

T32 This is a variable-length instruction set that uses both 16-bit and 32-bit instruction encodings.

In previous documentation, these instruction sets were called the ARM and Thumb® instruction sets. Armv8 and Armv9 extend each of these instruction sets. In AArch32 state, the Instruction set state determines the instruction set that the PE executes.

For information on the T32 and A32 instruction sets, see The AArch32 Instruction Sets Overview.

The instruction sets support SIMD and scalar floating-point instructions. See Floating-point support.

A1.3.3 System registers

System registers provide control and status information of architected features.

The System registers use a standard naming format: <register_name>.<bit_field_name> to identify specific registers as well as control and status bits within a register.

Bits can also be described by their numerical position in the form <register_name>[x:y] or the generic form bits[x:y].

In addition, in AArch64 state, most register names include the lowest Exception level that can access the register as a suffix to the register name:

- <register_name>_ELx, where x is 0, 1, 2, or 3.

For information about Exception levels, see Exception levels.

The System registers comprise:

- The following registers that are described in this Manual:
  - General system control registers.
  - Debug registers.
  - RAS registers.
  - Generic Timer registers.
  - Optionally, Performance Monitor registers.
  - Optionally, the Activity Monitors registers.
  - Optionally, the Scalable Vector Extension registers.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - Optionally, in Armv9, Trace System registers.
- Optionally, one or more of the following groups of registers that are defined in other Arm architecture specifications:
  - Trace System registers, as defined in the *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4*.
  - *Generic Interrupt Controller* (GIC) System registers, see The Arm Generic Interrupt Controller System registers.

For information about the AArch64 System registers, see AArch64 System Register Descriptions.

For information about the AArch32 System registers, see AArch32 System Register Descriptions.

A1.3.3.1 The Arm Generic Interrupt Controller System registers

From version 3 of the Arm Generic Interrupt Controller architecture, GICv3, the GIC architecture specification defines a System register interface to some of its functionality. The System register summaries in this Manual include these registers, see:

- About the GIC System registers, for more information about the AArch64 GIC System registers.
- About the GIC System registers, for more information about the AArch32 GIC System registers.

These sections give only short overviews of the GIC System registers. For more information, including descriptions of the registers, see the *Arm® Generic Interrupt Controller Architecture Specification, GIC architecture version 3 and version 4* (ARM IHI 0069) and *Arm® Generic Interrupt Controller Architecture Specification, GIC architecture version 5* (ARM IHI 111701).

Note

The programmers' model for earlier versions of the GIC architecture is wholly memory-mapped.

A1.3.4 Arm Debug

Armv8 and later architectures support the following:

Self-hosted debug

In this model, the PE generates *debug exceptions*. Debug exceptions are part of the Armv8 Exception model.

External debug

In this model, *debug events* cause the PE to enter *Debug state*. In Debug state, the PE is controlled by an external debugger.

All Armv8 and later implementations support both models. The model chosen by a particular user depends on the debug requirements during different stages of the design and development life cycle of the product. For example, external debug might be used during debugging of the hardware implementation and OS bring-up, and self-hosted debug might be used during application development.

For more information about self-hosted debug:

- In AArch64 state, see AArch64 Self-hosted Debug.
- In AArch32 state, see AArch32 Self-hosted Debug.

For more information about external debug, see External Debug.

A1.4 Supported data types

The Arm architecture supports the following integer data types:

Byte 8 bits.

Halfword 16 bits.

Word 32 bits.

Doubleword 64 bits.

Quadword 128 bits.

The architecture also supports the following floating-point data types:

- Half-precision. See Half-precision floating-point formats.
- Single-precision. See Single-precision floating-point format.
- Double-precision. See Double-precision floating-point format.
- BFloat16. See BFloat16 floating-point format.
- 8-bit floating-point. See FP8 floating-point formats.

It also supports vectors, where a register holds a vector of multiple elements, each the same size and data type. See Advanced SIMD vector formats and SVE vector formats.

The architecture provides the following:

- A general-purpose register file.
- A SIMD&FP register file.
- If FEAT_SVE or FEAT_SME is implemented, an SVE scalable vector register file and an SVE scalable predicate register file.
- If FEAT_SME is implemented, the scalable ZA storage.
- If FEAT_SME2 is implemented, the SME2 ZT0 register.

In each of these, the possible register widths depend on the Execution state.

In AArch64 state:

- The general-purpose register file contains 64-bit registers:
  - Many instructions can access these registers as 64-bit registers, or as 32-bit registers using only the bottom 32 bits.
- The SIMD&FP register file contains 128-bit registers:
  - While the AArch64 vector registers support 128-bit vectors, the effective vector length can be 64-bits or 128-bits depending on the A64 instruction encoding used, see Instruction Mnemonics.
- The SVE scalable vector register file contains registers of an IMPLEMENTATION DEFINED width:
  - An SVE scalable vector register has an IMPLEMENTATION DEFINED width that is a power of two, from a minimum of 128 bits up to a maximum of 2048 bits.
  - All SVE scalable vector registers in an implementation are the same width.
- The SVE scalable predicate register file contains registers of an IMPLEMENTATION DEFINED width:
  - An SVE predicate register has an IMPLEMENTATION DEFINED width that is a power of two, from a minimum of 16 bits up to a maximum of 256 bits.
- The SME scalable ZA storage is a two-dimensional array of bytes. See ZA storage.
- The SME2 ZT0 register is 512 bits. See SME2 ZT0 register.

For more information on the register files in AArch64 state, see Registers in AArch64 Execution state.

In AArch32 state:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The general-purpose register file contains 32-bit registers:
  - Two 32-bit registers can support a doubleword.
  - Vector formatting is supported, see Figure A1-4.
- The SIMD&FP register file contains 64-bit registers:
  - AArch32 state does not support quadword integer or floating-point data types.

Note

Two consecutive 64-bit registers can be used as a 128-bit register.

For more information on the register files in AArch32 state, see The general-purpose registers, and the PC, in AArch32 state.

A1.4.1 Advanced SIMD vector formats

In an implementation that includes the Advanced SIMD instructions that operate on the SIMD&FP register file, a register can hold one or more packed elements, all of the same size and type. In AArch32 state, the combination of a register and a data type describes a vector of elements, where the number of elements in the vector is implied by the size of the data type and the size of the register. In AArch64 state, the explicit combination of a register, number of elements, and element size describes a vector of elements. The vector is considered to be a one-dimensional array of elements of the data type specified in the instruction.

Vector indices are in the range 0 to (number of elements - 1). An index of 0 refers to the least significant bits of the vector.

For more information on the Advanced SIMD and floating-point registers in AArch32 state, see The SIMD and floating-point register file.

A1.4.1.1 Advanced SIMD vector formats in AArch64 state

In AArch64 state, the SIMD&FP registers can be referred to as V*n*, where *n* is a value from 0 to 31.

The SIMD&FP registers support the following data formats for loads, stores, and data-processing operations:

- A single, scalar, element in the least significant bits of the register. See Registers in AArch64 Execution state.
- A 128-bit vector of byte, halfword, word, or doubleword elements. See Figure A1-1.
- A 64-bit vector of byte, halfword, word, or doubleword elements. See Figure A1-1.

For vectors, the element sizes are defined in Table A1-1, with the vector format described as:

- For a 128-bit vector: Vn.{2D, 4S, 8H, 16B}.
- For a 64-bit vector: Vn.{1D, 2S, 4H, 8B}.

Table A1-1 SIMD elements in AArch64 state

Mnemonic	Size
B	8 bits
H	16 bits
S	32 bits
D	64 bits

Non-Confidential

Figure A1-1 SIMD vectors in AArch64 state

A1.4.1.2 Advanced SIMD vector formats in AArch32 state

Table A1-2 shows the available formats. Each instruction description specifies the data types that the instruction supports.

Table A1-2 Advanced SIMD data types in AArch32 state

Data type specifier	Meaning
`.<size>`	Any element of `<size>` bits
`.F<size>`	Floating-point number of `<size>` bits
`.I<size>`	Signed or unsigned integer of `<size>` bits
`.P<size>`	Polynomial over {0, 1} of degree less than `<size>`
`.S<size>`	Signed integer of `<size>` bits
`.U<size>`	Unsigned integer of `<size>` bits

Polynomial arithmetic over {0, 1} describes the polynomial data type.

The `.F16` data type is the half-precision data type selected by the FPSCR.AHP bit, see Half-precision floating-point formats.

The `.F32` data type is the Arm standard single-precision floating-point data type, see Single-precision floating-point format.

The instruction definitions use a data type specifier to define the data types appropriate to the operation. Figure A1-2 shows the hierarchy of the Advanced SIMD data types.

† Output format only. See `VMULL` instruction description.

‡ Available only if the Cryptographic Extension is implemented. See `VMULL` instruction description.

Figure A1-2 Advanced SIMD data type hierarchy in AArch32 state

For example, a multiply instruction must distinguish between integer and floating-point data types.

An integer multiply instruction that generates a double-width (long) result must specify the input data types as signed or unsigned. However, some integer multiply instructions use modulo arithmetic, and therefore do not have to distinguish between signed and unsigned inputs.

Figure A1-3 shows the Advanced SIMD vectors in AArch32 state.

Note

In AArch32 state, a pair of even and following odd numbered doubleword registers can be concatenated and treated as a single quadword register.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure A1-3 Advanced SIMD vectors in AArch32 state

The AArch32 general-purpose registers support vectors formats for use by the SIMD instructions in the Base instruction set. Figure A1-4 shows these formats, that means that a general-purpose register can be treated as either 2 halfwords or 4 bytes.

Figure A1-4 Vector formatting in AArch32 state

A1.4.2 SVE vector formats

In an implementation that includes the AArch64 SVE instructions, an SVE register can hold one or more packed or unpacked elements, all of the same size and type. The combination of a register and an element size describes a vector of elements. The vector is considered to be a one-dimensional array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the *Effective SVE vector length* of the register.

Vector element indexes are in the range 0 to (number of elements - 1). An index of 0 refers to bits 0 to (element size -1) of the vector.

For the definition of Effective SVE vector length, see Configurable SVE vector lengths.

A1.4.2.1 Scalable vector formats in AArch64 state

In AArch64 state, the SVE scalable vector registers can be referred to as Z*n*, where *n* is a value from 0 to 31.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The SVE scalable vector registers support the following data formats for loads, stores, and data-processing operations:

- Advanced SIMD data formats. Bits[127:0] of each Z*n* register hold the correspondingly numbered V*n* SIMD&FP register.
- A configurable-length vector of byte, halfword, word, doubleword, or quadword elements. See Figure A1-5. Also see Z0-Z31 in The AArch64 Application Level Programmers' Model.

The element sizes are defined in Table A1-3 with the vector format described as:

- Zn.{Q, D, S, H, B}.

Table A1-3 SVE elements in AArch64 state

Mnemonic	Element size
B	8 bits
H	16 bits
S	32 bits
D	64 bits
Q	128 bits

Figure A1-5 shows the vector formats of an SVE scalable vector register containing:

- A configurable-length vector, where the *Effective SVE vector length* is 256 bits.
- A fixed-length 128-bit Advanced SIMD vector.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure A1-5 SVE vectors, and Advanced SIMD vectors, in an SVE scalable vector register

A1.4.3 Half-precision floating-point formats

The Arm architecture supports two half-precision floating-point formats:

- IEEE half-precision, as described in the IEEE 754-2008 standard.
- Arm *alternative half-precision* format.

Note

BFloat16 is not a half-precision floating-point format, see BFloat16 floating-point format.

Both formats can be used for conversions to and from other floating-point formats.

FPCR.AHP controls the format in AArch64 state and FPSCR.AHP controls the format in AArch32 state. FEAT_FP16 adds half-precision data-processing instructions, which always use the IEEE format. These instructions ignore the value of the relevant AHP field, and behave as if it has an Effective value of 0.

All SVE half-precision data-processing instructions, including conversions, ignore the value of FPCR.AHP, and behave as if it has an Effective value of 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The description of IEEE half-precision includes Arm-specific details that are left open by the standard, and is only an introduction to the formats and to the values they can contain. For more information, especially on the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

For both half-precision floating-point formats, the layout of the 16-bit format is the same. The format is:

The interpretation of the format depends on the value of the exponent field, bits[14:10] and on which half-precision format is being used.

0 < exponent < `0x1F`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(exponent-15)} \times (1.fraction)$

The minimum positive normalized number is 2^{-14}, or approximately 6.104×10^{-5}.

The maximum positive normalized number is $(2 - 2^{-10}) \times 2^{15}$, or 65504.

Larger normalized numbers can be expressed using the alternative format when the exponent == `0x1F`.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 when S==0.

-0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-14} \times (0.fraction)$

The minimum positive denormalized number is 2^{-24}, or approximately 5.960×10^{-8}.

Half-precision denormalized numbers are not flushed to zero by default. When FEAT_FP16 is implemented, the FPCR.FZ16 bit controls whether flushing denormalized numbers to zero is enabled for half-precision data-processing instructions. For details, see Flushing denormalized numbers to zero.

exponent == `0x1F`

The value depends on which half-precision format is being used:

IEEE half-precision

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[9]:

bit[9] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[9] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

Alternative half-precision

The value is a normalized number and is equal to:

$-1^{S} \times 2^{16} \times (1.\text{fraction})$

The maximum positive normalized number is $(2-2^{-10}) \times 2^{16}$ or 131008.

A1.4.4 Single-precision floating-point format

The single-precision floating-point format is as defined by the IEEE 754 standard.

This description includes Arm-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A single-precision value is a 32-bit word with the format:

31	30 … 23	22 … 0
S	exponent	fraction

The interpretation of the format depends on the value of the exponent field, bits[30:23]:

0 < exponent < `0xFF`

The value is a normalized number and is equal to:

$(-1)^{S} \times 2^{(\text{exponent} - 127)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-126}, or approximately 1.175×10^{-38}.

The maximum positive normalized number is $(2 - 2^{-23}) \times 2^{127}$, or approximately 3.403×10^{38}.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 When S==0.

-0 When S==1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

These usually behave identically. In particular, the result is *equal* if +0 and -0 are compared as floating-point numbers. However, they yield different results in some circumstances. For example, the sign of the infinity produced as the result of dividing by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer comparison of the two words.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-126} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-149}, or approximately 1.401×10^{-45}.

Denormalized numbers are always flushed to zero in Advanced SIMD processing in AArch32 state. They are optionally flushed to zero in floating-point processing and in Advanced SIMD processing in AArch64 state. For details, see Flushing denormalized numbers to zero.

exponent == `0xFF`

The value is either an *infinity* or a *Not a Number* (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[22]:

bit[22] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[22] == 1

The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

For details of the *default NaN*, see Default NaN.

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.5 Double-precision floating-point format

The double-precision floating-point format is as defined by the IEEE 754 standard.

Double-precision floating-point is supported by both SIMD and floating-point instructions in AArch64 state, and only by floating-point instructions in AArch32 state.

This description includes IMPLEMENTATION SPECIFIC details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A double-precision value is a 64-bit doubleword, with the format:

Double-precision values represent numbers, infinities, and NaNs in a similar way to single-precision values, with the interpretation of the format depending on the value of the exponent:

0 < exponent < `0x7FF`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(exponent-1023)} \times (1.fraction)$

The minimum positive normalized number is 2^{-1022}, or approximately 2.225×10^{-308}.

The maximum positive normalized number is $(2 - 2^{-52}) \times 2^{1023}$, or approximately 1.798×10^{308}.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave in the same way as the two single-precision zeros:

+0 when S==0.

-0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-1022} \times (0.fraction)$

The minimum positive denormalized number is 2^{-1074}, or approximately 4.941×10^{-324}.

Optionally, denormalized numbers are flushed to zero in floating-point calculations. For details, see Flushing denormalized numbers to zero.

exponent == `0x7FF`

The value is either an infinity or a NaN, depending on the fraction bits:

fraction == 0

The value is an infinity. As for single-precision, there are two infinities:

+infinity When S==0.

-infinity When S==1.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[51] of the doubleword:

bit[51] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

bit[51] == 1

The NaN is a quiet NaN. The sign bit and the remaining fraction bits can take any value.

For details of the *default NaN*, see Default NaN.

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.6 BFloat16 floating-point format

BFloat16 is a 16-bit floating-point storage format that inherits many of its properties and behaviors from the IEEE 754 single-precision format described in Single-precision floating-point format.

The BFloat16 format is:

0 < exponent < `0xFF`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(exponent-127)} \times (1.fraction)$

The minimum positive normalized number is 2^{-126}, or approximately 1.175×10^{-38}.

The maximum positive normalized number is $(2 - 2^{-7}) \times 2^{127}$, or approximately 3.390×10^{38}.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 when S==0.

-0 when S==1.

These usually behave identically. However, they yield different results in some circumstances. For example, the sign of the result produced as the result of multiplying by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer bitwise comparison of the two halfwords.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-126} \times (0.fraction)$

The minimum positive denormalized number is 2^{-133}, or approximately 9.184×10^{-41}.

Denormalized numbers are always flushed to zero in Advanced SIMD processing in AArch32 state. They are optionally flushed to zero in floating-point processing and in Advanced SIMD processing in AArch64 state. For details, see Flushing denormalized numbers to zero.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

exponent == `0xFF`

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[6]:

bit[6] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[6] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

BFloat16 values are 16-bit halfwords that software can convert to single-precision format, by appending 16 zero bits, so that single-precision arithmetic instructions can be used. A single-precision value can be converted to a BFloat16 value, either by:

- Truncating, by removing the least significant 16 bits.
- Using the BFloat16 conversion instructions, see Table C3-112.

See also:

- Summary of BFloat16 instruction behaviors.

A1.4.7 FP8 floating-point formats

The Arm architecture supports two 8-bit floating-point (FP8) formats:

- OFP8 E4M3 format.
- OFP8 E5M2 format.

These formats are used by FP8 instructions, which are instructions, where the input or output elements are in FP8 floating-point format. FPMR.F8S1 controls the format for inputs named *First FP8 input data stream* and FPMR.F8S2 controls the format for inputs named *Second FP8 input data stream*. The format of an FP8 output from an FP8 instruction is determined by FPMR.F8D field.

For more information, see *OCP 8-bit Floating Point Specification (OFP8)*.

A1.4.7.1 OFP8 E4M3 format

The OFP8 E4M3 format is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

(0 < exponent < `0xF`) || (exponent == `0xF` && fraction < `0x7`)

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(exponent-7)} \times (1.fraction)$

The minimum positive normalized number is 2^{-6}.

The maximum positive normalized number is $(2 - 2^{-2}) \times 2^8$.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave in the same way as the two single-precision zeros:

+0 when S==0.

-0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-6} \times (0.fraction)$

The minimum positive denormalized number is 2^{-9}.

FP8 denormalized numbers are never flushed to zero.

exponent == `0xF` && fraction == `0x7`

The value is a *signaling NaN*.

An infinity is not supported.

A1.4.7.2 OFP8 E5M2 format

The OFP8 E5M2 format is:

0 < exponent < `0x1F`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(exponent-15)} \times (1.fraction)$

The minimum positive normalized number is 2^{-14}.

The maximum positive normalized number is $(2 - 2^{-2}) \times 2^{15}$.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave in the same way as the two single-precision zeros:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

+0 when S==0.

-0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-14} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-16}.

FP8 denormalized numbers are never flushed to zero.

exponent == `0x1F`

The value is either an infinity or a NaN, depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When S==1. This represents all negative numbers with an absolute that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[1]:

bit[1] == 0 The NaN is a signaling NaN. The sign bit can take any value, and bit[0] is 1.

bit[1] == 1 The NaN is a quiet NaN. The sign bit and bit[0] can take any value.

A1.4.8 Conversion between floating-point and fixed-point values

The Arm architecture supports the conversion of a scalar floating-point value to or from a signed or unsigned fixed-point value in a general-purpose register. Conversion instructions take an argument, #fbits, that specifies the number of fraction bits in the fixed-point number. That is, #fbits indicates that the general-purpose register holds a fixed-point number with fbits bits after the binary point, where fbits is in the range 1 to 64 for a 64-bit general-purpose register, or 1 to 32 for a 32-bit general-purpose register:

- For a 64-bit register X_d:
  - The integer part is X_d[63:#fbits].
  - The fractional part is X_d[(#fbits-1):0].
- For a 32-bit register W_d or R_d:
  - The integer part is W_d[31:#fbits] or R_d[31:#fbits].
  - The fractional part is W_d[(#fbits-1):0] or R_d[(#fbits-1):0].

These instructions can cause the following floating-point exceptions:

Invalid Operation When the floating-point input is NaN or Infinity or when a numerical value cannot be represented within the destination register.

Inexact When the numeric result differs from the input value.

Input Denormal When flushing denormalized numbers to zero is enabled and the denormal input is replaced by a zero, see Flushing denormalized numbers to zero and Input Denormal exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

An out of range fixed-point result is saturated to the destination size.

For more information, see Floating-point exceptions and exception traps.

A1.4.9 Polynomial arithmetic over {0, 1}

Some SIMD instructions that operate on SIMD&FP registers can operate on polynomials over {0, 1}, see Supported data types. The polynomial data type represents a polynomial in x of the form $b_{n-1}x^{n-1} + \ldots + b_1x + b_0$ where b_k is bit[k] of the value.

The coefficients 0 and 1 are manipulated using the rules of Boolean arithmetic:

- $0 + 0 = 1 + 1 = 0$.
- $0 + 1 = 1 + 0 = 1$.
- $0 \times 0 = 0 \times 1 = 1 \times 0 = 0$.
- $1 \times 1 = 1$.

That is:

- Adding two polynomials over {0, 1} is the same as a bitwise exclusive-OR.
- Multiplying two polynomials over {0, 1} is the same as integer multiplication except that partial products are exclusive-ORed instead of being added.

A64, A32, and T32 provide instructions for performing polynomial multiplication of 8-bit values.

- For AArch32, see VMUL (integer and polynomial) and VMULL (integer and polynomial).
- For AArch64, see PMUL and PMULL, PMULL2.

The Cryptographic Extension adds the ability to perform long polynomial multiplies of 64-bit values. See PMULL, PMULL2.

A1.4.9.1 Pseudocode description of polynomial multiplication

In pseudocode, polynomial addition is described by the EOR operation on bitstrings.

Polynomial multiplication is described by the `PolynomialMult()` function defined in A-profile Architecture Pseudocode.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.5 Floating-point support

The architecture includes the following types of floating-point instructions:

- Scalar floating-point instructions that operate on the lowest numbered element of the SIMD&FP registers.
- Advanced SIMD floating-point instructions that operate on multiple elements of the SIMD&FP registers.
- If FEAT_SVE is implemented, AArch64 SVE instructions that operate on multiple elements of the SVE scalable vector registers, in which the SIMD&FP registers occupy the least significant 128 bits.
- If FEAT_SME is implemented, AArch64 SME instructions that operate on multiple elements of the SVE scalable vector registers and the ZA storage.

The architecture can provide the following levels of floating-point support:

- No floating-point support. This option is licensed only for implementations targeting specialized markets.
- Advanced SIMD and floating-point support.
- SVE, plus Advanced SIMD and floating-point support.
- SME and SVE, plus Advanced SIMD and floating-point support.

Note

All Armv8-A systems that support standard operating systems with rich application environments provide hardware support for Advanced SIMD and floating-point instructions. All Armv9-A systems that support standard operating systems with rich application environments also provide hardware support for SVE2 instructions. It is a requirement of the ARM Procedure Call Standard for AArch64, see *Procedure Call Standard for the Arm 64-bit Architecture*.

The architecture supports the following floating-point formats:

Table A1-4 Floating-point formats

	AArch32 state	AArch64 state
IEEE 754 half-precision	Conversion instructions to and from IEEE 754 half-precision.	
	Supported for data processing if FEAT_FP16 is implemented.	
Arm *alternative half-precision*	Conversion instructions to and from non-IEEE 754 Arm alternative half-precision.	
IEEE 754 single-precision	Supported for scalar data processing.	Supported for scalar and vector data processing.
	Supported for Advanced SIMD, with restrictions. See Arm standard floating-point input and output values.	
IEEE 754 double-precision	Supported for scalar data processing.	Supported for scalar and vector data processing.
	Not supported for Advanced SIMD.	
BFloat16	Supported if FEAT_AA32BF16 is implemented.	Supported if FEAT_BF16 is implemented.
OFP8 E4M3	Not supported.	Supported if FEAT_FP8 is implemented.
OFP8 E5M2	Not supported.	Supported if FEAT_FP8 is implemented.

For many floating-point instructions, there are configurable behaviors, such as:

- Configurable rounding modes. See Rounding.
- Configurable trapping of floating-point exceptions. See Floating-point exceptions and exception traps and FEAT_TRAPFPE.
- Configurable non-IEEE 754 *default NaN* behavior. See NaN handling and the default NaN.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Configurable non-IEEE 754 flushing to zero of denormalized numbers. See Flushing denormalized numbers to zero.

Floating-point calculation using AArch32 Advanced SIMD instructions remains unchanged from Armv7. T32 and A32 Advanced SIMD floating-point instructions always use Arm standard floating-point arithmetic and perform IEEE 754 floating-point arithmetic with the following restrictions:

- Denormalized numbers are flushed to zero, see Flushing denormalized numbers to zero.
- Only default NaNs are supported, see Default NaN.
- The Round to Nearest rounding mode is used.
- Untrapped floating-point exception handling is used for all floating-point exceptions.

If floating-point exception trapping is supported, then unless stated otherwise, when a floating-point exception is not trapped, that exception causes a cumulative status register bit to be set to 1 and the operation produces a default result. For more information, see Floating-point exceptions and exception traps and FEAT_TRAPFPE.

In:

- AArch64 state, the Floating-point Control Register, FPCR, controls floating-point operation, and the Floating-point Status Register, FPSR, returns floating-point status information.
- AArch32 state, there is a single Floating-Point Status and Control Register, FPSCR, combining the FPCR and FPSR fields.

In AArch64 state, the PSTATE.{N, Z, C, V} condition flags are updated by floating-point comparison operations.

In AArch32 state, the FPSCR.{N, Z, C, V} condition flags are updated by floating-point comparison operations.

If FEAT_FlagM2 is implemented, the AArch64 instructions `AXFLAG` and `XAFLAG` convert between the Arm floating-point condition flags in PSTATE and an alternative format shown in Table C6-1.

Note

For additional details of AArch32 state floating-point support, see Advanced SIMD and floating-point support.

The remainder of this section contains:

- Instruction support
- Floating-point standards, and terminology
- Arm standard floating-point input and output values
- Summary of BFloat16 instruction behaviors
- Summary of FP8 instruction behaviors
- Flushing denormalized numbers to zero
- NaN handling and the default NaN
- Rounding
- Floating-point exceptions and exception traps
- Alternate BFloat16 behaviors
- BFloat16 behaviors for instructions that calculate sum-of-products

A1.5.1 Instruction support

The floating-point instructions support:

- Load and store for single elements and vectors of multiple elements.

  Note

  Single elements are also referred to as scalar elements.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Data processing on single and multiple elements.
- Complex number arithmetic.
- Floating-point conversion between different levels of precision.
- Conversion between floating-point and integer types.
- Floating-point rounding.
- Atomic floating-point in-memory operations.

For more information on floating-point instructions in AArch64 state, see A64 Instruction Set Overview.

For more information on floating-point instructions in AArch32 state, see The AArch32 Instruction Sets Overview.

A1.5.2 Floating-point standards, and terminology

The Arm architecture includes support for all the required features of ANSI/IEEE Std 754-2008, *IEEE Standard for Binary Floating-Point Arithmetic*, referred to as IEEE 754-2008. However, some terms in this Manual are based on the 1985 version of this standard, referred to as IEEE 754-1985:

- Arm floating-point terminology generally uses the IEEE 754-1985 terms. This section summarizes how IEEE 754-2008 changes these terms.
- References to IEEE 754 that do not include the issue year apply to either issue of the standard.

Table A1-5 shows how the terminology in this Manual differs from that used in IEEE 754-2008.

Table A1-5 Floating-point terminology

This Manual	IEEE 754-2008
Normalized[a]	Normal
Denormal, or denormalized	Subnormal
Round towards Minus Infinity (RM)	roundTowardsNegative
Round towards Plus Infinity (RP)	roundTowardsPositive
Round towards Zero (RZ)	roundTowardZero
Round to Nearest (RN)	roundTiesToEven
Round to Nearest with Ties to Away	roundTiesToAway
Rounding mode	Rounding-direction attribute

a. *Normalized number* is used in preference to *normal number*, because of the other specific uses of *normal* in this Manual.

A1.5.3 Arm standard floating-point input and output values

The Arm architecture provides full IEEE 754 floating-point arithmetic support. In AArch32 state, floating-point operations performed using Advanced SIMD instructions are limited to *Arm standard floating-point operation*, regardless of the selected rounding mode in the FPSCR.

Arm standard floating-point arithmetic supports the following input formats defined by the IEEE 754 floating-point standard:

- Zeros.
- Normalized numbers.
- Denormalized numbers are flushed to 0 before floating-point operations, see Flushing denormalized numbers to zero.
- NaNs.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Infinities.

Arm standard floating-point arithmetic supports the Round to Nearest (roundTiesToEven) rounding mode defined by the IEEE 754 standard.

Arm standard floating-point arithmetic supports the following output result formats defined by the IEEE 754 standard:

- Zeros.
- Normalized numbers.
- Results with an absolute value less than the minimum normalized number are flushed to zero, see Flushing denormalized numbers to zero.
- NaNs produced in floating-point operations are always the default NaN, see Default NaN.
- Infinities.

Note

AArch64 Advanced SIMD floating-point arithmetic is performed using the rounding mode selected by the FPCR.

A1.5.4 Summary of BFloat16 instruction behaviors

BFloat16 instructions follow the floating-point behaviors shown in Table A1-6 and Table A1-7:

Table A1-6 Advanced SIMD and floating-point, and SVE, BFloat16 instruction behaviors

		Behaviors when the PE is in Streaming SVE mode	Behaviors when the PE is not in Streaming SVE mode
Advanced SIMD & FP	`BFCVT`	Behaves as: Floating-point behaviors in Streaming SVE mode.	Follows single-precision behaviors.
		This instruction also supports the Alternate BFloat16 behaviors.	
	`BFCVTN`, `BFCVTN2` `BFMLALB`, `BFMLALT`	If *legal* when executed in Streaming SVE mode[a], behave as Floating-point behaviors in Streaming SVE mode.	Follows single-precision behaviors.
		These instructions also support the Alternate BFloat16 behaviors.	
	`BFDOT`, `BFMMLA`	If legal when executed in Streaming SVE mode[a], behave as BFloat16 behaviors for instructions that calculate sum-of-products.	Behave as BFloat16 behaviors for instructions that calculate sum-of-products.

SVE	`BFADD`, `BFSUB`
	`BFMLA`, `BFMLS`,
	`BFMUL`
		Behave as Floating-point behaviors in Streaming SVE mode.	Follows single-precision behaviors.

	`BFCLAMP`
	`BFMAX`, `BFMAXNM`
	`BFMIN`, `BFMINNM`
		Behave as both:
		• Floating-point behaviors in Streaming SVE mode.
		• Additional behaviors described in the individual instruction descriptions.
			Follows both:
			• Single-precision behaviors.
			• Additional behaviors described in the individual instruction descriptions.

	`BFCVT`, `BFCVTNT`
	`BFMLALB`, `BFMLALT`
	`BFMLSLB`, `BFMLSLT`
		Behave as Floating-point behaviors in Streaming SVE mode.	Follows single-precision behaviors.

		These instructions also support the Alternate BFloat16 behaviors.	
	`BFDOT`	Behave as BFloat16 behaviors for instructions that calculate sum-of-products.	
	`BFMMLA`	If legal when executed in Streaming SVE mode[a], behaves as BFloat16 behaviors for instructions that calculate sum-of-products.	Behaves as BFloat16 behaviors for instructions that calculate sum-of-products.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

a. These instructions generate an *SME illegal instruction exception* in *Streaming SVE mode* if FEAT_SME_FA64 is not implemented or not enabled at the current Exception level. See Streaming SVE mode and R_{ZFGJP}.

Table A1-7 SME BFloat16 instruction behaviors

SME	Behaviors in Streaming SVE mode		Behaviors when the PE is not in Streaming SVE mode
	ZA storage enabled	ZA storage disabled	
`BFADD`, `BFMLA`, `BFMLS`, `BFSUB` `BFMOPA` (non-widening) `BFMOPS` (non-widening)	Behave as Floating-point behaviors for instructions that target the SME ZA array.	Illegal[a]	Illegal[a]

`BFCLAMP`
`BFMAX`, `BFMAXNM`
`BFMIN`, `BFMINNM`
	Behave as both:
	• Floating-point behaviors in Streaming SVE mode.
	• Additional behaviors described in the instruction descriptions.
			Illegal[a]

`BFCVT` (single-precision to BFloat16), `BFCVTN`	Behave as Floating-point behaviors in Streaming SVE mode. These instructions also support the Alternate BFloat16 behaviors.		Illegal[a]
`BFDOT`, `BFVDOT` `BFMOPA` (widening) `BFMOPS` (widening)	Behave as BFloat16 behaviors for instructions that calculate sum-of-products.	Illegal[a]	Illegal[a]
`BFMLAL` `BFMLSL`	Behave as Floating-point behaviors for instructions that target the SME ZA array.	Illegal[a]	Illegal[a]

a. The instructions generate an *SME illegal instruction exception*. See Streaming SVE mode and R_{ZFGJP}.

Unless otherwise specified, BFloat16 instructions follow the behaviors defined in all of:

- Flushing denormalized numbers to zero.
- Rounding.
- Floating-point exceptions and exception traps

See also:

- Streaming SVE mode.
- ZA storage.

A1.5.5 Summary of FP8 instruction behaviors

All FP8 instructions:

- Use the Round to Nearest (RN) mode, ignoring FPCR.RMode.
- Do not flush denormalized inputs and outputs to zero, as if FPCR.{FZ, FIZ, FZ16} are all 0.
- Generate default NaN outputs, as if FPCR.DN is 1, unless otherwise specified.
- Honor FPCR.AH, if FEAT_AFP is implemented.
- Treat an unsupported FP8 input format, as defined in FPMR.F8S1 and FPMR.F8S2, as a CONSTRAINED UNPREDICTABLE choice of:
  - A signaling NaN.
  - Any of the supported FP8 formats.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Handle an unsupported FP8 output format, as defined in FPMR.F8D, by a CONSTRAINED UNPREDICTABLE choice of:
  - Setting the result to `0xff` and causing an Invalid Operation floating-point exception.
  - Generating the expected result of any of the supported FP8 formats.
- Do not cause an Input Denormal floating-point exception or update FPSR.IDC.

FP8 convert instructions:

- Produce the expected default result and update FPSR.{IOC, IXC, UFC} when they detect Invalid Operation, Inexact, or Underflow exceptional floating-point conditions.
- When the rounded result with unbounded exponent has an absolute value that is greater than the maximum normalized number for the output precision, or when an Infinity is converted from other floating-point formats to an FP8 format:
  - Generate one of the following outputs with the sign of the result:
    - When FPMR.OSC is 1, the maximum normalized number.
    - When FPMR.OSC is 0 and the output is in the OFP8 E4M3 format, a *signaling NaN*.
    - Otherwise, an Infinity.
  - Regardless of the value of FPMR.OSC, cause an Overflow and Inexact floating-point exception.
- When the PE is in Streaming SVE mode, disable trapped floating-point exceptions as if FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are all zero.

FP8 multiplication instructions:

- Produce the expected default result and do not update FPSR.{IOC, IXC, UFC} when they detect Invalid Operation, Inexact, or Underflow exceptional floating-point conditions.
- When the rounded result with unbounded exponent has an absolute value that is greater than the maximum normalized number for the output precision:
  - Generate one of the following outputs with the sign of the result:
    - When FPMR.OSM is 1, the maximum normalized number.
    - When FPMR.OSM is 0, an Infinity.
  - Do not update FPSR.OFC.
- Disable trapped floating-point exceptions, as if FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are all zero.

A1.5.6 Flushing denormalized numbers to zero

For this section if FEAT_AFP is not implemented, the behavior is the same as if FPCR.AH == 0, FPCR.FIZ == 0, and FPCR.NEP == 0.

Calculations involving denormalized numbers and Underflow exceptions can reduce the performance of floating-point processing. For many algorithms, replacing the denormalized operands and intermediate results with zeros can recover this performance, without significantly affecting the accuracy of the final result. Arm floating-point implementations allow denormalized numbers to be flushed to zero to permit this optimization.

If a number `value` satisfies the condition `0 < Abs(value) < MinNorm`, it is treated as a denormalized number.

`MinNorm` is defined as follows:

- For OFP8 E4M3 numbers, `MinNorm` is 2^{-6}.
- For half-precision and OFP8 E5M2 numbers, `MinNorm` is 2^{-14}.
- For single-precision and BFloat16 numbers, `MinNorm` is 2^{-126}.
- For double-precision numbers, `MinNorm` is 2^{-1022}.

Flushing denormals to zero is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Enabling flushing of denormals to zero must be done with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application-dependent:

- On many algorithms, it has no noticeable effect, because the algorithm does not usually process denormalized numbers.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On other algorithms, it can cause exceptions to occur and can seriously reduce the accuracy of the results of the algorithm.

For information about FP8 instruction behaviors, see Summary of FP8 instruction behaviors.

A1.5.6.1 Flushing denormalized inputs to zero

If flushing denormalized inputs to zero is enabled for an instruction and a data type, and an input to that instruction is a denormalized number of that data type, the input operand is flushed to zero, and its sign bit is not changed.

If a floating-point operation has a denormalized input that is flushed to zero, for all purposes within the instruction other than calculating Input Denormal floating-point exceptions, all inputs that are denormalized numbers are treated as though they were zero with the same sign as the input.

For floating-point instructions, if the instruction processes half-precision inputs, flushing denormalized inputs to zero can be controlled as follows:

- If FPCR.FZ16 == 0, denormalized half-precision inputs are not flushed to zero.
- If FPCR.FZ16 == 1:
  - Denormalized half-precision inputs to data processing instructions are flushed to zero.
  - Denormalized half-precision inputs to convert instructions are not flushed to zero.

If FPCR.FIZ == 1, or both FPCR.AH == 0 and FPCR.FZ == 1, then for floating-point instructions other than `FABS` and `FNEG`, for all inputs other than half-precision, denormalized inputs are flushed to zero.

If FPCR.FZ == 0, for all inputs other than half-precision, FPCR.FZ does not cause denormalized inputs to be flushed to zero, although other factors might cause denormalized inputs to be flushed to zero.

If FPCR.AH == 1, regardless of the value of FPCR.FIZ, all of the following instructions flush all input denormal numbers to zero:

- The BFloat16 instructions defined in Alternate BFloat16 behaviors.
- Single-precision and double-precision instructions: FRECPE, FRECPS, FRECPX, FRSQRTE, and FRSQRTS.

A1.5.6.2 Flushing denormalized outputs to zero

If a denormalized output is flushed to zero, the output is returned as zero with the same sign bit as the denormalized output value.

If FPCR.AH == 0, the test for a denormalized number for the purpose of flushing the output to zero occurs before rounding.

If FPCR.AH == 1, the test for a denormalized number for the purpose of flushing the output to zero occurs after rounding using an unbounded exponent.

If FPCR.FZ == 0, then unless otherwise specified, for all outputs other than half-precision, FPCR.FZ does not cause denormalized outputs to be flushed to zero, although other factors might cause denormalized outputs to be flushed to zero.

If FPCR.FZ == 1, for all outputs other than half-precision, for floating-point instructions other than `FABS`, `FNEG`, `FMAX`, `FMAXP`, `FMAXV`, `FMIN`, `FMINP`, `FMINV`, `BFMIN`, and `BFMAX`, denormalized outputs are flushed to zero.

If FPCR.EBF == 0, `BFDOT`, `BFMMLA`, BFVDOT, BFMOPA (widening), and BFMOPS (widening) instructions unconditionally flush denormalized outputs to zero, as defined in BFloat16 behaviors for instructions that calculate sum-of-products.

If FPCR.FZ16 == 0, denormalized half-precision outputs are not flushed to zero.

If FPCR.FZ16 == 1, for floating-point instructions other than `FABS`, `FNEG`, `FMAX`, `FMAXP`, `FMAXV`, `FMIN`, `FMINP`, `FMINV`, `BFMIN`, and `BFMAX`, denormalized half-precision outputs are flushed to zero.

If FPCR.AH == 1, regardless of the value of FPCR.{FZ, FZ16}, denormalized outputs of `FABS`, `FNEG`, `FMAX`, `FMAXP`, `FMAXV`, `FMIN`, `FMINP`, `FMINV`, `BFMIN`, and `BFMAX`, are not flushed to zero.

If FPCR.AH == 1, regardless of the value of FPCR.FZ, all of the following instructions flush all output denormal numbers to zero:

- The BFloat16 instructions defined in Alternate BFloat16 behaviors.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Single-precision and double-precision instructions: FRECPE, FRECPS, FRECPX, FRSQRTE, and FRSQRTS.

If FPCR.FIZ == 1, for the atomic floating-point memory instructions defined in Atomic floating-point memory operations, denormalized BFloat16, single-precision, and double-precision outputs are flushed to zero.

A1.5.6.3 Flushing denormalized BFloat16 intermediate results to zero

BFloat16 arithmetic instructions `BFDOT`, `BFMMLA`, `BFVDOT`, `BFMOPA (widening)`, and `BFMOPS (widening)` in AArch64 state, and VDOT (by element), VDOT (vector), VMMLA in AArch32 state when working with BFloat16 inputs, convert BFloat16 input values to IEEE single-precision format, and calculate N-way dot-products, accumulating the products in single-precision accumulators. If one of these instructions processes an intermediate result that is a single-precision denormalized number:

- If the instruction is one of AArch64 `BFDOT`, `BFMMLA`, `BFVDOT`, `BFMOPA (widening)`, and `BFMOPS (widening)`, the intermediate result is unconditionally flushed to zero if FEAT_EBF16 is not implemented or when FPCR.EBF is 0. See BFloat16 behaviors for instructions that calculate sum-of-products.
- If the instruction is one of AArch32 VDOT (by element), VDOT (vector), VMMLA, the intermediate result is unconditionally flushed to zero.

A1.5.7 NaN handling and the default NaN

The IEEE 754 standard defines a NaN as a number with all exponent bits set to 1 and a nonzero number in the mantissa, and specifies that the sign bit of a NaN has no significance.

The Arm architecture additionally defines the following in Table A1-8:

- A *default NaN*, compliant with the IEEE 754 standard.
- A BFloat16 NaN, that follows the encoding in BFloat16 floating-point format.
- OFP8 NaN, that follow the encodings in FP8 floating-point formats.

For a quiet NaN output derived from a signaling NaN operand, the most significant fraction bit is set to 1.

A PE is forbidden to generate a NaN whose value is strongly correlated to the values of non-NaN inputs as a speculative result of a floating-point calculation not involving NaN inputs.

A1.5.7.1 Default NaN

A default NaN is encoded as described in Table A1-8.

Table A1-8 Default NaN encodings

	Half-precision, IEEE Format	Single-precision	Double-precision	BFloat16	OFP8 E4M3	OFP8 E5M2
Sign bit if FPCR.AH == 0	0	0	0	0	0	0
Sign bit if FPCR.AH == 1	1	1	1	1	1	1
Exponent	`0x1F`	`0xFF`	`0x7FF`	`0xFF`	`0xF`	`0x1F`
Fraction	Bit[9] == ‘1’, bits[8:0] == 0	Bit[22] == ‘1’, bits[21:0] == 0	Bit[51] == ‘1’, bits[50:0] == 0	Bit[6] == ‘1’, bits[5:0] == 0	Bits[2:0] == ‘111’	Bit[1] == ‘1’, bit[0] == ‘0’

When FPCR.DN == 1, if any input to a floating-point operation is a NaN, the output is a default NaN, unless the instruction is one of the following:

- `FABS`, `FNEG`, `FMAX*`, `FMIN*`, `BFMAX*`, or `BFMIN*`. For these, see the individual instruction descriptions for their default NaN behavior.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The atomic floating-point memory instructions defined in Atomic floating-point memory operations generate only the default NaN value, as if FPCR.DN == 1.

Floating-point instructions that detect an Invalid Operation condition for a reason other than one of its inputs being a NaN, produce a default NaN as the result.

A1.5.7.2 NaN handling

The IEEE 754 standard does not specify which input NaN is used as the output NaN. Therefore, where the Arm architecture specifies which input NaN to use, this is an addition to the requirements in the IEEE 754 standard.

Depending on the operation, the exact value of a derived quiet NaN output might have both a different sign and different fraction bits from its source. See individual instruction descriptions for details.

A1.5.7.3 NaN propagation

For NaN propagation rules for:

- BFDOT and BFMMLA, see BFloat16 behaviors for instructions that calculate sum-of-products.
- FP8 instructions, see Summary of FP8 instruction behaviors.

Otherwise, behavior is as described in this section.

If an output NaN is derived from one of the operands, how the input NaN propagates to the output depends on the instruction and the number of operands.

If an output NaN is derived from an input NaN and if the size of the output format is the same as the input format, then all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is derived from the input NaN.
- If the input NaN is a signaling NaN, the output NaN is derived as follows:
  - If the handling of a signaling NaN by the instruction detects an Invalid Operation condition, the output NaN is derived from a quietened version of the input NaN.
  - If the handling of a signaling NaN by the instruction does not detect an Invalid Operation condition, the output NaN is derived from the input NaN.

If an output NaN is derived from an input NaN and if the size of the output format is larger than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is zero-extended in the low-order bit to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN, except that the mantissa is zero-extended in the low-order bits and the exponent field is set to all ones.

If an output NaN is derived from an input NaN and if the size of the output format is smaller than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.

For the following descriptions, the term “first operand” and “second operand” relate to the left-to-right ordering of the arguments of the pseudocode function that describes the operation.

If FPCR.DN == 0, for instructions that perform a floating-point operation, other than `FABS`, `FNEG`, `FMAX*`, and `FMIN*`, NaN outputs that derive from NaN inputs are derived as follows:

- If all of the following apply, an instruction outputs a quiet NaN derived from the first signaling NaN operand:
  - FPCR.AH == 0.
  - At least one operand is a signaling NaN.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - The instruction is not trapped.
- If all of the following apply, an instruction outputs a quiet NaN derived from the first NaN operand:
  - FPCR.AH == 0.
  - At least one operand is a NaN, but none of the operands is a signaling NaN.
  - The instruction is not trapped.
- If all of the following apply, the output is a quiet NaN derived from the NaN operand:
  - FPCR.AH == 1.
  - The operation has two floating-point inputs.
  - The operation has only one NaN operand.
- If all of the following apply, the output is a NaN derived from the `<Zn>`, `<Vn>`, `<Hn>`, `<Sn>`, or `<Dn>` register, except for SVE FSUBR (vectors) and SVE FDIVR, for which the output is a NaN derived from the `<Zm>` register:
  - FPCR.AH == 1.
  - The operation has two floating-point inputs.
  - The operation has two NaN operands.
- If all of the following apply, the output is a NaN derived from the NaN held in the `<Zn>`, `<Vn>`, `<Hn>`, `<Sn>`, or `<Dn>` registers:
  - FPCR.AH == 1
  - The instruction is one of those shown in Table A1-9.
  - One of the following applies:
    - The operation has three NaN operands.
    - The operation has two NaN operands and the `<Zn>`, `<Vn>`, `<Hn>`, `<Sn>` or `<Dn>` register holds a NaN.
- If all of the following apply, the output is a NaN derived from the NaN held in the `<Zm>`, `<Vm>`, `<Hm>`, `<Sm>`, or `<Dm>` registers:
  - FPCR.AH == 1
  - The instruction is one of those shown in Table A1-9.
  - The operation has two NaN operands and the `<Zn>`, `<Vn>`, `<Hn>`, `<Sn>` or `<Dn>` register does not hold a NaN.

Table A1-9

Advanced SIMD&FP	`BFMLALB`, `BFMLALT`, `FCMLA`, `FMADD`, `FMLA`, `FMLAL`, `FMLAL2`, `FMLS`, `FMLSL`, `FMLSL2`, `FMSUB`, `FNMADD`, and `FNMSUB`.
SVE	`BFMLA`, `BFMLALB`, `BFMLALT`, `BFMLS`, `BFMLSLB`, `BFMLSLT`, `FCMLA`, `FMAD`, `FMLA`, `FMLALB`, `FMLALT`, `FMLS`, `FMLSLB`, `FMLSLT`, `FMSB`, `FNMAD`, `FNMLA`, `FNMLS`, `FNMSB`.

- When the operation has four or more floating-point inputs:
  - If at least one argument to `FPDot()` is a signaling NaN, a function outputs a quiet NaN derived from the first signaling NaN argument.
  - If at least one argument to `FPDot()` is a NaN, but none of the arguments is a signaling NaN, a function outputs a quiet NaN derived from the first NaN argument.

If FPCR.AH == 0, and an output NaN is derived from an input NaN, the pseudocode functions `FPAbs()`, `FPNeg()`, `BFNeg()`, `FPTrigMAdd()`, and `FPTrigSSel()` can change the sign of the NaN.

If FPCR.AH == 1, and an output NaN is derived from an input NaN, for all cases, the sign bit of the NaN is unchanged.

For `FMAX*`, `FMIN*`, `BFMAX*`, `BFMIN*`, `FCLAMP`, and `BFCLAMP`, the NaN handling is described in the instruction description.

A1.5.8 Rounding

The rounding mode specifies how the exact result of a floating-point operation is rounded to a value in the destination format.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The rounding mode is either determined by the rounding mode control field FPCR.RMode or by the instruction.

If FPCR.AH == 1, for any value of FPCR.RMode, the following instructions use Round to Nearest on outputs:

- The BFloat16 instructions defined in Alternate BFloat16 behaviors.
- Single-precision and double-precision instructions FRECPE, FRECPS, FRECPX, FRSQRTE, and FRSQRTS.
- Half-precision instructions FRECPE, FRECPS, FRECPX, FRSQRTE, and FRSQRTS.

For information about FP8 instruction behaviors, see Summary of FP8 instruction behaviors.

FPCR.RMode can select one of:

- Round to Nearest (RN) mode.
- Round towards Plus Infinity (RP) mode.
- Round towards Minus Infinity (RM) mode.
- Round towards Zero (RZ) mode.

The following additional rounding behaviors are not selected by FPCR.RMode, but are used by some instructions:

- Round to Odd.
- Round to Nearest with Ties to Away.

A1.5.8.1 Round to Nearest (RN) mode

Round to Nearest rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity. The sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
  - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the number with an even least significant digit.
  - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

A1.5.8.2 Round towards Plus Infinity (RP) mode

Round towards Plus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not less than the value before rounding. The result can be plus infinity.

A1.5.8.3 Round towards Minus Infinity (RM) mode

Round towards Minus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the number in the output format that is closest to and not greater than the value before rounding. The result can be minus infinity.

A1.5.8.4 Round towards Zero (RZ) mode

Round towards Zero rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not greater in absolute value than the value before rounding.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.5.8.5 Round to Nearest with Ties to Away

Round to Nearest with Ties to Away rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is calculated as follows:

- If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the number with the largest absolute value.
- If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

Round to Nearest with Ties to Away rounding is used by FCVTAS (scalar), FCVTAS (vector), FCVTAU (scalar), FCVTAU (vector), FRINTA (scalar), and FRINTA (vector).

A1.5.8.6 Round to Odd

Round to Odd is not defined by IEEE 754.

Round to Odd rounds the exact result of a floating-point operation to a value that is representable in the destination format. If the result of the rounding is inexact, the least significant bit of the mantissa is forced to 1.

The following instructions use Round to Odd:

- BFloat16 instructions defined in BFloat16 behaviors for instructions that calculate sum-of-products.
- FCVTXN, FCVTXN2, FCVTX, and FCVTXNT, for which Round to Odd rounding can avoid double rounding errors when a floating-point value is converted to a lower precision destination format through an intermediate precision format.

Example A1-1 Converting 64-bit floating-point format to 16-bit floating-point format

A 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value using the following steps:

1. Use an `FCVTXN` instruction to produce a 32-bit value.
2. Use another instruction with the required rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

A1.5.9 Floating-point exceptions and exception traps

Execution of a floating-point instruction, or execution of an Advanced SIMD, SVE, or SME instruction that performs floating-point operations, can generate an exceptional condition, called a *floating-point exception*.

Predicated SVE floating-point instructions only generate floating-point exceptions in response to floating-point operations performed on *Active elements*.

Note

In AArch64 state, an Advanced SIMD, SVE, or SME instruction that operates on floating-point values can perform multiple floating-point operations. Therefore, this section describes the handling of a floating-point exception on an *operation*, rather than on an *instruction*.

The architecture does not support asynchronous reporting of floating-point exceptions.

If FEAT_TRAPFPE is implemented, the implementation includes controls to enable synchronous exception generation for the following floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Divide by Zero.
- Invalid Operation.

If FEAT_TRAPFPE is not implemented, the implementation does not support synchronous exception generation from floating-point exceptions, and all statements about synchronous exception generation from floating-point exceptions do not apply to the implementation.

If FEAT_TRAPFPE is implemented, synchronous exception generation by floating-point exceptions is enabled using the FPCR as follows:

- The relevant control bit chosen from FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} is used to enable synchronous exception generation for the corresponding floating-point exception.

If FEAT_TRAPFPE is not implemented, FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are RAZ/WI.

For information about FP8 instruction behaviors, see Summary of FP8 instruction behaviors.

A1.5.9.1 Operations that do not generate floating-point exceptions

The following instructions do not generate any floating-point exceptions:

- The SVE exponential accelerator instruction, FEXPA.
- The SVE trigonometric select coefficient instruction, FTSSEL.
- The BFloat16 instructions defined in BFloat16 behaviors for instructions that calculate sum-of-products.
- The SME instructions defined in Floating-point behaviors for instructions that target the SME ZA array.
- The instructions defined in Atomic floating-point memory operations.

If FPCR.AH is 1, all of the following instructions do not generate any floating-point exceptions regardless of their input values:

- The BFloat16 instructions defined in Alternate BFloat16 behaviors.
- Single-precision, double-precision and half-precision instructions FRECPE, FRECPS, FRECPX, FRSQRTE, and FRSQRTS.

All the following apply to `FPAbs()`, `FPNeg()`, and `BFNeg()`:

- They cannot generate floating-point exceptions.
- The floating-point behavior described in the Flushing denormalized numbers to zero does not apply to them.
- The floating-point behavior described in the section NaN handling and the default NaN does not apply to them.
- When FPCR.AH is 1, the sign of a NaN input is not changed. When FPCR.AH is 0, the sign of a NaN input can be changed.

A1.5.9.2 Input Denormal exceptions

The cumulative floating-point exception bit FPSR.IDC, and the trap enable bit FPCR.IDE both relate to Input Denormal exceptions.

Input Denormal exceptions are not generated for denormalized half-precision inputs. For BFloat16 denormalized inputs and FP8 denormalized inputs, see Summary of BFloat16 instruction behaviors and Summary of FP8 instruction behaviors respectively. For single-precision and double-precision inputs:

- When FPCR.{AH, FZ, FIZ} is {0, 0, x}, Input Denormal exceptions are not generated.
- When FPCR.{AH, FZ, FIZ} is {0, 1, x}, an Input Denormal exception is generated when an input is flushed to zero.
- When FPCR.{AH, FZ, FIZ} is {1, x, 1}, Input Denormal exceptions are not generated.
- When FPCR.{AH, FZ, FIZ} is {1, x, 0}, an operation with a denormalized input generates an Input Denormal exception unless any of the following are true:
  - Another operand to the operation is a NaN that the operation does not ignore when determining the result and whose handling suppresses generation of the Input Denormal exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The operation generates another floating-point exception that is not permitted to occur in combination with Input Denormal. For combinations of floating-point exceptions permitted with Input Denormal, and their priority, see Combinations of floating-point exceptions.
- The instruction that generated the operation was one of:
  - Advanced SIMD&FP convert from single-precision to BFloat16: BFCVT, BFCVTN, BFCVTN2.
  - Advanced SIMD&FP convert to integer: `FCVTAS`, `FCVTAU`, `FCVTMS`, `FCVTMU`, `FCVTNS`, `FCVTNU`, `FCVTPS`, `FCVTPU`, `FCVTZS`, `FCVTZU`.
  - Advanced SIMD&FP round to integral: `FRINT32X`, `FRINT32Z`, `FRINT64X`, `FRINT64Z`, `FRINTA`, `FRINTI`, `FRINTM`, `FRINTN`, `FRINTP`, `FRINTX`, `FRINTZ`.
  - Advanced SIMD&FP JavaScript convert to signed fixed-point: FJCVTZS.
  - SVE convert from single-precision to BFloat16: BFCVT, BFCVTNT.
  - SVE convert to integer: FCVTZS, FCVTZU.
  - SVE round to integral: FRINT<r>.
  - SME convert from single-precision to BFloat16: BFCVT, BFCVTN.
  - SME convert to integer: FCVTZS, FCVTZU.
  - SME round to integral: FRINTA, FRINTM, FRINTN, FRINTP.

When a denormalized input is flushed to zero, the occurrence of floating-point exceptions other than Input Denormal is determined by treating the input value that is flushed to zero as zero.

A1.5.9.3 Inexact exceptions

The cumulative floating-point exception bit FPSR.IXC and the trap enable bit FPCR.IXE both relate to Inexact exceptions.

If a denormalized output is flushed to zero, all of the following apply:

- If FPCR.AH is 1, an Inexact exception is generated.
- If FPCR.AH is 0, an Inexact exception is not generated.

If a result is not flushed to zero, and the result does not equal the result calculated with unbounded exponent range and unbounded precision, then an Inexact exception is generated.

A1.5.9.4 Underflow exceptions

The cumulative floating-point exception bit FPSR.UFC, and the trap enable bit FPCR.UFE both relate to Underflow exceptions.

If FPCR.AH is 0, for the purpose of Underflow floating-point exception generation, a denormalized number is detected before rounding is applied.

If FPCR.AH is 1, for the purpose of Underflow floating-point exception generation, a denormalized number is detected after rounding with an unbounded exponent.

If the result of a floating-point operation is a denormalized number that is not flushed to zero, then:

- If the result is exact, an Underflow floating-point exception is generated only if FPCR.UFE is 1.
- If the result is inexact, an Underflow floating-point exception is always generated.

If the result of a floating-point operation is a denormalized number that is flushed to zero, then the Underflow floating-point exception is generated, however this floating-point exception is not trapped regardless of the value of FPCR.UFE.

A1.5.9.5 Overflow exceptions

The cumulative floating-point exception bit FPSR.OFC, and the trap enable bit FPCR.OFE both relate to Overflow exceptions.

If the output of an instruction rounded with an unbounded exponent is greater than the maximum normalized number for the output precision, an Overflow exception is generated.

If an untrapped Overflow exception is generated, the result is determined by the selected rounding behavior and the sign of the result before rounding, as follows:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Round to Nearest carries all overflows to infinity with the sign of the result before rounding, except for FP8 instructions, for which, see Summary of FP8 instruction behaviors.
- Round towards Plus Infinity carries negative overflows to the most negative finite number of the output precision, and carries positive overflows to plus infinity.
- Round towards Minus Infinity carries positive overflows to the largest finite number of the output precision, and carries negative overflows to minus infinity.
- Round towards Zero carries all overflows to the output precision's largest finite number with the sign of the result before rounding.
- Round to Nearest Ties to Away carries all overflows to infinity with the sign of the result before rounding.
- Round to Odd, when used by convert instructions, carries all overflows to the output precision's largest finite number with the sign of the result before rounding.
- Round to Odd, when used by some BFloat16 instructions, carries all overflows to infinity with the sign of the result before rounding.

A1.5.9.6 Divide by Zero exceptions

The cumulative floating-point exception bit FPSR.DZC, and the trap enable bit FPCR.DZE both relate to Divide by Zero exceptions.

If a floating-point operation divides a finite nonzero number by zero, a Divide by Zero exception is generated.

If a floating-point operation divides a finite nonzero number by zero, and the Divide by Zero exception is untrapped, the result is a correctly signed infinity.

A1.5.9.7 Invalid Operation exceptions

The cumulative floating-point exception bit FPSR.IOC, and the trap enable bit FPCR.IOE both relate to Invalid Operation exceptions.

For any floating-point instruction that performs a floating-point operation, if any of the following apply, the instruction generates an Invalid Operation exception:

- At least one operand is a signaling NaN.
- Subtracting two equal-magnitude infinities that are of the same sign.
- When FPCR.AH is 0, multiplying a zero by an infinity.
- Dividing a zero by a zero.
- Dividing an infinity by an infinity.
- Taking the square root of an operand that is less than zero.

When FPCR.AH is 1, a floating-point instruction multiplying a zero by an infinity:

- Generates an Invalid Operation exception if the instruction is one of the following fused multiply-add instructions and the addend is not a quiet NaN:
  - Advanced SIMD `FMLA`, `FMLAL`, `FMLAL2`, `FMLS`, `FMLSL`, `FMLSL2`.
  - SVE `FMLA`, `FMLALB`, `FMLALT`, `FMLS`, `FMLSLB`, `FMLSLT`, `BFMLA`, `BFMLS`.
- Generates an Invalid Operation exception otherwise.

If the input is one of: a quiet NaN, an infinity, or a number that overflows the values that can be represented in the output format, and if another exception is not generated to signal the condition, then a conversion from floating-point to either integer or fixed-point format, generates an Invalid Operation exception.

For the signaling compare instructions FCMPE and FCCMPE, if either of the source operands is any type of NaN, the instruction generates an Invalid Operation floating-point exception.

If FPCR.AH is 1, for FMAX (vector), FMAX (scalar), FMAXP (scalar), FMAXP (vector), FMAXV, FMIN (vector), FMIN (scalar), FMINP (scalar), FMINP (vector), FMINV, BFMAX, and BFMIN, if either input is any type of NaN, then an Invalid Operation floating-point exception is generated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.5.9.8 Handling floating-point exceptions

If an implementation supports synchronous exception generation for floating-point exceptions, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception and that is not at a lower Exception level than where the exception was generated.

If an implementation supports synchronous exception generation for floating-point exceptions in AArch64 state, all of the following apply:

- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception, except that an implementation is permitted to not restore the cumulative floating-point exception bits in the event of such an exception.
- When the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the ESR_ELx reports one exception associated with one element that the instruction uses. The architecture does not specify which element is reported.

The `AArch64_FPTrappedException()` and `FPProcessException()` pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch64 state.

A1.5.9.9 Combinations of floating-point exceptions

More than one floating-point exception might occur on the same operation. The architecture permits only the following combinations of floating-point exceptions:

- Overflow with Inexact.
- Underflow with Inexact.
- If FPCR.AH is 0, Input Denormal with one or more of the other floating-point exception types.
- If FPCR.AH is 1, then it is an IMPLEMENTATION DEFINED choice of:
  - Input Denormal with Inexact, Underflow, or Overflow.
  - Input Denormal with one or more of the other floating-point exception types.

If two or more floating-point exceptions occur on the same operation, the priority of exceptions from highest to lowest is as follows:

- If FPCR.AH is 0, or if FPCR.AH is 1 with IMPLEMENTATION DEFINED choice allowing generation of Input Denormal with one or more of the other floating-point exception types:
  - Input Denormal.
  - Invalid Operation.
  - Divide by Zero.
  - Overflow or Underflow.
  - Inexact.
- If FPCR.AH is 1 with IMPLEMENTATION DEFINED choice allowing generation of Input Denormal with Inexact, Underflow, or Overflow:
  - Input Denormal.
  - Overflow or Underflow.
  - Inexact.

When FPCR.AH is 1, the priority between handling of a quiet NaN operand and generation of an Input Denormal exception is as follows:

- If the IMPLEMENTATION DEFINED choice permits Input Denormal only with Inexact, Underflow, or Overflow, then quiet NaN handling takes precedence over generation of the Input Denormal exception.
- If the IMPLEMENTATION DEFINED choice permits Input Denormal with one or more of the other floating-point exception types, then generation of the Input Denormal exception takes precedence over the quiet NaN handling.

Note

Arm recommends that if FPCR.AH is 1, implementations support the IMPLEMENTATION DEFINED choice of permitting only Input Denormal with Inexact, Underflow, or Overflow for operations generating two or more floating-point exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Some floating-point instructions specify more than one floating-point operation, this is indicated by the pseudocode descriptions of the instruction. In these cases, it is possible for one instruction to generate multiple exceptions. Multiple exceptions from one instruction are prioritized as follows:

- If an exception generating operation outputs a result that is used by a second exception generating operation, the exception generated by the operation that outputs the result is treated as higher priority than the exception generated by the second operation that uses the result.
- If exception generating operations do not use the outputs of other exception generating operations, it is CONSTRAINED UNPREDICTABLE which floating-point exception is treated as higher priority. The exception prioritized might differ between different instances of the same two floating-point exceptions being generated on the same operation during execution of the instruction.
- A trapped Underflow exception has priority over a trapped Inexact exception.

If none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative exception flag bit in the FPSR to be set to 1.

When FPCR.AH is 1, if the result of a floating-point operation is a denormalized number that is flushed to zero, both an untrapped Underflow floating-point exception and an Inexact floating-point exception are generated, which always sets the cumulative Underflow exception flag FPSR.UFC to 1 regardless of whether the Inexact floating-point exception is trapped. Otherwise, when a trapped floating-point exception is taken, it is IMPLEMENTATION DEFINED whether the FPSR is restored to the value it had immediately before the instruction that generated the trapped floating-point exception. If the IMPLEMENTATION DEFINED choice is that the FPSR is not restored, it is CONSTRAINED UNPREDICTABLE which trapped floating-point exceptions, if any, are indicated by the corresponding FPSR cumulative exception flag bits being set to 1.

When a trapped floating-point exception is taken, then in the ESR_ELx, all of the following apply:

- The highest priority trapped floating-point exception has a floating-point exception trapped bit set to 1.
- If any other untrapped floating-point exceptions are generated by the same operation, each untrapped exception has a floating-point exception trapped bit set to 0. This applies to both higher priority and lower priority untrapped floating-point exceptions.
- If any lower priority trapped floating-point exceptions are generated by the same operation, for each exception, it is CONSTRAINED UNPREDICTABLE whether the floating-point exception trapped bit is set to 1.

The architectural requirements for floating-point exception prioritization apply only to multiple floating-point exceptions generated on the same element of an Advanced SIMD, SVE or SME operation. For trapped floating-point exceptions from Advanced SIMD, SVE or SME instructions, the architecture does not define the floating-point exception prioritization between different elements of the instruction.

A1.5.10 Alternate BFloat16 behaviors

The behaviors in this section apply to the following instructions:

- Advanced SIMD&FP: `BFCVT`, `BFCVTN`, `BFCVTN2`, `BFMLALB`, `BFMLALT`.
- SVE: `BFCVT`, `BFCVTNT`, `BFMLALB`, `BFMLALT`, `BFMLSLB`, `BFMLSLT`.
- SME: `BFCVT` (single-precision to BFloat16), `BFCVTN`.

Table A1-6 and Table A1-7 describe when these instructions are legal.

When FPCR.AH is 1, the instructions:

- Produce the expected IEEE 754 default result but do not update the FPSR cumulative exception flag bits.
- Disable trapped floating-point exceptions, as if FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are all 0.
- Use Round to Nearest Even, ignoring FPCR.RMode.
- Flush denormalized inputs and outputs to zero, as if FPCR.{FZ, FIZ} is {1, 1}.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.5.11 BFloat16 behaviors for instructions that calculate sum-of-products

The behaviors in this section apply to the following instructions:

- Advanced SIMD: `BFDOT` and `BFMMLA`.
- SVE: `BFDOT` and `BFMMLA`.
- SME: `BFMOPA` (widening) and `BFMOPS` (widening), and SME2 `BFDOT` and `BFVDOT`.

Table A1-6 and Table A1-7 describe when these instructions are legal.

When FPCR.EBF is 0, the instructions:

- Perform unfused two-way sum-of-products for each pair of adjacent BFloat16 elements in the source vectors, with rounding of all intermediate products and sums.
- Ignore FPCR.RMode and use non-IEEE 754 Round to Odd behavior. See Round to Odd.
- Flush denormalized inputs and outputs to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Disable alternative floating-point behaviors, as if FPCR.AH is 0.

When FPCR.EBF is 1, the instructions:

- Perform a fused two-way sum-of-products for each pair of adjacent BFloat16 elements in the source vectors, without rounding of the intermediate products, but rounding the single-precision sum before addition to the single-precision accumulator element.
- Honor FPCR.RMode, supporting all four IEEE 754 rounding modes.
- Honor FPCR.{FZ, FIZ}.
- Honor FPCR.AH.

Regardless of the value of FPCR.EBF, the instructions:

- Produce the expected IEEE 754 single-precision default result but do not update the FPSR cumulative exception flag bits.
- Disable trapped floating-point exceptions, as if FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are all 0.
- Generate an intermediate sum-of-products of the same infinity when there are infinite products all with the same sign.
- Generate an intermediate sum-of-products that is a default NaN when any of the following are true:
  - Any multiplier input is a NaN.
  - Any product is infinity x 0.0.
  - Both products are infinity of differing signs.
- Generate a default NaN, as if FPCR.DN is 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.6 The Arm memory model

The Arm memory model supports:

- Generating an exception on an unaligned memory access.
- Restricting access by applications to specified areas of memory.
- Translating *virtual addresses* (VAs) provided by executing instructions to *physical addresses* (PAs).
- Altering the interpretation of multi-byte data between big-endian and little-endian.
- Controlling the order of accesses to memory.
- Controlling caches and address translation structures.
- Synchronizing access to shared memory by multiple PEs.
- Barriers that control and prevent speculative access to memory.

VA support depends on the Execution state, as follows:

AArch64 state

Supports 64-bit virtual addressing, with the Translation Control Register determining the supported VA range. Execution at EL1 and EL0 supports two independent VA ranges, each with its own translation controls.

AArch32 state

Supports 32-bit virtual addressing, with the Translation Control Register determining the supported VA range. For execution at EL1 and EL0, system software can split the VA range into two subranges, each with its own translation controls.

The supported PA space is IMPLEMENTATION DEFINED, and can be discovered by system software.

Regardless of the Execution state, the *Virtual Memory System Architecture* (VMSA) can translate VAs to blocks or pages of memory anywhere within the supported PA space.

For more information, see:

For execution in AArch64 state

- The AArch64 Application Level Memory Model.
- The AArch64 System Level Memory Model.
- The AArch64 Virtual Memory System Architecture.

For execution in AArch32 state

- The AArch32 Application Level Memory Model.
- The AArch32 System Level Memory Model.
- The AArch32 Virtual Memory System Architecture.

A1.7 Reliability, Availability, and Serviceability

A1.7.1 Introduction

I_{LMHPD} RAS are three aspects of the *dependability* of a system:

- Reliability, that is, the continuity of correct service.
- Availability, that is, the readiness for correct service.
- Serviceability, that is, the ability to undergo modifications and repairs.

I_{HWHJM} RAS techniques reduce unplanned outages because:

- Transient errors can be detected and corrected before they cause application or system failure.
- Failing components can be identified and replaced.
- Failure can be predicted ahead-of-time to allow replacement during planned maintenance.

A1.7.2 Faults, errors, and failures

R_{NVNNC} Correct service is delivered when the service implements the system function.

I_{QWSVK} Correct service might include:

- Producing correct results.
- Producing results within the time allotted to the task.
- Not divulging secret or secure information.

R_{KRTSC} For the purpose of describing the RAS Extension and RAS System Architecture, deviation from correct service is defined using the following terms:

- A failure is the event of deviation from correct service. This includes data corruption, data loss, and service loss.
- An error is the deviation from correct service. An incorrect value that has an error is corrupt.
- A fault is the cause of the error.

R_{JNBDX} Errors that are present but not detected are latent errors or undetected errors.

I_{TNQPK} In a system with no error detection, all errors are latent errors and are silently propagated by components until they are either masked or cause failure.

I_{GRYKV} The severity of a failure can range from minor to catastrophic:

- The harmful consequences of a minor failure are of a similar cost to the benefits provided by correct service delivery.
- The harmful consequences of a catastrophic failure are orders of magnitude, or even incommensurably, higher than the benefit provided by correct service delivery.

I_{NMGPQ} There are many sources of faults in a system, including both software and hardware faults:

- *Hardware faults* originate in, or affect, hardware.
- *Software faults* affect software, that is programs or data.

The RAS Extension and RAS System Architecture primarily address errors produced from hardware faults. These fall into two main areas:

- Transient faults.
- Non-transient or *persistent faults*.

A1.7.3 General taxonomy of errors

A1.7.3.1 Error detection

R_{FHXWP} When a component accesses memory or other state, an error might be detected in that memory or state.

I_{WKPVR} The error might be corrected or deferred by the component, or signaled to another component as either a Deferred error or a Detected error.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.7.3.2 Error propagation

R_{LRZDN} A transaction occurs when a producer of the transaction passes a value or other signal to a consumer of the transaction.

I_{VYCCX} Transactions are part of the service provided by the producer for the consumer.

I_{RHGDL} In many protocols and service interface definitions, a high-level transaction consists of a sequence of operations, for instance between a *Requester* and a *Completer*.

For the purposes of this Manual, the most basic form of a unidirectional transfer between a *producer* and *consumer* is considered as a transaction.

That is, each one of the sequence of operations is considered a separate transaction. For some operations, such as a request, the Requester is producer and the Completer is the consumer. For other operations, such as a response, the Completer is producer and the Requester is the consumer.

R_{SKZZG} An error is propagated by the producer of a transaction when the service interface is incorrect because of the error. The error is propagated to the consumer.

R_{CHCCV} An error is propagated by deviations from correct service, including when any of the following occurs that would not have been permitted to occur had the fault not been activated:

- A corrupt value is passed from producer to consumer.
- A transaction or other operation occurs that should not have occurred.
- A transaction or other operation that should have occurred does not occur.
- A loss of uniprocessor semantics or any other loss of coherency in a multiprocessor coherent system is observed.
- Changing the timing and/or order of transactions or other operations such that the timing and/or order of those transactions or operations is incorrect. In this case, the service interface defines acceptable timings and/or orders for transactions and other operations.

R_{YFBRV} The service interface for a transaction might include means to signal that the transaction is propagating either of the following:

- A Detected error.
- A Deferred error.

R_{BHWVX} An error is silently propagated by the producer of a transaction if the consumer of the transaction cannot detect the error and consumes an undetected error because of the transaction. This might be because of one of the following:

- The error is present on the transaction, but was not detected by the producer. The error is silently propagated by the producer.
- The error is present on the transaction, but was not signaled to the consumer as an error. For example, a corrupt value was passed in the transaction with no indication that it was corrupt. The error is silently propagated by the producer.

R_{FPBYS} A latent, possibly detectable, error is silently propagated by the consumer of an otherwise correct transaction if the transaction causes the error to become undetectable.

Example A1-2

A partial write to a protection granule removes poison, leaving the unchanged portion of the location corrupt. To implement a partial write, the consumer logically reads the current value of the location, modifies the value, and then writes the modified value back. These are internal transactions in the consumer that silently propagate the error. In this example there was no error at the producer nor on the transaction.

I_{QXRLB} Errors might be propagated by components in a system until one of the following occurs:

- They are masked and do not affect the outcome of the system.
  The error might be masked because a corrupt value is discarded or overwritten, or the error is detected and removed.
- They affect the service interface of the system and possibly cause failure. If the error has been silently propagated to the service interface, then:
  - This is a Silent Data Corruption, SDC.
  - The rate of such failures, measured as the number of failures per billion device-hours of operation, is called the Silent Data Corruption Failure-in-Time rate, SDC FIT rate.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alternatively, the error might have been detected, causing the system to invoke error handling and recovery. For more information, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

A1.7.3.3 Infected and poisoned

R_{KNHWB} The state of a component becomes infected when the component consumes an Uncorrected error that updates the state.

R_{TZBSW} A value is poisoned in the state of a component if it is marked as being in error, such that a subsequent access of the state will detect the value is so marked and is treated as a Detected error.

I_{YBMFK} Poison is used to defer an error.

A1.7.3.4 Containable and uncontainable

R_{DXQRD} An undetected error is uncontained at the component that failed to detect it.

R_{RJYRQ} A silently propagated error is uncontained at the component that silently propagated it.

R_{GJQNR} A Detected Uncorrected error is uncontainable at the component if it might be uncontained at the component. A Detected Uncorrected error is containable at the component if it is not uncontainable at the component. If the component cannot determine whether a Detected Uncorrected error is uncontainable at the component or containable at the component, then the component treats the Detected Uncorrected error as uncontainable at the component.

I_{MRDMR} An error that is uncontainable at the component might be containable at the system level.

I_{NWZGB} Reporting an error as containable allows software to contain the error. This does not mean that hardware has contained the error.

Chapter A2
A-profile Architecture Extensions

This chapter introduces the Arm A-profile architecture extensions. It contains the following sections:

- About the A-profile architecture extensions
- Armv8-A architecture extensions
- Armv9-A architecture extensions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A2.1 About the A-profile architecture extensions

An architecture extension defines a set of features that, when implemented, may make an implementation compliant with the extension.

Each feature description includes:

- A feature name.
- A brief description of the feature.
- The Execution state the feature is supported in.
- Whether the implementation of the feature is mandatory or OPTIONAL.
- Dependencies on the implementation of other features if any.
- The register field that identifies the presence of the feature.

A2.1.1 Permitted implementation of subsets of the A-profile architectural features

Arm regularly introduces new features to the architecture. When a feature is introduced, the architecture specifies when the feature can be implemented. Typically, a feature introduced as part of Armv8.*x* or Armv9.*x* is permitted to be built in Armv8.(*x*-1) or Armv9.(*x*-1), subject only to those constraints that require that certain features be implemented together.

See the individual feature descriptions for details of when each feature is permitted or required to be built.

A2.1.2 Withdrawn architecture features

This section lists features previously described in the architecture but subsequently withdrawn. Features listed in this section are not permitted to be included in any version of the architecture:

FEAT_TME, Transactional Memory Extension

FEAT_TME introduced a set of instructions to support hardware transaction memory, which means a group of instructions can appear to be collectively executed as a single atomic operation.

FEAT_SEBEP, Synchronous Exception-based Event Profiling

FEAT_SEBEP introduced support for synchronous, precise Performance Monitors Unit (PMU) profiling by permitting profiling events to be reported through synchronous exceptions.

Non-Confidential

A2.2 Armv8-A architecture extensions

A2.2.1 The Armv8.0 architecture extension

The original Armv8-A architecture is called Armv8.0. It contains mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.0 compliant if it includes all of the Armv8.0 architectural features that are mandatory.

An Armv8.0 compliant implementation can additionally include any features that are defined to be optional in Armv8.0.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_AA32, PE supports AArch32.

FEAT_AA32 is OPTIONAL.

If FEAT_AA32 is implemented, then FEAT_AA32EL0 is implemented.

FEAT_AA32EL0, Support for AArch32 at EL0

FEAT_AA32EL0 is OPTIONAL from Armv8.0.

If FEAT_AA32EL0 is implemented, then FEAT_EL0 is implemented.

If FEAT_AA32EL0 is implemented, then FEAT_AA32 is implemented.

FEAT_AA32EL1, Support for AArch32 at EL1

FEAT_AA32EL1 is OPTIONAL from Armv8.0.

If Armv9.0 is implemented, then FEAT_AA32EL1 is not implemented.

If FEAT_AA32EL1 is implemented, then FEAT_AA32EL0 is implemented.

If FEAT_AA32EL1 is implemented, then FEAT_EL1 is implemented.

FEAT_AA32EL2, Support for AArch32 at EL2

FEAT_AA32EL2 is OPTIONAL from Armv8.0.

If FEAT_AA32EL2 is implemented, then FEAT_AA32EL1 is implemented.

If FEAT_AA32EL2 is implemented, then FEAT_EL2 is implemented.

FEAT_AA32EL3, Support for AArch32 at EL3

FEAT_AA32EL3 is OPTIONAL from Armv8.0.

If FEAT_AA32EL3 is implemented, then FEAT_AA32EL1 is implemented.

When FEAT_AA32EL3 and FEAT_EL2 are implemented, FEAT_AA32EL2 is implemented.

If FEAT_AA32EL3 is implemented, then FEAT_EL3 is implemented.

FEAT_AA64, PE uses AArch64 after last reboot

FEAT_AA64 is OPTIONAL from Armv8.0.

If FEAT_AA64 is implemented, then FEAT_AA64EL0, FEAT_AA64EL1, FEAT_AA64EL2, or FEAT_AA64EL3 is implemented.

When FEAT_AA64EL0, FEAT_AA64EL1, FEAT_AA64EL2, or FEAT_AA64EL3 is implemented, FEAT_AA64 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_AA64EL0, Support for AArch64 at EL0

FEAT_AA64EL0 is OPTIONAL from Armv8.0.

FEAT_AA64EL0 is mandatory from Armv9.0.

If FEAT_AA64EL0 is implemented, then FEAT_AA64EL1 is implemented.

If FEAT_AA64EL0 is implemented, then FEAT_EL0 is implemented.

FEAT_AA64EL1, Support for AArch64 at EL1

FEAT_AA64EL1 is OPTIONAL from Armv8.0.

FEAT_AA64EL1 is mandatory from Armv9.0.

If FEAT_AA64EL1 is implemented, then FEAT_AA64EL0 is implemented.

When FEAT_AA64EL1 and FEAT_EL2 are implemented, FEAT_AA64EL2 is implemented.

When FEAT_AA64EL1 and FEAT_EL3 are implemented, FEAT_AA64EL3 is implemented.

If FEAT_AA64EL1 is implemented, then FEAT_EL1 is implemented.

FEAT_AA64EL2, Support for AArch64 at EL2

FEAT_AA64EL2 is OPTIONAL from Armv8.0.

If FEAT_AA64EL2 is implemented, then FEAT_AA64EL1 is implemented.

When FEAT_AA64EL2 and FEAT_EL3 are implemented, FEAT_AA64EL3 is implemented.

If FEAT_AA64EL2 is implemented, then FEAT_EL2 is implemented.

FEAT_AA64EL3, Support for AArch64 at EL3

FEAT_AA64EL3 is OPTIONAL from Armv8.0.

If FEAT_AA64EL3 is implemented, then FEAT_AA64EL1 is implemented.

When FEAT_AA64EL3 and FEAT_EL2 are implemented, FEAT_AA64EL2 is implemented.

If FEAT_AA64EL3 is implemented, then FEAT_EL3 is implemented.

FEAT_AES, Advanced SIMD AES instructions

FEAT_AES provides the AES* instructions to support AES encryption and decryption, AESD, AESE, AESMC, and AESIMC.

This feature is supported in both AArch64 and AArch32 states.

FEAT_AES is OPTIONAL from Armv8.0.

If FEAT_AES is implemented, then FEAT_Crypto is implemented.

The following field identifies the presence of FEAT_AES:

- ID_AA64ISAR0_EL1.AES.

FEAT_ASID16, 16 bit ASID

FEAT_ASID16 is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_ASID16:

- ID_AA64MMFR0_EL1.ASIDBits.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_AdvSIMD, Advanced SIMD Extension

FEAT_AdvSIMD includes support for the SISD and SIMD operations. All Armv8-A systems that support standard operating systems with rich application environments also provide hardware support for Advanced SIMD instructions.

This feature is supported in both AArch64 and AArch32 states.

FEAT_AdvSIMD is OPTIONAL from Armv8.0.

If FEAT_AdvSIMD is implemented, then FEAT_FP is implemented.

The following fields identify the presence of FEAT_AdvSIMD:

- ID_AA64PFR0_EL1.AdvSIMD.
- EDPFR.AdvSIMD.

For more information, see:

- Supported data types.
- A64 Advanced SIMD and Floating-point Instruction Descriptions.
- Advanced SIMD and floating-point instructions.
- T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions.

FEAT_BigEnd, Support for big-endian at EL1 and above

FEAT_BigEnd is OPTIONAL from Armv8.0.

If FEAT_BigEnd is implemented, then FEAT_BigEndEL0 is implemented.

If FEAT_MixedEnd is implemented, then FEAT_BigEnd is implemented.

FEAT_BigEndEL0, Support for big-endian at EL0

FEAT_BigEndEL0 is OPTIONAL from Armv8.0.

If FEAT_MixedEndEL0 is implemented, then FEAT_BigEndEL0 is implemented.

FEAT_CRC32, CRC32 instructions

FEAT_CRC32 introduces the support for the CRC32* instructions that perform cyclic redundancy check calculations.

This feature is supported in both AArch64 and AArch32 states.

FEAT_CRC32 is OPTIONAL from Armv8.0.

FEAT_CRC32 is mandatory from Armv8.1.

The following fields identify the presence of FEAT_CRC32:

- ID_AA64ISAR0_EL1.CRC32.
- ID_ISAR5_EL1.CRC32.
- ID_ISAR5.CRC32.

FEAT_CSV2, Cache Speculation Variant 2

FEAT_CSV2 introduces a mechanism to identify if hardware cannot disclose information about whether any prediction resource, such as branch target, data-value, or cache prefetch, trained in one hardware-defined context can control speculative execution in a different hardware-defined context.

This feature is supported in both AArch64 and AArch32 states.

FEAT_CSV2 is OPTIONAL from Armv8.0.

FEAT_CSV2 is mandatory from Armv8.5.

The following fields identify the presence of FEAT_CSV2:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64PFR0_EL1.CSV2.
- ID_PFR0_EL1.CSV2.
- ID_PFR0.CSV2.

For more information, see:

- For AArch64, Restrictions on the effects of speculation.
- AArch32 restrictions on the effects of speculation.

FEAT_CSV2_1p1, Cache Speculation Variant 2, version 1.1

For FEAT_CSV2_1p1, within a hardware-defined context, branch targets, or data values trained for instructions situated at one instruction address can control speculative execution of code from a different address only in a hard-to-determine way.

FEAT_CSV2_1p1 does not support the SCXTNUM_ELx registers.

This feature is supported in both AArch64 and AArch32 states.

FEAT_CSV2_1p1 is OPTIONAL from Armv8.0.

If FEAT_CSV2_1p1 is implemented, then FEAT_CSV2 is implemented.

The following fields identify the presence of FEAT_CSV2_1p1:

- ID_AA64PFR1_EL1.CSV2_frac.
- ID_AA64PFR0_EL1.CSV2.
- ID_PFR0_EL1.CSV2.
- ID_PFR0.CSV2.

For more information, see:

- For AArch64, Restrictions on the effects of speculation.
- AArch32 restrictions on the effects of speculation.

FEAT_CSV2_1p2, Cache Speculation Variant 2 version 1.2

For FEAT_CSV2_1p2, within a hardware-defined context, branch targets or data values trained for instructions situated at one instruction address can control speculative execution of code from a different address only in a hard-to-determine way.

FEAT_CSV2_1p2 introduces the SCXTNUM_ELx registers, but the contexts do not include the SCXTNUM_ELx register contexts.

This feature is supported in AArch64 state only.

FEAT_CSV2_1p2 is OPTIONAL from Armv8.0.

If FEAT_CSV2_1p2 is implemented, then FEAT_CSV2_1p1 is implemented.

The following fields identify the presence of FEAT_CSV2_1p2:

- ID_AA64PFR1_EL1.CSV2_frac.
- ID_AA64PFR0_EL1.CSV2.

For more information, see:

- For AArch64, Restrictions on the effects of speculation.
- AArch32 restrictions on the effects of speculation.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_CSV2_2, Cache Speculation Variant 2 version 2

FEAT_CSV2_2 introduces the SCXTNUM_ELx registers, which provide a number that can be used to separate out different context numbers within their respective Exception levels for the purpose of protecting against speculative attacks through prediction resources.

This feature is supported in AArch64 state only.

FEAT_CSV2_2 is OPTIONAL from Armv8.0.

If FEAT_CSV2_2 is implemented, then FEAT_CSV2 is implemented.

If FEAT_CSV2_2 is implemented, then FEAT_CSV2_1p1 is not implemented.

The following field identifies the presence of FEAT_CSV2_2:

- ID_AA64PFR0_EL1.CSV2.

For more information, see:

- For AArch64, Restrictions on the effects of speculation.
- AArch32 restrictions on the effects of speculation.

FEAT_CSV2_3, Cache Speculation Variant 2 version 3

FEAT_CSV2_3 introduces a mechanism to identify if hardware cannot disclose information about whether prediction resources based on branch history trained in one hardware-defined context can control speculative execution in a different hardware-defined context.

This feature is supported in AArch64 state only.

FEAT_CSV2_3 is OPTIONAL from Armv8.0.

If FEAT_CSV2_3 is implemented, then FEAT_CSV2_2 is implemented.

The following field identifies the presence of FEAT_CSV2_3:

- ID_AA64PFR0_EL1.CSV2.

For more information, see:

- For AArch64, Restrictions on the effects of speculation.
- AArch32 restrictions on the effects of speculation.

FEAT_CTI_PIDR, Support for CoreSight compliance for external CTI registers

FEAT_CTI_PIDR provides registers for compliance with the CoreSight architecture.

This feature is required for compliance with the CoreSight architecture.

FEAT_CTI_PIDR is OPTIONAL from Armv8.0.

For more information, see Management registers and CoreSight compliance.

FEAT_Crypto, Cryptographic Extension

The Arm Cryptographic Extension provides instructions for the acceleration of encryption and decryption. The presence of the Cryptographic Extension in an implementation is subject to export license controls.

The Cryptographic Extension is an extension of the SIMD support and operates on the vector register file. It also provides multiply instructions that operate on long polynomials.

In an implementation that supports both AArch64 state and AArch32 state, FEAT_AES, FEAT_PMULL, FEAT_SHA1 and FEAT_SHA256 provide the same functionality in both states.

This feature is supported in both AArch64 and AArch32 states.

FEAT_Crypto is OPTIONAL.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_Crypto is implemented, then FEAT_AES or FEAT_SHA1 is implemented.

In an Armv8.2 implementation, if FEAT_Crypto is implemented, FEAT_PMULL, FEAT_SHA256, FEAT_SM3, or FEAT_SM4 is implemented.

For more information, see:

- The Cryptographic Extension in AArch64 state.
- The Cryptographic Extension in AArch32 state.

FEAT_DoubleLock, Double Lock

FEAT_DoubleLock is the mnemonic used for the OS Double Lock.

FEAT_DoubleLock is OPTIONAL from Armv8.0.

If Armv9.0 is implemented, then FEAT_DoubleLock is not implemented.

The following fields identify the presence of FEAT_DoubleLock:

- ID_AA64DFR0_EL1.DoubleLock.
- DBGDEVID.DoubleLock.

FEAT_ED_PIDR, Support for CoreSight compliance for External Debug registers

FEAT_ED_PIDR provides registers for compliance with the CoreSight architecture.

This feature is required for compliance with the CoreSight architecture.

FEAT_ED_PIDR is OPTIONAL from Armv8.0.

For more information, see Management registers and CoreSight compliance.

FEAT_EL0, Support for execution at EL0

FEAT_EL0 is mandatory from Armv8.0.

If FEAT_EL0 is implemented, then FEAT_AA32EL0 or FEAT_AA64EL0 is implemented.

FEAT_EL1, Support for execution at EL1

FEAT_EL1 is mandatory from Armv8.0.

If FEAT_EL1 is implemented, then FEAT_AA32EL1 or FEAT_AA64EL1 is implemented.

FEAT_EL2, Support for execution at EL2

FEAT_EL2 is OPTIONAL from Armv8.0.

If FEAT_EL2 is implemented, then FEAT_AA32EL2 or FEAT_AA64EL2 is implemented.

FEAT_EL3, Support for EL3

FEAT_EL3 is OPTIONAL from Armv8.0.

If FEAT_EL3 is implemented, then FEAT_AA32EL3 or FEAT_AA64EL3 is implemented.

FEAT_ETMv4, Embedded Trace Macrocell version 4

FEAT_ETMv4 indicates support for the Embedded Trace Macrocell architecture ETMv4.

FEAT_ETMv4 is OPTIONAL from Armv8.0.

If Armv9.0 is implemented, then FEAT_ETMv4 is not implemented.

If FEAT_ETMv4 is implemented, then FEAT_TRC_SR or FEAT_TRC_EXT is implemented.

For more information, see the *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4(ARM IHI 0064)*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_ETS2, Enhanced Translation Synchronization

FEAT_ETS2 introduces support for enhanced memory access ordering requirements for translation table walks.

This feature is supported in both AArch64 and AArch32 states.

FEAT_ETS2 is OPTIONAL from Armv8.0.

FEAT_ETS2 is mandatory from Armv8.8.

The following fields identify the presence of FEAT_ETS2:

- ID_AA64MMFR1_EL1.ETS.
- ID_MMFR5_EL1.ETS.
- ID_MMFR5.ETS.

For more information, see:

- Ordering requirements defined by the formal concurrency model.
- Ordering of memory accesses from translation table walks.
- Ordering of translation table walks.

FEAT_FP, Floating Point extensions

FEAT_FP includes support for single-precision and double-precision floating-point types. All Armv8-A systems that support standard operating systems with rich application environments also provide hardware support for floating-point instructions.

This feature is supported in both AArch64 and AArch32 states.

FEAT_FP is OPTIONAL from Armv8.0.

If FEAT_FP is implemented, then FEAT_AdvSIMD is implemented.

The following fields identify the presence of FEAT_FP:

- ID_AA64PFR0_EL1.FP.
- EDPFR.FP.

For more information, see:

- Supported data types.
- Floating-point support.
- A64 Advanced SIMD and Floating-point Instruction Descriptions.
- Advanced SIMD and floating-point instructions.
- T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions.

FEAT_GICD_PIDR, Support for CoreSight compliance for External GIC Distributor registers

FEAT_GICD_PIDR provides registers for compliance with the CoreSight architecture.

This feature is required for compliance with the CoreSight architecture.

FEAT_GICD_PIDR is OPTIONAL from Armv8.0.

For more information, see *Arm™ Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0(ARM IHI 0069)*.

FEAT_GICR_PIDR, Support for CoreSight compliance for External GIC Redistributor registers

FEAT_GICR_PIDR provides registers for compliance with the CoreSight architecture.

This feature is required for compliance with the CoreSight architecture.

FEAT_GICR_PIDR is OPTIONAL from Armv8.0.

For more information, see *Arm™ Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0(ARM IHI 0069)*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_GITS_PIDR, Support for CoreSight compliance for External GIC ITS registers

FEAT_GITS_PIDR provides registers for compliance with the CoreSight architecture.

This feature is required for compliance with the CoreSight architecture.

FEAT_GITS_PIDR is OPTIONAL from Armv8.0.

For more information, see *Arm™ Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0(ARM IHI 0069)*.

FEAT_IVIPT, The IVIPT Extension

FEAT_IVIPT describes any permitted instruction cache implementation. This includes *Virtual Index, Physical tag* (VIPT) cache policy and *Physical Index, Physical Tag* (PIPT) cache policy.

FEAT_IVIPT is mandatory from Armv8.0.

For more information, see:

- Instruction caches.
- Instruction caches.

FEAT_LittleEnd, Support for little-endian at EL1 and above

FEAT_LittleEnd is OPTIONAL from Armv8.0.

If FEAT_LittleEnd is implemented, then FEAT_LittleEndEL0 is implemented.

If FEAT_MixedEnd is implemented, then FEAT_LittleEnd is implemented.

FEAT_LittleEndEL0, Support for little-endian at EL0

FEAT_LittleEndEL0 is OPTIONAL from Armv8.0.

If FEAT_MixedEndEL0 is implemented, then FEAT_LittleEndEL0 is implemented.

FEAT_MixedEnd, Mixed-endian support

FEAT_MixedEnd provides support for mixed-endian configuration.

FEAT_MixedEnd is OPTIONAL from Armv8.0.

If FEAT_MixedEnd is implemented, then FEAT_MixedEndEL0 is implemented.

The following field identifies the presence of FEAT_MixedEnd:

- ID_AA64MMFR0_EL1.BigEnd.

For more information, see:

- Mixed-endian support in AArch64.
- Mixed-endian support in AArch32.

FEAT_MixedEndEL0, Mixed-endian support at EL0

FEAT_MixedEndEL0 provides support for mixed-endian at EL0.

FEAT_MixedEndEL0 is OPTIONAL from Armv8.0.

The following fields identify the presence of FEAT_MixedEndEL0:

- ID_AA64MMFR0_EL1.BigEndEL0.
- ID_AA64MMFR0_EL1.BigEnd.

For more information, see:

- Mixed-endian support in AArch64.
- Mixed-endian support in AArch32.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_PCSRv8, PC Sample-based Profiling extension

FEAT_PCSRv8 introduces support for PC Sample-based Profiling Extension that provides coarse-grained, non-invasive profiling by an external debugger.

FEAT_PCSRv8 is OPTIONAL from Armv8.0.

If FEAT_PCSRv8 is implemented, then FEAT_PCSRv8p2 is not implemented.

The following fields identify the presence of FEAT_PCSRv8:

- DBGDEVID.PCSample.
- DBGDEVID1.PCSROffset.
- EDDEVID1.PCSROffset.
- EDDEVID.PCSample.

For more information, see About the PC Sample-based Profiling Extension.

FEAT_PMULL, Advanced SIMD PMULL instructions

FEAT_PMULL provides the AES* instructions that support multiplication of 64-bit polynomials, PMULL, PMULL2.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PMULL is OPTIONAL from Armv8.0.

If FEAT_PMULL is implemented, then FEAT_AES is implemented.

The following field identifies the presence of FEAT_PMULL:

- ID_AA64ISAR0_EL1.AES.

FEAT_PMU_PIDR, Support for CoreSight compliance for external PMU registers

FEAT_PMU_PIDR provides registers for compliance with the CoreSight architecture.

This feature is required for compliance with the CoreSight architecture.

FEAT_PMU_PIDR is OPTIONAL from Armv8.0.

If FEAT_PMU_PIDR is implemented, then FEAT_PMUv3_EXT is implemented.

For more information, see Management registers and CoreSight compliance.

FEAT_PMUv3, Performance Monitors Extension, version 3

The Performance Monitors Extension, FEAT_PMUv3, is an optional non-invasive debug component.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PMUv3 is OPTIONAL from Armv8.0.

The following fields identify the presence of FEAT_PMUv3:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.
- EDDFR.PMUVer.

For more information, see The Performance Monitors Extension.

FEAT_PMUv3_EXT, External interface to the Performance Monitors

FEAT_PMUv3_EXT indicates support for external access to the FEAT_PMUv3 and/or FEAT_PCSRv8p2 registers.

FEAT_PMUv3_EXT is OPTIONAL from Armv8.0.

If FEAT_PMUv3_EXT is implemented, then FEAT_PMUv3 or FEAT_PCSRv8p2 is implemented.

If FEAT_PMUv3_EXT is implemented, then FEAT_PMUv3_EXT32 or FEAT_PMUv3_EXT64 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_PMUv3_EXT32, 32-bit external interface to the Performance Monitors

FEAT_PMUv3_EXT32 indicates the external Performance Monitors and CoreSight registers are implemented as mostly 32-bit registers.

FEAT_PMUv3_EXT32 is OPTIONAL from Armv8.0.

If FEAT_PMUv3_EXT32 is implemented, then FEAT_PMUv3_EXT is implemented.

If FEAT_PMUv3_EXT32 is implemented, then FEAT_PMUv3_EXT64 is not implemented.

The following fields identify the presence of FEAT_PMUv3_EXT32:

- PMDEVARCH.ARCHVER.
- PMDEVARCH.ARCHPART.

For more information, see Recommended External Interface to the Performance Monitors.

FEAT_SHA1, Advanced SIMD SHA1 instructions

FEAT_SHA1 implements the SHA1* instructions.

This feature is supported in both AArch64 and AArch32 states.

FEAT_SHA1 is OPTIONAL from Armv8.0.

If FEAT_SHA1 is implemented, then FEAT_Crypto is implemented.

If FEAT_SHA1 is implemented, then FEAT_SHA256 is implemented.

The following field identifies the presence of FEAT_SHA1:

- ID_AA64ISAR0_EL1.SHA1.

FEAT_SHA256, Advanced SIMD SHA256 instructions

FEAT_SHA256 implements the SHA256* instructions.

This feature is supported in both AArch64 and AArch32 states.

FEAT_SHA256 is OPTIONAL from Armv8.0.

If FEAT_SHA256 is implemented, then FEAT_SHA1 is implemented.

The following field identifies the presence of FEAT_SHA256:

- ID_AA64ISAR0_EL1.SHA2.

FEAT_Secure, Support for Secure state

FEAT_Secure adds support for Secure state.

This feature is supported in both AArch64 and AArch32 states.

FEAT_Secure is OPTIONAL from Armv8.0.

If FEAT_RME is not implemented and FEAT_EL3 is implemented, then FEAT_Secure is implemented.

If FEAT_RME is implemented, then it is IMPLEMENTATION DEFINED whether FEAT_Secure is implemented.

In AArch32 state, Secure state execution at EL2 is not supported.

In AArch64 state, Secure state execution at EL2 requires FEAT_SEL2 to be implemented and enabled.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SpecSEI, SError interrupt exceptions from speculative reads of memory

Describes whether the PE can generate SError interrupt exceptions from speculative reads of memory, including speculative instruction fetches.

FEAT_SpecSEI is OPTIONAL from Armv8.0.

The following fields identify the presence of FEAT_SpecSEI:

- ID_AA64MMFR1_EL1.SpecSEI.
- ID_MMFR4_EL1.SpecSEI.
- ID_MMFR4.SpecSEI.

FEAT_TGran16K, Support for 16KB memory translation granule size at stage 1

FEAT_TGran16K is OPTIONAL from Armv8.0.

In an Armv8.5 implementation, if FEAT_AA64EL2 and FEAT_TGran16K are implemented, FEAT_S2TGran16K is implemented.

The following field identifies the presence of FEAT_TGran16K:

- ID_AA64MMFR0_EL1.TGran16.

FEAT_TGran4K, Support for 4KB memory translation granule size at stage 1

FEAT_TGran4K is OPTIONAL from Armv8.0.

In an Armv8.5 implementation, if FEAT_AA64EL2 and FEAT_TGran4K are implemented, FEAT_S2TGran4K is implemented.

The following field identifies the presence of FEAT_TGran4K:

- ID_AA64MMFR0_EL1.TGran4.

FEAT_TGran64K, Support for 64KB memory translation granule size at stage 1

FEAT_TGran64K is OPTIONAL from Armv8.0.

In an Armv8.5 implementation, if FEAT_AA64EL2 and FEAT_TGran64K are implemented, FEAT_S2TGran64K is implemented.

The following field identifies the presence of FEAT_TGran64K:

- ID_AA64MMFR0_EL1.TGran64.

FEAT_TRAPFPE, Synchronous exception generation from floating-point exceptions

FEAT_TRAPFPE implements the support of synchronous exception generation from Input Denormal, Inexact, Underflow, Overflow, Divide by Zero, and Invalid Operation floating-point exceptions.

This feature is supported in AArch64 state only.

FEAT_TRAPFPE is OPTIONAL from Armv8.0.

If FEAT_TRAPFPE is implemented, then FEAT_FP is implemented.

FEAT_TRC_EXT, Trace external registers

FEAT_TRC_EXT indicates support for external access to the ETMv4 or ETE registers.

FEAT_TRC_EXT is OPTIONAL from Armv8.0.

If FEAT_TRC_EXT is implemented, then FEAT_ETMv4 or FEAT_ETE is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_TRC_SR, Trace System registers

FEAT_TRC_SR indicates support for System registers for ETMv4 or ETE.

This feature is supported in both AArch64 and AArch32, but only when either of these are supported at EL1.

FEAT_TRC_SR is OPTIONAL from Armv8.0.

If FEAT_TRC_SR is implemented, then FEAT_ETMv4 or FEAT_ETE is implemented.

The following fields identify the presence of FEAT_TRC_SR:

- ID_AA64DFR0_EL1.TraceVer.
- EDDFR.TraceVer.
- ID_DFR0.CopTrc.
- ID_DFR0_EL1.CopTrc.

FEAT_nTLBPA, Intermediate caching of translation table walks

FEAT_nTLBPA introduces a mechanism to identify if the intermediate caching of translation table walks does not include non-coherent caches of previous valid translation table entries since the last completed TLBI applicable to the PE.

This feature is supported in both AArch64 and AArch32 states.

FEAT_nTLBPA is OPTIONAL from Armv8.0.

The following fields identify the presence of FEAT_nTLBPA:

- ID_AA64MMFR1_EL1.nTLBPA.
- ID_MMFR5_EL1.nTLBPA.
- ID_MMFR5.nTLBPA.

For more information, see:

- TLB maintenance.
- General TLB maintenance requirements.

A2.2.1.1 Features added to the Armv8.0 extension in later releases

- FEAT_AMU_PIDR.
- FEAT_CHK.
- FEAT_CLRBHB.
- FEAT_CP15SDISABLE2.
- FEAT_CSV3.
- FEAT_DGH.
- FEAT_ECBHB.
- FEAT_ETS3.
- FEAT_GTG.
- FEAT_PRFMSLC.
- FEAT_RAS.
- FEAT_RPRFM.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- FEAT_SB.
- FEAT_SCTLR2.
- FEAT_SPECRES2.
- FEAT_SPECRES.
- FEAT_SSBS2.
- FEAT_SSBS.
- FEAT_TCR2.

A2.2.2 The Armv8.1 architecture extension

The Armv8.1 architecture extension is an extension to Armv8.0. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.1 compliant if all of the following apply:

- It is Armv8.0 compliant.
- It includes all of the Armv8.1 architectural features that are mandatory.

An Armv8.1 compliant implementation can additionally include any features that are defined to be optional in Armv8.1.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_Debugv8p1, Debug v8.1

FEAT_Debugv8p1 is OPTIONAL from Armv8.0.

The following fields identify the presence of FEAT_Debugv8p1:

- ID_AA64DFR0_EL1.DebugVer.
- ID_DFR0_EL1.CopDbg.
- ID_DFR0.CopDbg.
- EDDEVARCH.ARCHVER.

FEAT_E2H0, Programming of HCR_EL2.E2H

When FEAT_VHE is implemented, FEAT_E2H0 indicates that HCR_EL2.E2H can be programmed to the value 0. The absence of FEAT_E2H0 results in a relaxed behavior where HCR_EL2.E2H is RES1, with EL2 host mode always enabled.

This feature is supported in AArch64 state only.

FEAT_E2H0 is OPTIONAL from Armv8.0.

If FEAT_E2H0 is implemented, then FEAT_VHE is implemented.

If FEAT_E2H0 is implemented, then FEAT_AA64EL2 is implemented.

The following field identifies the presence of FEAT_E2H0:

- ID_AA64MMFR4_EL1.E2H0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_HAF, Hardware management of the Access flag.

Hardware can perform updates to the translation tables to manage the Access flag.

This feature is supported in AArch64 state only.

FEAT_HAF is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_HAF:

- ID_AA64MMFR1_EL1.HAFDBS.

For more information, see Hardware management of the Access flag.

FEAT_HAFDBS, Hardware management of dirty state

Hardware can perform updates to dirty state in the translation tables.

This feature is supported in AArch64 state only.

FEAT_HAFDBS is OPTIONAL from Armv8.0.

If FEAT_HAFDBS is implemented, then FEAT_HAF is implemented.

The following field identifies the presence of FEAT_HAFDBS:

- ID_AA64MMFR1_EL1.HAFDBS.

For more information, see Hardware management of the dirty state.

FEAT_HPDS, Hierarchical permission disables in translations tables

FEAT_HPDS introduces the facility to disable the hierarchical permissions, APTable, PXNTable, and UXNTable, in the translation tables. This disable has no effect on the NSTable bit.

FEAT_HPDS is OPTIONAL from Armv8.0.

FEAT_HPDS is mandatory from Armv8.1.

The following field identifies the presence of FEAT_HPDS:

- ID_AA64MMFR1_EL1.HPDS.

This feature is added only to the VMSAv8-64 translation regimes. Armv8.2 extends this to the AArch32 translation regimes, see FEAT_AA32HPD.

FEAT_LOR, Limited ordering regions

Limited ordering regions allow large systems to perform special Load-Acquire and Store-Release instructions that provide order between the memory accesses to a region of the PA map as observed by a limited set of observers.

This feature is supported in AArch64 state only.

FEAT_LOR is OPTIONAL from Armv8.0.

FEAT_LOR is mandatory from Armv8.1.

The following field identifies the presence of FEAT_LOR:

- ID_AA64MMFR1_EL1.LO.

For more information, see Limited ordering regions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_LSE, Large System Extensions

FEAT_LSE introduces a set of atomic instructions:

- Compare and Swap instructions, `CAS` and `CASP`.
- Atomic memory operation instructions, LD<OP> and ST<OP>, where <OP> is one of ADD, CLR, EOR, SET, SMAX, SMIN, UMAX, and UMIN.
- Swap instruction, SWP.

This feature is supported in AArch64 state only.

FEAT_LSE is OPTIONAL from Armv8.0.

FEAT_LSE is mandatory from Armv8.1.

The following field identifies the presence of FEAT_LSE:

- ID_AA64ISAR0_EL1.Atomic.

For more information, see:

- Atomic integer memory operations.
- Swap operations.
- Compare and Swap operations.

FEAT_PAN, Privileged access never

FEAT_PAN introduces a bit to PSTATE. When the value of this PAN state bit is 1, any privileged data access from EL1, or EL2 when the Effective value of HCR_EL2.E2H is 1, to a virtual memory address that is accessible to data accesses at EL0, generates a Permission fault.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PAN is OPTIONAL from Armv8.0.

FEAT_PAN is mandatory from Armv8.1.

The following fields identify the presence of FEAT_PAN:

- ID_AA64MMFR1_EL1.PAN.
- ID_MMFR3_EL1.PAN.
- ID_MMFR3.PAN.

For more information, see:

- PSTATE.PAN.
- About the PAN bit.

FEAT_PMUv3p1, Armv8.1 PMU extensions

FEAT_PMUv3p1 introduces the following:

- The event number space is extended to 16 bits.
- The HPMD bit is added to MDCR_EL2. This bit disables event counting at EL2.
- The STALL_FRONTEND and STALL_BACKEND events are required to be implemented.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PMUv3p1 is OPTIONAL from Armv8.0.

In an Armv8.1 implementation, if FEAT_PMUv3 is implemented, FEAT_PMUv3p1 is implemented.

If FEAT_PMUv3p1 is implemented, then FEAT_PMUv3 is implemented.

The following fields identify the presence of FEAT_PMUv3p1:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.
- EDDFR.PMUVer.

For more information, see Required events.

FEAT_RDM, Advanced SIMD rounding double multiply-accumulate instructions

FEAT_RDM introduces Rounding Double Multiply Add/Subtract Advanced SIMD instructions. For more information, see:

For the A64 instruction set

- SQRDMLAH (by element).
- SQRDMLAH (vectors).
- SQRDMLSH (by element).
- SQRDMLSH (vector).

For the T32 and A32 instruction sets

- VQRDMLAH.
- VQRDMLSH.

This feature is supported in both AArch64 and AArch32 states.

FEAT_RDM is OPTIONAL from Armv8.0.

In an Armv8.1 implementation, if FEAT_AdvSIMD is implemented, FEAT_RDM is implemented.

The following fields identify the presence of FEAT_RDM:

- ID_AA64ISAR0_EL1.RDM.
- ID_ISAR5_EL1.RDM.
- ID_ISAR5.RDM.

FEAT_VHE, Virtualization Host Extensions

Armv8.1 introduces the *Virtualization Host Extensions* (VHE) that provide enhanced support for Type 2 hypervisors in Non-secure state.

FEAT_VHE is OPTIONAL from Armv8.0.

In an Armv8.1 implementation, if FEAT_AA64EL2 is implemented, FEAT_VHE is implemented.

If FEAT_VHE is implemented, then FEAT_LSE, FEAT_Debugv8p1, and FEAT_AA64EL2 are implemented.

The following field identifies the presence of FEAT_VHE:

- ID_AA64MMFR1_EL1.VH.

For more information, see Virtualization Host Extensions

FEAT_VMID16, 16-bit VMID

In an Armv8.1 implementation, when EL2 is using AArch64, the *virtual machine identifier* (VMID) size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits.

When implemented, this feature is supported only when EL2 is using AArch64.

FEAT_VMID16 is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_VMID16:

- ID_AA64MMFR1_EL1.VMIDBits.

For more information, see VMID size.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A2.2.2.1 Features added to the Armv8.1 extension in later releases

- FEAT_DPB2.
- FEAT_DotProd.
- FEAT_FHM.
- FEAT_FlagM.
- FEAT_PAN3.

A2.2.3 The Armv8.2 architecture extension

The Armv8.2 architecture extension is an extension to Armv8.1. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.2 compliant if all of the following apply:

- It is Armv8.1 compliant.
- It includes all of the Armv8.2 architectural features that are mandatory.

An Armv8.2 compliant implementation can additionally include any features that are defined to be optional in Armv8.2.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_AA32HPD, AArch32 Hierarchical permission disables

FEAT_HPDS introduced the ability to disable the hierarchical permissions, APTable, PXNTable, and UXNTable, in the VMSAv8-64 translation regimes. FEAT_AA32HPD extends this functionality to the VMSAv8-32 translation regimes when those regimes are using the Long descriptor Translation Table format.

This feature is supported in AArch32 state only.

FEAT_AA32HPD is OPTIONAL from Armv8.1.

If FEAT_AA32HPD is implemented, then FEAT_AA32 is implemented.

The following fields identify the presence of FEAT_AA32HPD:

- ID_MMFR4_EL1.HPDS.
- ID_MMFR4.HPDS.

For more information, see Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors

FEAT_AA32I8MM, AArch32 Int8 matrix multiply-accumulate

FEAT_AA32I8MM introduces integer matrix multiply-accumulate instructions and dot product instructions.

This feature is supported in AArch32 state only.

FEAT_AA32I8MM is OPTIONAL from Armv8.1.

If FEAT_AA32I8MM is implemented, then FEAT_I8MM is implemented.

If FEAT_AA32I8MM is implemented, then FEAT_AA32 is implemented.

The following fields identify the presence of FEAT_AA32I8MM:

- ID_ISAR6_EL1.I8MM.
- ID_ISAR6.I8MM.

For more information, see:

- Advanced SIMD dot product instructions.
- Advanced SIMD matrix multiply-accumulate instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_ASMv8p2, Armv8.2 changes to the A64 ISA

FEAT_ASMv8p2 introduces the BFC instruction to the A64 instruction set as an alias of BFM. It also requires that the BFC instruction and the A64 pseudo-instruction REV64 are implemented by assemblers.

In Armv8.0 and Armv8.1, the A64 pseudo-instruction REV64 is OPTIONAL.

FEAT_ASMv8p2 is OPTIONAL from Armv8.1.

FEAT_ASMv8p2 is mandatory from Armv8.2.

For more information, see:

- BFC.
- REV64.

FEAT_DPB, DC CVAP instruction

FEAT_DPB introduces a mechanism to identify and manage persistent memory locations in a shared memory hierarchy, including adding the DC CVAP instruction.

This feature is supported in AArch64 state only.

FEAT_DPB is OPTIONAL from Armv8.1.

FEAT_DPB is mandatory from Armv8.2.

The following field identifies the presence of FEAT_DPB:

- ID_AA64ISAR1_EL1.DPB.

For more information, see Memory hierarchy.

FEAT_Debugv8p2, Debug v8.2

FEAT_Debugv8p2 provides the following changes:

- If the Core power domain is powered up and DoubleLockStatus() == TRUE, EDPRSR.{DLK,SPD,PU} is only permitted to read {UNKNOWN, 0, 0}.
- The definition of Exception Catch debug events is extended to include reset entry.
- All CONSTRAINED UNPREDICTABLE cases that generate Exception Catch debug events are removed.
- Controls are added to EDECCR to control Exception Catch debug event generation on exception return.
- All IMPLEMENTATION DEFINED control of external debug accesses to OSLAR_EL1 is removed.
- ExternalSecureNoninvasiveDebugEnabled() cannot override software controls of counting attributable events in Secure state.

FEAT_Debugv8p2 is OPTIONAL from Armv8.1.

FEAT_Debugv8p2 is mandatory from Armv8.2.

If FEAT_Debugv8p2 is implemented, then FEAT_Debugv8p1 is implemented.

The following fields identify the presence of FEAT_Debugv8p2:

- ID_AA64DFR0_EL1.DebugVer.
- ID_DFR0_EL1.CopDbg.
- DBGDIDR.Version.
- ID_DFR0.CopDbg.
- EDDEVARCH.ARCHVER.

For more information, see:

- Exception Catch debug event.
- EDPRSR.{DLK, SPD, PU} and the Core power domain.
- Interaction with EL3.
- External access disabled.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_F32MM, Single-precision floating-point matrix multiply-accumulate

FEAT_F32MM introduces support for the SVE single-precision floating-point matrix multiply-accumulate variant of the FMMLA instruction.

This feature is supported in AArch64 state only.

FEAT_F32MM is OPTIONAL from Armv8.2.

If FEAT_F32MM is implemented, then FEAT_SVE is implemented.

The following field identifies the presence of FEAT_F32MM:

- ID_AA64ZFR0_EL1.F32MM.

FEAT_F64MM, Double-precision floating-point matrix multiply-accumulate

FEAT_F64MM introduces support for the following SVE instructions:

- FMMLA (double-precision floating-point matrix multiply-accumulate variant).
- LD1ROB (scalar plus immediate).
- LD1ROB (scalar plus scalar).
- LD1ROD (scalar plus immediate).
- LD1ROD (scalar plus scalar).
- LD1ROH (scalar plus immediate).
- LD1ROH (scalar plus scalar).
- LD1ROW (scalar plus immediate).
- LD1ROW (scalar plus scalar).
- TRN1, TRN2 (vectors) (128-bit variant).
- UZP1, UZP2 (vectors) (128-bit variant).
- ZIP1, ZIP2 (vectors) (128-bit variant).

This feature is supported in AArch64 state only.

FEAT_F64MM is OPTIONAL from Armv8.2.

If FEAT_F64MM is implemented, then FEAT_SVE is implemented.

The following field identifies the presence of FEAT_F64MM:

- ID_AA64ZFR0_EL1.F64MM.

FEAT_FP16, Half-precision floating-point data processing

FEAT_FP16 supports:

- Half-precision data-processing instructions for Advanced SIMD and floating-point.

The following fields enable flushing of denormalized numbers to zero for half-precision data-processing instructions:

- FPCR.FZ16.
- FPSCR.FZ16.

This feature is supported in both AArch64 and AArch32 states.

FEAT_FP16 is OPTIONAL from Armv8.2.

In an Armv8.4 implementation, if FEAT_FHM is not implemented, then FEAT_FP16 is not implemented.

In an Armv8.2 implementation, if FEAT_SVE or FEAT_FHM is implemented, FEAT_FP16 is implemented.

If FEAT_FP16 is implemented, then FEAT_FP is implemented.

If FEAT_FP16 is implemented, then FEAT_AdvSIMD is implemented.

The following fields identify the presence of FEAT_FP16:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64PFR0_EL1.FP.
- ID_AA64PFR0_EL1.AdvSIMD.
- EDPFR.FP.
- EDPFR.AdvSIMD.
- MVFR1_EL1.FPHP.
- MVFR1_EL1.SIMDHP.
- MVFR1.FPHP.
- MVFR1.SIMDHP.

For more information, see:

- Half-precision floating-point formats.
- Flushing denormalized numbers to zero.
- Modified immediate constants in A64 floating-point instructions.

FEAT_HPDS2, Hierarchical permission disables

FEAT_HPDS2 provides a mechanism to allow operating systems or hypervisors to make up to four bits of Translation Table final-level descriptors available for IMPLEMENTATION DEFINED hardware use.

This feature is supported in both AArch64 and AArch32 states.

FEAT_HPDS2 is OPTIONAL from Armv8.1.

When FEAT_AA32EL1 and FEAT_HPDS2 are implemented, FEAT_AA32HPD is implemented.

If FEAT_HPDS2 is implemented, then FEAT_HPDS is implemented.

The following fields identify the presence of FEAT_HPDS2:

- ID_AA64MMFR1_EL1.HPDS.
- ID_MMFR4_EL1.HPDS.
- ID_MMFR4.HPDS.

For more information, see:

- Page Based Hardware attributes.
- Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors.

FEAT_I8MM, AArch64 Int8 matrix multiply-accumulate

FEAT_I8MM introduces Advanced SIMD and SVE integer matrix multiply-accumulate instructions and dot product instructions.

This feature is supported in AArch64 state only.

FEAT_I8MM is OPTIONAL from Armv8.1.

FEAT_I8MM is mandatory from Armv8.6.

The following fields identify the presence of FEAT_I8MM:

- ID_AA64ISAR1_EL1.I8MM.
- ID_AA64ZFR0_EL1.I8MM.

For more information, see:

- SIMD integer dot product.
- SIMD integer matrix multiply-accumulate.
- SVE Integer dot product.
- SVE Integer matrix multiply operations.

Non-Confidential

FEAT_IESB, Implicit Error Synchronization event

FEAT_IESB introduces control for an implicit error synchronization event at exception entry and return.

The implicit error synchronization events affect the same synchronizable asynchronous events that are synchronized by the ESB instruction. This means that if an implementation has either no sources of SError exceptions, or all SError exceptions are not synchronizable errors, then the controls added by this feature have no effect.

This feature is supported in AArch64 state only.

FEAT_IESB is OPTIONAL from Armv8.1.

If FEAT_IESB is implemented, then FEAT_RAS is implemented.

The following field identifies the presence of FEAT_IESB:

- ID_AA64MMFR2_EL1.IESB.

For more information, see Error synchronization event.

FEAT_LPA, Large PA and IPA support

FEAT_LPA:

- Allows a larger *physical address* (PA) and *intermediate physical address* (IPA) space of up to 52 bits when using the 64KB translation granule.
- Allows a level 1 block size where the block covers a 4TB address range for the 64KB translation granule if the implementation support 52 bits of PA.

This feature is supported in AArch64 state only.

FEAT_LPA is OPTIONAL from Armv8.1.

The following field identifies the presence of FEAT_LPA:

- ID_AA64MMFR0_EL1.PARange.

For more information about FEAT_LPA, see:

- Implemented physical address size.
- Output address size configuration.
- Intermediate physical address size configuration
- Translation using the 64KB granule
- Table descriptor format
- Block descriptor and Page descriptor formats

FEAT_LSMAOC, AArch32 Load/Store Multiple instruction atomicity and ordering controls

FEAT_LSMAOC introduces controls that disable legacy behavior of AArch32 load multiple and store multiple instructions, and provide a trap of one aspect of this legacy behavior.

This feature is supported in both AArch64 and AArch32 states.

FEAT_LSMAOC is OPTIONAL from Armv8.1.

If FEAT_LSMAOC is implemented, then FEAT_AA32 is implemented.

The following fields identify the presence of FEAT_LSMAOC:

- ID_AA64MMFR2_EL1.LSM.
- ID_MMFR4_EL1.LSM.
- ID_MMFR4.LSM.

For more information, see the register field descriptions and:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Generation of Alignment faults by load/store multiple accesses to Device memory.
- Multi-register loads and stores that access Device memory.
- Taking an interrupt or other exception during a multiple-register load or store.

FEAT_LVA, Large VA support

FEAT_LVA supports a *virtual address* (VA) space for each translation table base register of up to 52 bits when using any of the following:

- VMSAv9-128 translation format.
- VMSAv8-64 translation format with the 64KB translation granule.

This feature is supported in AArch64 state only.

FEAT_LVA is OPTIONAL from Armv8.1.

The following field identifies the presence of FEAT_LVA:

- ID_AA64MMFR2_EL1.VARange.

For more information about FEAT_LVA, see:

- Supported virtual address ranges.
- Input address size configuration.
- Translation using the 64KB granule.

FEAT_PAN2, AT S1E1R and AT S1E1W instruction variants affected by PSTATE.PAN

FEAT_PAN2 introduces variants of the AArch64 AT S1E1R and AT S1E1W instructions and the AArch32 ATS1CPR and ATS1CPW instructions. These instructions factor in the PSTATE.PAN bit when determining whether or not the location will generate a Permission fault for a privileged access, as is reported in the PAR. For more information, see:

For the AArch64 System instructions:

- AT S1E1RP, Address Translate Stage 1 EL1 Read PAN.
- AT S1E1RP, Address Translate Stage 1 EL1 Write PA.

For the AArch32 System instructions:

- ATS1CPRP, Address Translate Stage 1 Current state PL1 Read PAN.
- ATS1CPRP, Address Translate Stage 1 Current state PL1 write PAN.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PAN2 is OPTIONAL from Armv8.1.

FEAT_PAN2 is mandatory from Armv8.2.

If FEAT_PAN2 is implemented, then FEAT_PAN is implemented.

The following fields identify the presence of FEAT_PAN2:

- ID_AA64MMFR1_EL1.PAN.
- ID_MMFR3_EL1.PAN.
- ID_MMFR3.PAN.

For more information, see:

- Address translation instructions.
- Address translation instructions.
- ATS1C**, Address translation stage 1, current security state.
- Encoding and availability of the address translation instructions.

FEAT_PCSRv8p2, PC Sample-based Profiling Extension

FEAT_PCSRv8p2 moves the control and implementation of the OPTIONAL PC Sample-based Profiling Extension from the ED*SR Debug registers to PM*SR registers in the Performance Monitors address space.

FEAT_PCSRv8p2 is OPTIONAL from Armv8.1.

If FEAT_PCSRv8p2 is implemented, then FEAT_PCSRv8 is not implemented.

The following field identifies the presence of FEAT_PCSRv8p2:

- PMDEVID.PCSample.

For more information, see The PC Sample-based Profiling Extension.

FEAT_RAS, Reliability, Availability and Serviceability (RAS) Extension

FEAT_RAS introduces the following:

- The *Error Synchronization Barrier* (ESB) instruction for the A32, T32, and A64 instruction sets.
- Error records.
- The Error synchronization event.
- Additional syndrome information on External Aborts.

FEAT_RAS is OPTIONAL from Armv8.0.

FEAT_RAS is mandatory from Armv8.2.

The following fields identify the presence of FEAT_RAS:

- ID_AA64PFR0_EL1.RAS.
- ID_PFR0_EL1.RAS.
- ID_PFR0.RAS.

For more information, see:

- Reliability, Availability, and Serviceability.
- RAS PE Architecture.
- *Arm® Reliability Availability and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

FEAT_SHA3, Advanced SIMD SHA3 instructions

FEAT_SHA3 introduces Advanced SIMD instructions that support SHA3 functionality.

These instructions are added to the A64 instruction set only.

FEAT_SHA3 is OPTIONAL from Armv8.1.

If FEAT_SHA3 is implemented, then FEAT_Crypto is implemented.

If FEAT_SHA3 is implemented, then FEAT_SHA256 and FEAT_SHA1 are implemented.

If FEAT_SHA3 is implemented, then FEAT_SHA512 is implemented.

The following field identifies the presence of FEAT_SHA3:

- ID_AA64ISAR0_EL1.SHA3.

For more information, see FEAT_SHA3, SHA3 functionality.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SHA512, Advanced SIMD SHA512 instructions

FEAT_SHA512 introduces Advanced SIMD instructions that support SHA2-512 functionality.

These instructions are added to the A64 instruction set only.

FEAT_SHA512 is OPTIONAL from Armv8.1.

If FEAT_SHA512 is implemented, then FEAT_Crypto is implemented.

If FEAT_SHA512 is implemented, then FEAT_SHA256 and FEAT_SHA1 are implemented.

If FEAT_SHA512 is implemented, then FEAT_SHA3 is implemented.

The following field identifies the presence of FEAT_SHA512:

- ID_AA64ISAR0_EL1.SHA2.

For more information, see FEAT_SHA512, SHA2-512 functionality.

FEAT_SM3, Advanced SIMD SM3 instructions

FEAT_SM3 introduces Advanced SIMD instructions that support the Chinese cryptography algorithm SM3.

These instructions are added to the A64 instruction set only.

FEAT_SM3 is OPTIONAL from Armv8.1.

If FEAT_SM3 is implemented, then FEAT_Crypto is implemented.

If FEAT_SM3 is implemented, then FEAT_SM4 is implemented.

The following field identifies the presence of FEAT_SM3:

- ID_AA64ISAR0_EL1.SM3.

For more information, see FEAT_SM3, SM3 functionality.

FEAT_SM4, Advanced SIMD SM4 instructions

FEAT_SM4 introduces Advanced SIMD instructions that support the Chinese cryptography algorithm SM4.

These instructions are added to the A64 instruction set only.

FEAT_SM4 is OPTIONAL from Armv8.1.

If FEAT_SM4 is implemented, then FEAT_Crypto is implemented.

If FEAT_SM4 is implemented, then FEAT_SM3 is implemented.

The following field identifies the presence of FEAT_SM4:

- ID_AA64ISAR0_EL1.SM4.

For more information, see FEAT_SM4, SM4 functionality.

FEAT_SPE, Statistical Profiling Extension

FEAT_SPE provides a non-invasive method of sampling software and hardware using randomized sampling of either architectural instructions, as defined by the instruction set architecture, or by microarchitectural operations.

This feature is supported in AArch64 state only.

FEAT_SPE is OPTIONAL from Armv8.1.

When FEAT_SPE and FEAT_PMUv3 are implemented, FEAT_PMUv3p1 is implemented.

The following field identifies the presence of FEAT_SPE:

- ID_AA64DFR0_EL1.PMSVer.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see The Statistical Profiling Extension.

FEAT_SPE_ArchInst, Statistical Profiling architectural instruction sampling

FEAT_SPE_ArchInst provides sampling of architectural instructions by FEAT_SPE. If FEAT_SPE is implemented and FEAT_SPE_ArchInst is not implemented, then the PE samples microarchitectural operations.

This feature is supported in AArch64 state only.

FEAT_SPE_ArchInst is OPTIONAL.

If FEAT_SPE_ArchInst is implemented, then FEAT_SPE is implemented.

The following field identifies the presence of FEAT_SPE_ArchInst:

- PMSIDR_EL1.ArchInst.

For more information, see The Statistical Profiling Extension.

FEAT_SPE_ERnd, Statistical Profiling random sampling at end of period

FEAT_SPE_ERnd provides a secondary counter, PMSICR_EL1.ECOUNT, that is used after the primary sample counter, PMSICR_EL1.COUNT, reaches zero when PMSIRR_EL1.RND is 1. If FEAT_SPE_ERnd is not implemented, then bits [7:0] of the primary counter are used to provide a random offset.

This feature is supported in AArch64 state only.

FEAT_SPE_ERnd is OPTIONAL.

If FEAT_SPE_ERnd is implemented, then FEAT_SPE is implemented.

The following field identifies the presence of FEAT_SPE_ERnd:

- PMSIDR_EL1.ERnd.

For more information, see The Statistical Profiling Extension.

FEAT_SPE_LDS, Statistical Profiling data source packet generation

FEAT_SPE_LDS indicates that the Statistical Profiling Unit (SPU) can generate Data Source packets.

This feature is supported in AArch64 state only.

FEAT_SPE_LDS is OPTIONAL.

If FEAT_SPE_LDS is implemented, then FEAT_SPE is implemented.

The following field identifies the presence of FEAT_SPE_LDS:

- PMSIDR_EL1.LDS.

FEAT_SVE, Scalable Vector Extension

The Scalable Vector Extension includes the following functionality:

- Configurable vector length with scalable vector lengths from 128 bits up to 2048 bits.
- Predication using scalable predicate registers from 16 bits up to 256 bits.
- Instructions that operate on scalable size vectors and predicates.
- Gather-load and scatter-store.
- Software-managed speculative vectorization.
- System registers and fields to configure the Effective SVE vector length and traps.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The Scalable Vector Extension complements the AArch64 Advanced SIMD and floating-point functionality. SVE does not replace the AArch64 Advanced SIMD and floating-point functionality.

This feature is supported in AArch64 state only.

FEAT_SVE is OPTIONAL from Armv8.2.

In an Armv8.3 implementation, if FEAT_SVE is implemented, FEAT_FCMA and FEAT_FP16 are implemented.

When FEAT_SVE and FEAT_PMUv3 are implemented, FEAT_PMUv3p1 is implemented.

The following field identifies the presence of FEAT_SVE:

- ID_AA64PFR0_EL1.SVE.

FEAT_TTCNP, Translation table Common not private translations

FEAT_TTCNP permits multiple PEs in the same Inner Shareable domain to use the same translation tables for a given stage of address translation.

This facility is available for all VMSAv8-64 translation regimes and for VMSAv8-32 translation stages that use the Long descriptor Translation Table format.

This feature is supported in both AArch64 and AArch32 states.

FEAT_TTCNP is OPTIONAL from Armv8.1.

FEAT_TTCNP is mandatory from Armv8.2.

The following fields identify the presence of FEAT_TTCNP:

- ID_AA64MMFR2_EL1.CnP.
- ID_MMFR4_EL1.CnP.
- ID_MMFR4.CnP.

For more information, see:

- Common not private translations.
- Common not private translations in VMSAv8-32.

FEAT_UAO, Unprivileged Access Override control

FEAT_UAO introduces the UAO bit to PSTATE. When the Effective value of UAO is 1, if memory accesses that are described as unprivileged are made by the unprivileged memory access instructions, they are privileged.

This feature is supported in AArch64 state only.

FEAT_UAO is OPTIONAL from Armv8.1.

FEAT_UAO is mandatory from Armv8.2.

The following field identifies the presence of FEAT_UAO:

- ID_AA64MMFR2_EL1.UAO.

For more information, see:

- PSTATE.UAO.
- Load/store unprivileged.
- UAO.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_XNX, Translation table stage 2 Unprivileged Execute-never

FEAT_XNX extends the stage 2 translation table access permissions to provide control of whether memory is executable at EL0 independent of whether it is executable at EL1.

This facility is available for stage 2 translation stages in VMSAv8-64 and VMSAv8-32.

This feature is supported in both AArch64 and AArch32 states.

FEAT_XNX is OPTIONAL from Armv8.1.

In an Armv8.2 implementation, if FEAT_EL2 is implemented, FEAT_XNX is implemented.

If FEAT_XNX is implemented, then FEAT_EL2 is implemented.

The following fields identify the presence of FEAT_XNX:

- ID_AA64MMFR1_EL1.XNX.
- ID_MMFR4_EL1.XNX.
- ID_MMFR4.XNX.

For more information, see:

- Stage 2 instruction execution using Direct permissions.
- Access permissions for instruction execution.

A2.2.3.1 Features added to the Armv8.2 extension in later releases

- FEAT_AA32BF16.
- FEAT_BF16.
- FEAT_EBF16.
- FEAT_EVT2.
- FEAT_EVT.
- FEAT_LRCPC2.
- FEAT_LRCPC3.
- FEAT_LSE2.
- FEAT_MPAM.
- FEAT_MPAMv1p0.
- FEAT_RASv1p1.

A2.2.4 The Armv8.3 architecture extension

The Armv8.3 architecture extension is an extension to Armv8.2. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.3 compliant if all of the following apply:

- It is Armv8.2 compliant.
- It includes all of the Armv8.3 architectural features that are mandatory.

An Armv8.3 compliant implementation can additionally include any features that are defined to be optional in Armv8.3.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_CCIDX, Extended cache index

FEAT_CCIDX introduces the following registers to allow caches to be described with greater numbers of sets and greater associativity:

- A 64-bit format of CCSIDR_EL1.
- CCSIDR2_EL1.
- CCSIDR2.

This feature is supported in both AArch64 and AArch32 states.

FEAT_CCIDX is OPTIONAL from Armv8.2.

The following fields identify the presence of FEAT_CCIDX:

- ID_AA64MMFR2_EL1.CCIDX.
- ID_MMFR4_EL1.CCIDX.
- ID_MMFR4.CCIDX.

For more information, see:

- Possible formats of the Cache Size Identification Register, CCSIDR_EL1.
- Possible formats of the Cache Size Identification Register, CCSIDR and CCSIDR2.

FEAT_CONSTPACFIELD, PAC algorithm enhancement

FEAT_CONSTPACFIELD introduces functionality that permits an implementation with pointer authentication to use the value of bit[55] in the virtual address to determine the size of the PAC field when adding a PAC to the virtual address, even when the top byte is not being ignored.

This feature is supported in AArch64 state only.

FEAT_CONSTPACFIELD is OPTIONAL from Armv8.2.

If FEAT_CONSTPACFIELD is implemented, then FEAT_PAuth2 is implemented.

The following field identifies the presence of FEAT_CONSTPACFIELD:

- ID_AA64ISAR2_EL1.PAC_frac.

For more information, see PAC field.

FEAT_DoPD, Debug over Powerdown

FEAT_DoPD provides a debug programmers' model where all debug and PMU registers are in the Core power domain and all CTI registers are in the Debug power domain. Power control is provided by an OPTIONAL external powerup request mechanism.

When FEAT_DoPD is implemented:

- The optional Software Lock is not implemented by the architecturally defined debug components in the PE Core power domain.
- If an ETMv4 trace unit is implemented, the ETM must implement:
  - FEAT_ETMv4p2.
  - The Unified Power Domain Model.
- If FEAT_ETE is implemented, the trace unit always implements a single power domain.

FEAT_DoPD is OPTIONAL from Armv8.2.

If FEAT_DoPD is implemented, then FEAT_DoubleLock is not implemented.

If FEAT_DoPD is implemented, then FEAT_Debugv8p2 is implemented.

The following field identifies the presence of FEAT_DoPD:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EDDEVID.DebugPower.

For more information, see Debug Reset and Powerdown Support.

FEAT_EPAC, Enhanced pointer authentication

FEAT_EPAC introduces functionality that permits setting the *Pointer Authentication Code* (PAC) field to 0 on performing a PAC operation on a non-canonical address.

Arm deprecates implementation of this feature.

This feature is supported in AArch64 state only.

FEAT_EPAC is OPTIONAL from Armv8.2.

If FEAT_EPAC is implemented, then FEAT_PAuth is implemented.

If FEAT_EPAC is implemented, then FEAT_PAuth2 is not implemented.

The following fields identify the presence of FEAT_EPAC:

- ID_AA64ISAR1_EL1.APA.
- ID_AA64ISAR1_EL1.API.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Pointer authentication.

FEAT_FCMA, Floating-point complex number instructions

FEAT_FCMA introduces instructions for floating-point multiplication and addition of complex numbers.

These instructions are added to the A64 and A32/T32 instruction sets.

FEAT_FCMA is OPTIONAL from Armv8.2.

In an Armv8.3 implementation, if FEAT_FP is implemented, FEAT_FCMA is implemented.

If FEAT_FCMA is implemented, then FEAT_FP is implemented.

The following fields identify the presence of FEAT_FCMA:

- ID_AA64ISAR1_EL1.FCMA.
- ID_ISAR5_EL1.VCMA.
- ID_ISAR5.VCMA.

For more information, see:

- AArch64 Advanced SIMD complex number arithmetic instructions.
- AArch32 Advanced SIMD complex number arithmetic instructions.

FEAT_FPAC, Faulting on AUT* instructions

FEAT_FPAC introduces faulting on an AUT* instruction.

FEAT_FPAC is added as a further extension to FEAT_PAuth2.

This feature is supported in AArch64 state only.

FEAT_FPAC is OPTIONAL from Armv8.2.

If FEAT_FPAC is implemented, then FEAT_PAuth2 is implemented.

The following fields identify the presence of FEAT_FPAC:

- ID_AA64ISAR1_EL1.APA.
- ID_AA64ISAR1_EL1.API.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64ISAR2_EL1.APA3.

For more information, see Faulting on pointer authentication.

FEAT_FPACCOMBINE, Faulting on combined pointer authentication instructions

FEAT_FPACCOMBINE introduces faulting on the combined instructions that perform pointer authentication.

FEAT_FPACCOMBINE is added as a further extension to FEAT_FPAC.

FEAT_FPACCOMBINE is OPTIONAL from Armv8.2.

If FEAT_FPACCOMBINE is implemented, then FEAT_FPAC is implemented.

The following fields identify the presence of FEAT_FPACCOMBINE:

- ID_AA64ISAR1_EL1.APA.
- ID_AA64ISAR1_EL1.API.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Faulting on pointer authentication.

FEAT_FPACC_SPEC, Speculative behavior of pointer authentication instructions

FEAT_FPACC_SPEC introduces consistent impact of speculation for instructions that perform authentication.

FEAT_FPACC_SPEC is added as a further extension to FEAT_FPACCOMBINE.

This feature is supported in AArch64 state only.

FEAT_FPACC_SPEC is OPTIONAL from Armv8.2.

If FEAT_FPACC_SPEC is implemented, then FEAT_FPACCOMBINE is implemented.

The following field identifies the presence of FEAT_FPACC_SPEC:

- ID_AA64MMFR3_EL1.Spec_FPACC.

For more information, see Faulting on pointer authentication.

FEAT_JSCVT, JavaScript conversion instructions

FEAT_JSCVT introduces JavaScript convert instructions that truncate a double-precision value to a 32-bit signed integer, setting the condition flags to indicate whether the converted value was in range.

These instructions are added to the A64 and A32/T32 instruction sets.

FEAT_JSCVT is OPTIONAL from Armv8.2.

In an Armv8.3 implementation, if FEAT_FP is implemented, FEAT_JSCVT is implemented.

If FEAT_JSCVT is implemented, then FEAT_FP is implemented.

The following fields identify the presence of FEAT_JSCVT:

- ID_AA64ISAR1_EL1.JSCVT.
- ID_ISAR6_EL1.JSCVT.
- ID_ISAR6.JSCVT.

For more information, see:

- Floating-point conversion.
- About the A64 Advanced SIMD and floating-point instructions.
- Advanced SIMD and floating-point instructions.
- Floating-point data-processing instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_LRCPC, Load-Acquire RCpc instructions

FEAT_LRCPC introduces instructions that support the weaker *Release Consistency processor consistent* (RCpc) model that enables the reordering of a Store-Release followed by a Load-Acquire to a different address.

These instructions are added to the A64 instruction set only.

FEAT_LRCPC is OPTIONAL from Armv8.2.

FEAT_LRCPC is mandatory from Armv8.3.

The following field identifies the presence of FEAT_LRCPC:

- ID_AA64ISAR1_EL1.LRCPC.

For more information, see:

- Load-Acquire, Load-AcquirePC, and Store-Release.
- Load-Acquire/Store-Release.

FEAT_NV, Nested Virtualization

FEAT_NV provides support for a Guest Hypervisor to run in EL1 and ensures that the Guest Hypervisor is unaware that it is running at that Exception level. A Guest Hypervisor is supported regardless of the Effective value of HCR_EL2.E2H.

This feature is supported in AArch64 state only.

FEAT_NV is OPTIONAL from Armv8.2.

If FEAT_NV is implemented, then FEAT_EL2 is implemented.

The following fields identify the presence of FEAT_NV:

- ID_AA64MMFR4_EL1.NV_frac.
- ID_AA64MMFR2_EL1.NV.

For more information, see Nested virtualization.

FEAT_PACIMP, Pointer authentication - IMPLEMENTATION DEFINED algorithm

FEAT_PACIMP permits an IMPLEMENTATION DEFINED cryptographic algorithm to be used for PAC calculation.

This feature is supported in AArch64 state only.

FEAT_PACIMP is OPTIONAL from Armv8.2.

If FEAT_PACIMP is implemented, then FEAT_PAuth is implemented.

If FEAT_PACIMP is implemented, then FEAT_PACQARMA5 is not implemented.

If FEAT_PACIMP is implemented, then FEAT_PACQARMA3 is not implemented.

The following fields identify the presence of FEAT_PACIMP:

- ID_AA64ISAR1_EL1.GPI.
- ID_AA64ISAR1_EL1.API.

For more information, see Pointer authentication.

FEAT_PACQARMA3, Pointer authentication - QARMA3 algorithm

FEAT_PACQARMA3 introduces the QARMA3 cryptographic algorithm for PAC calculation.

This feature is supported in AArch64 state only.

FEAT_PACQARMA3 is OPTIONAL from Armv8.2.

If FEAT_PACQARMA3 is implemented, then FEAT_PAuth is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_PACQARMA3 is implemented, then FEAT_PACQARMA5 is not implemented.

If FEAT_PACQARMA3 is implemented, then FEAT_PACIMP is not implemented.

The following fields identify the presence of FEAT_PACQARMA3:

- ID_AA64ISAR3_EL1.PACM.
- ID_AA64ISAR2_EL1.GPA3.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Pointer authentication.

FEAT_PACQARMA5, Pointer authentication - QARMA5 algorithm

FEAT_PACQARMA5 introduces the QARMA5 cryptographic algorithm for PAC calculation.

This feature is supported in AArch64 state only.

FEAT_PACQARMA5 is OPTIONAL from Armv8.2.

If FEAT_PACQARMA5 is implemented, then FEAT_PAuth is implemented.

If FEAT_PACQARMA5 is implemented, then FEAT_PACQARMA3 is not implemented.

If FEAT_PACQARMA5 is implemented, then FEAT_PACIMP is not implemented.

The following fields identify the presence of FEAT_PACQARMA5:

- ID_AA64ISAR3_EL1.PACM.
- ID_AA64ISAR1_EL1.GPA.
- ID_AA64ISAR1_EL1.APA.

For more information, see Pointer authentication.

FEAT_PAuth, Pointer authentication

FEAT_PAuth introduces functionality that supports address authentication of the contents of a register before that register is used as the target of an indirect branch, or as a load.

When FEAT_PAuth is implemented, all of the following must be true:

- Exactly one of the PAC algorithms is implemented.
- The PACGA instruction and other Pointer authentication instructions use the same algorithm.

The PAC algorithm features are:

- FEAT_PACQARMA5.
- FEAT_PACIMP.
- FEAT_PACQARMA3.

This feature is supported in AArch64 state only.

FEAT_PAuth is OPTIONAL from Armv8.2.

FEAT_PAuth is mandatory from Armv8.3.

The following fields identify the presence of FEAT_PAuth:

- ID_AA64ISAR1_EL1.APA.
- ID_AA64ISAR1_EL1.API.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Pointer authentication.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_PAuth2, Enhancements to pointer authentication

FEAT_PAuth2 introduces enhanced pointer authentication functionality that changes the mechanism by which a PAC is added to the pointer.

This feature is supported in AArch64 state only.

FEAT_PAuth2 is OPTIONAL from Armv8.2.

FEAT_PAuth2 is mandatory from Armv8.6.

If FEAT_PAuth2 is implemented, then FEAT_PAuth is implemented.

If FEAT_PAuth2 is implemented, then FEAT_EPAC is not implemented.

The following fields identify the presence of FEAT_PAuth2:

- ID_AA64ISAR1_EL1.APA.
- ID_AA64ISAR1_EL1.API.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Pointer authentication.

FEAT_SPEv1p1, Statistical Profiling Extension version 1.1

FEAT_SPEv1p1 introduces the following to the Statistical Profiling Extension:

- Support for an Alignment Flag in the Events packet and filtering on this event using PMSEVFR_EL1.
- Support for the profiling of Scalable Vector Extension operations.

This feature is supported in AArch64 state only.

FEAT_SPEv1p1 is OPTIONAL from Armv8.2.

In an Armv8.5 implementation, if FEAT_SPE is implemented, FEAT_SPEv1p1 is implemented.

If FEAT_SPEv1p1 is implemented, then FEAT_SPE is implemented.

The following field identifies the presence of FEAT_SPEv1p1:

- ID_AA64DFR0_EL1.PMSVer.

An implementation that includes FEAT_SVE and the Statistical Profiling Extension is strongly recommended to implement FEAT_SPEv1p1 whenever possible.

For more information, see:

- The Statistical Profiling Extension.
- Statistical Profiling Extension Sample Record Specification.

A2.2.5 The Armv8.4 architecture extension

The Armv8.4 architecture extension is an extension to Armv8.3. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.4 compliant if all of the following apply:

- It is Armv8.3 compliant.
- It includes all of the Armv8.4 architectural features that are mandatory.

An Armv8.4 compliant implementation can additionally include any features that are defined to be optional in Armv8.4.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_AMU_EXT, External interface to the Activity Monitors

FEAT_AMU_EXT indicates support for external access to the Activity Monitors.

FEAT_AMU_EXT is OPTIONAL.

If FEAT_AMU_EXT is implemented, then FEAT_AMU_EXT32 or FEAT_AMU_EXT64 is implemented.

If FEAT_AMU_EXT is implemented, then FEAT_AMUv1 is implemented.

FEAT_AMU_EXT32, 32-bit external interface to the Activity Monitors

FEAT_AMU_EXT32 indicates the external AMU registers are implemented as mostly 32-bit registers.

FEAT_AMU_EXT32 is OPTIONAL.

If FEAT_AMU_EXT32 is implemented, then FEAT_AMU_EXT is implemented.

If FEAT_AMU_EXT32 is implemented, then FEAT_AMU_EXT64 is not implemented.

The following field identifies the presence of FEAT_AMU_EXT32:

- AMDEVARCH.ARCHID.

For more information, see Recommended External Interface to the Activity Monitors.

FEAT_AMU_PIDR, Support for CoreSight compliance for external AMU registers

FEAT_AMU_PIDR provides registers for compliance with the CoreSight architecture.

This feature is required for compliance with the CoreSight architecture.

FEAT_AMU_PIDR is OPTIONAL from Armv8.0.

If FEAT_AMU_PIDR is implemented, then FEAT_AMU_EXT is implemented.

For more information, see Management registers and CoreSight compliance.

FEAT_AMUv1, Activity Monitors Extension version 1

FEAT_AMUv1 provides a function similar to a subset of the existing Performance Monitors Extension functionality, intended for system management use rather than debugging and profiling.

This feature is supported in both AArch64 and AArch32 states.

FEAT_AMUv1 is OPTIONAL from Armv8.3.

The following fields identify the presence of FEAT_AMUv1:

- ID_AA64PFR0_EL1.AMU.
- ID_PFR0_EL1.AMU.
- ID_PFR0.AMU.
- EDPFR.AMU.

For more information, see The Activity Monitors Extension.

FEAT_BBML1, Translation table break-before-make level 1

FEAT_BBML1 provides support for reducing the requirements for following a break-before-make sequence when changing between table or block sizes for a translation.

This feature is supported in AArch64 state only.

FEAT_BBML1 is OPTIONAL from Armv8.3.

The following field identifies the presence of FEAT_BBML1:

- ID_AA64MMFR2_EL1.BBM.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see:

- Block descriptor and Page descriptor formats.
- Block translation entry.
- Support levels for changing block size.

FEAT_BBML2, Translation table break-before-make level 2

FEAT_BBML2 provides support for further reducing the requirements for following a break-before-make sequences when changing between table or block sizes for a translation.

This feature is supported in AArch64 state only.

FEAT_BBML2 is OPTIONAL from Armv8.3.

If FEAT_BBML2 is implemented, then FEAT_BBML1 is implemented.

The following field identifies the presence of FEAT_BBML2:

- ID_AA64MMFR2_EL1.BBM.

For more information, see FEAT_BBML1.

FEAT_CNTSC, Generic Counter Scaling

FEAT_CNTSC introduces a scaling register to the memory-mapped counter module that allows the frequency of the counter that is generated to be scaled from the basic frequency reported in the counter ID mechanisms.

This feature is supported in both AArch64 and AArch32 states.

FEAT_CNTSC is OPTIONAL from Armv8.3.

The following field identifies the presence of FEAT_CNTSC:

- CNTID.CNTSC.

For more information, see CNTCR.

FEAT_DIT, Data Independent Timing instructions

FEAT_DIT provides a mechanism for software to indicate that a sequence of code is intended to be independent from data values from certain instructions within the sequence.

This feature is supported in both AArch64 and AArch32 states.

FEAT_DIT is OPTIONAL from Armv8.3.

FEAT_DIT is mandatory from Armv8.4.

The following fields identify the presence of FEAT_DIT:

- ID_AA64PFR0_EL1.DIT.
- ID_PFR0_EL1.DIT.
- ID_PFR0.DIT.

For more information, see:

- About PSTATE.DIT.
- About the DIT bit.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_Debugv8p4, Debug v8.4

FEAT_Debugv8p4 provides the following mandatory changes:

- The fields MDCR_EL3.{EPMAD, EDAD} control Non-secure access to the debug and PMU registers. The bus Requester is responsible for other debug authentication.
- The Software Lock is obsolete.
- Non-invasive Debug controls are relaxed.
- Secure and Non-secure views of the debug registers are enabled.

FEAT_Debugv8p4 is OPTIONAL from Armv8.3.

FEAT_Debugv8p4 is mandatory from Armv8.4.

If FEAT_Debugv8p4 is implemented, then FEAT_Debugv8p2 is implemented.

If FEAT_SEL2 is implemented, then FEAT_Debugv8p4 is implemented.

The following fields identify the presence of FEAT_Debugv8p4:

- ID_DFR0_EL1.CopDbg.
- ID_AA64DFR0_EL1.DebugVer.
- DBGDIDR.Version.
- ID_DFR0.CopDbg.
- EDDEVARCH.ARCHVER.

For more information, see:

- Definition and constraints of a debugger in the context of external debug.
- External debug interface register access permissions.

FEAT_DotProd, Advanced SIMD dot product instructions

FEAT_DotProd provides instructions to perform a four-way vector dot product of 8-bit integers, accumulating each sum of four products into a 32-bit integer. Each 8-bit input can be treated as a signed or unsigned value.

These instructions are added to the A64 and A32/T32 instruction sets.

FEAT_DotProd is OPTIONAL from Armv8.1.

In an Armv8.4 implementation, if FEAT_AdvSIMD is implemented, FEAT_DotProd is implemented.

The following fields identify the presence of FEAT_DotProd:

- ID_AA64ISAR0_EL1.DP.
- ID_ISAR6_EL1.DP.
- ID_ISAR6.DP.

For more information, see:

- SIMD integer dot product.
- Advanced SIMD dot product instructions.

FEAT_DoubleFault, Double Fault Extension

FEAT_DoubleFault provides controls for routing and masking error exceptions.

This feature is supported in AArch64 state only.

FEAT_DoubleFault is OPTIONAL from Armv8.3.

In an Armv8.4 implementation, if FEAT_AA64EL3 is implemented, FEAT_DoubleFault is implemented.

If FEAT_DoubleFault is implemented, then FEAT_DoubleFault2 or FEAT_AA64EL3 is implemented.

The following field identifies the presence of FEAT_DoubleFault:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64PFR0_EL1.RAS.

For more information, see:

- Taking error exceptions.
- Error synchronization event.

FEAT_FHM, Floating-point half-precision to single-precision multiply-add instructions

FEAT_FHM introduces half-precision to single-precision fused multiply-add instructions.

These instructions are added to the A64 and A32/T32 instruction sets.

FEAT_FHM is OPTIONAL from Armv8.1.

In an Armv8.4 implementation, if FEAT_FP16 is implemented, FEAT_FHM is implemented.

In an Armv8.2 implementation, if FEAT_FHM is implemented, FEAT_FP16 is implemented.

If FEAT_FHM is implemented, then FEAT_AdvSIMD is implemented.

The following fields identify the presence of FEAT_FHM:

- ID_AA64ISAR0_EL1.FHM.
- ID_ISAR6_EL1.FHM.
- ID_ISAR6.FHM.

For more information, see:

- SIMD arithmetic.
- SIMD by element arithmetic.
- Advanced SIMD multiply instructions.

FEAT_FlagM, Condition flag manipulation instructions

FEAT_FlagM provides instructions that manipulate the PSTATE.{N,Z,C,V} flags.

These instructions are added to the A64 instruction set only.

FEAT_FlagM is OPTIONAL from Armv8.1.

FEAT_FlagM is mandatory from Armv8.4.

The following field identifies the presence of FEAT_FlagM:

- ID_AA64ISAR0_EL1.TS.

For more information, see Flag manipulation instructions.

FEAT_IDST, ID space trap handling

FEAT_IDST causes all AArch64 read accesses to the feature ID space when exceptions are generated to be reported in ESR_ELx using the EC code `0x18`.

This feature is supported in AArch64 state only.

FEAT_IDST is OPTIONAL from Armv8.3.

FEAT_IDST is mandatory from Armv8.4.

The following field identifies the presence of FEAT_IDST:

- ID_AA64MMFR2_EL1.IDS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_LRCPC2, Load-Acquire RCpc instructions version 2

FEAT_LRCPC2 provides versions of `LDAPR` and `STLR` with a 9-bit unscaled signed immediate offset.

These instructions are added to the A64 instruction set only.

FEAT_LRCPC2 is OPTIONAL from Armv8.2.

FEAT_LRCPC2 is mandatory from Armv8.4.

If FEAT_LRCPC2 is implemented, then FEAT_LRCPC is implemented.

The following field identifies the presence of FEAT_LRCPC2:

- ID_AA64ISAR1_EL1.LRCPC.

For more information, see:

- Changes to single-copy atomicity in Armv8.4.
- Load-Acquire/Store-Release.
- A64 instructions that are changed in Debug state.

FEAT_LSE2, Large System Extensions version 2

FEAT_LSE2 introduces changes to single-copy atomicity requirements for loads and stores, and changes to alignment requirements for loads and stores.

This feature is supported in AArch64 state only.

FEAT_LSE2 is OPTIONAL from Armv8.2.

FEAT_LSE2 is mandatory from Armv8.4.

The following field identifies the presence of FEAT_LSE2:

- ID_AA64MMFR2_EL1.AT.

For more information, see:

- Requirements for single-copy atomicity.
- Alignment of data accesses.

FEAT_MPAM, Memory System Resource Partitioning and Monitoring Extension

The MPAM Extension provides a framework for memory-system component controls that partition one or more of the performance resources of the component. There are three versions of the MPAM extension: v1p0, v1p1, and v0p1.

This feature is supported in AArch64 state only.

FEAT_MPAM is OPTIONAL from Armv8.2.

If FEAT_MPAM is implemented, then FEAT_AA64 is implemented.

If FEAT_MPAM is implemented, then FEAT_MPAMv1p0 or FEAT_MPAMv0p1 is implemented.

For more information, see MPAM PE Architecture.

FEAT_MPAMv1p0, Memory Partitioning and Monitoring Extension version 1.0

FEAT_MPAMv1p0 introduces support for version 1.0 of the MPAM extension.

This feature is supported in AArch64 state only.

FEAT_MPAMv1p0 is OPTIONAL from Armv8.2.

If FEAT_MPAMv1p0 is implemented, then FEAT_MPAM is implemented.

If FEAT_MPAMv1p0 is implemented, then FEAT_MPAMv0p1 is not implemented.

The following field identifies the presence of FEAT_MPAMv1p0:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64PFR0_EL1.MPAM.

For more information, see MPAM PE Architecture.

FEAT_NV2, Enhanced nested virtualization support

FEAT_NV2 supports nested virtualization by redirecting register accesses that would be trapped to EL1 and EL2 to access memory instead. The address of the memory access depends on information held in VNCR_EL2.

This feature is supported in AArch64 state only.

FEAT_NV2 is OPTIONAL from Armv8.3.

If FEAT_NV2 is implemented, then FEAT_NV is implemented.

The following fields identify the presence of FEAT_NV2:

- ID_AA64MMFR4_EL1.NV_frac.
- ID_AA64MMFR2_EL1.NV.

For more information, see Enhanced support for nested virtualization.

FEAT_PMUv3p4, Armv8.4 PMU extensions

FEAT_PMUv3p4 introduces:

- PMMIR_EL1
- PMMIR registers.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PMUv3p4 is OPTIONAL from Armv8.3.

In an Armv8.4 implementation, if FEAT_PMUv3 is implemented, FEAT_PMUv3p4 is implemented.

If FEAT_PMUv3p4 is implemented, then FEAT_PMUv3p1 is implemented.

The following fields identify the presence of FEAT_PMUv3p4:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.
- EDDFR.PMUVer.

For more information, see PMU Event Descriptions.

FEAT_RASv1p1, RAS extension v1.1

FEAT_RASv1p1 introduces support for System register access to the following RAS System Architecture v1.1 features:

- Additional ERR<n>MISC<m> registers.
- The optional RAS Common Fault Injection Model Extension.

This feature is supported in both AArch64 and AArch32 states.

FEAT_RASv1p1 is OPTIONAL from Armv8.2.

In an Armv8.4 implementation, if FEAT_RAS is implemented, FEAT_RASv1p1 is implemented.

If FEAT_RASv1p1 is implemented, then FEAT_RAS is implemented.

If FEAT_RASv1p1 is implemented, then FEAT_RASSAv1p1 is implemented.

The following fields identify the presence of FEAT_RASv1p1:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64PFR0_EL1.RAS.
- ID_AA64PFR1_EL1.RAS_frac.
- ID_PFR0_EL1.RAS.
- ID_PFR2_EL1.RAS_frac.
- ID_PFR0.RAS.
- ID_PFR2.RAS_frac.

For more information, see *Arm® Reliability Availability and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

FEAT_S2FWB, Stage 2 forced Write-Back

FEAT_S2FWB reduces the requirement of additional cache maintenance instructions in systems where the data Cacheability attributes used by the Guest operating system are different from those expected by the Hypervisor. If this feature is implemented, there is no meaningful distinction between the Inner and Outer Shareability domains for accesses to Normal Cacheable memory.

This feature is supported in AArch64 state only.

FEAT_S2FWB is OPTIONAL from Armv8.3.

In an Armv8.4 implementation, if FEAT_AA64EL2 is implemented, FEAT_S2FWB is implemented.

If FEAT_S2FWB is implemented, then FEAT_AA64EL2 is implemented.

The following fields identify the presence of FEAT_S2FWB:

- ID_AA64MMFR2_EL1.FWB.
- CLIDR_EL1.LoUU.
- CLIDR_EL1.LoUIS.

For more information, see:

- Block descriptor and Page descriptor formats.
- Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled.

FEAT_SEL2, Secure EL2

FEAT_SEL2 permits EL2 to be implemented in Secure state. When Secure EL2 is enabled, a translation regime is introduced that follows the same format as the other Secure translation regimes.

This feature is not supported if EL2 is using AArch32.

FEAT_SEL2 is OPTIONAL from Armv8.3.

In an Armv8.4 implementation, if FEAT_AA64EL2 and FEAT_Secure are implemented, FEAT_SEL2 is implemented.

If FEAT_SEL2 is implemented, then FEAT_TTST is implemented.

If FEAT_SEL2 is implemented, then FEAT_PCSRv8 is not implemented.

If FEAT_SEL2 is implemented, then FEAT_EL2 is implemented.

If FEAT_SEL2 is implemented, then FEAT_Secure is implemented.

The following field identifies the presence of FEAT_SEL2:

- ID_AA64PFR0_EL1.SEL2.

For more information, see:

- Security states
- Translation regimes.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_TLBIOS, TLB invalidate instructions in Outer Shareable domain

FEAT_TLBIOS provides TLBI maintenance instructions that extend to the Outer Shareable domain.

This feature is supported in AArch64 state only.

FEAT_TLBIOS is OPTIONAL from Armv8.3.

FEAT_TLBIOS is mandatory from Armv8.4.

The following field identifies the presence of FEAT_TLBIOS:

- ID_AA64ISAR0_EL1.TLB.

For more information, see TLB maintenance instructions.

FEAT_TLBIRANGE, TLB invalidate range instructions

FEAT_TLBIRANGE provides TLBI maintenance instructions that apply to a range of input addresses.

This feature is supported in AArch64 state only.

FEAT_TLBIRANGE is OPTIONAL from Armv8.3.

FEAT_TLBIRANGE is mandatory from Armv8.4.

If FEAT_TLBIRANGE is implemented, then FEAT_TLBIOS is implemented.

The following field identifies the presence of FEAT_TLBIRANGE:

- ID_AA64ISAR0_EL1.TLB.

For more information, see:

- TLB maintenance instructions.
- TLB maintenance instructions that do not apply to a range of addresses.

FEAT_TRF, Self-hosted Trace extensions

FEAT_TRF introduces control of trace in a self-hosted system through System registers.

The feature provides:

- Control of Exception levels and Security states where trace generation is prohibited.
- Control of whether an offset is used for the timestamp recorded with trace information.
- A context synchronization instruction, TSB CSYNC, that can be used to prevent reordering of trace operation accesses with respect to other accesses of the same System registers.

This feature is supported in both AArch64 and AArch32 states.

FEAT_TRF is OPTIONAL from Armv8.3.

In an Armv8.4 implementation, if FEAT_ETMv4 and FEAT_TRC_SR are implemented, FEAT_TRF is implemented.

If FEAT_TRF is implemented, then FEAT_TRC_SR is implemented.

The following fields identify the presence of FEAT_TRF:

- ID_DFR0_EL1.TraceFilt.
- ID_AA64DFR0_EL1.TraceFilt.
- ID_DFR0.TraceFilt.
- EDDFR.TraceFilt.

For more information on FEAT_TRF, see:

- AArch64 Self-hosted Trace.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- AArch32 Self-hosted Trace.

If any of the following are true, then Arm recommends that FEAT_TRF is implemented, but this is not mandatory:

- An Armv8.4 implementation implements an IMPLEMENTATION DEFINED trace unit.
- An Armv9 implementation implements an IMPLEMENTATION DEFINED trace unit.
- An Armv8.4 implementation implements an ETM Architecture trace unit but does not implement FEAT_TRC_SR.

FEAT_TTL, Translation Table Level

FEAT_TTL provides the TTL field to indicate the level of translation table walk holding the leaf entry for the address that is being invalidated. This field is provided in all TLB maintenance instructions that take a VA or an IPA argument.

This feature is supported in AArch64 state only.

FEAT_TTL is OPTIONAL from Armv8.3.

FEAT_TTL is mandatory from Armv8.4.

The following field identifies the presence of FEAT_TTL:

- ID_AA64MMFR2_EL1.TTL.

For more information, see:

- TLB maintenance instructions.
- TLB maintenance instructions that do not apply to a range of addresses.

FEAT_TTST, Small translation tables

FEAT_TTST relaxes the lower limit on the size of translation tables, by increasing the maximum permitted value of the T1SZ and T0SZ fields in TCR_EL1, TCR_EL2, TCR_EL3, VTCR_EL2 and VSTCR_EL2.

This feature is supported in AArch64 state only.

FEAT_TTST is OPTIONAL from Armv8.3.

If FEAT_SEL2 is implemented, then FEAT_TTST is implemented.

The following field identifies the presence of FEAT_TTST:

- ID_AA64MMFR2_EL1.ST.

For more information, see:

- Input address size configuration.
- Translation using the 4KB granule.
- Translation using the 16KB granule.
- Translation using the 64KB granule.

A2.2.5.1 Features added to the Armv8.4 extension in later releases

- FEAT_AMU_EXTACR.

- FEAT_NV2p1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A2.2.6 The Armv8.5 architecture extension

The Armv8.5 architecture extension is an extension to Armv8.4. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.5 compliant if all of the following apply:

- It is Armv8.4 compliant.
- It includes all of the Armv8.5 architectural features that are mandatory.

An Armv8.5 compliant implementation can additionally include any features that are defined to be optional in Armv8.5.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_BTI, Branch Target Identification

FEAT_BTI allows memory pages to be guarded against the execution of instructions that are not the intended target of a branch. To do this, it introduces:

- The GP field, which denotes the blocks and pages in stage 1 translation tables that are guarded pages.
- The PSTATE.BTYPE field, which is used to determine whether an access to a guarded memory region will generate a Branch Target exception.
- The BTI instruction, which is used to guard against the execution of instructions that are not the intended target of a branch.

This feature is supported in AArch64 state only.

FEAT_BTI is OPTIONAL from Armv8.4.

FEAT_BTI is mandatory from Armv8.5.

The following field identifies the presence of FEAT_BTI:

- ID_AA64PFR1_EL1.BT.

For more information, see:

- Table descriptor format.
- PSTATE.BTYPE.
- Effect of entering Debug state on PSTATE.

FEAT_CSV3, Cache Speculation Variant 3

FEAT_CSV3 introduces a mechanism to identify whether data loaded or read from a register under speculation where the data load or register read would not be permitted architecturally, can be used by instructions newer than the load or register read in a manner that allows the value of the inaccessible data to be recovered by code architecturally executed.

This feature is supported in both AArch64 and AArch32 states.

FEAT_CSV3 is OPTIONAL from Armv8.0.

FEAT_CSV3 is mandatory from Armv8.5.

The following field identifies the presence of FEAT_CSV3:

- ID_AA64PFR0_EL1.CSV3.

FEAT_DPB2, DC CVADP instruction

FEAT_DPB2 allows two levels of cache clean to the Point of Persistence by:

- Redefining Point of Persistence, which changes the scope of DC CVAP.
- Defining a Point of Deep Persistence.
- Adding the DC CVADP System instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This feature is supported in AArch64 state only.

FEAT_DPB2 is OPTIONAL from Armv8.1.

FEAT_DPB2 is mandatory from Armv8.5.

If FEAT_DPB2 is implemented, then FEAT_DPB is implemented.

The following field identifies the presence of FEAT_DPB2:

- ID_AA64ISAR1_EL1.DPB.

For more information, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

FEAT_E0PD, Preventing EL0 access to halves of address maps

FEAT_E0PD prevents access at EL0 to half of the addresses in the memory map.

This feature is supported in AArch64 state only. When EL1 is using AArch64 state, this feature affects access to EL0, in either Execution state.

FEAT_E0PD is OPTIONAL from Armv8.4.

FEAT_E0PD is mandatory from Armv8.5.

If FEAT_E0PD is implemented, then FEAT_CSV3 is implemented.

The following field identifies the presence of FEAT_E0PD:

- ID_AA64MMFR2_EL1.E0PD.

For more information, see Preventing EL0 access to halves of the address map.

FEAT_EVT, Enhanced Virtualization Traps

FEAT_EVT introduces additional traps for EL1 and EL0 Cache controls in:

- HCR_EL2
- HCR2.

These traps are independent of existing controls.

This feature is supported in both AArch64 and AArch32 states.

FEAT_EVT is OPTIONAL from Armv8.2.

In an Armv8.5 implementation, if FEAT_EL2 is implemented, FEAT_EVT is implemented.

The following fields identify the presence of FEAT_EVT:

- ID_AA64MMFR2_EL1.EVT.
- ID_MMFR4_EL1.EVT.
- ID_MMFR4.EVT.

FEAT_EVT2, Enhanced Virtualization Traps 2

FEAT_EVT2 extends FEAT_EVT to introduce additional traps for further EL1 and EL0 system control operations in:

- HCR_EL2.
- HCR2.

This feature is supported in both AArch64 and AArch32 states.

FEAT_EVT2 is OPTIONAL from Armv8.2.

In an Armv8.5 implementation, if FEAT_EL2 is implemented, FEAT_EVT2 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_EVT2 is implemented, then FEAT_EVT is implemented.

The following fields identify the presence of FEAT_EVT2:

- ID_AA64MMFR2_EL1.EVT.
- ID_MMFR4_EL1.EVT.
- ID_MMFR4.EVT.

FEAT_ExS, Context synchronization and exception handling

FEAT_ExS provides a mechanism to control whether exception entry and exception return are Context Synchronization events.

Fields in the SCTLR_ELx registers enable and disable context synchronization at exception entry and return at an Exception level.

This feature is supported in AArch64 state only.

FEAT_ExS is OPTIONAL from Armv8.4.

The following field identifies the presence of FEAT_ExS:

- ID_AA64MMFR0_EL1.ExS.

For more information, see Context Synchronization event.

FEAT_FRINTTS, Floating-point to integer instructions

FEAT_FRINTTS provides instructions that round a floating-point number to an integral valued floating-point number that fits in a 32-bit or 64-bit integer number range.

These instructions are added to the A64 instruction set only.

FEAT_FRINTTS is OPTIONAL from Armv8.4.

In an Armv8.5 implementation, if FEAT_FP is implemented, FEAT_FRINTTS is implemented.

If FEAT_FRINTTS is implemented, then FEAT_FP and FEAT_AdvSIMD are implemented.

The following field identifies the presence of FEAT_FRINTTS:

- ID_AA64ISAR1_EL1.FRINTTS.

For more information, see Floating-point round to integral value.

FEAT_FlagM2, Enhancements to flag manipulation instructions

FEAT_FlagM2 provides instructions that convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format described in Condition flags and related instructions.

These instructions are added to the A64 instruction set only.

FEAT_FlagM2 is OPTIONAL from Armv8.4.

FEAT_FlagM2 is mandatory from Armv8.5.

If FEAT_FlagM2 is implemented, then FEAT_FlagM is implemented.

The following field identifies the presence of FEAT_FlagM2:

- ID_AA64ISAR0_EL1.TS.

For more information, see Flag manipulation instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_GTG, Guest translation granule size

FEAT_GTG allows a hypervisor to support different granule sizes for stage 2 and stage 1 translation, and allows a nested hypervisor to determine what stage 2 granule sizes are available.

This feature is supported in AArch64 state only.

FEAT_GTG is OPTIONAL from Armv8.0.

In an Armv8.5 implementation, if FEAT_AA64EL2 is implemented, FEAT_GTG is implemented.

The following fields identify the presence of FEAT_GTG:

- ID_AA64MMFR0_EL1.TGran4_2.
- ID_AA64MMFR0_EL1.TGran16_2.
- ID_AA64MMFR0_EL1.TGran64_2.

For more information, see Translation granules.

FEAT_MTE, Memory Tagging Extension

FEAT_MTE provides architectural support for runtime, always-on detection of various classes of memory error to aid with software debugging to eliminate vulnerabilities arising from memory-unsafe languages.

This feature is supported in AArch64 state only.

FEAT_MTE is OPTIONAL from Armv8.4.

The following field identifies the presence of FEAT_MTE:

- ID_AA64PFR1_EL1.MTE.

For more information, see:

- The Memory Tagging Extension.
- The AArch64 Application Level Memory Model.
- PMU Event Descriptions.
- The Statistical Profiling Extension.
- Debug State.

FEAT_MTE2, Memory Tagging Extension

FEAT_MTE2 provides architectural support for runtime, always-on detection of various classes of memory error to aid with software debugging to eliminate vulnerabilities arising from memory-unsafe languages.

This feature is supported in AArch64 state only.

FEAT_MTE2 is OPTIONAL from Armv8.4.

If FEAT_MTE2 is implemented, then FEAT_MTE is implemented.

The following field identifies the presence of FEAT_MTE2:

- ID_AA64PFR1_EL1.MTE.

For more information, see:

- The Memory Tagging Extension.
- The AArch64 Application Level Memory Model.
- PMU Event Descriptions.
- The Statistical Profiling Extension.
- Debug State.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_PMUv3p5, Armv8.5 PMU extensions

FEAT_PMUv3p5 extends event counters to 64-bit event counters, and introduces mechanisms to disable the cycle counter in Secure state, in EL3, and in EL2.

FEAT_PMUv3p5 relaxes the behavior of PMCR.{IMP, IDCODE}, and deprecates use of these fields.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PMUv3p5 is OPTIONAL from Armv8.4.

In an Armv8.5 implementation, if FEAT_PMUv3 is implemented, FEAT_PMUv3p5 is implemented.

If FEAT_PMUv3p5 is implemented, then FEAT_PMUv3p4 is implemented.

The following fields identify the presence of FEAT_PMUv3p5:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.
- EDDFR.PMUVer.

For more information, see:

- Behavior on overflow.
- Controlling the PMU counters.
- PMU Event Descriptions.

FEAT_RNG, Random number generator

FEAT_RNG introduces the RNDR and RNDRRS registers. Reads to these registers return a 64-bit random number. A read to RNDRRS will cause a reseeding of the random number before the generation of the random number that is returned.

This feature is supported in AArch64 state only.

FEAT_RNG is OPTIONAL from Armv8.4.

The following field identifies the presence of FEAT_RNG:

- ID_AA64ISAR0_EL1.RNDR.

For more information, see:

- Effect of random number generation instructions on Condition flags
- Appendix K14 Random Number Generation

FEAT_RNG_TRAP, Trapping support for RNDR/RNDRRS

FEAT_RNG_TRAP introduces support for EL3 trapping of reads of the RNDR and RNDRRS registers.

This feature is supported in AArch64 state only.

FEAT_RNG_TRAP is OPTIONAL from Armv8.4.

The following field identifies the presence of FEAT_RNG_TRAP:

- ID_AA64PFR1_EL1.RNDR_trap.

FEAT_S2TGran16K, Support for 16KB memory translation granule size at stage 2

FEAT_S2TGran16K is OPTIONAL.

If FEAT_S2TGran16K is implemented, then FEAT_AA64EL2 and FEAT_TGran16K are implemented.

The following field identifies the presence of FEAT_S2TGran16K:

- ID_AA64MMFR0_EL1.TGran16_2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_S2TGran4K, Support for 4KB memory translation granule size at stage 2

FEAT_S2TGran4K is OPTIONAL.

If FEAT_S2TGran4K is implemented, then FEAT_AA64EL2 and FEAT_TGran4K are implemented.

The following field identifies the presence of FEAT_S2TGran4K:

- ID_AA64MMFR0_EL1.TGran4_2.

FEAT_S2TGran64K, Support for 64KB memory translation granule size at stage 2

FEAT_S2TGran64K is OPTIONAL.

If FEAT_S2TGran64K is implemented, then FEAT_AA64EL2 and FEAT_TGran64K are implemented.

The following field identifies the presence of FEAT_S2TGran64K:

- ID_AA64MMFR0_EL1.TGran64_2.

FEAT_SB, Speculation Barrier

Speculation Barrier FEAT_SB introduces a barrier to control speculation.

This feature is supported in both AArch64 and AArch32 states.

FEAT_SB is OPTIONAL from Armv8.0.

FEAT_SB is mandatory from Armv8.5.

The following fields identify the presence of FEAT_SB:

- ID_AA64ISAR1_EL1.SB.
- ID_ISAR6_EL1.SB.
- ID_ISAR6.SB.

For more information, see:

- Speculation Barrier (SB).
- Barriers and CLREX instructions.
- Speculation Barrier (SB).
- Miscellaneous instructions.

FEAT_SPECRES, Speculation restriction instructions

FEAT_SPECRES introduces System instructions that prevent predictions based on information gathered from earlier execution within a particular execution context from affecting the later speculative execution within that context, to the extent that the speculative execution is observable through side channels.

This feature is supported in both AArch64 and AArch32 states.

FEAT_SPECRES is OPTIONAL from Armv8.0.

FEAT_SPECRES is mandatory from Armv8.5.

The following fields identify the presence of FEAT_SPECRES:

- ID_AA64ISAR1_EL1.SPECRES.
- ID_ISAR6_EL1.SPECRES.
- ID_ISAR6.SPECRES.

For more information, see:

- Prediction restriction instructions.
- Execution, data prediction and prefetching restriction System instructions.
- Execution and data prediction restriction System instructions.

Non-Confidential

FEAT_SSBS, Speculative Store Bypass Safe

FEAT_SSBS allows software to indicate whether hardware is permitted to load or store speculatively in a manner that could give rise to a cache timing side channel, which in turn could be used to derive an address from values loaded to a register from memory.

This feature is supported in both AArch64 and AArch32 states.

FEAT_SSBS is OPTIONAL from Armv8.0.

The following fields identify the presence of FEAT_SSBS:

- ID_AA64PFR1_EL1.SSBS.
- ID_PFR2_EL1.SSBS.
- ID_PFR2.SSBS.

For more information, see:

- AArch64 Speculative Store Bypass Safe.
- AArch32 Speculative Store Bypass Safe.

FEAT_SSBS2, MRS and MSR instructions for SSBS version 2

FEAT_SSBS2 provides controls for the MSR and MRS instructions to read and write the PSTATE.SSBS field.

This feature is supported in AArch64 state only.

FEAT_SSBS2 is OPTIONAL from Armv8.0.

If FEAT_SSBS2 is implemented, then FEAT_SSBS is implemented.

The following field identifies the presence of FEAT_SSBS2:

- ID_AA64PFR1_EL1.SSBS.

For more information, see:

- AArch64 Speculative Store Bypass Safe.
- AArch32 Speculative Store Bypass Safe.

A2.2.6.1 Features added to the Armv8.5 extension in later releases

- FEAT_MTE3.
- FEAT_MTE_ASYNC.

A2.2.7 The Armv8.6 architecture extension

The Armv8.6 architecture extension is an extension to Armv8.5. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.6 compliant if all of the following apply:

- It is Armv8.5 compliant.
- It includes all of the Armv8.6 architectural features that are mandatory.

An Armv8.6 compliant implementation can additionally include any features that are defined to be optional in Armv8.6.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_AA32BF16, AArch32 BFloat16 instructions

FEAT_AA32BF16 supports the BFloat16, or BF16, 16-bit floating-point storage format in AArch32 state. This format supports:

- Arithmetic instructions to multiply BFloat16 values and accumulate into single-precision results.
- Arithmetic instructions to accelerate dot product and matrix multiply-accumulate of BFloat16 values into single-precision results.
- Instructions to convert single-precision floating-point values to BFloat16 format.

This feature is supported in AArch32 state only.

FEAT_AA32BF16 is OPTIONAL from Armv8.2.

If FEAT_AA32BF16 is implemented, then FEAT_BF16 is implemented.

If FEAT_AA32BF16 is implemented, then FEAT_AA32 is implemented.

The following fields identify the presence of FEAT_AA32BF16:

- ID_ISAR6_EL1.BF16.
- ID_ISAR6.BF16.

For more information, see:

- BFloat16 floating-point format.
- Advanced SIMD BFloat16 instructions.
- Floating-point data-processing.

FEAT_AMUv1p1, Activity Monitors Extension version 1.1

FEAT_AMUv1p1 introduces support for virtualization of Activity Monitors event counters, and introduces controls to disable access to auxiliary event counters below the highest Exception level.

This feature is supported in AArch32 state and AArch64 state, if the hypervisor is using AArch64.

FEAT_AMUv1p1 is OPTIONAL from Armv8.5.

If FEAT_AMUv1p1 is implemented, then FEAT_AMUv1 is implemented.

The following fields identify the presence of FEAT_AMUv1p1:

- ID_AA64PFR0_EL1.AMU.
- ID_PFR0_EL1.AMU.
- ID_PFR0.AMU.
- EDPFR.AMU.

For more information, see The Activity Monitors Extension.

FEAT_BF16, AArch64 BFloat16 instructions

FEAT_BF16 supports the BFloat16 floating-point format in AArch64 state. This format supports:

- Arithmetic instructions to multiply BFloat16 values and accumulate into single-precision results.
- Arithmetic instructions to accelerate dot product and matrix multiply-accumulate of BFloat16 values into single-precision results.
- Instructions to convert single-precision floating-point values to BFloat16 format.

This feature is supported in AArch64 state only.

FEAT_BF16 is OPTIONAL from Armv8.2.

In an Armv8.6 implementation, if FEAT_FP is implemented, FEAT_BF16 is implemented.

The following fields identify the presence of FEAT_BF16:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64ISAR1_EL1.BF16.
- ID_AA64ZFR0_EL1.BF16.

For more information, see:

- BFloat16 floating-point format.
- Summary of BFloat16 instruction behaviors.

FEAT_CP15SDISABLE2, CP15SDISABLE2

FEAT_CP15SDISABLE2 provides an implementation-defined mechanism, the **CP15SDISABLE2** signal, which when asserted HIGH prevents writes to a set of Secure CP15 registers. This signal is analogous to the existing **CP15SDISABLE** signal.

This feature is supported only when EL3 is executing in AArch32 state.

FEAT_CP15SDISABLE2 is OPTIONAL from Armv8.0.

If FEAT_CP15SDISABLE2 is implemented, then FEAT_AA32EL3 is implemented.

For more information, see The CP15SDISABLE and CP15SDISABLE2 input signals.

FEAT_DGH, Data Gathering Hint

FEAT_DGH introduces the Data Gathering Hint instruction to the hint space.

These instructions are added to the A64 instruction set only.

FEAT_DGH is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_DGH:

- ID_AA64ISAR1_EL1.DGH.

For more information, see Hint instructions.

FEAT_ECV, Enhanced Counter Virtualization

FEAT_ECV enhances the Generic Timer architecture. FEAT_ECV provides:

- Self-synchronizing views of the virtual and physical timers in AArch64 state and AArch32 state.
- The ability to scale the generation of the event stream when executing in AArch64 state or AArch32 state.
- When EL2 is using AArch64 state, traps to EL0 and EL1 access to the virtual counter or timer registers, and the physical timer registers when accessed using an EL02 mnemonic. The traps are configured in CNTHCTL_EL2, and apply to EL1 and EL0 accesses, whether EL1 and EL0 are in AArch64 state or AArch32 state.

For more information on the offset to views of physical time, see FEAT_ECV_POFF.

This feature is supported in both AArch64 and AArch32 states.

FEAT_ECV is OPTIONAL from Armv8.5.

FEAT_ECV is mandatory from Armv8.6.

The following field identifies the presence of FEAT_ECV:

- ID_AA64MMFR0_EL1.ECV.

For more information, see:

- Self-hosted trace timestamps.
- The profiling data.
- The AArch64 view of the Generic Timer.
- The AArch32 view of the Generic Timer.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_ECV_POFF, Enhanced Counter Virtualization Physical Offset

FEAT_ECV_POFF provides an offset between the EL1 or EL0 view of physical time, and the EL2 or EL3 view of physical time.

The offset to views of physical time at EL1 and EL0 apply in AArch64 state and AArch32 state.

This feature is supported in both AArch64 and AArch32 states.

FEAT_ECV_POFF is OPTIONAL from Armv8.5.

If FEAT_ECV_POFF is implemented, then FEAT_ECV is implemented.

When FEAT_AA64 and FEAT_ECV_POFF are implemented, FEAT_AA64EL2 is implemented.

If FEAT_RME is implemented, then FEAT_ECV_POFF is implemented.

The following field identifies the presence of FEAT_ECV_POFF:

- ID_AA64MMFR0_EL1.ECV.

FEAT_FGT, Fine Grain Traps

FEAT_FGT introduces additional traps to EL2 of EL1 and EL0 access to individual or small groups of System registers and instructions, and traps to EL3 and EL2 of the Debug Communications Channel registers. The traps are independent of existing controls.

This feature is supported in AArch64, and when EL1 is using AArch64, EL0 accesses using AArch32 are also trapped.

FEAT_FGT is OPTIONAL from Armv8.5.

In an Armv8.6 implementation, if FEAT_AA64EL2 or FEAT_AA64EL3 is implemented, FEAT_FGT is implemented.

If FEAT_FGT is implemented, then FEAT_EL2 or FEAT_EL3 is implemented.

The following field identifies the presence of FEAT_FGT:

- ID_AA64MMFR0_EL1.FGT.

For more information, see Configurable instruction controls.

FEAT_HPMN0, Setting of MDCR_EL2.HPMN to zero

FEAT_HPMN0 permits a hypervisor to provide zero PMU event counters for a guest operating system by setting MDCR_EL2.HPMN to zero.

This feature is supported in both AArch64 and AArch32 states.

FEAT_HPMN0 is OPTIONAL from Armv8.5.

In an Armv8.8 implementation, if FEAT_PMUv3 and FEAT_EL2 are implemented, FEAT_HPMN0 is implemented.

If FEAT_HPMN0 is implemented, then FEAT_EL2 is implemented.

If FEAT_HPMN0 is implemented, then FEAT_PMUv3 and FEAT_FGT are implemented.

The following fields identify the presence of FEAT_HPMN0:

- ID_AA64DFR0_EL1.HPMN0.
- ID_DFR1_EL1.HPMN0.
- ID_DFR1.HPMN0.

For more information, see:

- Interaction with EL2.
- Controlling the PMU counters.
- The Performance Monitors Extension.
- The Performance Monitors Extension.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_MPAMv0p1, Memory System Resource Partitioning and Monitoring extension version 0.1

FEAT_MPAMv0p1 introduces support for version 0.1 of the MPAM extension.

This feature is supported in AArch64 state only.

FEAT_MPAMv0p1 is OPTIONAL from Armv8.5.

If FEAT_MPAMv0p1 is implemented, then FEAT_MPAM is implemented.

The following fields identify the presence of FEAT_MPAMv0p1:

- ID_AA64PFR0_EL1.MPAM.
- ID_AA64PFR1_EL1.MPAM_frac.

For more information, see MPAM PE Architecture.

FEAT_MPAMv1p1, Memory Partitioning and Monitoring extension version 1.1

FEAT_MPAMv1p1 introduces support for version 1.1 of the MPAM extension.

This feature is supported in AArch64 state only.

FEAT_MPAMv1p1 is OPTIONAL from Armv8.5.

If FEAT_MPAMv1p1 is implemented, then FEAT_MPAM is implemented.

If FEAT_MPAMv1p1 is implemented, then FEAT_MPAMv1p0 is implemented.

If FEAT_MPAMv1p1 is implemented, then FEAT_MPAMv0p1 is not implemented.

The following fields identify the presence of FEAT_MPAMv1p1:

- ID_AA64PFR0_EL1.MPAM.
- ID_AA64PFR1_EL1.MPAM_frac.

For more information, see MPAM PE Architecture.

FEAT_MTPMU, Multi-threaded PMU extensions

FEAT_MTPMU introduces controls to disable PMEVTYPER<n>_EL0.MT.

From Armv8.6, when FEAT_PMUv3 is implemented, multithreaded event counting is only supported in multithreaded implementations that also include FEAT_MTPMU.

This feature is supported in both AArch64 and AArch32 states.

FEAT_MTPMU is OPTIONAL from Armv8.5.

If FEAT_MTPMU is implemented, then FEAT_PMUv3 is implemented.

If FEAT_MTPMU is implemented, then FEAT_EL2 or FEAT_EL3 is implemented.

The following fields identify the presence of FEAT_MTPMU:

- ID_AA64DFR0_EL1.MTPMU.
- ID_DFR1.MTPMU.
- ID_DFR1_EL1.MTPMU.

For more information, see:

- Multithreaded implementations.
- MDCR_EL3.MTPME
- SDCR.MTPME
- MDCR_EL2.MTPME
- HDCR.MTPME.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_TWED, Delayed Trapping of WFE

FEAT_TWED introduces support for configurable delayed trapping of the WFE and WFET instructions.

FEAT_TWED is OPTIONAL from Armv8.5.

The following field identifies the presence of FEAT_TWED:

- ID_AA64MMFR1_EL1.TWED.

For more information, see The Wait for Event and Wait for Event with Timeout instructions.

A2.2.7.1 Features added to the Armv8.6 extension in later releases

- FEAT_SPE_DPFZS.

A2.2.8 The Armv8.7 architecture extension

The Armv8.7 architecture extension is an extension to Armv8.6. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.7 compliant if all of the following apply:

- It is Armv8.6 compliant.
- It includes all of the Armv8.7 architectural features that are mandatory.

An Armv8.7 compliant implementation can additionally include any features that are defined to be optional in Armv8.7.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_AFP, Alternate floating-point behavior

FEAT_AFP allows alternate behavior for specified floating-point instructions including:

- Flushing of denormalized numbers to zero can be controlled separately on inputs and outputs.
- Alternate NaN propagation rules and default NaN values can apply.
- Certain scalar SIMD and floating-point instructions can be configured to preserve higher numbered SIMD vector elements.
- Changes to floating-point exception generation.

This feature is supported in AArch64 state only.

FEAT_AFP is OPTIONAL from Armv8.6.

In an Armv8.7 implementation, if FEAT_FP is implemented, FEAT_AFP is implemented.

If FEAT_AFP is implemented, then FEAT_FP is implemented.

The following field identifies the presence of FEAT_AFP:

- ID_AA64MMFR1_EL1.AFP.

For more information, see:

- Flushing denormalized numbers to zero.
- NaN handling and the default NaN.
- Rounding.
- Floating-point exceptions and exception traps.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_EBF16, AArch64 Extended BFloat16 behaviors

FEAT_EBF16 supports the Extended BFloat16 behaviors.

This feature is supported in AArch64 state only.

FEAT_EBF16 is OPTIONAL from Armv8.2.

If FEAT_EBF16 is implemented, then FEAT_BF16 is implemented.

If FEAT_EBF16 is implemented, then FEAT_AdvSIMD, FEAT_FP, FEAT_SVE, or FEAT_SME is implemented.

The following fields identify the presence of FEAT_EBF16:

- ID_AA64ISAR1_EL1.BF16.
- ID_AA64ZFR0_EL1.BF16.

For more information, see:

- BFloat16 floating-point format.
- Floating-point behaviors for instructions that calculate sum-of-products.

FEAT_HCX, Support for the HCRX_EL2 register

FEAT_HCX introduces the Extended Hypervisor Configuration Register, HCRX_EL2, that provides configuration controls for virtualization in addition to those provided by HCR_EL2, including defining whether various operations are trapped to EL2.

This feature is supported in AArch64 state only.

FEAT_HCX is OPTIONAL from Armv8.6.

In an Armv8.7 implementation, if FEAT_AA64EL2 is implemented, FEAT_HCX is implemented.

When FEAT_AA64 and FEAT_HCX are implemented, FEAT_AA64EL2 is implemented.

The following field identifies the presence of FEAT_HCX:

- ID_AA64MMFR1_EL1.HCX.

For more information, see Configurable instruction controls.

FEAT_LPA2, Larger physical address for 4KB and 16KB translation granules

FEAT_LPA2:

- Allows a larger VA space for each translation table base register of up to 52 bits when using the 4KB or 16KB translation granules.
- Allows a larger intermediate physical address (IPA) and PA space of up to 52 bits when using the 4KB or 16KB translation granules.
- Allows a level 0 block size where the block covers a 512GB address range for the 4KB translation granule if the implementation supports 52 bits of PA.
- Allows a level 1 block size where the block covers a 64GB address range for the 16KB translation granule if the implementation supports 52 bits of PA.

This feature is supported in AArch64 state only.

FEAT_LPA2 is OPTIONAL from Armv8.6.

If FEAT_LPA2 is implemented, then FEAT_LVA is implemented.

The following fields identify the presence of FEAT_LPA2:

- ID_AA64MMFR0_EL1.TGran4_2.
- ID_AA64MMFR0_EL1.TGran16_2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64MMFR0_EL1.TGran4.
- ID_AA64MMFR0_EL1.TGran16.

For more information, see:

- Implemented physical address size.
- Output address size configuration.
- Supported virtual address ranges.
- Input address size configuration.
- Intermediate physical address size configuration.
- Translation using the 4KB granule.
- Translation using the 16KB granule.
- Table descriptor format.
- Block descriptor and Page descriptor formats.

FEAT_LS64, Support for 64-byte loads and stores without status

FEAT_LS64 introduces support for single-copy atomic 64-byte loads and stores without status result. For more information, see:

- LD64B.
- ST64B.

This feature is supported in AArch64 state only.

FEAT_LS64 is OPTIONAL from Armv8.6.

The following field identifies the presence of FEAT_LS64:

- ID_AA64ISAR1_EL1.LS64.

For more information, see Single-copy atomic 64-byte load/store.

FEAT_LS64_ACCDATA, Support for 64-byte EL0 stores with status

FEAT_LS64_ACCDATA introduces support for single-copy atomic 64-byte EL0 stores with status result. For more information, see:

- ST64BV0.
- ACCDATA_EL1.

Note

The meaning of any status being returned by the ST64BV0 instruction is defined by the peripheral providing the response.

This feature is supported in AArch64 state only.

FEAT_LS64_ACCDATA is OPTIONAL from Armv8.6.

If FEAT_LS64_ACCDATA is implemented, then FEAT_LS64_V is implemented.

The following field identifies the presence of FEAT_LS64_ACCDATA:

- ID_AA64ISAR1_EL1.LS64.

For more information, see Single-copy atomic 64-byte load/store.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_LS64_V, Support for 64-byte stores with status

FEAT_LS64_V introduces support for single-copy atomic 64-byte stores with status result. For more information, see:

- ST64BV.

Note

The meaning of any status being returned by the ST64BV instruction is defined by the peripheral providing the response.

This feature is supported in AArch64 state only.

FEAT_LS64_V is OPTIONAL from Armv8.6.

If FEAT_LS64_V is implemented, then FEAT_LS64 is implemented.

The following field identifies the presence of FEAT_LS64_V:

- ID_AA64ISAR1_EL1.LS64.

For more information, see Single-copy atomic 64-byte load/store.

FEAT_MTE3, MTE Asymmetric Fault Handling

FEAT_MTE3 introduces support for asymmetric Tag Check Fault handling.

This feature is supported in AArch64 state only.

FEAT_MTE3 is OPTIONAL from Armv8.5.

In an Armv8.7 implementation, if FEAT_MTE_ASYNC is implemented, FEAT_MTE3 is implemented.

If FEAT_MTE3 is implemented, then FEAT_MTE2 is implemented.

The following field identifies the presence of FEAT_MTE3:

- ID_AA64PFR1_EL1.MTE.

For more information, see The Memory Tagging Extension.

FEAT_MTE_ASYM_FAULT, Memory tagging asymmetric faults

FEAT_MTE_ASYM_FAULT introduces support for asymmetric MTE Tag Check fault handling.

This feature is supported in AArch64 state only.

FEAT_MTE_ASYM_FAULT is OPTIONAL.

If FEAT_MTE3 is implemented, then FEAT_MTE_ASYM_FAULT is implemented.

If FEAT_MTE_ASYM_FAULT is implemented, then FEAT_MTE3 is implemented.

In an Armv8.9 implementation, if FEAT_MTE_ASYM_FAULT is implemented, FEAT_MTE_ASYNC is implemented.

The following field identifies the presence of FEAT_MTE_ASYM_FAULT:

- ID_AA64PFR1_EL1.MTE.

FEAT_PAN3, Support for SCTLR_ELx.EPAN

FEAT_PAN3 introduces a bit to SCTLR_EL1 and SCTLR_EL2, EPAN, to support using Privileged Access Never with instruction accesses for stage 1 translation regimes.

This feature is supported in AArch64 state only.

FEAT_PAN3 is OPTIONAL from Armv8.1.

FEAT_PAN3 is mandatory from Armv8.7.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_PAN3 is implemented, then FEAT_PAN2 is implemented.

The following field identifies the presence of FEAT_PAN3:

- ID_AA64MMFR1_EL1.PAN.

For more information, see PSTATE PAN.

FEAT_PMUv3p7, Armv8.7 PMU extensions

FEAT_PMUv3p7 introduces the following to the Performance Monitors Extension:

- PMU counters can be frozen when an event counter has an unsigned overflow.
- Event counters can be prohibited from counting events at EL3 without affecting other Exception levels in Secure state.
- The cycle counter can be prohibited from counting cycles at EL3 without affecting other Exception levels in Secure state.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PMUv3p7 is OPTIONAL from Armv8.6.

In an Armv8.7 implementation, if FEAT_PMUv3 is implemented, FEAT_PMUv3p7 is implemented.

If FEAT_PMUv3p7 is implemented, then FEAT_PMUv3p5 is implemented.

The following fields identify the presence of FEAT_PMUv3p7:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.
- EDDFR.PMUVer.
- PMCFGR.FZO.

For more information, see:

- Controlling the PMU counters.
- Freezing event counters.

FEAT_RPRES, Increased precision of FRECPE and FRSQRTE

FEAT_RPRES allows an increase in the precision of the single-precision floating-point reciprocal estimate and reciprocal square root estimate from an 8-bit mantissa to a 12-bit mantissa.

This feature is supported in AArch64 state only.

FEAT_RPRES is OPTIONAL from Armv8.6.

If FEAT_RPRES is implemented, then FEAT_AFP is implemented.

The following field identifies the presence of FEAT_RPRES:

- ID_AA64ISAR2_EL1.RPRES.

For more information, see `RecipEstimate()` and `RecipSqrtEstimate()`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SPE_FnE, Statistical Profiling inverse event filter

FEAT_SPE_FnE provides the capability to filter sample records by the inverse value of bits in the sampled Events packet.

This feature is supported in AArch64 state only.

FEAT_SPE_FnE is OPTIONAL.

If FEAT_SPE_FnE is implemented, then FEAT_SPEv1p2 is implemented.

If FEAT_SPEv1p2 is implemented, then FEAT_SPE_FnE is implemented.

The following field identifies the presence of FEAT_SPE_FnE:

- PMSIDR_EL1.FnE.

For more information, see Filtering sample records.

FEAT_SPE_PBT, Statistical Profiling previous branch target

FEAT_SPE_PBT provides support for generating a packet that provides the target address for the previous taken branch.

This feature is supported in AArch64 state only.

FEAT_SPE_PBT is OPTIONAL.

If FEAT_SPE_PBT is implemented, then FEAT_SPEv1p2 is implemented.

The following field identifies the presence of FEAT_SPE_PBT:

- PMSIDR_EL1.PBT.

For more information, see:

- Previous branch target.
- Address packet.

FEAT_SPEv1p2, Statistical Profiling Extensions version 1.2

FEAT_SPEv1p2 introduces the following to the Statistical Profiling Extension:

- Controls to freeze the PMU event counters after an SPE buffer management event occurs.
- A discard mode that allows all SPE data to be discarded rather than written to memory.

This feature is supported in AArch64 state only.

FEAT_SPEv1p2 is OPTIONAL from Armv8.6.

In an Armv8.7 implementation, if FEAT_SPE is implemented, FEAT_SPEv1p2 is implemented.

If FEAT_SPEv1p2 is implemented, then FEAT_SPEv1p1 is implemented.

The following field identifies the presence of FEAT_SPEv1p2:

- ID_AA64DFR0_EL1.PMSVer.

For more information, see:

- Freezing event counters.
- Discard mode.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_WFxT, WFE and WFI instructions with timeout

FEAT_WFxT introduces WFET and WFIT. These instructions support the generation of a local timeout event to act as a wake-up event for the PE when the virtual count in CNTVCT_EL0 equals or exceeds the value supplied by the instruction for the first time.

These instructions are added to the A64 instruction set only.

FEAT_WFxT is OPTIONAL from Armv8.6.

FEAT_WFxT is mandatory from Armv8.7.

The following field identifies the presence of FEAT_WFxT:

- ID_AA64ISAR2_EL1.WFxT.

For more information, see:

- Wait for Event.
- Wait for Interrupt mechanism.

FEAT_XS, XS attribute

FEAT_XS introduces the XS attribute for memory to indicate that an access could take a long time to complete. This feature provides variants of DSB instructions and TLB maintenance instructions, the completion of which does not depend on the completion of memory accesses with the XS attribute.

FEAT_XS adds:

- A mechanism to define the XS attribute for memory.
- An optional nXS variant to the AArch64 DSB instruction and OPTIONAL nXS qualifier to each AArch64 TLBI instruction to handle memory accesses with the XS attribute.
- The HCRX_EL2.FGTnXS bit to determine the behavior of fine-grained traps in HFGITR_EL2 for TLB maintenance instructions with the nXS qualifier.
- The HCRX_EL2.FnXS bit to determine the behavior of pre-existing TLB maintenance instructions in relation to the XS attribute.

This feature is supported in AArch64 state only, but the XS attribute also impacts AArch32 state execution.

FEAT_XS is OPTIONAL from Armv8.6.

FEAT_XS is mandatory from Armv8.7.

The following field identifies the presence of FEAT_XS:

- ID_AA64ISAR1_EL1.XS.

For more information, see:

- Data Synchronization Barrier (DSB).
- Behavior when stage 1 address translation is disabled.
- Block descriptor and Page descriptor formats.
- Stage 1 memory type and Cacheability attributes.
- XS attribute modifier.
- Overview of memory region attributes for stage 1 translations.
- Ordering and completion of TLB maintenance instructions.

A2.2.8.1 Features added to the Armv8.7 extension in later releases

- FEAT_CSSC.
- FEAT_HAFT.
- FEAT_MTE4.
- FEAT_MTE_PERM.

A2.2.9 The Armv8.8 architecture extension

The Armv8.8 architecture extension is an extension to Armv8.7. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.8 compliant if all of the following apply:

- It is Armv8.7 compliant.
- It includes all of the Armv8.8 architectural features that are mandatory.

An Armv8.8 compliant implementation can additionally include any features that are defined to be optional in Armv8.8.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_CMOW, Control for cache maintenance permission

FEAT_CMOW introduces support for controlling the required permissions for some cache maintenance instructions that operate by VA and perform translation such that:

- Stage 1 can be configured to generate a Permission fault if write permission is not present for cache maintenance instructions executed at EL0.
- Stage 2 can be configured to generate a Permission fault if write permission is not present for cache maintenance instructions executed at EL1 or EL0.

This feature is supported in AArch64 state only, but also impacts AArch32 instructions.

FEAT_CMOW is OPTIONAL from Armv8.7.

FEAT_CMOW is mandatory from Armv8.8.

The following field identifies the presence of FEAT_CMOW:

- ID_AA64MMFR1_EL1.CMOW.

For more information, see:

- A64 Cache maintenance instructions.
- Permission fault.

FEAT_Debugv8p8, Debug v8.8

FEAT_Debugv8p8 introduces support to allow another exception to be taken after an exception which generates an Exception Catch debug event, before the PE halts.

This feature is supported in both AArch64 and AArch32 states.

FEAT_Debugv8p8 is OPTIONAL from Armv8.7.

FEAT_Debugv8p8 is mandatory from Armv8.8.

If FEAT_Debugv8p8 is implemented, then FEAT_Debugv8p4 is implemented.

The following fields identify the presence of FEAT_Debugv8p8:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64DFR0_EL1.DebugVer.
- ID_DFR0_EL1.CopDbg.
- DBGDIDR.Version.
- ID_DFR0.CopDbg.
- EDDEVARCH.ARCHVER.

For more information, see Exception Catch debug event.

FEAT_HBC, Hinted conditional branches

FEAT_HBC provides the BC.cond instruction to give a conditional branch to a label at a PC-relative offset, with a hint that this branch is very unlikely to change direction.

This feature is supported in AArch64 state only.

FEAT_HBC is OPTIONAL from Armv8.7.

FEAT_HBC is mandatory from Armv8.8.

The following field identifies the presence of FEAT_HBC:

- ID_AA64ISAR2_EL1.BC.

For more information, see Conditional branch.

FEAT_MOPS, Standardization of memory operations

FEAT_MOPS provides instructions that perform a memory copy or memory set, and introduces Memory Copy and Memory Set exceptions.

FEAT_MOPS also introduces the HCRX_EL2.{MSCEn, MCE2}, SCTLR_EL1.MSCEn, and SCTLR_EL2.MSCEn control bits.

This feature is supported in AArch64 state only.

FEAT_MOPS is OPTIONAL from Armv8.7.

FEAT_MOPS is mandatory from Armv8.8.

The following field identifies the presence of FEAT_MOPS:

- ID_AA64ISAR2_EL1.MOPS.

For more information, see:

- Memory Copy and Memory Set instructions.
- Memory Copy and Memory Set exceptions.

FEAT_NMI, Non-maskable Interrupts

FEAT_NMI provides a mechanism to support *non-maskable interrupts* (NMI) and *less-masked interrupts* (LMI). In addition to legacy behavior, the feature includes the following:

- A mode for supporting an LMI interrupt mask that is distinct from PSTATE.{I, F}.
- A mode for supporting a limited NMI, where the value when PSTATE.SP is 1 is taken as an interrupt mask for all interrupts targeting that Exception level, and where the LMI interrupt mask can also be used

FEAT_NMI adds:

- The AllIntMask variable.
- An Optional Superpriority attribute to denote virtual and physical IRQ and FIQ interrupts as non-maskable.
- The SCTLR_ELx.{NMI, SPINTMASK} control bits.
- The PSTATE.ALLINT bit and associated instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The HCRX_EL2.TALLINT bit to enable trapping of ALLINT instructions at EL1.

This feature is supported in AArch64 state only.

FEAT_NMI is OPTIONAL from Armv8.7.

FEAT_NMI is mandatory from Armv8.8.

When FEAT_GICv3 and FEAT_NMI are implemented, FEAT_GICv3_NMI is implemented.

The following field identifies the presence of FEAT_NMI:

- ID_AA64PFR1_EL1.NMI.

For more information, see:

- Asynchronous exception types.
- Virtual interrupts.
- PSTATE fields that are meaningful in AArch64 state.
- WFE wake-up events.

FEAT_PMUv3_EXT64, 64-bit external interface to the Performance Monitors

FEAT_PMUv3_EXT64 indicates the external Performance Monitors registers are implemented as 64-bit registers. The 32-bit CoreSight management registers remain 32-bit registers.

FEAT_PMUv3_EXT64 is OPTIONAL from Armv8.8.

If FEAT_PMUv3_EXT64 is implemented, then FEAT_PMUv3_EXT is implemented.

If FEAT_PMUv3_EXT64 is implemented, then FEAT_PMUv3_EXT32 is not implemented.

The following fields identify the presence of FEAT_PMUv3_EXT64:

- PMDEVARCH.ARCHVER.
- PMDEVARCH.ARCHPART.

For more information, see Recommended External Interface to the Performance Monitors.

FEAT_PMUv3_TH, Event counting threshold

FEAT_PMUv3_TH introduces threshold condition controls to each PMEVTYPER<n>_EL0 register. This feature permits the counter to count only when PMEVTYPER<n>.{MT, evtCount} describe an event whose count meets a specified threshold condition.

This feature is supported in both AArch64 and AArch32 states. The threshold condition controls are accessible only in AArch64 state. However, threshold conditions still apply in AArch32 state.

FEAT_PMUv3_TH is OPTIONAL from Armv8.7.

If FEAT_PMUv3_TH is implemented, then FEAT_PMUv3 is implemented.

The following fields identify the presence of FEAT_PMUv3_TH:

- PMMIR_EL1.THWIDTH.
- PMMIR.THWIDTH.
- PMMIR.THWIDTH.

For more information, see Event threshold and edge counting.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_PMUv3p8, Armv8.8 PMU extensions

FEAT_PMUv3p8 introduces the following to the Performance Monitors Extension:

- The Common event number space is extended to include the ranges `0x0040-0x00BF` and `0x4040-0x40BF`.
- For an event counter n, if any reserved or unimplemented PMU event number is written to PMEVTYPER<n>.evtCount, then event counter n does not count, and a read of PMEVTYPER<n>.evtCount returns the value written.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PMUv3p8 is OPTIONAL from Armv8.7.

In an Armv8.8 implementation, if FEAT_PMUv3 is implemented, FEAT_PMUv3p8 is implemented.

If FEAT_PMUv3p8 is implemented, then FEAT_PMUv3p7 is implemented.

The following fields identify the presence of FEAT_PMUv3p8:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.
- EDDFR.PMUVer.

For more information, see PMU Event Descriptions.

FEAT_SCTLR2, Extension to SCTLR_ELx

FEAT_SCTLR2 introduces the SCTLR2_ELx registers, which provide top-level control of the system, including its memory system. These registers are extensions of the corresponding SCTLR_ELx registers.

This feature is supported in AArch64 state only.

FEAT_SCTLR2 is OPTIONAL from Armv8.0.

FEAT_SCTLR2 is mandatory from Armv8.9.

When FEAT_SCTLR2 and FEAT_AA64EL2 are implemented, FEAT_HCX is implemented.

The following field identifies the presence of FEAT_SCTLR2:

- ID_AA64MMFR3_EL1.SCTLRX.

FEAT_SPEv1p3, Statistical Profiling Extensions version 1.3

FEAT_SPEv1p3 introduces the following to the Statistical Profiling Extension:

- Support for sampling Tag operations.
- Support for sampling Memory Copy and Set operations.

This feature is supported in AArch64 state only.

FEAT_SPEv1p3 is OPTIONAL from Armv8.7.

In an Armv8.8 implementation, if FEAT_SPE is implemented, FEAT_SPEv1p3 is implemented.

If FEAT_SPEv1p3 is implemented, then FEAT_SPEv1p2 is implemented.

The following field identifies the presence of FEAT_SPEv1p3:

- ID_AA64DFR0_EL1.PMSVer.

For more information, see:

- Additional information for each profiled memory access operation.
- About the Statistical Profiling Extension sample records.
- Address packet.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_TCR2, Support for TCR2_ELx

FEAT_TCR2 introduces the TCR2_ELx registers which provide top-level control of the EL1&0 and EL2&0 translation regimes respectively. These registers are extensions of the corresponding TCR_ELx registers.

This feature is supported in AArch64 state only.

FEAT_TCR2 is OPTIONAL from Armv8.0.

FEAT_TCR2 is mandatory from Armv8.9.

When FEAT_TCR2 and FEAT_AA64EL2 are implemented, FEAT_HCX is implemented.

The following field identifies the presence of FEAT_TCR2:

- ID_AA64MMFR3_EL1.TCRX.

FEAT_TIDCP1, EL0 use of IMPLEMENTATION DEFINED functionality

FEAT_TIDCP1 introduces a control at EL1 and EL2 to enable trapping of EL0 accesses to registers that might control IMPLEMENTATION DEFINED functions.

This feature introduces controls only in AArch64 state, and controls IMPLEMENTATION DEFINED execution at EL0 in both AArch32 and AArch64 states.

FEAT_TIDCP1 is OPTIONAL from Armv8.7.

FEAT_TIDCP1 is mandatory from Armv8.8.

The following field identifies the presence of FEAT_TIDCP1:

- ID_AA64MMFR1_EL1.TIDCP1.

For more information, see Prioritization of Synchronous exceptions taken to AArch64 state

A2.2.10 The Armv8.9 architecture extension

The Armv8.9 architecture extension is an extension to Armv8.8. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.9 compliant if all of the following apply:

- It is Armv8.8 compliant.
- It includes all of the Armv8.9 architectural features that are mandatory.

An Armv8.9 compliant implementation can additionally include any features that are defined to be optional in Armv8.9.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_ADERR, Asynchronous Device Error Exceptions

FEAT_ADERR introduces controls for whether an error signaled on a load from Device memory is handled precisely and synchronously.

This feature is supported in both AArch64 and AArch32 states.

FEAT_ADERR is OPTIONAL from Armv8.8.

If FEAT_ADERR is implemented, then FEAT_SCTLR2 is implemented.

When FEAT_ADERR and FEAT_AA64EL2 are implemented, FEAT_HCX is implemented.

The following fields identify the presence of FEAT_ADERR:

- ID_AA64MMFR3_EL1.ADERR.
- ID_AA64MMFR3_EL1.SDERR.

For more information, see:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- About the RAS Extension.
- Taking error exceptions.

FEAT_AIE, Memory Attribute Index Enhancement

FEAT_AIE increases the stage 1 descriptor attribute index bit width from 3 to 4, allowing use of up to 16 memory attributes.

This feature is supported in AArch64 state only.

FEAT_AIE is OPTIONAL from Armv8.8.

If FEAT_AIE is implemented, then FEAT_TCR2 is implemented.

If FEAT_AIE is implemented, then FEAT_HPDS is implemented.

The following field identifies the presence of FEAT_AIE:

- ID_AA64MMFR3_EL1.AIE.

For more information, see Stage 1 memory type and Cacheability attributes.

FEAT_AMU_EXT64, 64-bit external interface to the Activity Monitors

FEAT_AMU_EXT64 indicates the external AMU registers are implemented as 64-bit registers.

FEAT_AMU_EXT64 is OPTIONAL.

If FEAT_AMU_EXT64 is implemented, then FEAT_AMU_EXT is implemented.

If FEAT_AMU_EXT64 is implemented, then FEAT_AMU_EXT32 is not implemented.

The following field identifies the presence of FEAT_AMU_EXT64:

- AMDEVARCH.ARCHID.

For more information, see Recommended External Interface to the Activity Monitors.

FEAT_ANERR, Asynchronous Normal Error Exceptions

FEAT_ANERR introduces controls for whether an error signaled on a load from Normal memory is handled precisely and synchronously.

This feature is supported in both AArch64 and AArch32 states.

FEAT_ANERR is OPTIONAL from Armv8.8.

If FEAT_ANERR is implemented, then FEAT_SCTLR2 is implemented.

When FEAT_ANERR and FEAT_AA64EL2 are implemented, FEAT_HCX is implemented.

The following fields identify the presence of FEAT_ANERR:

- ID_AA64MMFR3_EL1.ANERR.
- ID_AA64MMFR3_EL1.SNERR.

For more information, see:

- About the RAS Extension.
- Taking error exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_ATS1A, Address Translation operations that ignore stage 1 permissions

FEAT_ATS1A introduces instructions that provide the output address and attributes of a valid translation without checking for stage 1 permissions.

These instructions are added to the A64 instruction set only.

FEAT_ATS1A is OPTIONAL from Armv8.8.

The following field identifies the presence of FEAT_ATS1A:

- ID_AA64ISAR2_EL1.ATS1A.

FEAT_CLRBHB, Support for Clear Branch History instruction

FEAT_CLRBHB provides a CLRBHB instruction, which can be used to clear the branch history.

This feature is supported in both AArch64 and AArch32 states.

FEAT_CLRBHB is OPTIONAL from Armv8.0.

FEAT_CLRBHB is mandatory from Armv8.9.

The following fields identify the presence of FEAT_CLRBHB:

- ID_AA64ISAR2_EL1.CLRBHB.
- ID_ISAR6_EL1.CLRBHB.
- ID_ISAR6.CLRBHB.

For more information, see:

- Branch prediction.
- AArch32 cache and branch predictor maintenance instructions.

FEAT_CSSC, Common Short Sequence Compression instructions

FEAT_CSSC introduces a set of instructions for optimization of short instruction sequences using general-purpose registers.

This feature is supported in AArch64 state only.

FEAT_CSSC is OPTIONAL from Armv8.7.

FEAT_CSSC is mandatory from Armv8.9.

The following field identifies the presence of FEAT_CSSC:

- ID_AA64ISAR2_EL1.CSSC.

For more information, see:

- Integer minimum and maximum (immediate).
- Integer maximum and minimum (register).
- Absolute value.
- Bit operation.

FEAT_Debugv8p9, Debug v8.9

FEAT_Debugv8p9 introduces all of the following:

- The ability to implement more than 16 breakpoints.
- The ability to implement more than 16 watchpoints.
- DBGBCR<n>_EL1 and DBGWCR<n>_EL1 are 64-bit registers in the external debug interface.
- DSPSR2 is added to extend DSPSR for holding the saved process state for Debug state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This feature is supported in both AArch64 and AArch32 states.

FEAT_Debugv8p9 is OPTIONAL from Armv8.8.

FEAT_Debugv8p9 is mandatory from Armv8.9.

If FEAT_Debugv8p9 is implemented, then FEAT_Debugv8p8 is implemented.

When FEAT_Debugv8p9 and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

The following fields identify the presence of FEAT_Debugv8p9:

- ID_AA64DFR0_EL1.DebugVer.
- ID_DFR0_EL1.CopDbg.
- ID_DFR0.CopDbg.
- DBGDIDR.Version.
- EDDEVARCH.ARCHVER.
- EDDEVID1.HSR.

For more information, see:

- About Breakpoint exceptions.
- About Watchpoint exceptions.

FEAT_DoubleFault2, Double Fault Extension v2

FEAT_DoubleFault2 provides additional controls for routing and masking error exceptions.

This feature is supported in AArch64 state only.

FEAT_DoubleFault2 is OPTIONAL from Armv8.8.

If FEAT_DoubleFault2 is implemented, then FEAT_SCTLR2 is implemented.

When FEAT_AA64 and FEAT_DoubleFault2 are implemented, FEAT_AA64EL1 is implemented.

When FEAT_DoubleFault2 and FEAT_AA64EL2 are implemented, FEAT_HCX is implemented.

If FEAT_DoubleFault2 is implemented, then FEAT_DoubleFault is implemented.

The following field identifies the presence of FEAT_DoubleFault2:

- ID_AA64PFR1_EL1.DF2.

For more information, see:

- Synchronous exception types.
- Asynchronous exception types.
- Error synchronization event.

FEAT_ECBHB, Exploitative control using branch history information

FEAT_ECBHB imposes restrictions on branch history speculation around exceptions.

This feature is supported in AArch64 state only.

FEAT_ECBHB is OPTIONAL from Armv8.0.

FEAT_ECBHB is mandatory from Armv8.9.

The following field identifies the presence of FEAT_ECBHB:

- ID_AA64MMFR1_EL1.ECBHB.

For more information, see Branch prediction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_EDHSR, Support for EDHSR

FEAT_EDHSR introduces the EDHSR, which holds syndrome information of a Debug event.

FEAT_EDHSR is OPTIONAL.

If FEAT_Debugv8p9 is implemented, then FEAT_EDHSR is implemented.

If FEAT_EDHSR is implemented, then FEAT_Debugv8p2 is implemented.

The following field identifies the presence of FEAT_EDHSR:

- EDDEVID1.HSR.

FEAT_FGT2, Fine-grained traps 2

FEAT_FGT2 introduces the hypervisor registers HFGITR2_EL2, HFGRTR2_EL2, HFGWTR2_EL2, HDFGRTR2_EL2, and HDFGWTR2_EL2. These registers are extensions of the corresponding FGT registers.

This feature is supported in AArch64, and when EL1 is using AArch64, EL0 accesses using AArch32 are also trapped.

FEAT_FGT2 is OPTIONAL from Armv8.8.

In an Armv8.9 implementation, if FEAT_AA64EL2 is implemented, FEAT_FGT2 is implemented.

If FEAT_FGT2 is implemented, then FEAT_AA64EL2 is implemented.

If FEAT_FGT2 is implemented, then FEAT_FGT is implemented.

The following field identifies the presence of FEAT_FGT2:

- ID_AA64MMFR0_EL1.FGT.

FEAT_HAFT, Hardware managed Access Flag for Table descriptors

FEAT_HAFT introduces the support for hardware management of the Table descriptor Access flag.

This feature is supported in AArch64 state only.

FEAT_HAFT is OPTIONAL from Armv8.7.

If FEAT_HAFT is implemented, then FEAT_HAFDBS is implemented.

If FEAT_HAFT is implemented, then FEAT_TCR2 is implemented.

The following field identifies the presence of FEAT_HAFT:

- ID_AA64MMFR1_EL1.HAFDBS.

For more information, see Hardware management of the Table descriptor Access Flag.

FEAT_LRCPC3, Load-Acquire RCpc instructions version 3

FEAT_LRCPC3 introduces variants of load/store pair and load/store single register instructions, with release consistency, to optimize additional use cases where ordering is required. FEAT_LRCPC3 also introduces a set of additional load/store instructions with release consistency ordering in the Advanced SIMD and floating-point instruction set.

This feature is supported in AArch64 state only.

FEAT_LRCPC3 is OPTIONAL from Armv8.2.

If FEAT_LRCPC3 is implemented, then FEAT_LRCPC2 is implemented.

The following field identifies the presence of FEAT_LRCPC3:

- ID_AA64ISAR1_EL1.LRCPC.

For more information, see:

- Changes to single-copy atomicity in Armv8.4.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Load-Acquire/Store-Release.
- A64 instructions that are changed in Debug state.

FEAT_MTE4, Enhanced Memory Tagging Extension

FEAT_MTE4 introduces support for the following sub-features:

- Canonical tag checking, identified as FEAT_MTE_CANONICAL_TAGS.
- Reporting of all non-address bits on a fault, identified as FEAT_MTE_TAGGED_FAR.
- Store-only Tag checking, identified as FEAT_MTE_STORE_ONLY.
- Memory tagging with Address tagging disabled, identified as FEAT_MTE_NO_ADDRESS_TAGS.

This feature is supported in AArch64 state only.

FEAT_MTE4 is OPTIONAL from Armv8.7.

In an Armv8.9 implementation, if FEAT_MTE2 is implemented, FEAT_MTE4 is implemented.

If FEAT_MTE4 is implemented, then FEAT_MTE2 is implemented.

If FEAT_MTE4 is implemented, then FEAT_MTE_PERM is implemented.

If FEAT_MTE4 is implemented, then FEAT_MTE_CANONICAL_TAGS, FEAT_MTE_NO_ADDRESS_TAGS, FEAT_MTE_TAGGED_FAR, and FEAT_MTE_STORE_ONLY are implemented.

FEAT_MTE_ASYNC, Asynchronous reporting of Tag Check Fault

FEAT_MTE_ASYNC provides support for asynchronously accumulating Tag Check Faults into the TFSRE0_EL1 or TFSR_ELx registers. A PE that is compliant with FEAT_MTE2 is compliant with the behavior defined for this feature.

This feature is supported in AArch64 state only.

FEAT_MTE_ASYNC is OPTIONAL from Armv8.5.

If FEAT_MTE_ASYNC is implemented, then FEAT_MTE2 is implemented.

The following field identifies the presence of FEAT_MTE_ASYNC:

- ID_AA64PFR1_EL1.MTE_frac.

For more information, see:

- The Memory Tagging Extension.
- The AArch64 Application Level Memory Model.
- PMU Event Descriptions.
- The Statistical Profiling Extension.
- Debug State.

FEAT_MTE_CANONICAL_TAGS, Canonical Tag checking for Untagged memory

FEAT_MTE_CANONICAL_TAGS introduces support for MTE canonical tag checking.

This feature is supported in AArch64 state only.

FEAT_MTE_CANONICAL_TAGS is OPTIONAL.

If FEAT_MTE_CANONICAL_TAGS is implemented, then FEAT_MTE4 is implemented.

The following field identifies the presence of FEAT_MTE_CANONICAL_TAGS:

- ID_AA64PFR1_EL1.MTEX.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_MTE_NO_ADDRESS_TAGS, Memory tagging with Address tagging disabled

FEAT_MTE_NO_ADDRESS_TAGS introduces support for MTE tagging with Address tagging disabled.

This feature is supported in AArch64 state only.

FEAT_MTE_NO_ADDRESS_TAGS is OPTIONAL.

If FEAT_MTE_NO_ADDRESS_TAGS is implemented, then FEAT_MTE4 is implemented.

The following field identifies the presence of FEAT_MTE_NO_ADDRESS_TAGS:

- ID_AA64PFR1_EL1.MTEX.

FEAT_MTE_PERM, Allocation tag access permission

FEAT_MTE_PERM introduces support for the Stage 2 NoTagAccess memory attribute.

This feature is supported in AArch64 state only.

FEAT_MTE_PERM is OPTIONAL from Armv8.7.

In an Armv8.9 implementation, if FEAT_MTE2 is implemented, FEAT_MTE_PERM is implemented.

If FEAT_MTE_PERM is implemented, then FEAT_MTE2 is implemented.

The following field identifies the presence of FEAT_MTE_PERM:

- ID_AA64PFR2_EL1.MTEPERM.

FEAT_MTE_STORE_ONLY, Store-only Tag Checking

This feature is supported in AArch64 state only.

FEAT_MTE_STORE_ONLY is OPTIONAL.

If FEAT_MTE_STORE_ONLY is implemented, then FEAT_MTE4 is implemented.

The following field identifies the presence of FEAT_MTE_STORE_ONLY:

- ID_AA64PFR2_EL1.MTESTOREONLY.

FEAT_MTE_TAGGED_FAR, FAR_ELx on a Tag Check Fault

FEAT_MTE_TAGGED_FAR introduces support for reporting all non-address bits on a synchronous MTE tag check fault.

This feature is supported in AArch64 state only.

FEAT_MTE_TAGGED_FAR is OPTIONAL.

If FEAT_MTE_TAGGED_FAR is implemented, then FEAT_MTE4 is implemented.

The following field identifies the presence of FEAT_MTE_TAGGED_FAR:

- ID_AA64PFR2_EL1.MTEFAR.

FEAT_PCSRv8p9, Armv8.9 PC Sample-based Profiling Extension

FEAT_PCSRv8p9 introduces a mechanism to suspend PC Sample-based Profiling.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PCSRv8p9 is OPTIONAL from Armv8.8.

If FEAT_PCSRv8p9 is implemented, then FEAT_PCSRv8p2 is implemented.

The following field identifies the presence of FEAT_PCSRv8p9:

- PMDEVID.PCSample.

For more information, see Suspending and activating PC Sample-based Profiling.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_PFAR, Physical Fault Address Register Extension

FEAT_PFAR introduces the Physical Fault Address Registers, PFAR_ELx, that record the faulting physical address for a synchronous External abort or SError exception.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PFAR is OPTIONAL from Armv8.8.

When FEAT_AA64 and FEAT_PFAR are implemented, FEAT_AA64EL1 is implemented.

When FEAT_PFAR and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

The following field identifies the presence of FEAT_PFAR:

- ID_AA64PFR1_EL1.PFAR.

FEAT_PMUv3_EDGE, PMU event edge detection

FEAT_PMUv3_EDGE introduces edge-detection logic to support counting threshold crossing events.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PMUv3_EDGE is OPTIONAL from Armv8.8.

If FEAT_PMUv3_EDGE is implemented, then FEAT_PMUv3_TH is implemented.

The following fields identify the presence of FEAT_PMUv3_EDGE:

- PMMIR_EL1.EDGE.
- PMMIR.EDGE.
- PMMIR.EDGE.

For more information, see Event threshold and edge counting.

FEAT_PMUv3_ICNTR, Fixed-function instruction counter

FEAT_PMUv3_ICNTR introduces a fixed-function instruction counter to the PMU.

This feature is supported in both AArch64 and AArch32 states. The counter is not accessible from AArch32 state.

FEAT_PMUv3_ICNTR is OPTIONAL from Armv8.8.

If FEAT_PMUv3_ICNTR is implemented, then FEAT_PMUv3p9 is implemented.

When FEAT_PMUv3_ICNTR and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

The following fields identify the presence of FEAT_PMUv3_ICNTR:

- ID_AA64DFR1_EL1.PMICNTR.
- PMCFGR.NCG.

For more information, see About the Performance Monitors.

FEAT_PMUv3_SS, PMU Snapshot extension

FEAT_PMUv3_SS defines an IMPLEMENTATION DEFINED Snapshot Extension, compatible with the CoreSight PMU Snapshot Extension.

This feature is supported in both AArch64 and AArch32 states. The PMU snapshot registers are not accessible from AArch32 state.

FEAT_PMUv3_SS is OPTIONAL from Armv8.8.

If FEAT_PMUv3_SS is implemented, then FEAT_PMUv3p9 is implemented.

When FEAT_PMUv3_SS and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

If FEAT_PMUv3_SS is implemented, then FEAT_AA32EL1 is not implemented.

The following fields identify the presence of FEAT_PMUv3_SS:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64DFR0_EL1.PMSS.
- PMDEVID.PMSS.

For more information, see PMU snapshots.

FEAT_PMUv3p9, Armv8.9 PMU extensions

FEAT_PMUv3p9 introduces the following to the Performance Monitors Extension:

- Provides finer-grained control over allocation of PMU event counters to an EL0 process.
- Allows an arbitrary combination of event counters and fixed-function counters to be zeroed.
- Provides controls to configure the PMU to directly request the PE enters Debug state without using the CTI.
- Updates PMU event definitions.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PMUv3p9 is OPTIONAL from Armv8.8.

In an Armv8.9 implementation, if FEAT_PMUv3 is implemented, FEAT_PMUv3p9 is implemented.

If FEAT_PMUv3p9 is implemented, then FEAT_PMUv3p8 is implemented.

When FEAT_PMUv3p9 and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

The following fields identify the presence of FEAT_PMUv3p9:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.
- EDDFR.PMUVer.

For more information, see:

- PMU Overflow external debug request.
- EL0 access controls.
- PMU Event Descriptions.
- Resetting counters.

FEAT_PRFMSLC, SLC target support for PRFM and PRFUM instructions

FEAT_PRFMSLC introduces a system level cache option for the PRFM and PRFUM instructions.

This feature is supported in AArch64 state only.

FEAT_PRFMSLC is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_PRFMSLC:

- ID_AA64ISAR2_EL1.PRFMSLC.

FEAT_RASv2, RAS Extension v2

FEAT_RASv2 introduces the following to the Reliability, Availability, and Serviceability Extension:

- The features defined by FEAT_RASSAv2 in the System register error records.
- The error group status register, ERXGSR_EL1.
- A control to trap writes to RAS error record System registers to EL3.
- An additional syndrome to ESR_ELx for error exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This feature is supported in both AArch64 and AArch32 states.

FEAT_RASv2 is OPTIONAL from Armv8.8.

In an Armv8.9 implementation, if FEAT_RAS is implemented, FEAT_RASv2 is implemented.

When FEAT_RASv2 and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

If FEAT_RASv2 is implemented, then FEAT_RASv1p1 is implemented.

If FEAT_RASv2 is implemented, then FEAT_RASSAv2 is implemented.

The following fields identify the presence of FEAT_RASv2:

- ID_AA64PFR0_EL1.RAS.
- ID_PFR0_EL1.RAS.
- ID_PFR0.RAS.

For more information, see:

- RAS PE architecture.
- *Arm® Reliability Availability and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

FEAT_RPRFM, Support for Range Prefetch Memory instruction

FEAT_RPRFM introduces the Range Prefetch Memory hint instruction, RPRFM which specifies the range of addresses that are likely to be accessed in the near future and their expected reuse.

This feature is supported in AArch64 state only.

FEAT_RPRFM is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_RPRFM:

- ID_AA64ISAR2_EL1.RPRFM.

FEAT_S1PIE, Stage 1 permission indirections

FEAT_S1PIE introduces a way to set stage 1 permissions that allows more efficient use of the permission bits in translation table descriptors and provides the ability to introduce additional permission types.

This feature is supported in AArch64 state only.

FEAT_S1PIE is OPTIONAL from Armv8.8.

If FEAT_S1PIE is implemented, then FEAT_ATS1A is implemented.

If FEAT_S1PIE is implemented, then FEAT_TCR2 is implemented.

The following field identifies the presence of FEAT_S1PIE:

- ID_AA64MMFR3_EL1.S1PIE.

For more information, see Stage 1 Indirect permissions.

FEAT_S1POE, Stage 1 permission overlays

FEAT_S1POE allows stage 1 permissions to be progressively restricted without requiring TLB maintenance. The feature is available at all Exception levels, including EL0, and can reduce the number of calls to privileged software.

This feature is supported in AArch64 state only.

FEAT_S1POE is OPTIONAL from Armv8.8.

If FEAT_S1POE is implemented, then FEAT_TCR2 is implemented.

If FEAT_S1POE is implemented, then FEAT_ATS1A is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_S1POE is implemented, then FEAT_HPDS is implemented.

The following field identifies the presence of FEAT_S1POE:

- ID_AA64MMFR3_EL1.S1POE.

For more information, see Stage 1 Overlay permissions.

FEAT_S2PIE, Stage 2 permission indirections

FEAT_S2PIE introduces all of the following:

- A method to set stage 2 permissions that allows more efficient use of the permission bits in translation table descriptors and provides the ability to introduce additional permission types.
- The Mostly Read Only (MRO) permission in stage 2 translations.

This feature is supported in AArch64 state only.

FEAT_S2PIE is OPTIONAL from Armv8.8.

If FEAT_S2PIE is implemented, then FEAT_EL2 is implemented.

The following field identifies the presence of FEAT_S2PIE:

- ID_AA64MMFR3_EL1.S2PIE.

For more information, see Stage 2 Indirect permissions.

FEAT_S2POE, Stage 2 permission overlays

FEAT_S2POE provides a mechanism for stage 2 permissions to be progressively restricted, such that different EL1&0 contexts that are using the same stage 2 translation tables can be provided with different sets of permissions.

This feature is supported in AArch64 state only.

FEAT_S2POE is OPTIONAL from Armv8.8.

If FEAT_S2POE is implemented, then FEAT_EL2 is implemented.

If FEAT_S2POE is implemented, then FEAT_S2PIE is implemented.

The following field identifies the presence of FEAT_S2POE:

- ID_AA64MMFR3_EL1.S2POE.

For more information, see Stage 2 Overlay permissions.

FEAT_SPECRES2, Enhanced speculation restriction instructions

FEAT_SPECRES2 introduces a speculation restriction instruction, Clear Other Speculative Prediction Restriction by Context (COSP), to the instructions that are part of FEAT_SPECRES.

This feature is supported in both AArch64 and AArch32 states.

FEAT_SPECRES2 is OPTIONAL from Armv8.0.

FEAT_SPECRES2 is mandatory from Armv8.9.

If FEAT_SPECRES2 is implemented, then FEAT_SPECRES is implemented.

The following fields identify the presence of FEAT_SPECRES2:

- ID_AA64ISAR1_EL1.SPECRES.
- ID_ISAR6_EL1.SPECRES.
- ID_ISAR6.SPECRES.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see:

- Prediction restriction instructions.
- Execution, data prediction and prefetching restriction System instructions.
- Execution and data prediction restriction System instructions.

FEAT_SPE_CRR, Statistical Profiling call return branch records

FEAT_SPE_CRR extends the Operation Type packet to provide more information whether the branch is a procedure call or a procedure return.

This feature is supported in AArch64 state only.

FEAT_SPE_CRR is OPTIONAL.

In an Armv8.9 implementation, if FEAT_SPE is implemented, FEAT_SPE_CRR is implemented.

If FEAT_SPE_CRR is implemented, then FEAT_SPEv1p4 is implemented.

If FEAT_SPE and FEAT_GCS are implemented, then FEAT_SPE_CRR is implemented.

The following field identifies the presence of FEAT_SPE_CRR:

- PMSIDR_EL1.CRR.

FEAT_SPE_DPFZS, Disable Cycle Counter on SPE Freeze

FEAT_SPE_DPFZS introduces controls to disable cycle counting when event counting is frozen on a Statistical Profiling Buffer Management event.

This feature is supported in AArch64 state only.

FEAT_SPE_DPFZS is OPTIONAL from Armv8.6.

If FEAT_PMUv3p9 and FEAT_SPEv1p4 are implemented, then FEAT_SPE_DPFZS is implemented.

If FEAT_SPE_DPFZS is implemented, then FEAT_PMUv3p7 and FEAT_SPEv1p2 are implemented.

The following field identifies the presence of FEAT_SPE_DPFZS:

- ID_AA64DFR1_EL1.DPFZS.

FEAT_SPE_FDS, Statistical Profiling data source filtering

FEAT_SPE_FDS provides the capability to filter sample records by all or part of the sampled Data Source packet.

This feature is supported in AArch64 state only.

FEAT_SPE_FDS is OPTIONAL from Armv8.8.

In an Armv8.9 implementation, if FEAT_SPE_LDS is implemented, FEAT_SPE_FDS is implemented.

If FEAT_SPE_FDS is implemented, then FEAT_SPE_LDS is implemented.

If FEAT_SPE_FDS is implemented, then FEAT_SPEv1p4 is implemented.

When FEAT_SPE_FDS and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

The following field identifies the presence of FEAT_SPE_FDS:

- PMSIDR_EL1.FDS.

For more information, see Filtering sample records.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SPEv1p4, Statistical Profiling Extension version 1.4

FEAT_SPEv1p4 introduces the following to the Statistical Profiling Extension:

- Additions to the Events packet to provide more information about the data source.
- Additional event-based record filtering control bits in PMSEVFR_EL1 and PMSNEVFR_EL1 that add the ability to filter by additional existing bits in the Events packet.

This feature is supported in AArch64 state only.

FEAT_SPEv1p4 is OPTIONAL from Armv8.8.

In an Armv8.9 implementation, if FEAT_SPE is implemented, FEAT_SPEv1p4 is implemented.

If FEAT_SPEv1p4 is implemented, then FEAT_SPEv1p3 is implemented.

The following field identifies the presence of FEAT_SPEv1p4:

- ID_AA64DFR0_EL1.PMSVer.

FEAT_SPMU, System Performance Monitors Extension

FEAT_SPMU provides a framework of architectural System registers and behaviors for System PMUs, which are PMUs other than the Performance Monitors Extension PMU, that are accessible by the PE.

This feature is supported in both AArch64 and AArch32 states.

FEAT_SPMU is OPTIONAL from Armv8.8.

When FEAT_SPMU and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

The following field identifies the presence of FEAT_SPMU:

- ID_AA64DFR1_EL1.SPMU.

For more information, see System Performance Monitors Extension.

FEAT_THE, Translation Hardening Extension

FEAT_THE provides a mechanism to prevent modification of an arbitrary subset of translation table entries from within the Exception level that owns the translation tables, and introduces the following:

- The stage 1 Assured Translation property and the stage 2 AssuredOnly property.
- Stage 2 TopLevel checks.
- Read-Check-Write instructions, RCW* and RCWS*.
- Read-Check-Write mask registers, RCWMASK_EL1 and RCWSMASK_EL1.
- The Protected attribute in stage 1 descriptors.

This feature is supported in AArch64 state only.

FEAT_THE is OPTIONAL from Armv8.8.

When FEAT_THE and FEAT_AA64EL2 are implemented, FEAT_S2PIE is implemented.

When FEAT_THE and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

If FEAT_THE is implemented, then FEAT_TCR2 is implemented.

The following field identifies the presence of FEAT_THE:

- ID_AA64PFR1_EL1.THE.

For more information, see:

- Translation Hardening Extension.
- Read-Check-Write.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A2.3 Armv9-A architecture extensions

The AArch32 state might optionally be implemented at EL0. The AArch32 state is not implemented at EL1, EL2, and EL3.

The implementation of FEAT_DoubleLock in an Armv9 implementation is prohibited.

An implementation of the Armv9-A architecture cannot include an ETM.

A2.3.1 The Armv9.0 architecture extension

The Armv9.0 architecture extension adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv9.0 compliant if all of the following apply:

- It is Armv8.5 compliant.
- It includes all of the Armv9.0 architectural features that are mandatory.

An Armv9.0 compliant implementation can additionally include any features that are defined to be optional in Armv9.0 or Armv8.5.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

In an Armv9.0 implementation, the AArch32 state might optionally be implemented at EL0. The AArch32 state is not implemented at EL1, EL2, and EL3.

An implementation of Armv9.0 cannot implement FEAT_DoubleLock.

An implementation of the Armv9.0 architecture cannot include an ETM.

In an Armv9.0 implementation, if FEAT_FP and FEAT_AdvSIMD are implemented, the following features are implemented:

- FEAT_RDM.
- FEAT_FP16.
- FEAT_DotProd.
- FEAT_FHM.
- FEAT_FCMA.
- FEAT_JSCVT.
- FEAT_FlagM2.
- FEAT_FRINTTS.

FEAT_Armv9_Crypto, Armv9 Cryptographic Extension

The Armv9 Cryptographic Extension provides instructions for the acceleration of encryption and decryption. The presence of the Cryptographic Extension in an implementation is subject to export license controls.

This feature is supported in AArch64 state only.

FEAT_Armv9_Crypto is OPTIONAL.

If FEAT_Armv9_Crypto is implemented, then FEAT_Crypto is implemented.

If FEAT_Armv9_Crypto is implemented, then FEAT_PMULL, FEAT_AES, FEAT_SHA1, FEAT_SHA3, FEAT_SHA256, and FEAT_SHA512 are implemented.

When FEAT_Armv9_Crypto, FEAT_SVE and FEAT_SVE_SHA3 are implemented, FEAT_SVE_AES, and FEAT_SVE_PMULL128 are implemented.

When FEAT_Armv9_Crypto, FEAT_SVE and FEAT_SVE_AES are implemented, FEAT_SVE_PMULL128, and FEAT_SVE_SHA3 are implemented.

When FEAT_Armv9_Crypto, FEAT_SVE and FEAT_SVE_PMULL128 are implemented, FEAT_SVE_AES, and FEAT_SVE_SHA3 are implemented.

For more information, see:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Cryptographic Extension in AArch64 state.
- The Cryptographic Extension in AArch32 state.

FEAT_ETE, Embedded Trace Extension

FEAT_ETE provides a trace unit that records details about software control flow running on a PE, which can be used to aid debugging or optimizing. The trace unit provides filtering functionality to allow the targeting of the information to specific code regions or periods of operation.

This feature is supported in AArch64 state, and performs trace in both AArch64 and AArch32 states.

FEAT_ETE is OPTIONAL from Armv9.0.

If FEAT_ETE is implemented, then FEAT_TRBE is implemented.

If FEAT_ETE is implemented, then FEAT_TRF is implemented.

If FEAT_ETE is implemented, then FEAT_TRC_SR is implemented.

If FEAT_ETE is implemented, then FEAT_ETMv4 is not implemented.

When FEAT_ETE and FEAT_PMUv3 are implemented, FEAT_PMUv3p1 is implemented.

For more information, see The Embedded Trace Extension.

FEAT_SVE2, Scalable Vector Extension version 2

The *Scalable Vector Extension version 2* (SVE2) is a superset of SVE that incorporates functionality similar to Advanced SIMD, and other enhancements. In this Manual, unless stated otherwise, when SVE is used, the behavior also applies to SVE2. All Armv9-A systems that support standard operating systems with rich application environments also provide hardware support for SVE2 instructions.

This feature is supported in AArch64 state only.

FEAT_SVE2 is OPTIONAL from Armv9.0.

If FEAT_SVE2 is implemented, then FEAT_SVE is implemented.

The following field identifies the presence of FEAT_SVE2:

- ID_AA64ZFR0_EL1.SVEver.

For more information, see:

- FEAT_SVE.
- Data processing - SVE2.

FEAT_SVE_AES, Scalable Vector AES instructions

FEAT_SVE_AES provides the following scalable vector AES cryptographic instructions:

- AESD.
- AESE.
- AESIMC.
- AESMC.
- PMULLB.
- PMULLT.

This feature is supported in AArch64 state only.

FEAT_SVE_AES is OPTIONAL from Armv9.0.

If FEAT_SVE_AES is implemented, then FEAT_SVE2 or FEAT_SSVE_AES is implemented.

If FEAT_SVE_AES is implemented, then FEAT_SVE_PMULL128 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_SVE_PMULL128 is implemented, then FEAT_SVE_AES is implemented.

If FEAT_SVE_AES is implemented, then FEAT_Armv9_Crypto is implemented.

The following field identifies the presence of FEAT_SVE_AES:

- ID_AA64ZFR0_EL1.AES.

FEAT_SVE_BitPerm, Scalable Vector Bit Permutes instructions

FEAT_SVE_BitPerm provides the following scalable vector bit permute instructions:

- BEXT.
- BDEP.
- BGRP.

This feature is supported in AArch64 state only.

FEAT_SVE_BitPerm is OPTIONAL from Armv9.0.

If FEAT_SVE_BitPerm is implemented, then FEAT_SVE2 is implemented.

The following field identifies the presence of FEAT_SVE_BitPerm:

- ID_AA64ZFR0_EL1.BitPerm.

For more information, see:

- Bit permutation.

FEAT_SVE_PMULL128, SVE single-vector Advanced Encryption Standard and 128-bit polynomial multiply long instructions

FEAT_SVE_PMULL128 implements the SVE single-vector Advanced Encryption Standard and 128-bit destination element variants of PMULLB and PMULLT instructions, when the PE is not in Streaming SVE mode.

This feature is supported in AArch64 state only.

FEAT_SVE_PMULL128 is OPTIONAL from Armv9.0.

If FEAT_SVE_PMULL128 is implemented, then FEAT_SVE2 or FEAT_SSVE_AES is implemented.

If FEAT_SVE_PMULL128 is implemented, then FEAT_SVE_AES is implemented.

The following field identifies the presence of FEAT_SVE_PMULL128:

- ID_AA64ZFR0_EL1.AES.

FEAT_SVE_SHA3, Scalable Vector SHA3 instructions

FEAT_SVE_SHA3 provides the following scalable vector SHA3 instruction:

- RAX1.

This feature is supported in AArch64 state only.

FEAT_SVE_SHA3 is OPTIONAL from Armv9.0.

If FEAT_SVE_SHA3 is implemented, then FEAT_SVE2 or FEAT_SME2p1 is implemented.

If FEAT_SVE_SHA3 is implemented, then FEAT_Armv9_Crypto is implemented.

The following field identifies the presence of FEAT_SVE_SHA3:

- ID_AA64ZFR0_EL1.SHA3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SVE_SM4, Scalable Vector SM4 instructions

FEAT_SVE_SM4 provides the following scalable vector SM4 instructions:

- SM4E.
- SM4EKEY.

This feature is supported in AArch64 state only.

FEAT_SVE_SM4 is OPTIONAL from Armv9.0.

If FEAT_SVE_SM4 is implemented, then FEAT_SVE2 is implemented.

If FEAT_SVE_SM4 is implemented, then FEAT_SM4 is implemented.

The following field identifies the presence of FEAT_SVE_SM4:

- ID_AA64ZFR0_EL1.SM4.

FEAT_TRBE, Trace Buffer Extension

FEAT_TRBE enables support for a Trace Buffer Unit within a PE. When the Trace Buffer Unit is enabled, program-flow trace generated by a trace unit is written directly to memory by the Trace Buffer Unit, rather than routing trace data to a trace sink.

This feature is supported in AArch64 state, and collects trace in both AArch64 and AArch32 states.

FEAT_TRBE is OPTIONAL from Armv9.0.

If FEAT_TRBE is implemented, then FEAT_TRF is implemented.

If FEAT_TRBE is implemented, then FEAT_ETE is implemented.

When FEAT_TRBE and FEAT_PMUv3 are implemented, FEAT_PMUv3p1 is implemented.

The following field identifies the presence of FEAT_TRBE:

- ID_AA64DFR0_EL1.TraceBuffer.

For more information, see The Trace Buffer Extension.

A2.3.1.1 Features added to the Armv9.0 extension in later releases

- FEAT_HINTE.
- FEAT_IDTE3.
- FEAT_PCDPHINT.
- FEAT_UINJ.

A2.3.2 The Armv9.1 architecture extension

The Armv9.1 architecture extension is an extension to Armv9.0. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv9.1 compliant if all of the following apply:

- It is Armv8.6 compliant.
- It is Armv9.0 compliant.
- It includes all of the Armv9.1 architectural features that are mandatory.

An Armv9.1 compliant implementation can additionally include any features that are defined to be optional in Armv9.1 or Armv8.6.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_ETEv1p1, Embedded Trace Extension

FEAT_ETEv1p1 extends FEAT_ETE to provide more flexibility for tracing Timestamp values.

This feature is supported in AArch64 state, and performs trace in both AArch64 and AArch32 states.

FEAT_ETEv1p1 is OPTIONAL from Armv9.0.

If FEAT_ETEv1p1 is implemented, then FEAT_ETE is implemented.

The following fields identify the presence of FEAT_ETEv1p1:

- TRCDEVARCH.REVISION.
- TRCDEVARCH.REVISION.

For more information, see The Embedded Trace Extension..

A2.3.3 The Armv9.2 architecture extension

The Armv9.2 architecture extension is an extension to Armv9.1. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv9.2 compliant if all of the following apply:

- It is Armv8.7 compliant.
- It is Armv9.1 compliant.
- It includes all of the Armv9.2 architectural features that are mandatory.

An Armv9.2 compliant implementation can additionally include any features that are defined to be optional in Armv9.2 or Armv8.7.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_AMU_EXTACR, Activity Monitors External Control Register

FEAT_AMU_EXTACR implements a control register to enable access to the Activity Monitors External registers.

- If FEAT_RME is implemented, the register AMROOTCR is implemented to control Root, Realm, Secure and Non-secure accesses to the external AMU registers.
- If FEAT_RME is not implemented, the register AMSCR is implemented to control Secure and Non-secure accesses to the external AMU registers.

FEAT_AMU_EXTACR is OPTIONAL from Armv8.4.

If FEAT_AMU_EXTACR is implemented, then FEAT_AMU_EXT is implemented.

For more information, see The Activity Monitors Extension.

FEAT_BRBE, Branch Record Buffer Extension

FEAT_BRBE provides a Branch record buffer for capturing control path history.

This feature is supported in AArch64 state only.

FEAT_BRBE is OPTIONAL from Armv9.1.

The following field identifies the presence of FEAT_BRBE:

- ID_AA64DFR0_EL1.BRBE.

For more information, see The Branch Record Buffer Extension.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_ETEv1p2, Embedded Trace Extension

FEAT_ETEv1p2 extends FEAT_ETE to support FEAT_RME.

This feature is supported in AArch64 state, and performs trace in both AArch64 and AArch32 states.

FEAT_ETEv1p2 is OPTIONAL from Armv9.1.

If FEAT_ETEv1p2 is implemented, then FEAT_ETEv1p1 is implemented.

If FEAT_ETE and FEAT_RME are implemented, then FEAT_ETEv1p2 is implemented.

The following fields identify the presence of FEAT_ETEv1p2:

- TRCDEVARCH.REVISION.
- TRCDEVARCH.REVISION.

For more information, see The Embedded Trace Extension..

FEAT_RME, Realm Management Extension

The Realm Management Extension (RME) is an extension to the Armv9 A-profile architecture.

RME introduces all of the following features:

- Two additional Security states, Root and Realm.
- Two additional physical address spaces, Root and Realm.
- The ability to dynamically transition memory granules between physical address spaces.
- Granule Protection Check mechanism.

FEAT_RME is one component of the Arm Confidential Compute Architecture (Arm CCA). Together with the other components of the Arm CCA, RME enables support for dynamic, attestable, and trusted execution environments (Realms) to be run on an Arm PE.

This feature is supported in AArch64 state only.

FEAT_RME is OPTIONAL from Armv9.1.

If FEAT_RME is implemented, then FEAT_AA64EL3, FEAT_AA64EL2, and FEAT_RNG or FEAT_RNG_TRAP are implemented.

When FEAT_RME and FEAT_AES or FEAT_SHA1 are implemented, FEAT_PMULL, FEAT_AES, FEAT_SHA3, FEAT_SHA256, and FEAT_SHA512 are implemented.

When FEAT_RME, FEAT_SVE and FEAT_AES or FEAT_SHA1 are implemented, FEAT_SVE_PMULL128, and FEAT_SVE_SHA3 are implemented.

When FEAT_ETE and FEAT_RME are implemented, FEAT_ETEv1p2 is implemented.

When FEAT_PMUv3 and FEAT_RME are implemented, FEAT_PMUv3p7 is implemented.

When FEAT_SPE and FEAT_RME are implemented, FEAT_SPEv1p2 is implemented.

When FEAT_MPAM and FEAT_RME are implemented, FEAT_MPAMv1p1 is implemented.

If FEAT_RME is implemented, then FEAT_PCSRv8 is not implemented.

The following fields identify the presence of FEAT_RME:

- ID_AA64PFR0_EL1.RME.
- MPAMIDR_EL1.MPAMv0or1px.SP4.
- MPAMIDR_EL1.MPAMv0or1px.HAS_ALTSP.

If the Activity Monitors Extension is implemented, then Arm strongly recommends that a PE that implements FEAT_RME also implements FEAT_AMUv1p1.

Arm recommends that a PE that implements FEAT_RME also implements all of the following:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- FEAT_VMID16.
- FEAT_HAFDBS.

For more information, see:

- The AArch64 System Level Programmers´ Model.
- The AArch64 Virtual Memory System Architecture.
- The Granule Protection Check Mechanism.

FEAT_SME, Scalable Matrix Extension

FEAT_SME introduces two AArch64 execution modes that can be enabled and disabled by application software:

- In ZA storage enabled mode, scalable, two-dimensional, architectural ZA tile storage becomes available and instructions are defined to load, store, extract, insert, and clear rows and columns of the ZA tiles.
- In Streaming SVE mode, the Effective SVE vector length changes to match the Effective ZA tile width, support for a substantial subset of the SVE2 instruction set is available, and, when ZA mode is also enabled, instructions are defined that accumulate the matrix outer product of two SVE vectors into a ZA tile.

This feature is supported in AArch64 state only.

FEAT_SME is OPTIONAL from Armv9.2.

If FEAT_SME is implemented, then FEAT_FCMA, FEAT_FP16, FEAT_BF16, and FEAT_FHM are implemented.

When FEAT_SME and FEAT_EL2 are implemented, FEAT_FGT and FEAT_HCX are implemented.

When FEAT_SME and FEAT_PMUv3 are implemented, FEAT_PMUv3p1 is implemented.

The following fields identify the presence of FEAT_SME:

- ID_AA64PFR1_EL1.SME.
- ID_AA64SMFR0_EL1.F16F32.
- ID_AA64SMFR0_EL1.B16F32.
- ID_AA64SMFR0_EL1.F32F32.
- ID_AA64SMFR0_EL1.I8I32.

If FEAT_SME is implemented, this does not imply that FEAT_SVE and FEAT_SVE2 are implemented when the PE is not in Streaming SVE mode.

For more information, see The Scalable Matrix Extension.

FEAT_SME_F64F64, Double-precision floating-point instructions

FEAT_SME_F64F64 indicates SME support for instructions that accumulate into double-precision floating-point elements in the ZA array.

This feature is supported in AArch64 state only.

FEAT_SME_F64F64 is OPTIONAL from Armv9.2.

If FEAT_SME_F64F64 is implemented, then FEAT_SME is implemented.

The following field identifies the presence of FEAT_SME_F64F64:

- ID_AA64SMFR0_EL1.F64F64.

For more information, see The Scalable Matrix Extension.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SME_FA64, Full A64 instruction set support in Streaming SVE mode

FEAT_SME_FA64 indicates support for execution of the full A64 instruction set in Streaming SVE mode.

This feature is supported in AArch64 state only.

FEAT_SME_FA64 is OPTIONAL from Armv9.2.

If FEAT_SME_FA64 is implemented, then FEAT_SME is implemented.

If FEAT_SME_FA64 is implemented, then FEAT_SVE2 is implemented.

The following field identifies the presence of FEAT_SME_FA64:

- ID_AA64SMFR0_EL1.FA64.

For more information, see The Scalable Matrix Extension.

FEAT_SME_I16I64, 16-bit to 64-bit integer widening instructions

FEAT_SME_I16I64 indicates SME support for instructions that accumulate into 64-bit integer elements in the ZA array.

This feature is supported in AArch64 state only.

FEAT_SME_I16I64 is OPTIONAL from Armv9.2.

If FEAT_SME_I16I64 is implemented, then FEAT_SME is implemented.

The following field identifies the presence of FEAT_SME_I16I64:

- ID_AA64SMFR0_EL1.I16I64.

For more information, see The Scalable Matrix Extension.

A2.3.3.1 Features added to the Armv9.2 extension in later releases

- FEAT_F8F16MM.
- FEAT_F8F32MM.
- FEAT_FAMINMAX.
- FEAT_FP8DOT2.
- FEAT_FP8DOT4.
- FEAT_FP8FMA.
- FEAT_FP8.
- FEAT_FPMR.
- FEAT_LS64WB.
- FEAT_LUT.
- FEAT_SME2p1.
- FEAT_SME_B16B16.
- FEAT_SME_F16F16.
- FEAT_SME_F8F16.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- FEAT_SME_F8F32.
- FEAT_SME_LUTv2.
- FEAT_SPE_SME.
- FEAT_SSVE_FP8DOT2.
- FEAT_SSVE_FP8DOT4.
- FEAT_SSVE_FP8FMA.
- FEAT_SVE2p1.
- FEAT_SVE_B16B16.
- FEAT_SVE_BFSCALE.
- FEAT_SVE_F16F32MM.

A2.3.4 The Armv9.3 architecture extension

The Armv9.3 architecture extension is an extension to Armv9.2. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv9.3 compliant if all of the following apply:

- It is Armv8.8 compliant.
- It is Armv9.2 compliant.
- It includes all of the Armv9.3 architectural features that are mandatory.

An Armv9.3 compliant implementation can additionally include any features that are defined to be optional in Armv9.3 or Armv8.8.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_BRBEv1p1, Branch Record Buffer Extension version 1.1

FEAT_BRBEv1p1 extends FEAT_BRBE to enable branch recording at EL3.

This feature is supported in AArch64 state only.

FEAT_BRBEv1p1 is OPTIONAL from Armv9.2.

In an Armv9.3 implementation, if FEAT_BRBE is implemented, FEAT_BRBEv1p1 is implemented.

If FEAT_BRBEv1p1 is implemented, then FEAT_BRBE is implemented.

The following field identifies the presence of FEAT_BRBEv1p1:

- ID_AA64DFR0_EL1.BRBE.

For more information, see The Branch Record Buffer Extension.

FEAT_MEC, Memory Encryption Contexts

Memory Encryption Contexts (MEC) is an extension to the RME.

An existing RME enabled system uses a combination of isolation and external memory protection to guarantee privacy of the Realm Security state. Isolation between Realms is enforced by the Realm stage 2 translation tables.

FEAT_MEC introduces all of the following features:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Memory encryption contexts are provided to all physical address spaces.
- Multiple memory encryption contexts are provided to the Realm physical address space for assignment to Realm virtual machines, with policy controlled by Realm EL2.
- The Non-secure, Secure, and Root, physical address spaces each have one encryption context.

This feature is supported in AArch64 state only.

FEAT_MEC is OPTIONAL from Armv9.2.

If FEAT_MEC is implemented, then FEAT_RME is implemented.

If FEAT_MEC is implemented, then FEAT_SCTLR2 is implemented.

If FEAT_MEC is implemented, then FEAT_TCR2 is implemented.

The following field identifies the presence of FEAT_MEC:

- ID_AA64MMFR3_EL1.MEC.

FEAT_SME2, Scalable Matrix Extensions version 2

FEAT_SME2 is a superset of FEAT_SME that introduces the following:

- The ability to treat the SME ZA array as containing addressable groups of one-dimensional ZA array vectors, instead of two-dimensional ZA tiles.
- Multi-vector instructions that operate on groups of Z vector registers and ZA array vectors.
- A multi-vector predication mechanism for multi-vector load and store.
- A dedicated 512-bit lookup table register, ZT0, for data decompression.

This feature is supported in AArch64 state only.

FEAT_SME2 is OPTIONAL from Armv9.2.

If FEAT_SME2 is implemented, then FEAT_SME is implemented.

The following fields identify the presence of FEAT_SME2:

- ID_AA64SMFR0_EL1.SMEver.
- ID_AA64PFR1_EL1.SME.
- ID_AA64SMFR0_EL1.BI32I32.
- ID_AA64SMFR0_EL1.I16I32.

For more information, see The Scalable Matrix Extension.

A2.3.4.1 Features added to the Armv9.3 extension in later releases

- FEAT_CMPBR.
- FEAT_LSFE.
- FEAT_MPAM_PE_BW_CTRL.
- FEAT_OCCMO.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A2.3.5 The Armv9.4 architecture extension

The Armv9.4 architecture extension is an extension to Armv9.3. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv9.4 compliant if all of the following apply:

- It is Armv8.9 compliant.
- It is Armv9.3 compliant.
- It includes all of the Armv9.4 architectural features that are mandatory.

An Armv9.4 compliant implementation can additionally include any features that are defined to be optional in Armv9.4 or Armv8.9.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_ABLE, Address Breakpoint Linking Extension

FEAT_ABLE introduces the capability to link a watchpoint to an address matching breakpoint.

This feature is supported in both AArch64 and AArch32 states.

FEAT_ABLE is OPTIONAL from Armv9.3.

If FEAT_ABLE is implemented, then FEAT_BWE is implemented.

If FEAT_ABLE is implemented, then FEAT_Debugv8p9 is implemented.

The following fields identify the presence of FEAT_ABLE:

- ID_AA64DFR1_EL1.ABLE.
- EDDFR1.ABLE.

For more information, see About Breakpoint exceptions.

FEAT_BWE, Breakpoint and watchpoint enhancements

FEAT_BWE introduces the capability to define an included-range-based breakpoint and an excluded-range-based breakpoint.

This feature is supported in AArch64 state only.

FEAT_BWE is OPTIONAL from Armv9.3.

The following fields identify the presence of FEAT_BWE:

- ID_AA64DFR2_EL1.BWE.
- EDDFR2.BWE.

For more information, see Other usage constraints for Address breakpoints.

FEAT_CHK, Check Feature Status

FEAT_CHK introduces the CHKFEAT instruction, which allows software to detect when certain features are enabled.

A PE that is compliant with architectures from Armv8.0 to Armv9.3 is compliant with the behavior defined for this feature.

This feature is supported in AArch64 state only.

FEAT_CHK is OPTIONAL from Armv8.0.

FEAT_CHK is mandatory from Armv9.4.

For more information, see Detecting when FEAT_GCS is enabled.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_D128, 128-bit Translation Tables, 56 bit PA

FEAT_D128 introduces support for the VMSAv9-128 translation system, comprising the following:

- 128-bit translation table descriptors.
- Support for encoding up to 56-bit physical addresses in translation table descriptors.
- If FEAT_LVA or FEAT_LVA3 are implemented, support for translating up to 56-bit virtual addresses.
- TLBIP VA*, TLBIP RVA*, TLBIP IPA*, TLBIP RIPA* instructions that can take 128-bit inputs.

This feature is supported in AArch64 state only.

FEAT_D128 is OPTIONAL from Armv9.3.

If FEAT_D128 is implemented, then FEAT_SYSREG128 is implemented.

If FEAT_D128 is implemented, then FEAT_SYSINSTR128 is implemented.

If FEAT_D128 is implemented, then FEAT_LSE128 is implemented.

If FEAT_D128 is implemented, then FEAT_S1PIE is implemented.

When FEAT_D128 and FEAT_EL2 are implemented, FEAT_S2PIE is implemented.

If FEAT_D128 is implemented, then FEAT_AIE is implemented.

If FEAT_D128 is implemented, then FEAT_TCR2 is implemented.

The following fields identify the presence of FEAT_D128:

- ID_AA64MMFR3_EL1.D128_2.
- ID_AA64MMFR3_EL1.D128.

For more information, see The AArch64 Virtual Memory System Architecture.

FEAT_EBEP, Exception-based Event Profiling

FEAT_EBEP provides support for reporting PMU counter overflows as PMU Profiling exceptions. This allows generation of higher quality profiles by eliminating the interrupt latency and jitter incurred outside the PE.

This feature is supported in both AArch64 and AArch32 states.

FEAT_EBEP is OPTIONAL from Armv9.3.

In an Armv9.3 implementation, if FEAT_PMUv3p9 is implemented, FEAT_EBEP is implemented.

If FEAT_EBEP is implemented, then FEAT_PMUv3p8 is implemented.

When FEAT_EBEP and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

When FEAT_EBEP and FEAT_AA32EL0 are implemented, FEAT_Debugv8p9 is implemented.

The following field identifies the presence of FEAT_EBEP:

- ID_AA64DFR1_EL1.EBEP.

For more information, see Exception-based event profiling.

FEAT_ETEv1p3, Embedded Trace Extension version 1.3

FEAT_ETEv1p3 extends FEAT_ETE to support all of the following:

- The ETE External Debug Request, when FEAT_Debugv8p9 is implemented.
- The ETE Trace Output Enable, which is mandatory for FEAT_ETEv1p3 and OPTIONAL for FEAT_ETE.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This feature is supported in AArch64 state, and performs trace in both AArch64 and AArch32 states.

FEAT_ETEv1p3 is OPTIONAL from Armv9.3.

If FEAT_ETEv1p3 is implemented, then FEAT_ETEv1p2 is implemented.

The following fields identify the presence of FEAT_ETEv1p3:

- TRCDEVARCH.REVISION.
- TRCDEVARCH.REVISION.

For more information, see The Embedded Trace Extension.

FEAT_GCS, Guarded Control Stack Extension

FEAT_GCS introduces support for a Guarded Control Stack, an area of memory in which procedure return addresses and exception return addresses are stored and protected from modification.

This feature is supported in AArch64 state only.

FEAT_GCS is OPTIONAL from Armv9.3.

If FEAT_GCS is implemented, then FEAT_CHK is implemented.

If FEAT_GCS is implemented, then FEAT_S1PIE is implemented.

The following field identifies the presence of FEAT_GCS:

- ID_AA64PFR1_EL1.GCS.

For more information, see Guarded Control Stack.

FEAT_ITE, Instrumentation Trace Extension

FEAT_ITE provides all of the following to allow software to inject instrumentation information into the ETE trace stream:

- The TRCIT instruction, that injects the value of a general purpose register into the ETE trace stream.
- Instrumentation Packet that contains the value written by the TRCIT instruction.
- Controls that define the behavior of the TRCIT instruction.

This feature is supported in both AArch64 and AArch32 states.

FEAT_ITE is OPTIONAL from Armv9.3.

If FEAT_ITE is implemented, then FEAT_TRF is implemented.

If FEAT_ITE is implemented, then FEAT_ETE is implemented.

If FEAT_ITE is implemented, then FEAT_TRBE is implemented.

When FEAT_ITE and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

The following fields identify the presence of FEAT_ITE:

- ID_AA64DFR1_EL1.ITE.
- TRCIDR0.ITE.
- TRCIDR0.ITE.

For more information, see:

- Instrumentation extension.
- Instrumentation element.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_LSE128, 128-bit Atomics

FEAT_LSE128 introduces support for 128-bit atomic instructions.

This feature is supported in AArch64 state only.

FEAT_LSE128 is OPTIONAL from Armv9.3.

If FEAT_LSE128 is implemented, then FEAT_LSE is implemented.

The following field identifies the presence of FEAT_LSE128:

- ID_AA64ISAR0_EL1.Atomic.

For more information, see:

- Atomic integer memory operations.
- Swap operations.

FEAT_LVA3, 56-bit VA

FEAT_LVA3 introduces support for 56-bit virtual addresses.

This feature is supported in AArch64 state only.

FEAT_LVA3 is OPTIONAL from Armv9.3.

If FEAT_LVA3 is implemented, then FEAT_D128 is implemented.

If FEAT_LVA3 is implemented, then FEAT_LVA is implemented.

The following field identifies the presence of FEAT_LVA3:

- ID_AA64MMFR2_EL1.VARange.

For more information, see Supported virtual address ranges.

FEAT_SME2p1, Scalable Matrix Extension version 2.1

The Scalable Matrix Extension version 2.1 (SME2.1) is a superset of SME2 that adds:

- Support for SVE RAX1 instructions in Streaming SVE mode if FEAT_SVE_SHA3 is implemented.
- SME MOVAZ instructions that move and zero ZA array vectors or ZA tile slices.
- SME ZERO instructions that zero ZA array vectors.
- SME LUTI2 and LUTI4 lookup table instructions to Z vectors with strided numbering.

In this Manual, unless stated otherwise, when SME is used, the behavior also applies to SME2.1.

This feature is supported in AArch64 state only.

FEAT_SME2p1 is OPTIONAL from Armv9.2.

In an Armv9.4 implementation, if FEAT_SME2 is implemented, FEAT_SME2p1 is implemented.

If FEAT_SME2p1 is implemented, then FEAT_SME2 is implemented.

If FEAT_SME and FEAT_SVE2p1 are implemented, then FEAT_SME2p1 is implemented.

The following field identifies the presence of FEAT_SME2p1:

- ID_AA64SMFR0_EL1.SMEver.

For more information, see:

- Data processing - SME, SME2.
- The Scalable Matrix Extension.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SME_B16B16, Non-widening BFloat16 to BFloat16 SME ZA-targeting arithmetic

FEAT_SME_B16B16 introduces SME ZA-targeting non-widening BFloat16 floating-point instructions to SME.

This feature is supported in AArch64 state only.

FEAT_SME_B16B16 is OPTIONAL from Armv9.2.

If FEAT_SME_B16B16 is implemented, then FEAT_SME2 is implemented.

If FEAT_SME_B16B16 is implemented, then FEAT_SVE_B16B16 is implemented.

The following field identifies the presence of FEAT_SME_B16B16:

- ID_AA64SMFR0_EL1.B16B16.

FEAT_SME_F16F16, Non-widening half-precision FP16 to FP16 arithmetic for SME2

FEAT_SME_F16F16 introduces the SME2 half-precision to single-precision convert instructions and non-widening half-precision floating-point instructions.

This feature is supported in AArch64 state only.

FEAT_SME_F16F16 is OPTIONAL from Armv9.2.

If FEAT_SME_F16F16 is implemented, then FEAT_SME2 is implemented.

The following field identifies the presence of FEAT_SME_F16F16:

- ID_AA64SMFR0_EL1.F16F16.

For more information, see:

- Data processing - SME, SME2.
- The Scalable Matrix Extension.

FEAT_SVE2p1, Scalable Vector Extensions version 2.1

The Scalable Vector Extension version 2.1 (SVE2.1) is a superset of SVE2 that adds:

- SVE instructions in Non-streaming SVE mode, which were previously added by SME in Streaming SVE mode. These are:
  - Contiguous multi-vector load and store instructions.
  - Predicate-as-counter instructions.
  - General-purpose SVE instructions.
- Other relaxations and enhancements.

In this Manual, unless stated otherwise, when SVE is used, the behavior also applies to SVE2.1.

This feature is supported in AArch64 state only.

FEAT_SVE2p1 is OPTIONAL from Armv9.2.

In an Armv9.4 implementation, if FEAT_SVE2 is implemented, FEAT_SVE2p1 is implemented.

If FEAT_SVE2p1 is implemented, then FEAT_SVE2 is implemented.

If FEAT_SVE2 and FEAT_SME2p1 are implemented, then FEAT_SVE2p1 is implemented.

The following field identifies the presence of FEAT_SVE2p1:

- ID_AA64ZFR0_EL1.SVEver.

For more information, see:

- FEAT_SVE.
- Loads and stores - SME, SME2, SVE2p1.
- Data processing - SVE2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SVE_B16B16, Non-widening BFloat16 to BFloat16 arithmetic for SVE2 and SME2

FEAT_SVE_B16B16 introduces the following:

- If FEAT_SVE2 is implemented, the SVE non-widening BFloat16 instructions when the PE is not in Streaming SVE mode.
- If FEAT_SME2 is implemented, the SVE non-widening BFloat16 instructions when the PE is in Streaming SVE mode, and the SME Z-targeting multi-vector non-widening BFloat16 instructions.

This feature is supported in AArch64 state only.

FEAT_SVE_B16B16 is OPTIONAL from Armv9.2.

If FEAT_SVE_B16B16 is implemented, then FEAT_SME2 or FEAT_SVE2 is implemented.

In an Armv9.6 implementation, if FEAT_SVE_B16B16 is implemented, FEAT_SVE_BFSCALE is implemented.

The following field identifies the presence of FEAT_SVE_B16B16:

- ID_AA64ZFR0_EL1.B16B16.

For more information, see:

- BFloat16 arithmetic.
- BFloat16 minimum/maximum.
- Clamp to minimum/maximum.

FEAT_SYSINSTR128, 128-bit System instructions

FEAT_SYSINSTR128 introduces support for IMPLEMENTATION DEFINED System instructions that can take 128-bit inputs.

This feature is supported in AArch64 state only.

FEAT_SYSINSTR128 is OPTIONAL from Armv9.3.

If FEAT_SYSINSTR128 is implemented, then FEAT_SCTLR2 is implemented.

If FEAT_SYSINSTR128 is implemented, then FEAT_D128 is implemented.

The following field identifies the presence of FEAT_SYSINSTR128:

- ID_AA64ISAR2_EL1.SYSINSTR_128.

For more information, see The A64 System Instruction Class.

FEAT_SYSREG128, 128-bit System registers

FEAT_SYSREG128 introduces the following support for 128-bit System registers:

- The MRRS instruction to move a 128-bit System register into a pair of 64-bit general-purpose registers.
- The MSRR instruction to move a pair of 64-bit general-purpose registers to a 128-bit System register.
- 128-bit formats of the following system registers:
- The Physical Address Register, PAR_EL1.
- The Read-Check-Write mask registers, RCWMASK_EL1 and RCWSMASK_EL1.
- The following translation table base address registers, TTBR0_EL1, TTBR0_EL2, TTBR1_EL1, TTBR1_EL2, VTTBR_EL2.

This feature is supported in AArch64 state only.

FEAT_SYSREG128 is OPTIONAL from Armv9.3.

If FEAT_SYSREG128 is implemented, then FEAT_SCTLR2 is implemented.

If FEAT_SYSREG128 is implemented, then FEAT_D128 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_SYSREG128 is implemented, then FEAT_BigEnd is not implemented.

If FEAT_SYSREG128 is implemented, then FEAT_MixedEnd is not implemented.

The following field identifies the presence of FEAT_SYSREG128:

- ID_AA64ISAR2_EL1.SYSREG_128.

FEAT_TRBE_EXT, Trace Buffer external mode

FEAT_TRBE_EXT allows an external debugger, as well as a self-hosted debugger, to use the Trace Buffer Unit. All of the following registers are introduced to determine the parameters of the implementation:

- TRBDEVARCH.
- TRBDEVID.
- TRBDEVID1.

This feature is supported in both AArch64 and AArch32 states.

FEAT_TRBE_EXT is OPTIONAL from Armv9.3.

If FEAT_TRBE_EXT is implemented, then FEAT_TRBE is implemented.

The following fields identify the presence of FEAT_TRBE_EXT:

- ID_AA64DFR0_EL1.ExtTrcBuff.
- EDDFR.ExtTrcBuff.
- EDDFR.TraceBuffer.
- TRBIDR_EL1.MPAM.
- TRBIDR_EL1.MPAM.

For more information, see Trace buffer External mode.

FEAT_TRBE_MPAM, Trace Buffer MPAM extensions

FEAT_TRBE_MPAM allows software to program the MPAM PARTID and PMG to use different MPAM values for trace data. TRBDEVID1.{PMG_MAX, PARTID_MAX} are used to determine the parameters of the MPAM implementation.

This feature is supported in both AArch64 and AArch32 states.

FEAT_TRBE_MPAM is OPTIONAL from Armv9.3.

If FEAT_TRBE_MPAM is implemented, then FEAT_TRBE_EXT is implemented.

If FEAT_TRBE_MPAM is implemented, then FEAT_MPAM is implemented.

When FEAT_TRBE_MPAM and FEAT_AA64EL2 are implemented, FEAT_FGT2 is implemented.

The following fields identify the presence of FEAT_TRBE_MPAM:

- TRBIDR_EL1.MPAM.
- TRBIDR_EL1.MPAM.

For more information, see External mode and FEAT_MPAM.

A2.3.5.1 Features added to the Armv9.4 extension in later releases

- FEAT_RME_GDI.
- FEAT_SME2p2.
- FEAT_SME_MOP4.
- FEAT_SME_TMOP.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- FEAT_SSVE_BitPerm.
- FEAT_SSVE_FEXPA.
- FEAT_SVE2p2.

A2.3.6 The Armv9.5 architecture extension

The Armv9.5 architecture extension is an extension to Armv9.4. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv9.5 compliant if all of the following apply:

- It is Armv9.4 compliant.
- It includes all of the Armv9.5 architectural features that are mandatory.

An Armv9.5 compliant implementation can additionally include any features that are defined to be optional in Armv9.5.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_ASID2, Support for concurrent use of two ASIDs

FEAT_ASID2 introduces support for use of one ASID for each TTBR_ELx.

This feature is supported in AArch64 state only.

FEAT_ASID2 is OPTIONAL from Armv9.4.

FEAT_ASID2 is mandatory from Armv9.5.

If FEAT_ASID2 is implemented, then FEAT_TCR2 is implemented.

The following field identifies the presence of FEAT_ASID2:

- ID_AA64MMFR4_EL1.ASID2.

For more information, see Use of ASIDs and VMIDs to reduce TLB maintenance requirements.

FEAT_BWE2, Breakpoint and watchpoint enhancements 2

FEAT_BWE2 provides the capability to generate a Watchpoint exception or debug event when software accesses an address outside of one or more user-supplied address regions.

This feature is supported in both AArch64 and AArch32 states.

FEAT_BWE2 is OPTIONAL from Armv9.4.

In an Armv9.5 implementation, if FEAT_BWE is implemented, FEAT_BWE2 is implemented.

If FEAT_BWE2 is implemented, then FEAT_BWE is implemented.

The following fields identify the presence of FEAT_BWE2:

- ID_AA64DFR2_EL1.BWE.
- EDDFR2.BWE.

For more information, see:

- About Watchpoint exceptions.
- Exception syndrome information, fault address information, and preferred return address.
- Watchpoint data address comparisons.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_CPA, Instruction-only Checked Pointer Arithmetic

FEAT_CPA introduces support for Checked Pointer Arithmetic instructions.

This feature is supported in AArch64 state only.

FEAT_CPA is OPTIONAL from Armv9.4.

FEAT_CPA is mandatory from Armv9.5.

The following field identifies the presence of FEAT_CPA:

- ID_AA64ISAR3_EL1.CPA.

For more information, see Checked Pointer Arithmetic.

FEAT_CPA2, Checked Pointer Arithmetic

FEAT_CPA2 introduces support for enabling Checked Pointer Arithmetic. Checked Pointer Arithmetic detects and reports corruption of the following:

- The top 8 bits of a pointer.
- Multiplication overflows that lead to invalid array indices being calculated.

This feature is supported in AArch64 state only.

FEAT_CPA2 is OPTIONAL from Armv9.4.

If FEAT_CPA2 is implemented, then FEAT_CPA is implemented.

If FEAT_CPA2 is implemented, then FEAT_SCTLR2 is implemented.

The following field identifies the presence of FEAT_CPA2:

- ID_AA64ISAR3_EL1.CPA.

For more information, see Checked Pointer Arithmetic.

FEAT_E3DSE, Delegated SError exception injection

FEAT_E3DSE provides an SError injection mechanism for EL3 called delegated SErrors.

This feature is supported in AArch64 state only.

FEAT_E3DSE is OPTIONAL from Armv9.4.

In an Armv9.5 implementation, if FEAT_AA64EL3 is implemented, FEAT_E3DSE is implemented.

The following field identifies the presence of FEAT_E3DSE:

- ID_AA64MMFR4_EL1.E3DSE.

For more information, see Asynchronous exception types.

FEAT_ETS3, Enhanced Translation Synchronization

FEAT_ETS3 introduces support for enhanced memory access ordering requirements for translation table walks.

This feature is supported in both AArch64 and AArch32 states.

FEAT_ETS3 is OPTIONAL from Armv8.0.

FEAT_ETS3 is mandatory from Armv9.5.

If FEAT_ETS3 is implemented, then FEAT_ETS2 is implemented.

The following fields identify the presence of FEAT_ETS3:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64MMFR1_EL1.ETS.
- ID_MMFR5_EL1.ETS.
- ID_MMFR5.ETS.

For more information, see:

- Ordering requirements defined by the formal concurrency model.
- Ordering of memory accesses from translation table walks.
- Ordering of translation table walks.

FEAT_FAMINMAX, Floating-point maximum and minimum absolute value instructions

FEAT_FAMINMAX introduces the Advanced SIMD, SVE and SME `FAMAX` and `FAMIN` instructions that calculate floating-point maximum and minimum absolute value.

FEAT_FAMINMAX is OPTIONAL from Armv9.2.

In an Armv9.5 implementation, if FEAT_FP is implemented, FEAT_FAMINMAX is implemented.

If FEAT_FAMINMAX is implemented, then FEAT_AdvSIMD, FEAT_SVE2, or FEAT_SME2 is implemented.

The following field identifies the presence of FEAT_FAMINMAX:

- ID_AA64ISAR3_EL1.FAMINMAX.

For more information, see:

- SIMD arithmetic.
- Floating-point minimum/maximum absolute value.
- Multi-vector minimum/maximum.

FEAT_FGWTE3, Fine-Grained Write Trap EL3

FEAT_FGWTE3 introduces traps for write accesses at EL3 to individual *_EL3 System registers. The traps are independent of existing controls. The bits in the control register FGWTE3_EL3 are sticky, and writes of 0 are ignored.

This feature is supported in AArch64 state only.

FEAT_FGWTE3 is OPTIONAL from Armv9.4.

If FEAT_FGWTE3 is implemented, then FEAT_EL3 is implemented.

The following field identifies the presence of FEAT_FGWTE3:

- ID_AA64MMFR4_EL1.FGWTE3.

For more information, see EL3 configurable instruction controls.

FEAT_FP8, FP8 convert instructions

FEAT_FP8 introduces the following:

- OFP8 formats E5M2 and E4M3 for FP8 instructions.
- Advanced SIMD: FP8 convert instructions and a floating point scaling `FSCALE` instruction.
- SME: FP8 convert instructions and floating point scaling `FSCALE` instructions.
- SVE: FP8 convert instructions.

FEAT_FP8 is OPTIONAL from Armv9.2.

If FEAT_FP8 is implemented, then FEAT_FPMR is implemented.

If FEAT_FP8 is implemented, then FEAT_FAMINMAX is implemented.

If FEAT_FP8 is implemented, then FEAT_LUT is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_FP8 is implemented, then FEAT_BF16 is implemented.

If FEAT_FP8 is implemented, then FEAT_AdvSIMD, FEAT_SVE2, or FEAT_SME2 is implemented.

The following fields identify the presence of FEAT_FP8:

- ID_AA64FPFR0_EL1.F8CVT.
- ID_AA64FPFR0_EL1.F8E4M3.
- ID_AA64FPFR0_EL1.F8E5M2.

For more information, see:

- FP8 floating-point formats.
- Summary of FP8 instruction behaviors.
- For Advanced SIMD, FP8 floating-point conversion.
- For SVE, FP8 floating-point conversions.
- For SME, FP8 floating-point conversions.
- The *OCP 8-bit Floating Point Specification (OFP8)*.

FEAT_FP8DOT2, FP8 2-way dot product to half-precision instructions

FEAT_FP8DOT2 introduces the Advanced SIMD FP8 to half-precision 2-way dot product instructions.

If FEAT_SVE2 is implemented, FEAT_FP8DOT2 also implements the SVE versions of these instructions.

Note

This feature does not enable execution of the SVE instructions in Streaming SVE mode.

FEAT_FP8DOT2 is OPTIONAL from Armv9.2.

If FEAT_FP8DOT2 is implemented, then FEAT_FP8DOT4 is implemented.

If FEAT_FP8DOT2 is implemented, then FEAT_AdvSIMD or FEAT_SVE2 is implemented.

The following field identifies the presence of FEAT_FP8DOT2:

- ID_AA64FPFR0_EL1.F8DP2.

For more information, see:

- Summary of FP8 instruction behaviors.
- For Advanced SIMD, FP8 floating-point dot product.
- For SVE, FP8 floating-point dot product.

FEAT_FP8DOT4, FP8 4-way dot product to single-precision instructions

FEAT_FP8DOT4 introduces the following:

- Advanced SIMD: FP8 to single-precision 4-way dot product instructions.
- SVE: SVE FP8 to single-precision 4-way dot product instructions.

Note

This feature does not enable execution of the SVE instructions in Streaming SVE mode.

FEAT_FP8DOT4 is OPTIONAL from Armv9.2.

If FEAT_FP8DOT4 is implemented, then FEAT_FP8FMA is implemented.

If FEAT_FP8DOT4 is implemented, then FEAT_AdvSIMD or FEAT_SVE2 is implemented.

The following field identifies the presence of FEAT_FP8DOT4:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64FPFR0_EL1.F8DP4.

For more information, see:

- Summary of FP8 instruction behaviors.
- For Advanced SIMD, FP8 floating-point dot product.
- For SVE, FP8 floating-point dot product.

FEAT_FP8FMA, FP8 multiply-accumulate to half-precision and single-precision instructions

FEAT_FP8FMA introduces the following:

- Advanced SIMD: FP8 to half-precision and single-precision multiply-accumulate instructions.
- SVE: FP8 to half-precision and single-precision multiply-accumulate instructions.

Note

This feature does not enable execution of the SVE instructions in Streaming SVE mode.

FEAT_FP8FMA is OPTIONAL from Armv9.2.

If FEAT_FP8FMA is implemented, then FEAT_FP8 is implemented.

If FEAT_FP8FMA is implemented, then FEAT_AdvSIMD or FEAT_SVE2 is implemented.

The following field identifies the presence of FEAT_FP8FMA:

- ID_AA64FPFR0_EL1.F8FMA.

For more information, see:

- Summary of FP8 instruction behaviors.
- For Advanced SIMD, FP8 floating-point widening multiply-accumulate.
- For SVE, FP8 floating-point widening multiply-accumulate.

FEAT_FPMR, Floating-point Mode Register

FEAT_FPMR introduces the Special-purpose register FPMR.

FEAT_FPMR is OPTIONAL from Armv9.2.

If FEAT_FPMR is implemented, then FEAT_AdvSIMD is implemented.

When FEAT_FPMR and FEAT_EL2 are implemented, FEAT_FGT is implemented.

When FEAT_FPMR and FEAT_EL2 are implemented, FEAT_HCX is implemented.

The following field identifies the presence of FEAT_FPMR:

- ID_AA64PFR2_EL1.FPMR.

For more information, see Summary of FP8 instruction behaviors.

FEAT_HACDBS, Hardware accelerator for cleaning Dirty state

FEAT_HACDBS introduces the Hardware accelerator for cleaning Dirty state, which enhances the process of updating stage 2 descriptors from writable-dirty to writable-clean.

This feature is supported in AArch64 state only.

FEAT_HACDBS is OPTIONAL from Armv9.4.

If FEAT_HACDBS is implemented, then FEAT_HDBSS is implemented.

The following field identifies the presence of FEAT_HACDBS:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64MMFR4_EL1.HACDBS.

For more information, see Hardware accelerator for cleaning dirty state.

FEAT_HDBSS, Hardware Dirty state tracking structure

FEAT_HDBSS introduces the Hardware Dirty state tracking structure, which enhances tracking the dirty state of stage 2 translation table descriptors.

This feature is supported in AArch64 state only.

FEAT_HDBSS is OPTIONAL from Armv9.4.

If FEAT_HDBSS is implemented, then FEAT_HAFT is implemented.

If FEAT_HDBSS is implemented, then FEAT_AA64EL2 is implemented.

The following field identifies the presence of FEAT_HDBSS:

- ID_AA64MMFR1_EL1.HAFDBS.

For more information, see Hardware dirty state tracking structure.

FEAT_LUT, Lookup table instructions with 2-bit and 4-bit indices

FEAT_LUT introduces the following lookup table instructions with 2-bit and 4-bit indices:

- The Advanced SIMD `LUTI2` and `LUTI4` instructions.
- If FEAT_SVE2 is implemented, the SVE `LUTI2` and `LUTI4` instructions when the PE is not in Streaming SVE mode.
- If FEAT_SME2 is implemented, the SVE `LUTI2` and `LUTI4` instructions when the PE is in Streaming SVE mode.

FEAT_LUT is OPTIONAL from Armv9.2.

In an Armv9.5 implementation, if FEAT_AdvSIMD is implemented, FEAT_LUT is implemented.

If FEAT_LUT is implemented, then FEAT_AdvSIMD, FEAT_SVE2, or FEAT_SME2 is implemented.

The following field identifies the presence of FEAT_LUT:

- ID_AA64ISAR2_EL1.LUT.

For more information, see:

- For Advanced SIMD, Lookup table using 2-bit or 4-bit indices.
- For SVE, Lookup table using 2-bit or 4-bit indices.

FEAT_PAuth_LR, Pointer authentication instructions that allow signing of LR using SP and PC as diversifiers

FEAT_PAuth_LR introduces instructions that allow signing of the 64-bit value in LR against the value of SP, and a PC-relative instruction address.

This feature is supported in AArch64 state only.

FEAT_PAuth_LR is OPTIONAL from Armv9.4.

If FEAT_PAuth_LR is implemented, then FEAT_FPACCOMBINE is implemented.

If FEAT_PAuth_LR is implemented, then FEAT_SCTLR2 is implemented.

When FEAT_PAuth_LR and FEAT_AA64EL2 are implemented, FEAT_HCX is implemented.

The following fields identify the presence of FEAT_PAuth_LR:

- ID_AA64ISAR3_EL1.PACM.
- ID_AA64ISAR1_EL1.APA.
- ID_AA64ISAR1_EL1.API.
- ID_AA64ISAR2_EL1.APA3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_PMUv3_SME, Performance Monitors extensions for SME

FEAT_PMUv3_SME supports filtering to control counting events in Streaming and Non-streaming SVE modes.

This feature is supported in AArch64 state only.

FEAT_PMUv3_SME is OPTIONAL from Armv9.4.

In an Armv9.5 implementation, if FEAT_PMUv3 and FEAT_SME are implemented, FEAT_PMUv3_SME is implemented.

If FEAT_PMUv3_SME is implemented, then FEAT_PMUv3 is implemented.

If FEAT_PMUv3_SME is implemented, then FEAT_SME is implemented.

The following field identifies the presence of FEAT_PMUv3_SME:

- PMMIR_EL1.SME.

For more information, see Filtering by SVE Streaming mode.

FEAT_PMUv3_TH2, Performance Monitors event counter linking extension

FEAT_PMUv3_TH2 extends the Performance Monitors Extension to add the ability to program an event counter to count the logical combination of two events.

This feature is supported in both AArch64 and AArch32 states. The threshold condition controls are accessible only in AArch64 state. However, threshold conditions still apply in AArch32 state.

FEAT_PMUv3_TH2 is OPTIONAL from Armv9.4.

If FEAT_PMUv3_TH2 is implemented, then FEAT_PMUv3_TH is implemented.

If FEAT_PMUv3_TH2 is implemented, then FEAT_PMUv3_EDGE is implemented.

The following fields identify the presence of FEAT_PMUv3_TH2:

- PMMIR_EL1.EDGE.
- PMMIR.EDGE.

For more information, see Event threshold and edge counting.

FEAT_RME_GPC2, RME Granule Protection Check 2 Extension

FEAT_RME_GPC2 introduces two mechanisms to the GPC that enable memory isolation models:

- Non-secure Only GPI encoding.
- Physical Address Space Disable.

This feature is supported in AArch64 state only.

FEAT_RME_GPC2 is OPTIONAL from Armv9.4.

If FEAT_RME_GPC2 is implemented, then FEAT_RME is implemented.

The following field identifies the presence of FEAT_RME_GPC2:

- ID_AA64PFR0_EL1.RME.

For more information, see:

- GPC faults.
- GPI field encoding in GPT descriptors.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SME_F8F16, SME2 ZA-targeting FP8 multiply-accumulate, dot product, and outer product to half-precision instructions

FEAT_SME_F8F16 introduces the following SME instructions:

- ZA-targeting FP8 to half-precision multiply-accumulate, dot product, and outer product instructions.
- ZA-targeting multi-vector non-widening half-precision FADD and FSUB instructions.

FEAT_SME_F8F16 is OPTIONAL from Armv9.2.

If FEAT_SME_F8F16 is implemented, then FEAT_SME_F8F32 is implemented.

The following field identifies the presence of FEAT_SME_F8F16:

- ID_AA64SMFR0_EL1.F8F16.

For more information, see:

- Summary of FP8 instruction behaviors.
- FP8 floating-point widening multiply-accumulate.
- FP8 floating-point dot product.
- FP8 floating-point outer product.

FEAT_SME_F8F32, SME2 ZA-targeting FP8 multiply-accumulate, dot product, and outer product to single-precision instructions

FEAT_SME_F8F32 introduces the SME ZA-targeting FP8 to single-precision multiply-accumulate, dot product, and outer product instructions.

FEAT_SME_F8F32 is OPTIONAL from Armv9.2.

If FEAT_SME_F8F32 is implemented, then FEAT_SME2 is implemented.

If FEAT_SME_F8F32 is implemented, then FEAT_FP8 is implemented.

The following field identifies the presence of FEAT_SME_F8F32:

- ID_AA64SMFR0_EL1.F8F32.

For more information, see:

- Summary of FP8 instruction behaviors.
- FP8 floating-point widening multiply-accumulate.
- FP8 floating-point dot product.
- FP8 floating-point outer product.

FEAT_SME_LUTv2, Lookup table instructions with 4-bit indices and 8-bit elements

FEAT_SME_LUTv2 introduces the following:

- The LUTI4 (four registers, 8-bit) instruction.
- The MOVT (vector to table) instruction.

FEAT_SME_LUTv2 is OPTIONAL from Armv9.2.

If FEAT_SME_LUTv2 is implemented, then FEAT_SME2 is implemented.

The following field identifies the presence of FEAT_SME_LUTv2:

- ID_AA64SMFR0_EL1.LUTv2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SPE_ALTCLK, Statistical Profiling alternate clock domain extension

FEAT_SPE_ALTCLK supports collection of timing data using the Statistical Profiling Extension when profiling a PE that includes asynchronous accelerators, such as a Streaming Mode Compute Unit (SMCU).

This feature is supported in AArch64 state only.

FEAT_SPE_ALTCLK is OPTIONAL from Armv9.4.

If FEAT_SPE_ALTCLK is implemented, then FEAT_SPE is implemented.

The following field identifies the presence of FEAT_SPE_ALTCLK:

- PMSIDR_EL1.ALTCLK.

For more information, see Asynchronous operation.

FEAT_SPE_EFT, Statistical Profiling extended filtering by type

FEAT_SPE_EFT extends SPE filtering to support targeted profiling of floating-point and SIMD operations.

This feature is supported in AArch64 state only.

FEAT_SPE_EFT is OPTIONAL from Armv9.4.

In an Armv9.5 implementation, if FEAT_SPE is implemented, FEAT_SPE_EFT is implemented.

If FEAT_SPE_EFT is implemented, then FEAT_SPE is implemented.

If FEAT_SPE_EFT is implemented, then FEAT_SPE_FPF is implemented.

The following field identifies the presence of FEAT_SPE_EFT:

- PMSIDR_EL1.EFT.

For more information, see Filtering by operation type.

FEAT_SPE_FPF, Statistical Profiling floating-point and SIMD flag extension

FEAT_SPE_FPF extends the profiling information recorded by the Statistical Profiling Extension to identify sampled scalar floating-point and Advanced SIMD instructions.

This feature is supported in AArch64 state only.

FEAT_SPE_FPF is OPTIONAL from Armv9.4.

In an Armv9.5 implementation, if FEAT_SPE is implemented, FEAT_SPE_FPF is implemented.

If FEAT_SPE_FPF is implemented, then FEAT_SPE is implemented.

If FEAT_SPE_FPF is implemented, then FEAT_SPE_EFT is implemented.

The following field identifies the presence of FEAT_SPE_FPF:

- PMSIDR_EL1.FPF.

For more information, see Additional information for other operations.

FEAT_SPE_SME, Statistical Profiling extensions for SME

FEAT_SPE_SME provides support for profiling of software that uses SME instructions using the Statistical Profiling Extension.

This feature is supported in AArch64 state only.

FEAT_SPE_SME is OPTIONAL from Armv9.2.

In an Armv9.5 implementation, if FEAT_SPEv1p1 and FEAT_SME are implemented, FEAT_SPE_SME is implemented.

If FEAT_SPE_SME is implemented, then FEAT_SPEv1p1 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_SPE_SME is implemented, then FEAT_SME is implemented.

The following field identifies the presence of FEAT_SPE_SME:

- PMSIDR_EL1.SME.

For more information, see Additional information for each profiled SVE and SME operation.

FEAT_SPMU2, System Performance Monitors Extension, version 2

FEAT_SPMU2 provides the functionality to set multiple event counters in a System PMU to zero in a single operation.

This feature is supported in both AArch64 and AArch32 states.

FEAT_SPMU2 is OPTIONAL from Armv9.4.

In an Armv9.5 implementation, if FEAT_SPMU is implemented, FEAT_SPMU2 is implemented.

If FEAT_SPMU2 is implemented, then FEAT_SPMU is implemented.

The following field identifies the presence of FEAT_SPMU2:

- ID_AA64DFR1_EL1.SPMU.

For more information, see Zeroing System PMU counters.

FEAT_SSVE_FP8DOT2, SVE FP8 2-way dot product to half-precision instructions in Streaming SVE mode

FEAT_SSVE_FP8DOT2 enables execution of SVE FP8 to half-precision 2-way dot product instructions in Streaming SVE mode.

FEAT_SSVE_FP8DOT2 is OPTIONAL from Armv9.2.

If FEAT_SSVE_FP8DOT2 is implemented, then FEAT_SSVE_FP8DOT4 is implemented.

If FEAT_SME2 and FEAT_FP8DOT2 are implemented, then FEAT_SSVE_FP8DOT2 is implemented.

The following field identifies the presence of FEAT_SSVE_FP8DOT2:

- ID_AA64SMFR0_EL1.SF8DP2.

For more information, see:

- Summary of FP8 instruction behaviors.
- FP8 floating-point dot product.

FEAT_SSVE_FP8DOT4, SVE2 FP8 4-way dot product to single-precision instructions in Streaming SVE mode

FEAT_SSVE_FP8DOT4 enables execution of SVE FP8 to single-precision 4-way dot product instructions in Streaming SVE mode.

FEAT_SSVE_FP8DOT4 is OPTIONAL from Armv9.2.

If FEAT_SSVE_FP8DOT4 is implemented, then FEAT_SSVE_FP8FMA is implemented.

If FEAT_SME2 and FEAT_FP8DOT4 are implemented, then FEAT_SSVE_FP8DOT4 is implemented.

The following field identifies the presence of FEAT_SSVE_FP8DOT4:

- ID_AA64SMFR0_EL1.SF8DP4.

For more information, see:

- Summary of FP8 instruction behaviors.
- FP8 floating-point dot product.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SSVE_FP8FMA, SVE2 FP8 multiply-accumulate to half-precision and single-precision instructions in Streaming SVE mode

FEAT_SSVE_FP8FMA enables execution of SVE FP8 to half-precision and single-precision multiply-accumulate instructions in Streaming SVE mode.

FEAT_SSVE_FP8FMA is OPTIONAL from Armv9.2.

If FEAT_SSVE_FP8FMA is implemented, then FEAT_FP8 is implemented.

If FEAT_SSVE_FP8FMA is implemented, then FEAT_SME2 is implemented.

If FEAT_SME2 and FEAT_FP8FMA are implemented, then FEAT_SSVE_FP8FMA is implemented.

The following field identifies the presence of FEAT_SSVE_FP8FMA:

- ID_AA64SMFR0_EL1.SF8FMA.

For more information, see:

- Summary of FP8 instruction behaviors.
- FP8 floating-point widening multiply-accumulate.

FEAT_STEP2, Enhanced Software Step Extension

FEAT_STEP2 introduces support for a debugger to control the instruction executed by the PE when single-stepping, without modifying the instruction in memory.

This feature is supported in both AArch64 and AArch32 states.

FEAT_STEP2 is OPTIONAL from Armv9.4.

FEAT_STEP2 is mandatory from Armv9.5.

When FEAT_STEP2 and FEAT_EL2 are implemented, FEAT_FGT2 is implemented.

The following field identifies the presence of FEAT_STEP2:

- ID_AA64DFR2_EL1.STEP.

For more information, see Behavior in the active-not-pending state.

FEAT_TLBIW, TLBI VMALL for Dirty state

FEAT_TLBIW provides the following TLBI instructions that remove the stage 2 dirty state from TLB entries:

- TLBI VMALLWS2E1, TLBI VMALLWS2E1NXS.
- TLBI VMALLWS2E1IS, TLBI VMALLWS2E1ISNXS.
- TLBI VMALLWS2E1OS, TLBI VMALLWS2E1OSNXS.

This feature is supported in AArch64 state only.

FEAT_TLBIW is OPTIONAL from Armv9.4.

If FEAT_TLBIW is implemented, then FEAT_AA64EL2 is implemented.

The following field identifies the presence of FEAT_TLBIW:

- ID_AA64ISAR3_EL1.TLBIW.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A2.3.7 The Armv9.6 architecture extension

The Armv9.6 architecture extension is an extension to Armv9.5. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv9.6 compliant if all of the following apply:

- It is Armv9.5 compliant.
- It includes all of the Armv9.6 architectural features that are mandatory.

An Armv9.6 compliant implementation can additionally include any features that are defined to be optional in Armv9.6.

The implemented features must meet the constraints that require certain features to be implemented together, as specified in the individual feature descriptions.

FEAT_CMPBR, Compare and Branch instructions

FEAT_CMPBR introduces the A64 base compare and branch instructions.

This feature is supported in AArch64 state only.

FEAT_CMPBR is OPTIONAL from Armv9.3.

FEAT_CMPBR is mandatory from Armv9.6.

If FEAT_CMPBR is implemented, then FEAT_CSSC is implemented.

The following field identifies the presence of FEAT_CMPBR:

- ID_AA64ISAR2_EL1.CSSC.

For more information, see:

- Conditional branch.
- Concurrent modification and execution of instructions.

FEAT_F8F16MM, 8-bit floating-point matrix multiply-accumulate to half-precision

FEAT_F8F16MM introduces the Advanced SIMD 8-bit floating-point matrix multiply-accumulate to half-precision instruction.

If FEAT_SVE2 is implemented, FEAT_F8F16MM implements the SVE 8-bit floating-point matrix multiply-accumulate to half-precision instruction, when the PE is not in Streaming SVE mode.

This feature is supported in AArch64 state only.

FEAT_F8F16MM is OPTIONAL from Armv9.2.

If FEAT_F8F16MM is implemented, then FEAT_F8F32MM is implemented.

If FEAT_F8F16MM is implemented, then FEAT_FP8DOT2 is implemented.

The following field identifies the presence of FEAT_F8F16MM:

- ID_AA64FPFR0_EL1.F8MM4.

For more information, see:

- For Advanced SIMD: FP8 matrix multiply-accumulate.
- For SVE: FP8 floating-point matrix multiply-accumulate.

FEAT_F8F32MM, 8-bit floating-point matrix multiply-accumulate to single-precision

FEAT_F8F32MM introduces the Advanced SIMD 8-bit floating-point matrix multiply-accumulate to single-precision instruction.

If FEAT_SVE2 is implemented, FEAT_F8F32MM implements the SVE 8-bit floating-point matrix multiply-accumulate to single-precision instruction, when the PE is not in Streaming SVE mode.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This feature is supported in AArch64 state only.

FEAT_F8F32MM is OPTIONAL from Armv9.2.

If FEAT_F8F32MM is implemented, then FEAT_FP8DOT4 is implemented.

The following field identifies the presence of FEAT_F8F32MM:

- ID_AA64FPFR0_EL1.F8MM8.

For more information, see:

- For Advanced SIMD: FP8 matrix multiply-accumulate.
- For SVE: FP8 floating-point matrix multiply-accumulate.

FEAT_FPRCVT, Floating-Point to/from Integer in Scalar FP register

FEAT_FPRCVT introduces A64 base floating-point to integer and integer to floating-point convert instructions with only scalar SIMD&FP register operands and results, and with different input and output register sizes.

FEAT_FPRCVT implements the Advanced SIMD scalar floating-point to integer and integer to floating-point convert instructions with only scalar SIMD&FP register operands and results, and with different and same input and output register sizes, when the PE is in Streaming SVE mode.

This feature is supported in AArch64 state only.

FEAT_FPRCVT is OPTIONAL from Armv9.5.

If FEAT_FPRCVT is implemented, then FEAT_FP is implemented.

The following field identifies the presence of FEAT_FPRCVT:

- ID_AA64ISAR3_EL1.FPRCVT.

For more information, see:

- Floating-point conversion.

FEAT_HINTE, Extended hint instruction space

FEAT_HINTE extends the A64 architectural hint instructions space.

This feature is supported in AArch64 state only.

FEAT_HINTE is OPTIONAL from Armv9.0.

FEAT_HINTE is mandatory from Armv9.6.

The following field identifies the presence of FEAT_HINTE:

- ID_AA64ISAR3_EL1.HINTE.

For more information, see:

- Architectural hint instructions.

FEAT_IDTE3, Trapping ID register accesses to EL3

FEAT_IDTE3 introduces support for trapping ID register accesses to EL3.

This feature is supported in AArch64 state only.

In an Armv9.6 implementation, if FEAT_EL3 is implemented, FEAT_IDTE3 is implemented.

FEAT_IDTE3 is OPTIONAL from Armv9.0.

The following field identifies the presence of FEAT_IDTE3:

- ID_AA64MMFR2_EL1.IDS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_LS64WB, LS64 for Write-back cacheable memory

FEAT_LS64WB provides support for large single-copy atomic load and store instructions for accesses to Conventional memory to enable scalability of atomic message passing without relying on separate flag and data accesses.

This feature is supported in AArch64 state only.

FEAT_LS64WB is OPTIONAL from Armv9.2.

If FEAT_LS64WB is implemented, then FEAT_LS64_ACCDATA is implemented.

The following field identifies the presence of FEAT_LS64WB:

- ID_AA64ISAR1_EL1.LS64.

FEAT_LSFE, Large System Float Extension

FEAT_LSFE implements A64 base Atomic floating-point in-memory instructions.

This feature is supported in AArch64 state only.

FEAT_LSFE is OPTIONAL from Armv9.3.

If FEAT_LSFE is implemented, then FEAT_FP is implemented.

The following field identifies the presence of FEAT_LSFE:

- ID_AA64ISAR3_EL1.LSFE.

For more information, see:

- Atomic floating-point memory operations.

FEAT_LSUI, Unprivileged Load Store

FEAT_LSUI introduces unprivileged variants of load and store instructions so that clearing PSTATE.PAN is never required in privileged software.

This feature is supported in AArch64 state only.

FEAT_LSUI is OPTIONAL from Armv9.5.

FEAT_LSUI is mandatory from Armv9.6.

The following field identifies the presence of FEAT_LSUI:

- ID_AA64ISAR3_EL1.LSUI.

FEAT_MPAM_PE_BW_CTRL, MPAM PE-side Bandwidth Controls

FEAT_MPAM_PE_BW_CTRL introduces support for PE-side bandwidth controls.

This feature is supported in AArch64 state only.

FEAT_MPAM_PE_BW_CTRL is OPTIONAL from Armv9.3.

If FEAT_MPAM_PE_BW_CTRL is implemented, then FEAT_MPAMv1p1 or FEAT_MPAMv0p1 is implemented.

The following field identifies the presence of FEAT_MPAM_PE_BW_CTRL:

- MPAMIDR_EL1.HAS_BW_CTRL.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_NV2p1, Enhanced nested virtualization support

FEAT_NV2p1 further supports nested virtualization by ensuring that control bits in EL1 registers are stateful if the corresponding bits in the corresponding EL2 registers are stateful. This is to prevent loss of the Guest hypervisor's state, and to permit the Host hypervisor to correctly emulate the EL2 environment.

This feature is supported in AArch64 state only.

FEAT_NV2p1 is OPTIONAL from Armv8.4.

In an Armv9.6 implementation, if FEAT_NV is implemented, FEAT_NV2p1 is implemented.

If FEAT_NV2p1 is implemented, then FEAT_NV2 is implemented.

The following field identifies the presence of FEAT_NV2p1:

- ID_AA64MMFR4_EL1.NV_frac.

FEAT_OCCMO, Outer Cacheable Cache Maintenance Operation

FEAT_OCCMO introduces the DC system instruction that provides software with a mechanism to publish writes to the Outer cache level.

This feature is supported in AArch64 state only.

FEAT_OCCMO is OPTIONAL from Armv9.3.

FEAT_OCCMO is mandatory from Armv9.6.

The following field identifies the presence of FEAT_OCCMO:

- ID_AA64ISAR3_EL1.OCCMO.

FEAT_PCDPHINT, Producer-Consumer Data Placement Hints

FEAT_PCDPHINT provides instructions to hint to the memory system the following:

- A store in the current execution thread is generating data at a specific location that one or more other observers are waiting on.
- The thread of execution on the current PE will read a location that might not yet have been updated with the value the thread needs, and the memory system should optimize for low-latency delivery of that value when the write by the other observer does occur.

This feature is supported in AArch64 state only.

FEAT_PCDPHINT is OPTIONAL from Armv9.0.

The following field identifies the presence of FEAT_PCDPHINT:

- ID_AA64ISAR2_EL1.PCDPHINT.

For more information about FEAT_PCDPHINT, see:

- Use of the FEAT_PCDPHINT STSHH and PRFM IR (immediate) hint instructions.
- STSHH.
- PRFM (immediate).

FEAT_PMUv3_EXTPMN, Reserving PMU event counters for external agents

FEAT_PMUv3_EXTPMN provides external agents with a mechanism to reserve event counters for external use.

This feature is supported in both AArch64 and AArch32 states.

FEAT_PMUv3_EXTPMN is OPTIONAL from Armv9.5.

If FEAT_PMUv3_EXTPMN is implemented, then FEAT_PMUv3 is implemented.

If FEAT_PMUv3_EXTPMN is implemented, then FEAT_PMUv3_EXT is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_PMUv3_EXTPMN is implemented, then FEAT_FGT is implemented.

When FEAT_PMUv3_EXTPMN and FEAT_EL2 are implemented, FEAT_HPMN0 is implemented.

The following field identifies the presence of FEAT_PMUv3_EXTPMN:

- PMDEVID.EXTPMN.

FEAT_PoPS, Point of Physical Storage

FEAT_PoPS defines the Point of Physical Storage (PoPS) and introduces System instructions to clean and invalidate to the PoPS.

This feature is supported in AArch64 state only.

FEAT_PoPS is OPTIONAL from Armv9.5.

The following field identifies the presence of FEAT_PoPS:

- ID_AA64MMFR4_EL1.PoPS.

For more information, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

FEAT_RME_GDI, RME Granular Data Isolation extension

FEAT_RME_GDI introduces additional GPT GPI encodings to enable memory isolation of non-PE data flows from the PEs, within an RME system.

This feature is supported in AArch64 state only.

FEAT_RME_GDI is OPTIONAL from Armv9.4.

If FEAT_RME_GDI is implemented, then FEAT_RME is implemented.

If FEAT_RME_GDI is implemented, then FEAT_RME_GPC2 is implemented.

The following field identifies the presence of FEAT_RME_GDI:

- ID_AA64MMFR4_EL1.RMEGDI.

FEAT_RME_GPC3, RME Granule Protection Check 3 Extension

FEAT_RME_GPC3 introduces a method for defining a set of windows in the memory map for which Granule Protection Table lookups are skipped, and instead applies a set of default settings associated with the window.

FEAT_RME_GPC3 introduces the APAS system instruction, which provides an architected mechanism for directly programming the PA space association for regions of memory that support memory-side dynamic PA space association.

This feature is supported in AArch64 state only.

FEAT_RME_GPC3 is OPTIONAL from Armv9.5.

If FEAT_RME_GPC3 is implemented, then FEAT_RME is implemented.

If FEAT_RME_GPC3 is implemented, then FEAT_RME_GPC2 is implemented.

The following field identifies the presence of FEAT_RME_GPC3:

- ID_AA64PFR0_EL1.RME.

FEAT_SME2p2, Scalable Matrix Extension version 2.2

The Scalable Matrix Extension version 2.2 (SME2.2) is a superset of SME2.1 that adds:

- SME multi-vector Z-targeting non-widening floating-point FMUL instruction.
- Quarter-tile outer product instructions.
- Structured sparsity outer product instructions.
- Support for SVE2.2 instructions in Streaming SVE mode.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This feature is supported in AArch64 state only.

FEAT_SME2p2 is OPTIONAL from Armv9.4.

If FEAT_SME2p2 is implemented, then FEAT_SME2p1 is implemented.

If FEAT_SME2p2 is implemented, then FEAT_SME_MOP4 is implemented.

If FEAT_SME2p2 is implemented, then FEAT_SME_TMOP is implemented.

If FEAT_SME2p2 is implemented, then FEAT_SSVE_FEXPA is implemented.

If FEAT_SME and FEAT_SVE2p2 are implemented, then FEAT_SME2p2 is implemented.

The following field identifies the presence of FEAT_SME2p2:

- ID_AA64SMFR0_EL1.SMEver.

For more information, see:

- The Scalable Matrix Extension.
- Multi-vector multiply.
- Quarter-tile outer product.
- Structured sparsity outer product.

FEAT_SME_MOP4, Quarter-tile outer product instructions

FEAT_SME_MOP4 introduces the SME Quarter-tile outer product instructions

FEAT_SME_MOP4 is OPTIONAL from Armv9.4.

If FEAT_SME_MOP4 is implemented, then FEAT_SME2p1 is implemented.

The following field identifies the presence of FEAT_SME_MOP4:

- ID_AA64SMFR0_EL1.SMOP4.

For more information, see:

- Quarter-tile outer product.

FEAT_SME_TMOP, Structured sparsity outer product instructions

FEAT_SME_TMOP introduces the SME Structured sparsity outer product instructions.

FEAT_SME_TMOP is OPTIONAL from Armv9.4.

If FEAT_SME_TMOP is implemented, then FEAT_SME2p1 is implemented.

The following field identifies the presence of FEAT_SME_TMOP:

- ID_AA64SMFR0_EL1.STMOP.

For more information, see:

- Structured sparsity outer product.

FEAT_SPE_EXC, SPE Profiling exception extension

FEAT_SPE_EXC provides support for reporting Profiling Buffer management events as SPE Profiling exceptions.

This feature is supported in AArch64 state only.

FEAT_SPE_EXC is OPTIONAL from Armv9.5.

If FEAT_SPE_EXC is implemented, then FEAT_SPEv1p5 is implemented.

The following field identifies the presence of FEAT_SPE_EXC:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64DFR2_EL1.SPE_EXC.

FEAT_SPE_nVM, Statistical Profiling physical addressing mode extension

FEAT_SPE_nVM provides support for defining the Profiling Buffer using physical addresses or intermediate physical addresses.

This feature is supported in AArch64 state only.

FEAT_SPE_nVM is OPTIONAL from Armv9.5.

If FEAT_SPE_nVM is implemented, then FEAT_SPE is implemented.

When FEAT_SPE_nVM and FEAT_EL2 are implemented, FEAT_FGT2 is implemented.

The following field identifies the presence of FEAT_SPE_nVM:

- ID_AA64DFR2_EL1.SPE_nVM.

FEAT_SPEv1p5, Statistical Profiling Extension version 1.5

FEAT_SPEv1p5 introduces the following to the Statistical Profiling Extension:

- If EL2 and FEAT_FGT are implemented, a fine-grained trap on the `PSB CSYNC` instruction.
- The SPE Profiling exception extension, FEAT_SPE_EXC.
- The Statistical Profiling physical addressing mode extension, FEAT_SPE_nVM.

This feature is supported in AArch64 state only.

FEAT_SPEv1p5 is OPTIONAL from Armv9.5.

In an Armv9.6 implementation, if FEAT_SPE is implemented, FEAT_SPEv1p5 is implemented.

If FEAT_SPEv1p5 is implemented, then FEAT_SPEv1p4 is implemented.

If FEAT_SPEv1p5 is implemented, then FEAT_SPE_CRR is implemented.

If FEAT_SPEv1p5 is implemented, then FEAT_SPE_EXC is implemented.

If FEAT_SPEv1p5 is implemented, then FEAT_SPE_nVM is implemented.

The following field identifies the presence of FEAT_SPEv1p5:

- ID_AA64DFR0_EL1.PMSVer.

FEAT_SRMASK, Bitwise System Register Write Masks

FEAT_SRMASK introduces aliases and bitwise write masks for EL1 control registers to reduce trapping of EL1 System register accesses to EL2. The equivalent bitwise write masks are also present for EL2.

This feature is supported in AArch64 state only.

FEAT_SRMASK is OPTIONAL from Armv9.5.

FEAT_SRMASK is mandatory from Armv9.6.

If FEAT_SRMASK is implemented, then FEAT_E2H0 is not implemented.

The following field identifies the presence of FEAT_SRMASK:

- ID_AA64MMFR4_EL1.SRMASK.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SSVE_AES, Streaming SVE Mode Advanced Encryption Standard and 128-bit polynomial multiply long instructions

FEAT_SSVE_AES implements the SVE AES and 128-bit polynomial multiply long instructions, identified as implemented by ID_AA64ZFR0_EL1.AES field, when the PE is in Streaming SVE mode.

This feature is supported in AArch64 state only.

FEAT_SSVE_AES is OPTIONAL from Armv9.5.

If FEAT_SSVE_AES is implemented, then FEAT_SME2p1 is implemented.

The following field identifies the presence of FEAT_SSVE_AES:

- ID_AA64SMFR0_EL1.AES.

For more information, see:

- AES-128 instructions.
- Polynomial arithmetic.

FEAT_SSVE_BitPerm, Streaming Scalable Vector Bit Permutes instructions

FEAT_SSVE_BitPerm implements the SVE2 bit permute instructions, identified as implemented by ID_AA64ZFR0_EL1.BitPerm, when the PE is in Streaming SVE mode.

This feature is supported in AArch64 state only.

FEAT_SSVE_BitPerm is OPTIONAL from Armv9.4.

If FEAT_SSVE_BitPerm is implemented, then FEAT_SME2p1 is implemented.

When FEAT_SSVE_BitPerm and FEAT_SVE2 is implemented, FEAT_SVE_BitPerm is implemented.

The following field identifies the presence of FEAT_SSVE_BitPerm:

- ID_AA64SMFR0_EL1.SBitPerm.

For more information, see:

- Bit permutation.

FEAT_SSVE_FEXPA, Streaming FEXPA instruction

FEAT_SSVE_FEXPA implements the SVE FEXPA instruction when the PE is in Streaming SVE mode.

This feature is supported in AArch64 state only.

FEAT_SSVE_FEXPA is OPTIONAL from Armv9.4.

If FEAT_SSVE_FEXPA is implemented, then FEAT_SME2p1 is implemented.

The following field identifies the presence of FEAT_SSVE_FEXPA:

- ID_AA64SMFR0_EL1.SFEXPA.

FEAT_SVE2p2, Scalable Vector Extensions version 2.2

The Scalable Vector Extension version 2.2 (SVE2.2) is a superset of SVE2.1 that adds:

- Floating-point round to integral floating-point value instructions.
- Scalar index of first/last true predicate element.
- Zeroing-predication variant to all SVE unary instructions.
- Additional variants of `COMPACT` and `EXPAND` instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This feature is supported in AArch64 state only.

FEAT_SVE2p2 is OPTIONAL from Armv9.4.

If FEAT_SVE2p2 is implemented, then FEAT_SVE2p1 is implemented.

If FEAT_SVE2 and FEAT_SME2p2 are implemented, then FEAT_SVE2p2 is implemented.

The following field identifies the presence of FEAT_SVE2p2:

- ID_AA64ZFR0_EL1.SVEver.

For more information, see:

- Predicate element index.
- Floating-point round.
- Vector permutation.

FEAT_SVE_AES2, SVE multi-vector Advanced Encryption Standard and 128-bit polynomial multiply long instructions

FEAT_SVE_AES2 implements the SVE multi-vector Advanced Encryption Standard and 128-bit destination element polynomial multiply long instructions, when the PE is not in Streaming SVE mode.

This feature is supported in AArch64 state only.

FEAT_SVE_AES2 is OPTIONAL from Armv9.5.

If FEAT_SVE_AES2 is implemented, then FEAT_SVE_PMULL128 is implemented.

If FEAT_SVE_AES2 is implemented, then FEAT_SVE2p1 or FEAT_SSVE_AES is implemented.

The following field identifies the presence of FEAT_SVE_AES2:

- ID_AA64ZFR0_EL1.AES.

For more information, see:

- AES-128 instructions.
- Polynomial arithmetic.

FEAT_SVE_BFSCALE, BFloat16 Floating-Point Adjust Exponent

FEAT_SVE_BFSCALE introduces the following:

- If FEAT_SVE2 is implemented, the SVE `BFSCALE` instruction when the PE is not in Streaming SVE mode.
- If FEAT_SME2 is implemented, the SVE `BFSCALE` instruction when the PE is in Streaming SVE mode, and the SME multi-vector Z-targeting BFloat16 scaling instructions, `BFSCALE` and `BFMUL`.

This feature is supported in AArch64 state only.

FEAT_SVE_BFSCALE is OPTIONAL from Armv9.2.

If FEAT_SVE_BFSCALE is implemented, then FEAT_SVE_B16B16 is implemented.

The following field identifies the presence of FEAT_SVE_BFSCALE:

- ID_AA64ZFR0_EL1.B16B16.

For more information, see:

- For SVE: Floating-point adjust exponent.
- For SME: Floating-point adjust exponent.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SVE_F16F32MM, SVE Half-precision floating-point matrix multiply-accumulate to single-precision

FEAT_SVE_F16F32MM introduces the SVE half-precision floating-point matrix multiply-accumulate to single-precision instruction.

This feature is supported in AArch64 state only.

FEAT_SVE_F16F32MM is OPTIONAL from Armv9.2.

If FEAT_SVE_F16F32MM is implemented, then FEAT_SVE2p1 is implemented.

The following field identifies the presence of FEAT_SVE_F16F32MM:

- ID_AA64ZFR0_EL1.F16MM.

For more information, see:

- Floating-point matrix multiply-accumulate.

FEAT_TRBE_EXC, Trace Buffer Profiling exception extension

FEAT_TRBE_EXC provides support for reporting trace buffer management events as TRBE Profiling exceptions.

This feature is supported in AArch64 state only.

FEAT_TRBE_EXC is OPTIONAL from Armv9.5.

If FEAT_TRBE_EXC is implemented, then FEAT_TRBEv1p1 is implemented.

The following field identifies the presence of FEAT_TRBE_EXC:

- ID_AA64DFR2_EL1.TRBE_EXC.

FEAT_TRBEv1p1, Trace Buffer Extension version 1.1

FEAT_TRBEv1p1 introduces the following to the Trace Buffer Extension:

- If EL2 and FEAT_FGT are implemented, a fine-grained trap on the `TSB CSYNC` instruction.
- If EL2 is implemented, an EL2 control to override TRBLIMITR_EL1.nVM.
- Support for the TRBE Profiling exception extension, FEAT_TRBE_EXC.

This feature is supported in AArch64 state only.

FEAT_TRBEv1p1 is OPTIONAL from Armv9.5.

In an Armv9.6 implementation, if FEAT_TRBE is implemented, FEAT_TRBEv1p1 is implemented.

If FEAT_TRBEv1p1 is implemented, then FEAT_TRBE is implemented.

If FEAT_TRBEv1p1 is implemented, then FEAT_TRBE_EXC is implemented.

The following fields identify the presence of FEAT_TRBEv1p1:

- ID_AA64DFR0_EL1.TraceBuffer.
- TRBDEVARCH.REVISION.
- EDDFR.TraceBuffer.

FEAT_UINJ, Injection of Undefined Instruction exceptions

FEAT_UINJ introduces support for software injection of Undefined Instruction exceptions.

This feature is supported in AArch64 state only.

FEAT_UINJ is OPTIONAL from Armv9.0.

FEAT_UINJ is mandatory from Armv9.6.

The following field identifies the presence of FEAT_UINJ:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64PFR2_EL1.UINJ.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

Part B
The AArch64 Application Level Architecture

Chapter B1
The AArch64 Application Level Programmers' Model

This chapter describes the AArch64 application level programmers' model. It contains the following sections:

- About the Application level programmers' model
- Registers in AArch64 Execution state
- Process state, PSTATE
- The Scalable Vector Extension and Scalable Matrix Extension
- Software control features and EL0

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B1.1 About the Application level programmers' model

This chapter contains the programmers' model information required for application development.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of the system information is needed to put the Application level programmers' model into context.

Depending on the implementation choices, the architecture supports multiple levels of execution privilege, indicated by different *Exception levels* that number upwards from EL0 to EL3. EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers' model is the programmers' model for software executing at EL0. For more information, see Exception levels.

System software determines the Exception level, and therefore the level of privilege, at which software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged at EL0. This:

- Permits the operating system to allocate system resources to an application in a unique or shared manner.
- Provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some system level understanding is necessary, and where relevant it gives a reference to the system level description.

Execution at any Exception level above EL0 is often referred to as privileged execution.

For more information on the system level view of the architecture refer to The AArch64 System Level Programmers' Model.

B1.2 Registers in AArch64 Execution state

The following registers are visible at EL0 using AArch64:

R0-R30 31 general-purpose registers, R0 to R30. Each can be accessed as:

- A 64-bit general-purpose register named X0 to X30.
- A 32-bit general-purpose register named W0 to W30.

Figure B1-1 General-purpose register naming

The X30 general-purpose register is used as the procedure call link register.

SP A 64-bit dedicated Stack Pointer register. The least significant 32 bits of the stack pointer can be accessed using the register name WSP.

The use of SP as an operand in an instruction, indicates the use of the current stack pointer.

Note

Stack pointer alignment to a 16-byte boundary is configurable at EL1. For more information, see the *Procedure Call Standard for the Arm 64-bit Architecture*.

PC A 64-bit Program Counter holding the address of the current instruction.

Software cannot write directly to the PC. It can be updated only on a branch, exception entry or exception return.

Note

Attempting to execute an A64 instruction that is not word-aligned generates a PC alignment fault, see PC alignment checking.

V0-V31 32 SIMD&FP registers, V0 to V31. Each can be accessed as:

- A 128-bit register named Q0 to Q31.
- A 64-bit register named D0 to D31.
- A 32-bit register named S0 to S31.
- A 16-bit register named H0 to H31.
- An 8-bit register named B0 to B31.
- A 128-bit vector of elements. See Figure A1-1.
- A 64-bit vector of elements. See Figure A1-1.

Where the number of bits described by a register name does not occupy an entire SIMD&FP register, it refers to the least significant bits. See Figure B1-2.

For more information about data types and vector formats, see Supported data types.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure B1-2 SIMD and floating-point register naming

FPCR, FPSR The FPCR is the floating-point control register. The FPSR is the floating-point status register.

Z0-Z31 32 SVE scalable vector registers, Z0 to Z31, of equal length. Each register can be accessed as:

- A configurable-length vector of elements. The length, VL, is a power of two, from a minimum of 128 bits to an IMPLEMENTATION DEFINED maximum no greater than 2048 bits. See Figure B1-3, Figure A1-5, and Configurable SVE vector lengths.
- A SIMD&FP register, as described in V0-V31. Bits[127:0] of each Zn register hold the correspondingly numbered V0-V31 SIMD&FP register, as Figure B1-3 shows:

Figure B1-3 SVE scalable vector register naming

See also:

- Maximum implemented SVE vector lengths.
- Configurable SVE vector lengths.
- Treatment of SVE scalable vector registers.
- SVE writes of scalar values to registers.

P0-P15 16 SVE predicate registers, named P0 to P15. Each SVE predicate register holds one bit for each byte of an SVE scalar vector register.

Note

The *Maximum implemented SVE predicate length* is the *Maximum implemented SVE vector length* divided by 8. See Maximum implemented SVE vector lengths.

Also see Vector predication.

FFR The dedicated SVE First Fault Register that has the same size and format as the SVE predicate registers, P0-P15. See FFR, First Fault Register.

ZA Architectural state capable of holding a two-dimensional array of bytes. See ZA storage.

ZT0 A 512-bit SME2 lookup table register. See SME2 ZT0 register.

See also:

Non-Confidential

- System registers.
- Pseudocode description of registers in AArch64 state.
- Registers for instruction processing and exception handling.

B1.2.1 FFR, First Fault Register

R_{TRLWH} SVE has a dedicated First Fault Register named FFR.

I_{XPLQW} The FFR captures the cumulative fault status of a sequence of SVE First-fault and Non-fault vector load instructions.

R_{CPQQN} The FFR and the predicate registers have the same size and format.

I_{PBWPM} The FFR is a Special-purpose register.

R_{CGHCK} All bits in the FFR that are accessible at the current Exception level are initialized to 1 by using the `SETFFR` instruction.

R_{WZJVT} Bits in the FFR are indirectly set to 0 as a result of a suppressed access or suppressed fault corresponding to an *Active element* of an SVE First-fault or Non-fault vector load.

R_{BZLJG} Bits in the FFR are never set to 1 as a result of a vector load instruction.

I_{XLZQY} After a sequence of one or more SVE First-fault or Non-fault loads that follow a `SETFFR` instruction, without any intervening `WRFFR` instruction, the FFR contains a monotonic predicate value.

D_{SRDGX} A monotonic predicate value is one that consists of, starting from predicate element 0, a sequence of zero or more TRUE elements, followed only by zero or more FALSE elements.

I_{TQMTV} The TRUE elements in the FFR indicate the shortest sequence of consecutive elements that could contain valid data loaded from memory.

R_{GHFRQ} The only instructions that directly read the FFR are:

- `RDFFR`.
- `RDFFRS`.

R_{LHBRN} The only instructions that directly write the FFR are:

- `WRFFR`.
- `SETFFR`.

I_{DTHXN} The `WRFFR` instruction requires that its source predicate contains a monotonic predicate value. If the source is not a monotonic predicate value, then the resulting value in the FFR is UNKNOWN.

R_{XXMMP} All direct and indirect reads and writes to the FFR occur in program order relative to other instructions, without explicit synchronization.

B1.2.2 System registers

System registers provide support for execution control, status and general system configuration. The majority of the System registers are not accessible at EL0.

However, some System registers can be configured to allow access from software executing at EL0. Any access from EL0 to a System register without access permission causes the instruction to be trapped. The registers that can be accessed from EL0 are:

Debug registers A Debug Communications Channel is supported by the MDCCSR_EL0, DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0, DLR_EL0 and DSPSR_EL0 registers.

General system control registers

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The CTR_EL0 and DCZID_EL0 registers provide implementation parameters for EL0 cache management support.
- The SCXTNUM_EL0 register provides a number that can be used to separate out different context numbers.
- The POR_EL0 Permission Overlay register determines the unprivileged stage 1 overlay permissions for the EL1&0 and EL2&0 translation regimes.
- The TPIDR_EL0, TPIDR2_EL0, and TPIDRRO_EL0 registers provide locations where software can store thread identifying information.

Generic timer registers

- Read access to the system counter effective frequency using CNTFRQ_EL0.
- Physical and virtual timer count registers, CNTPCT_EL0, CNTVCT_EL0, CNTPCTSS_EL0 and CNTVCTSS_EL0.
- Physical up-count comparison, down-count value and timer control registers, CNTP_CVAL_EL0, CNTP_TVAL_EL0, and CNTP_CTL_EL0.
- Virtual up-count comparison, down-count value and timer control registers, CNTV_CVAL_EL0, CNTV_TVAL_EL0, and CNTV_CTL_EL0.

Performance Monitors registers

The Performance Monitors Extension provides counters and configuration registers. Software executing at EL1 or a higher Exception level can configure some of these registers to be accessible at EL0.

For more details, see The Performance Monitors Extension.

Activity Monitors registers

The Activity Monitors Extension provides counters and configuration registers. Software executing at EL1 or a higher Exception level can configure these registers to be accessible at EL0.

For more details, see The Activity Monitors Extension.

B1.2.3 Pseudocode description of registers in AArch64 state

The AArch64 pseudocode uses getter and setter accessor functions to read and write register files that are visible at EL0:

- The setter or assignment accessor, for example "`X{width}(num) = result`", is used for register writes.
- The getter or non-assignment accessor, "`operand = X{width}(num)`", is used for register reads.
- The *num* parameter specifies the register number to be accessed within the named register file, and *width* specifies the bit width of the register access.
- For the general-purpose register `X{width}()` accessor, register number 31 accesses the zero register which reads as zero and ignores writes.
- For other register accessors, such as the SIMD&FP `V{width}()` accessors, there is no special interpretation of the register number.

Other special AArch64 accessors include:

- The `SP{width}()` accessors have no parameters and are used to read or write the currently selected 64-bit stack pointer at the current Exception level.
- The `PC64{width}()` accessor has no argument list and is used to read the 64-bit Program Counter.
- The `Vpart{width}()` accessors are used to perform a partial read or write of an Advanced SIMD vector register, using an additional *part* parameter to select which half of the vector register to access.
- The `Z{width}()`, `V{width}()`, and `Vpart{width}()` accessors read and write the same underlying vector register file.

Other register accessors are defined as required by other architectural features. See A-profile Architecture Pseudocode, sections aarch64/functions/registers/.

B1.3 Process state, PSTATE

Process state, or PSTATE, is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

For the system level view of PSTATE, see Process state, PSTATE in The AArch64 System Level Programmers' Model.

The following PSTATE information is accessible at EL0:

The Condition flags

Flag-setting instructions set these. They are:

N Negative Condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:

- 1 if the result is negative.
- 0 if the result is positive or zero.

Z Zero Condition flag. Set to:

- 1 if the result of the instruction is zero.
- 0 otherwise.

A result of zero often indicates an equal result from a comparison.

C Carry Condition flag. Set to:

- 1 if the instruction results in a carry condition, for example, an unsigned overflow that is the result of an addition.
- 0 otherwise.

V Overflow Condition flag. Set to:

- 1 if the instruction results in an overflow condition, for example, a signed overflow that is the result of an addition.
- 0 otherwise.

Conditional instructions test the N, Z, C, and V Condition flags, combining them with the Condition code for the instruction to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see Condition flags and related instructions.

The exception masking bits

D Debug exception mask bit. When EL0 is enabled to modify the mask bits, this bit is visible and can be modified. However, this bit is architecturally ignored at EL0.

A SError mask bit.

I IRQ interrupt mask bit.

F FIQ interrupt mask bit.

For each bit, the values are:

0 Exception not masked.

1 Exception masked.

Access at EL0 using AArch64 state depends on SCTLR_EL1.UMA.

SME enable controls

SM *Streaming SVE mode* enable:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0 Streaming SVE mode not enabled.

1 Streaming SVE mode enabled.

See Streaming SVE mode.

ZA *ZA storage* and *ZT0 register* enable:

0 ZA storage and the ZT0 register are not enabled.

1 ZA storage and the ZT0 register are enabled.

See About PSTATE.ZA, ZA storage, and SME2 ZT0 register.

B1.3.1 Accessing PSTATE fields at EL0

At EL0 using AArch64 state, PSTATE fields can be accessed using Special-purpose registers that can be directly read using the MRS instruction and directly written using the MSR (register) instructions. Table B1-1 shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state when the PE is at EL0 using AArch64. All other PSTATE fields do not have direct read and write access at EL0.

Table B1-1 Accessing PSTATE fields at EL0 using MRS and MSR (register)

Special-purpose register	PSTATE fields
NZCV	N, Z, C, V
DAIF	D, A, I, F
SVCR	SM, ZA
SSBS	SSBS
DIT	DIT
TCO	TCO

Software can also use the MSR (immediate) instruction to directly write to PSTATE.{D, A, I, F, SM, ZA, SSBS, DIT, TCO}. Table B1-2 shows the MSR (immediate) operands that can directly write to PSTATE.{D, A, I, F, SM, ZA, SSBS, DIT, TCO} when the PE is at EL0 using AArch64 state.

Table B1-2 Accessing PSTATE.{D, A, I, F, SM, ZA, SSBS, DIT, TCO} at EL0 using MSR (immediate)

Operand	PSTATE fields	Notes
DAIFSet	D, A, I, F	Directly sets any of the PSTATE.{D, A, I, F} bits to 1
DAIFClr	D, A, I, F	Directly clears any of the PSTATE.{D, A, I, F} bits to 0
SVCRSM	SM	Directly sets the PSTATE.SM bit to CRm<0>.
SVCRZA	ZA	Directly sets the PSTATE.ZA bit to CRm<0>.
SVCRSMZA	SM, ZA	Directly sets the PSTATE.{SM, ZA} bits to CRm<0>.
SSBS	SSBS	Directly sets the PSTATE.SSBS bit to CRm<0>
DIT	DIT	Directly sets the PSTATE.DIT bit to CRm<0>
TCO	TCO	Directly sets the PSTATE.TCO bit to CRm<0>

Access to the PSTATE.{D, A, I, F} fields at EL0 using AArch64 state depends on SCTLR_EL1.UMA.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Software can more efficiently change PSTATE.{SM, ZA} by using SMSTART and SMSTOP instructions.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects, are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

B1.3.2 SVE use of PSTATE N, Z, C, and V Condition flags

I_{WYXLS} This section describes the SVE-specific use of PSTATE.

I_{YZYCQ} PSTATE N, Z, C and V condition flags can be updated by any of the following:

- An SVE instruction that generates a predicate result and updates the PSTATE N, Z, C and V Condition flags based on the value of the result.
- An SVE instruction that updates the PSTATE N, Z, C and V Condition flags based on the value in its predicate source register or FFR:
  - PTEST.
  - RDFFRS (predicated).
- An SVE instruction that updates the PSTATE N, Z, C and V Condition flags based on the values in its general-purpose source registers:
  - CTERMEQ.
  - CTERMNE.

R_{TPXTF} When setting the PSTATE N, Z, C and V Condition flags for SVE predicated flag-setting instructions, the instruction's *Governing predicate* determines which predicate elements are considered Active.

R_{QJBRW} When setting the PSTATE N, Z, C and V Condition flags for SVE unpredicated flag-setting instructions, all predicate elements are considered Active.

R_{ZMRXC} Unless otherwise specified in an instruction description, the SVE flag-setting instructions update the PSTATE N, Z, C and V Condition flags as follows:

Flag	SVE Name	SVE interpretation
N	First	Set to 1 if the *First active element* was TRUE, otherwise cleared to 0.
Z	None	Cleared to 0 if any *Active element* was TRUE, otherwise set to 1.
C	Not last	Cleared to 0 if the *Last active element* was TRUE, otherwise set to 1.
V	-	Cleared to 0.

Non-Confidential

B1.4 The Scalable Vector Extension and Scalable Matrix Extension

This section contains:

- Maximum implemented SVE vector lengths
- Configurable SVE vector lengths
- Treatment of SVE scalable vector registers
- SVE writes of scalar values to registers
- Vector predication
- Streaming SVE mode
- About PSTATE.ZA
- ZA storage
- ZA array vector access
- ZA tile access
- ZA storage layout
- SME2 Multi-vector operands
- SME2 ZT0 register

B1.4.1 Maximum implemented SVE vector lengths

R_{QSVCQ} There are the following IMPLEMENTATION DEFINED vector lengths for the SVE scalable vector registers, Z0-Z31:

- A *Maximum implemented Streaming SVE vector length*.
- A *Maximum implemented Non-streaming SVE vector length*.

For each IMPLEMENTATION DEFINED vector length, all the following apply:

- The smallest architecturally defined maximum length is 128 bits.
- The largest architecturally defined maximum length is 2048 bits.
- The length is a power of 2.

I_{GZRPL} There is no requirement for the Maximum implemented Streaming SVE vector length to be greater than or equal to the Maximum implemented Non-streaming SVE vector length.

I_{SGCVT} Where this architecture specification uses the term *Maximum implemented SVE vector length*, it means:

- The Maximum implemented Streaming SVE vector length when the PE is in *Streaming SVE mode*.
- The Maximum implemented Non-streaming SVE vector length otherwise.

See also:

- Z0-Z31.
- Configurable SVE vector lengths.

B1.4.2 Configurable SVE vector lengths

R_{KFTHG} There are the following configurable vector lengths for the SVE scalable vector registers, Z0-Z31:

- *Effective Streaming SVE vector length* (SVL).
- *Effective Non-streaming SVE vector length* (NSVL).

I_{QQRNR} SMCR_ELx.LEN requests an SVL. The architecturally defined SVL set is all powers of two from 128 to 2048 bits inclusive. Implementing any subset is permitted, up to and including the *Maximum implemented Streaming SVE vector length*. The subset is not required to be contiguous and is not required to start at 128 bits. Implementing a single SVL is permitted.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{NWYBP} ZCR_ELx.LEN requests an NSVL. The architecturally defined NSVL set is all powers of two from 128 to 2048 bits inclusive. An implementation is required to implement all architecturally defined values up to and including the *Maximum implemented Non-streaming SVE vector length*.

I_{WDKGR} An implementation is permitted to implement an SVL set that does not overlap with the implemented NSVL set.

R_{GWVHP} When SMCR_ELx.LEN requests an SVL, the PE selects an SVL according to the steps described in the SMCR_ELx.LEN field descriptions.

R_{MMCTJ} When ZCR_ELx.LEN requests an NSVL, the PE selects an NSVL according to the steps described in the ZCR_ELx.LEN field descriptions.

I_{VCQBB} Where this architecture specification uses the term *Effective SVE vector length (VL)*, it means:

- SVL when the PE is in *Streaming SVE mode*.
- NSVL otherwise.

R_{PXZTM} When executing at an Exception level where VL is less than the *Maximum implemented SVE vector length*, bits VL and higher in the SVE scalable vector registers, and bits VL ÷ 8 and higher in the SVE predicate registers and FFR, are inaccessible.

R_{YRPDH} When VL is increased, it is CONSTRAINED UNPREDICTABLE whether the previously inaccessible bits that become accessible have:

- A value of zero.
- The value they had before executing at the more constrained length.

I_{HGYPV} VL might increase because of an explicit action such as writing to SMCR_ELx.LEN or ZCR_ELx.LEN, or an implicit action such as taking an exception to an Exception level with a less constrained VL.

I_{PDLWX} When changing VL, the contents in the bits that consistently remain accessible remain the same.

R_{KXKNK} VL at Exception level ELx is 128 bits if all the following are true:

- SVE instructions are disabled or trapped at ELx, or are not available because ELx is using AArch32.
- Floating-point instructions are not trapped at ELx.

R_{DMBPN} When taking an exception to a target Exception level, if SVE, SME, and floating-point instructions are disabled, trapped, or not available at all Exception levels below the target Exception level, for the current Security state, the SVE register state at the target Exception level is preserved.

I_{FMWZZ} When VL is increased, steps must be taken to ensure the newly accessible area does not expose values unrelated to another body of software in a different trust or security scope. This might be achieved by, for example, ensuring that the previously inaccessible bits in the SVE Z, P, and FFR registers, and the SME ZA storage and ZT0 register, are reset to zero before they are next used.

I_{BRMMV} System software provides a maximum VL to lower-privileged software, which might further constrain the VL. However, system software must initialize and context switch values consistent with the maximum VL it provides and should not make assumptions about any smaller length that lower-privileged software is using. For example, if a hypervisor exposes a VL of 512 to a VM, that VM might choose to constrain VL to 256. The hypervisor must still save and restore 512-bit vectors to prevent leakage of values between VMs, because the VM might later raise its SVL to 512 and must not be able to observe values created by other software in the newly visible upper portion of the registers.

See also:

- Maximum implemented SVE vector lengths.
- Streaming SVE mode.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B1.4.3 Treatment of SVE scalable vector registers

I_{GKWYJ} Unless an instruction description states otherwise, SVE instructions treat an SVE scalable vector register as containing one or more *vector elements* of equal size.

I_{CDKJQ} SVE instructions can process vector elements in parallel, unless an instruction description states otherwise.

R_{CJZLM} If the order of operations performed by an SVE instruction on vector or predicate elements has observable significance, elements are processed in increasing element number order.

R_{KHDBN} When an SVE instruction treats an SVE scalable vector register as containing multiple vector elements, the element size is encoded in the opcode of the instruction. The element size is 8, 16, 32, 64, or 128 bits.

R_{WKYLB} When the *Effective SVE vector length* (VL) at the current Exception level is greater than 128 bits, any AArch64 instruction that writes to a 128-bit SIMD&FP register, V0-V31, sets bits [VL-1:128] to zero.

B1.4.4 SVE writes of scalar values to registers

I_{ZDLGD} Certain SVE instructions generate a scalar result that is written to an AArch64 general-purpose register or to element[0] of a vector register.

R_{HNVTM} When an SVE instruction generates a scalar result of width N bits, the instruction places the result in bits [N-1:0] of the destination register.

R_{QCLSH} When an SVE instruction generates a scalar result of width N bits, and N is less than the maximum accessible destination register width RW, the instruction sets bits [RW-1:N] of the destination register to zero.

B1.4.5 Vector predication

R_{JFJZX} There are the following vector predication concepts:

- Predicate-as-mask, if FEAT_SVE or FEAT_SME is implemented.
- Predicate-as-counter, if FEAT_SME2 or FEAT_SVE2p1 is implemented.

I_{HWRFM} The assembler syntax for a predicate register is of the form:

- `Pg` for predicate-as-mask.
- `PNg` for predicate-as-counter.

`Pg` and `PNg` refer to the same SVE predicate register.

The remainder of this section contains:

- Predicate-as-mask
- Predicate-as-counter
- SVE predicated instructions

B1.4.5.1 Predicate-as-mask

I_{JHCTW} Most SVE instructions interpret SVE predicate registers as a predicate-as-mask encoding.

R_{XMPLM} A predicate-as-mask encoding is divided into 1-bit, 2-bit, 4-bit, or 8-bit *predicate elements*. Each predicate element corresponds to a vector element in an SVE scalable vector register.

R_{XVRKX} Unless an instruction description states otherwise, SVE instructions treat an SVE predicate register as containing one or more predicate elements of equal size.

R_{XCZQR} When an SVE instruction treats an SVE predicate register as containing multiple predicate elements, the element size is encoded in the opcode of the instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{HRPMD} If the lowest-numbered bit of a predicate element is 0, the value of the predicate element is FALSE.

R_{DNMFH} If the lowest-numbered bit of a predicate element is 1, the value of the predicate element is TRUE.

R_{LTGQC} For SVE instructions that generate predicate-as-mask encodings, all bits except the lowest-numbered bit of each destination predicate element are set to zero if all the following are true:

- The instructions are not used to move and permute predicate elements.
- The instructions are not predicate logical operations.

R_{HBMLS} For SVE instructions that consume predicate-as-mask encodings, all bits except the lowest-numbered bit of each source predicate element are ignored on reads if all the following are true:

- The instructions are not used to move and permute predicate elements.
- The instructions are not predicate logical operations.

B1.4.5.2 Predicate-as-counter

R_{DSFKR} SME2 and SVE2.1 multi-vector instructions interpret bits[15:0] of SVE predicate registers as a *predicate-as-counter encoding*:

Table B1-4 Predicate-as-counter encoding

Bit[15] Invert	Bits[14:(LSZ+1)][a] Element count[b]	Bits[LSZ:0] Element size	Meaning
`0bX`	`0bXXXXXXXXXXXXXXX`	`0b1`	Byte-size elements
`0bX`	`0bXXXXXXXXXXXXXX`	`0b10`	Halfword-size elements
`0bX`	`0bXXXXXXXXXXXXX`	`0b100`	Word-size elements
`0bX`	`0bXXXXXXXXXXXX`	`0b1000`	Doubleword-size elements
`0bX`	`0bXXXXXXXXXXXX`	`0b0000`	Any-size elements. All FALSE predicate.

a. LSZ is the number of trailing zeros in the element size field.
b. The 4 most significant bits are reserved.

Element size, bits[LSZ:0]

For values shown in Table B1-4 other than `0b0000`:

- Number of trailing zeros is $\log_2$(element size in bytes).
  For example, 2 trailing zeros is $\log_2$(4 bytes). This means word-size elements.

Element count, bits[14:(LSZ+1)]

An unsigned integer value:

- The number of consecutive elements, starting from element 0, that are TRUE or FALSE according to bit[15].

Invert, bit[15]

`0b0` [14:(LSZ+1)] is holding the number of TRUE elements. All other elements are FALSE.

`0b1` [14:(LSZ+1)] is holding the number of FALSE elements. All other elements are TRUE.

I_{ZPLKP} The maximum number of elements that the predicate-as-counter encoding can count is four vectors of byte elements, where the length of each vector is the largest architecturally defined length, 2048 bits:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table B1-5

Bit[15] Invert	Bits[14:(LSZ+1)] Element count	Bits[LSZ:0] Element size	Total number of bits
1 bit	4 reserved bits. 10 count bits. 10 count bits can count 1024 elements, which is the number of byte elements in four 2048-bit long vectors.	1 bit	16 bits

D_{BJMYH} The canonical all-FALSE predicate-as-counter encoding has an element count of zero, with the invert bit set to 0 and an element size field set to `0b0000`.

D_{JGSYR} The canonical all-TRUE predicate-as-counter encoding has an element count of zero, with the invert bit set to 1 and a nonzero element size field determined by the generating instruction.

R_{YCRMW} If the *Effective SVE vector length* (VL) is greater than 128 bits, then an instruction generating a predicate-as-counter encoding sets bits 16 and higher to zero.

R_{SGVTC} If VL is greater than 128 bits, then an instruction consuming a predicate-as-counter encoding ignores bits 16 and higher.

R_{YSTVC} An instruction consuming a predicate-as-counter encoding uses the least significant bits of the element count field required to count the number of bytes in VL times four. The instruction ignores the more significant bits in the element count field. Table B1-6 gives an example for VL = 512 bits and byte-size elements:

Table B1-6

Bit[15]Invert	Bits[14:(LSZ+1)] Element count	Bits[LSZ:0] Element size
1 bit	4 reserved bits, bits[14:11]. The instruction ignores these. 2 bits, bits[10:9]. The instruction ignores these. 8 count bits, bits[8:1]. The instruction uses these. 8 count bits can count 256 elements, which is the number of byte elements in four 512-bit long vectors.	1 bit

See also:

- P0-P15.
- Configurable SVE vector lengths.

B1.4.5.3 SVE predicated instructions

I_{VKHDR} If an instruction supports predication, it is known as a *predicated instruction*.

I_{FNFRN} The predicate operand that is used to determine the *Active elements* of a predicated instruction is known as the *Governing predicate*.

I_{SVYXB} An instruction that does not have a Governing predicate operand and implicitly treats all other vector and predicate elements as Active is known as an *unpredicated instruction*.

I_{KNKBN} Many predicated instructions can only use P0-P7 as the Governing predicate.

R_{LZVFJ} When a Governing predicate element is TRUE, the corresponding element in other vector or predicate operands is an Active element.

R_{CNFLG} When a Governing predicate element is FALSE, the corresponding element in other vector or predicate operands is an *Inactive element*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{CBYJH} Predicated instructions process Active elements.

R_{LDXSF} Predicated instructions do not process Inactive elements.

R_{GJLPZ} Unpredicated instructions process all elements in their vector or predicate operands.

R_{WLQBD} When a predicated instruction writes to a vector destination register or a predicate destination register, one of the following happens:

- The Inactive elements in the destination register are set to zero.
- The Inactive elements in the destination register retain their previous value.

I_{QBHRN} Zeroing predication is performed when the Inactive elements in the destination register are set to zero.

I_{YPYRF} Merging predication is performed when Inactive elements in the destination register retain their previous value.

B1.4.6 Streaming SVE mode

R_{XDPXS} A PE with FEAT_SME has *Streaming SVE mode*.

I_{ZTTNW} In Streaming SVE mode:

- SME and SME2 instructions access *Streaming SVE register state*, which comprises:
  - — SVE scalable vector registers, Z0 to Z31.
  - — SVE predicate registers, P0 to P15.
  - — SVE First Fault register, FFR, if FEAT_SME_FA64 is implemented and enabled at the current Exception level.
- PSTATE.ZA can be toggled, to enable and disable the *ZA storage* and *ZT0 register* as required.

R_{RSWFQ} When the Effective value of PSTATE.SM is changed by any method from 0 to 1, an entry to Streaming SVE mode is performed, and all implemented bits of Streaming SVE register state are set to zero.

R_{KFRQZ} When the Effective value of PSTATE.SM is changed by any method from 1 to 0, an exit from Streaming SVE mode is performed, and in the newly-entered mode, all implemented bits of the SVE scalable vector registers, SVE predicate registers, and FFR, are set to zero.

I_{NHNFF} A *legal* instruction is an instruction that the architecture permits execution of when PSTATE.{SM, ZA} are in the required state, unless its execution at the current Exception level is prevented by a configurable trap or enable.

I_{HZFSG} An *illegal* instruction is an instruction whose attempted execution by a PE when PSTATE.SM and PSTATE.ZA are not in the required state causes an *SME illegal instruction exception* to be taken, unless its execution at the current Exception level is prevented by a higher-priority configurable trap or enable.

R_{VJZBC} In Streaming SVE mode:

- Streaming SVE register state is valid, and SME and SME2 instructions that access it are legal.
- When PSTATE.ZA is 1, SME and SME2 instructions that access ZA storage or the ZT0 register are legal.
- SME and SME2 instructions that do not access ZA storage or the ZT0 register are legal.
- Legal instructions that access the SVE scalable vector registers or their correspondingly numbered SIMD&FP registers access Streaming SVE register state.
- The following are illegal if FEAT_SME_FA64 is not implemented or not enabled at the current Exception level:
  - — Some SVE and SVE2 instructions. The individual instruction descriptions in SVE Instruction Descriptions describe which are illegal.
  - — All those instructions that call the `AArch64.CheckFPAdvSIMDEnabled()` function.

R_{XBBFD} When the PE is not in Streaming SVE mode:

- Streaming SVE register state is not valid, and SME and SME2 instructions that access it are illegal.
- When PSTATE.ZA is 1:
  - — SME `LDR` (array vector), `STR` (array vector), and `ZERO` (tiles) instructions that access ZA storage are legal. All other instructions that access ZA storage are illegal.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— SME2 `LDR` (table), `STR` (table), and `ZERO` (table) instructions that access the ZT0 register are legal. All other instructions that access the ZT0 register are illegal.

I_{TDSPN} In Streaming SVE mode, the following instructions might be significantly delayed if FEAT_SME_FA64 is not implemented or not enabled at the current Exception level:

- Instructions that are dependent on results generated from vector or SIMD&FP register sources written to a general-purpose destination register, a predicate destination register, or the NZCV condition flags.

The Operational information sections of instruction descriptions in A64 Advanced SIMD and Floating-point Instruction Descriptions and SVE Instruction Descriptions describe which instructions are affected.

I_{MHTLZ} When the Effective value of PSTATE.SM is changed by any method from 0 to 1 or from 1 to 0, the FPSR is set to the value `0x0000_0000_0800_009F`, setting all the cumulative status bits to 1.

I_{YTZVD} Statements which refer to the value of the SVE scalable vector registers, Z0-Z31, implicitly also refer to the lower bits of those registers accessed by the SIMD&FP register names V0-V31, Q0-Q31, D0-D31, S0-S31, H0-H31, and B0-B31.

See also:

- Registers in AArch64 Execution state.
- About PSTATE.ZA.
- Accessing PSTATE fields at EL0.
- Floating-point behaviors in Streaming SVE mode.

B1.4.7 About PSTATE.ZA

I_{HVKTL} PSTATE.ZA enables ZA storage and, if FEAT_SME2 is implemented, the ZT0 register.

R_{JHMYL} When PSTATE.ZA is 0, the contents of ZA storage and the ZT0 register are not valid, and SME and SME2 instructions that access them are *illegal*.

R_{SFWMY} When PSTATE.ZA is 1, the contents of ZA storage and the ZT0 register are valid and are retained by hardware irrespective of whether the PE is in *Streaming SVE mode*, and:

- SME `LDR` (array vector), `STR` (array vector), and `ZERO` (tiles) instructions that access ZA storage are legal.
- SME2 `LDR` (table), `STR` (table), and `ZERO` (table) instructions that access the ZT0 register are legal.
- When the PE is in Streaming SVE mode, all other SME and SME2 instructions that access ZA storage or the ZT0 register are legal.

R_{YRZRM} When PSTATE.ZA is changed by any method from 0 to 1, all implemented bits of ZA storage and the ZT0 register are set to zero.

I_{LRDZR} When PSTATE.ZA is changed from 1 to 0, there is no architecturally defined effect on ZA storage and the ZT0 register, because the contents of ZA storage and the ZT0 register cannot be observed when PSTATE.ZA is 0.

I_{QWCJS} When PSTATE.ZA is changed from 0 to 1, or from 1 to 0, there is no effect on the SVE scalable vector registers, SVE predicate registers, and FPSR if PSTATE.SM is not changed.

See also:

- Streaming SVE mode.
- ZA storage.
- SME2 ZT0 register.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B1.4.8 ZA storage

R_{FFWLL} A PE with FEAT_SME has *ZA storage*.

D_{JBVYJ} There are the following terms for the number of elements in a vector of SVL bits:

SVL_B The number of byte elements, SVL ÷ 8.

SVL_H The number of halfword elements, SVL ÷ 16.

SVL_S The number of word elements, SVL ÷ 32.

SVL_D The number of doubleword elements, SVL ÷ 64.

SVL_Q The number of quadword elements, SVL ÷ 128.

R_{SSXPL} ZA storage is architectural register state consisting of a two-dimensional ZA array of [$SVL_B \times SVL_B$] bytes.

See also:

- About PSTATE.ZA.
- Accessing PSTATE fields at EL0.
- Streaming SVE mode.

B1.4.9 ZA array vector access

R_{FFWNB} The *ZA* array can be accessed as vectors of SVL bits.

D_{PPPCM} An untyped vector access to the *ZA* array is represented by ZA[*N*], where *N* is in the range 0 to SVL_B-1 inclusive.

D_{DTVZN} In SME `LDR` (array vector) and `STR` (array vector) instructions, an untyped *ZA array vector* is selected by the sum of a 32-bit general-purpose vector select register W*v* and an immediate vector select offset *offs*, modulo SVL_B.

D_{YXHFR} The preferred disassembly for an untyped *ZA* array vector is ZA[W*v*, *offs*], where *offs* is an immediate in the range 0-15 inclusive.

D_{CRJPC} The *ZA* array can be accessed as vectors of 8-bit, 16-bit, 32-bit, 64-bit, or 128-bit elements.

D_{WMVZT} An elementwise vector access to the *ZA* array is indicated by appending a vector index "[*N*]" to the *ZA* array name and element size qualifier, where *N* is in the range 0 to SVL_B-1 inclusive, as follows:

- An 8-bit element vector access to the *ZA* array is represented by ZA.B[*N*].
- A 16-bit element vector access to the *ZA* array is represented by ZA.H[*N*].
- A 32-bit element vector access to the *ZA* array is represented by ZA.S[*N*].
- A 64-bit element vector access to the *ZA* array is represented by ZA.D[*N*].
- A 128-bit element vector access to the *ZA* array is represented by ZA.Q[*N*].

B1.4.10 ZA tile access

D_{VSVMX} A *ZA tile* is a square, two-dimensional sub-array of elements within the *ZA* array.

I_{WLRTV} Depending on the element size with which it is accessed, the ZA array is treated as containing one or more *ZA* tiles, as described in the following sections.

D_{DWMYT} A *ZA* tile is indicated by appending the tile number to the *ZA* name.

D_{ZGBHT} A *ZA tile slice* is a one-dimensional set of horizontally or vertically contiguous elements within a *ZA* tile.

R_{PZNWB} A vector access to a tile reads or writes a *ZA* tile slice.

I_{NFXHH} A *ZA* tile can be accessed as vectors of 8-bit, 16-bit, 32-bit, 64-bit, or 128-bit elements.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{YZDBS} A *ZA* tile can be accessed as horizontal slices of SVL bits.

R_{GPVSZ} A *ZA* tile is accessed as horizontal slices if the V field in the accessing instruction opcode is 0.

D_{TRHTX} An access to horizontal tile slices is indicated by an "H" suffix on the *ZA* tile name.

I_{HBYTT} A *ZA* tile can be accessed as vertical slices of SVL bits.

R_{GPPPK} A *ZA* tile is accessed as vertical slices if the V field in the accessing instruction opcode is 1.

D_{WSBVG} An access to vertical tile slices is indicated by a "V" suffix on the *ZA* tile name.

R_{TWWTL} In SME instructions, the tile slice is selected by the sum of a 32-bit general-purpose slice index register W*s* and an immediate slice index offset *offs*, modulo the number of slices in the named tile.

B1.4.10.1 Accessing an 8-bit element ZA tile

D_{HMSNH} An 8-bit element *ZA* tile is indicated by a ".B" qualifier following the tile name.

D_{NLCNH} There is a single tile named ZA0.B which consists of $[SVL_B \times SVL_B]$ 8-bit elements and occupies all of the *ZA* storage.

R_{NBSMJ} An access to a horizontal or vertical 8-bit element ZA tile slice reads or writes SVL_B 8-bit elements.

D_{NMHLM} An access to a horizontal or vertical 8-bit element ZA tile slice is indicated by appending a slice index "[*N*]" to the tile name, direction suffix, and qualifier. For example, where *N* is in the range 0 to SVL_B-1 inclusive:

- ZA0H.B[*N*] indicates a horizontal 8-bit element *ZA* tile slice selection.
- ZA0V.B[*N*] indicates a vertical 8-bit element *ZA* tile slice selection.

I_{JVTNY} Horizontal and vertical ZA0.B slice accesses are illustrated in the following diagram for SVL of 256 bits:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure B1-4 Horizontal and vertical ZA0.B slice for SVL of 256

R_{DCSDX} An access to the horizontal slice ZA0H.B[*N*] reads or writes the SVL_B bytes in *ZA* array vector ZA.B[*N*].

R_{FHYSQ} An access to the vertical slice ZA0V.B[*N*] reads or writes the 8-bit element [*N*] within each horizontal slice of ZA0.B.

D_{CDDVV} The preferred disassembly is:

- ZA0H.B[W*s*, *offs*], for a horizontal 8-bit element *ZA* tile slice selection.
- ZA0V.B[W*s*, *offs*], for a vertical 8-bit element *ZA* tile slice selection.

Where *offs* is an immediate in the range 0-15 inclusive.

B1.4.10.2 Accessing a 16-bit element ZA tile

D_{LNXPD} A 16-bit element *ZA* tile is indicated by a ".H" qualifier following the tile name.

D_{GWZDM} There are two tiles named ZA0.H and ZA1.H. Each tile consists of [$SVL_H \times SVL_H$] 16-bit elements, and occupies half of the *ZA* storage.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{NMGXG} An access to a horizontal or vertical 16-bit element ZA tile slice reads or writes SVL_H 16-bit elements.

D_{DHKMC} An access to a horizontal or vertical 16-bit element ZA tile slice is indicated by appending a slice index "[*N*]" to the tile name, direction suffix, and qualifier. For example, where *t* is 0 or 1, and *N* is in the range 0 to SVL_H-1 inclusive:

- ZA*t*H.H[*N*] indicates a horizontal 16-bit element *ZA* tile slice selection.
- ZA*t*V.H[*N*] indicates a vertical 16-bit element *ZA* tile slice selection.

I_{ZSWJW} Horizontal and vertical ZA*t*.H slice accesses, where *t* is 0 or 1, are illustrated in the following diagram for SVL of 256 bits:

Figure B1-5 Horizontal and vertical ZAt.H slice for SVL of 256

R_{BTLQC} An access to the horizontal slice ZA*t*H.H[*N*] reads or writes the SVL_H 16-bit elements in *ZA* array vector ZA.H[$t + 2 * N$].

R_{NGJBJ} An access to the vertical slice ZA*t*V.H[*N*] reads or writes the 16-bit element [*N*] within each horizontal slice of ZA*t*.H.

D_{RHQJT} The preferred disassembly is as follows:

- ZA*t*H.H[W*s*, *offs*], for a horizontal 16-bit element *ZA* tile slice selection.
- ZA*t*V.H[W*s*, *offs*], for a vertical 16-bit element *ZA* tile slice selection.

Where *t* is 0 or 1, and *offs* is an immediate in the range 0-7 inclusive.

B1.4.10.3 Accessing a 32-bit element ZA tile

D_{HBKZV} A 32-bit element *ZA* tile is indicated by a ".S" qualifier following the tile name.

D_{RDRRT} There are four tiles named ZA0.S, ZA1.S, ZA2.S, and ZA3.S. Each tile consists of [$SVL_S \times SVL_S$] 32-bit elements, and occupies a quarter of the *ZA* storage.

R_{XFPPL} An access to a horizontal or vertical 32-bit element ZA tile slice reads or writes SVL_S 32-bit elements.

D_{JFPSJ} An access to a horizontal or vertical 32-bit element ZA tile slice is indicated by appending a slice index "[*N*]" to the tile name, direction suffix, and qualifier. For example, where *t* is 0, 1, 2, or 3, and *N* is in the range 0 to SVL_S-1 inclusive:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ZA*t*H.S[*N*] indicates a horizontal 32-bit element *ZA* tile slice selection.
- ZA*t*V.S[*N*] indicates a vertical 32-bit element *ZA* tile slice selection.

I_{SZXZR} Horizontal and vertical ZA*t*.S slice accesses, where *t* is 0, 1, 2, or 3, are illustrated in the following diagram for SVL of 256 bits:

Figure B1-6 Horizontal and vertical ZAt.S slice for SVL of 256

R_{JBJZY} An access to the horizontal slice ZA*t*H.S[*N*] reads or writes the SVL_S 32-bit elements in *ZA* array vector ZA.S[*t* + 4 * *N*].

R_{GBYSJ} An access to the vertical slice ZA*t*V.S[*N*] reads or writes the 32-bit element [*N*] within each horizontal slice of ZA*t*.S.

D_{LQLJH} The preferred disassembly is:

- ZA*t*H.S[W*s*, *offs*], for a horizontal 32-bit element *ZA* tile slice selection.
- ZA*t*V.S[W*s*, *offs*], for a vertical 32-bit element *ZA* tile slice selection.

Where *t* is 0, 1, 2, or 3, and *offs* is 0, 1, 2, or 3.

B1.4.10.4 Accessing a 64-bit element ZA tile

D_{TWMMM} A 64-bit element *ZA* tile is indicated by a ".D" qualifier following the tile name.

D_{THPSD} There are eight tiles named ZA0.D, ZA1.D, ZA2.D, ZA3.D, ZA4.D, ZA5.D, ZA6.D, and ZA7.D. Each tile consists of [$SVL_D \times SVL_D$] 64-bit elements, and occupies an eighth of the *ZA* storage.

R_{ZXYBQ} An access to a horizontal or vertical 64-bit element ZA tile slice reads or writes SVL_D 64-bit elements.

D_{DCXSX} An access to a horizontal or vertical 64-bit element ZA tile slice is indicated by appending a slice index "[*N*]" to the tile name, direction suffix, and qualifier. For example, where *t* is in the range 0-7 inclusive, and *N* is in the range 0 to SVL_D-1 inclusive:

- ZA*t*H.D[*N*] indicates a horizontal 64-bit element *ZA* tile slice selection.
- ZA*t*V.D[*N*] indicates a vertical 64-bit element *ZA* tile slice selection.

I_{LGJZC} Horizontal and vertical ZA*t*.D slice accesses, where *t* is in the range 0-7 inclusive, are illustrated in the following diagram for SVL of 256 bits:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure B1-7 Horizontal and vertical ZAt.D slice for SVL of 256

RCVVJK An access to the horizontal slice ZA*t*H.D[*N*] reads or writes the SVL_D 64-bit elements in *ZA* array vector ZA.D[*t* + 8 * *N*].

RJYQKK An access to the vertical slice ZA*t*V.D[*N*] reads or writes the 64-bit element [*N*] within each horizontal slice of ZA*t*.D.

DMQQPX The preferred disassembly is:

- ZA*t*H.D[W*s*, *offs*], for a horizontal 64-bit element *ZA* tile slice selection.
- ZA*t*V.D[W*s*, *offs*], for a vertical 64-bit element *ZA* tile slice selection.

Where *t* is in the range 0-7 inclusive, and *offs* is 0 or 1.

B1.4.10.5 Accessing a 128-bit element ZA tile

DGZDSH A 128-bit element *ZA* tile is indicated by a ".Q" qualifier following the tile name.

DRPMJL There are 16 tiles named ZA0.Q, ZA1.Q, ZA2.Q, ZA3.Q, ZA4.Q, ZA5.Q, ZA6.Q, ZA7.Q, ZA8.Q, ZA9.Q, ZA10.Q, ZA11.Q, ZA12.Q, ZA13.Q, ZA14.Q, and ZA15.Q. Each tile consists of [$SVL_Q \times SVL_Q$] 128-bit elements, and occupies 1/16 of the *ZA* storage.

RQGHPF An access to a horizontal or vertical 128-bit element ZA tile slice reads or writes SVL_Q 128-bit elements.

DRLQKW An access to a horizontal or vertical 128-bit element ZA tile slice is indicated by appending a slice index "[*N*]" to the tile name, direction suffix, and qualifier. For example, where *t* is in the range 0-15 inclusive, and *N* is in the range 0 to SVL_Q-1 inclusive:

- ZA*t*H.Q[*N*] indicates a horizontal 128-bit element *ZA* tile slice selection.
- ZA*t*V.Q[*N*] indicates a vertical 128-bit element *ZA* tile slice selection.

IYQPWS Horizontal and vertical ZA*t*.Q slice accesses, where *t* is in the range 0-15 inclusive, are illustrated in the following diagram for SVL of 256 bits:

Figure B1-8 Horizontal and vertical ZAt.Q slice for SVL of 256

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{PJTQJ} An access to the horizontal slice ZA*t*H.Q[*N*] reads or writes the SVL_Q 128-bit elements in *ZA* array vector ZA.Q[*t* + 16 * *N*].

R_{TRJFZ} An access to the vertical slice ZA*t*V.Q[*N*] reads or writes the 128-bit element [*N*] within each horizontal slice of ZA*t*.Q.

D_{VCLJP} The preferred disassembly is:

- ZA*t*H.Q[W*s*, 0], for a horizontal 128-bit element *ZA* tile slice selection.
- ZA*t*V.Q[W*s*, 0], for a vertical 128-bit element *ZA* tile slice selection.

Where *t* is in the range 0-15 inclusive, and the slice index offset is always zero.

B1.4.11 ZA storage layout

B1.4.11.1 ZA array vector and tile slice mappings

I_{PYTLW} Each horizontal tile slice corresponds to one *ZA* array vector.
The horizontal slice mappings for all tile sizes are illustrated by this table:

ZA array Vector	8-bit element tile Horizontal slice	16-bit element tile Horizontal slice	32-bit element tile Horizontal slice	64-bit element tile Horizontal slice	128-bit element tile Horizontal slice
ZA[0]	ZA0H.B[0]	ZA0H.H[0]	ZA0H.S[0]	ZA0H.D[0]	ZA0H.Q[0]
ZA[1]	ZA0H.B[1]	ZA1H.H[0]	ZA1H.S[0]	ZA1H.D[0]	ZA1H.Q[0]
ZA[2]	ZA0H.B[2]	ZA0H.H[1]	ZA2H.S[0]	ZA2H.D[0]	ZA2H.Q[0]
ZA[3]	ZA0H.B[3]	ZA1H.H[1]	ZA3H.S[0]	ZA3H.D[0]	ZA3H.Q[0]
ZA[4]	ZA0H.B[4]	ZA0H.H[2]	ZA0H.S[1]	ZA4H.D[0]	ZA4H.Q[0]
ZA[5]	ZA0H.B[5]	ZA1H.H[2]	ZA1H.S[1]	ZA5H.D[0]	ZA5H.Q[0]
ZA[6]	ZA0H.B[6]	ZA0H.H[3]	ZA2H.S[1]	ZA6H.D[0]	ZA6H.Q[0]
ZA[7]	ZA0H.B[7]	ZA1H.H[3]	ZA3H.S[1]	ZA7H.D[0]	ZA7H.Q[0]
ZA[8]	ZA0H.B[8]	ZA0H.H[4]	ZA0H.S[2]	ZA0H.D[1]	ZA8H.Q[0]
ZA[9]	ZA0H.B[9]	ZA1H.H[4]	ZA1H.S[2]	ZA1H.D[1]	ZA9H.Q[0]
ZA[10]	ZA0H.B[10]	ZA0H.H[5]	ZA2H.S[2]	ZA2H.D[1]	ZA10H.Q[0]
ZA[11]	ZA0H.B[11]	ZA1H.H[5]	ZA3H.S[2]	ZA3H.D[1]	ZA11H.Q[0]
ZA[12]	ZA0H.B[12]	ZA0H.H[6]	ZA0H.S[3]	ZA4H.D[1]	ZA12H.Q[0]
ZA[13]	ZA0H.B[13]	ZA1H.H[6]	ZA1H.S[3]	ZA5H.D[1]	ZA13H.Q[0]
ZA[14]	ZA0H.B[14]	ZA0H.H[7]	ZA2H.S[3]	ZA6H.D[1]	ZA14H.Q[0]
ZA[15]	ZA0H.B[15]	ZA1H.H[7]	ZA3H.S[3]	ZA7H.D[1]	ZA15H.Q[0]
if applicable ZA[16] to ZA[SVL_B-1]	. . .	. . .	. . .	. . .	. . .

B1.4.11.2 Tile mappings

I_{YVYJP} The smallest *ZA* tile granule is the 128-bit element tile. When the *ZA* storage is viewed as an array of tiles, the larger 64-bit, 32-bit, 16-bit, and 8-bit element tiles overlap multiple 128-bit element tiles as follows:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Tile	Overlaps
ZA0.B	ZA0.Q, ZA1.Q, ZA2.Q, ZA3.Q, ZA4.Q, ZA5.Q, ZA6.Q, ZA7.Q, ZA8.Q, ZA9.Q, ZA10.Q, ZA11.Q, ZA12.Q, ZA13.Q, ZA14.Q, ZA15.Q
ZA0.H	ZA0.Q, ZA2.Q, ZA4.Q, ZA6.Q, ZA8.Q, ZA10.Q, ZA12.Q, ZA14.Q
ZA1.H	ZA1.Q, ZA3.Q, ZA5.Q, ZA7.Q, ZA9.Q, ZA11.Q, ZA13.Q, ZA15.Q
ZA0.S	ZA0.Q, ZA4.Q, ZA8.Q, ZA12.Q
ZA1.S	ZA1.Q, ZA5.Q, ZA9.Q, ZA13.Q
ZA2.S	ZA2.Q, ZA6.Q, ZA10.Q, ZA14.Q
ZA3.S	ZA3.Q, ZA7.Q, ZA11.Q, ZA15.Q
ZA0.D	ZA0.Q, ZA8.Q
ZA1.D	ZA1.Q, ZA9.Q
ZA2.D	ZA2.Q, ZA10.Q
ZA3.D	ZA3.Q, ZA11.Q
ZA4.D	ZA4.Q, ZA12.Q
ZA5.D	ZA5.Q, ZA13.Q
ZA6.D	ZA6.Q, ZA14.Q
ZA7.D	ZA7.Q, ZA15.Q

I_{WGZBT} The architecture permits concurrent use of different element size tiles.

B1.4.11.3 Horizontal tile slice mappings

I_{NJJXW} The following diagram illustrates the *ZA* storage mapping for SVL of 256 bits, for a 32-bit element and 64-bit element horizontal tile slice.

Each small numbered square represents 8 bits.

Figure B1-11 ZA storage mapping for SVL of 256 bits: 32-bit and 64-bit element vertical tile slices

An SME vector load, store, or move instruction which accesses vertical tile slices ZA2V.S[1] or ZA4V.D[2] treats the slices as vectors with the following layout:

Figure B1-12 ZA2V.S[1] and ZA4V.D[2] vector layout

B1.4.11.5 Mixed horizontal and vertical tile slice mappings

ICGXPJ

The following diagram illustrates the *ZA* storage mapping for SVL of 256 bits, for various element size tiles, horizontal tile slices, and vertical tile slices.

Each small square represents 8 bits.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure B1-13 ZA storage mapping for SVL of 256 bits: various vertical and tile slices

I_{HVFMB} It is possible to simultaneously use non-overlapping *ZA* array vectors within tiles of differing element sizes. For example, tiles ZA1.H, ZA0.S, and ZA2.D have no *ZA* array vectors in common, as illustrated in the following diagram for SVL of 256 bits:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure B1-14 Using various non-overlapping ZA array vectors within tiles of different element sizes

IWDMCK It is possible to access overlapping *ZA* array vectors within tiles of differing element sizes. For example, tiles ZA0.H, ZA2.S, and ZA6.D have common *ZA* array vectors.

B1.4.12 SME2 Multi-vector operands

RKLRKJ Multi-vector operands allow certain SME2 instructions to access as source and destination operands:

- A group of 2 or 4 SVE *Z* vector registers.
- A group of 2 or 4 *ZA* tile slices.
- A group of 2, 4, 8, or 16 *ZA* array vectors.

B1.4.12.1 Z multi-vector operands

DPSTFY A multi-vector operand consisting of 2 or 4 SVE *Z* vector registers is called *Z* multi-vector operand.

RVCXBQ A *Z* multi-vector operand can occupy:

- Consecutively numbered *Z* registers.
- *Z* registers with strided numbering.

DNYNRZ A *Z* multi-vector operand occupying 2 consecutively numbered *Z* vectors consists of Z*n+0* and Z*n+1*, where (*n+x* modulo 32) is a register number in the range 0 to 31 inclusive.

DDZDBM A *Z* multi-vector operand occupying 4 consecutively numbered *Z* vectors consists of Z*n+0* to Z*n+3*, where (*n+x* modulo 32) is a register number in the range 0 to 31 inclusive.

DVYKCM The preferred disassembly for a *Z* multi-vector operand of consecutively numbered *Z* vectors is a dash-separated register range, for example { Z0.S-Z1.S } or { Z30.B-Z1.B }. Toolchains must also support assembler source code which uses the

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

alternative comma-separated list notation, for example { Z0.S, Z1.S } or { Z30.B, Z31.B, Z0.B, Z1.B}, and disassemblers may provide an option to select between the dash-separated range and comma-separated list notations.

D_{PCYZS} A *Z* multi-vector operand occupying two *Z* vectors with strided register numbering consists of a first register in the range Z0-Z7 or Z16-Z23, followed by a second register with a number that is 8 higher than the first.

D_{RZTTV} A *Z* multi-vector operand occupying four *Z* vectors with strided register numbering consists of a first register in the range Z0-Z3 or Z16-Z19, followed by three registers with a number that is each 4 higher than the last.

D_{DMTSL} The preferred disassembly for a *Z* multi-vector operand of *Z* vectors with strided register numbering is a comma-separated register list, for example { Z0.D, Z8.D } or { Z0.H, Z4.H, Z8.H, Z12.H }.

B1.4.12.2 ZA multi-slice operands

D_{JMCTK} A multi-vector operand consisting of two or four *ZA* tile slices is called *ZA* multi-slice operand.

R_{SCHNH} A *ZA* multi-slice operand can occupy:

- Consecutively numbered horizontal *ZA* tile slices.
- Consecutively numbered vertical *ZA* tile slices.

D_{VXMGC} In a *ZA* multi-slice operand that consists of:

- Two *ZA* tile slices, the lowest numbered slice is a multiple of 2.
- Four *ZA* tile slices, the lowest numbered slice is a multiple of 4.

D_{JFDSB} In instructions operating on *ZA* multi-slice operands, the lowest-numbered slice is selected by rounding down the sum of a 32-bit general-purpose register (slice index register W*s*) and an offset (slice index offset *offs*) to the nearest lower multiple of the number of the slices in the ZA multi-slice operand, modulo the number of slices in the named tile.

R_{XMMKZ} Instructions operating on the following *ZA* multi-slice operands are treated as UNDEFINED:

- The four-slice operand in a 64-bit element tile when SVL is 128 bits.
- The two-slice operand in a 128-bit element tile when SVL is 128 bits.
- The four-slice operand in a 128-bit element tile when SVL is 128 bits or 256 bits.

D_{GJTMX} The preferred disassembly for a *ZA* multi-slice operand is as follows:

- ZA*t*H.*T*[W*s*, *offs1*:*offs2*], for horizontal *ZA* two-slice operands, where *offs2* = *offs1* + 1.
- ZA*t*H.*T*[W*s*, *offs1*:*offs4*], for horizontal *ZA* four-slice operands, where *offs4* = *offs1* + 3.
- ZA*t*V.*T*[W*s*, *offs1*:*offs2*], for vertical *ZA* two-slice operands, where *offs2* = *offs1* + 1.
- ZA*t*V.*T*[W*s*, *offs1*:*offs4*], for vertical *ZA* four-slice operands, where *offs4* = *offs1* + 3.

B1.4.12.3 ZA multi-vector operands

D_{RGXBK} A multi-vector operand consisting of two, four, eight, or sixteen *ZA* array vectors is called *ZA* multi-vector operand.

D_{TGDRF} One *ZA* array vector is called a *ZA* single-vector group.

D_{FCYGL} Two consecutively-numbered vectors in the *ZA* array are called a *ZA* double-vector group.

D_{GCTYB} Four consecutively-numbered vectors in the *ZA* array are called a *ZA* quad-vector group.

I_{PMQRQ} The *ZA* multi-vector operand consists of one, two, or four vector groups, where a vector group is one of the following:

- *ZA* single-vector group.
- *ZA* double-vector group.
- *ZA* quad-vector group.

I_{KLBYZ} The SME2 architecture includes multi-vector instructions that access a *ZA* multi-vector operand consisting of the same number of vector groups as there are vectors in each *Z* multi-vector operand.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{HPKZM} The preferred disassembly for a *ZA* multi-vector operand consisting of two or four vector groups, defined in declarations D_{KQZYZ}, D_{JWRSN}, and D_{TTNGH}, includes the symbol `VGx2` or `VGx4`, respectively. The symbol `VGx2` or `VGx4` can optionally be omitted in assembler source code if it can be inferred from the other operands.

D_{CLJBX} In instructions that access a *ZA* multi-vector operand, the lowest-numbered vector is selected by the sum of a 32-bit general-purpose register (vector select register W*v*) and an offset (vector select offset *offs*), modulo one of the following values:

- SVL_B when the operand consists of one *ZA* vector group.
- $SVL_B/2$ when the operand consists of two *ZA* vector groups.
- $SVL_B/4$ when the operand consists of four *ZA* vector groups.

B1.4.12.3.1 ZA multi-vector operands of single-vector groups

D_{QFPHH} In instructions where the *ZA* multi-vector operand consists of two single-vector groups, each vector group is held in a separate half of the *ZA* array: ZA[*n+0*] and ZA[$SVL_B/2$ + *n+0*], where *n* is in the range 0 to ($SVL_B/2$ - 1) inclusive.

D_{TTHGQ} In instructions where the *ZA* multi-vector operand consists of four single-vector groups, each vector group is held in a separate quarter of the *ZA* array: ZA[*n+0*], ZA[$SVL_B/4$ + *n+0*], ZA[$SVL_B/2$ + *n+0*], and ZA[SVL_B*3/4 + *n+0*], where *n* is in the range 0 to ($SVL_B/4$ - 1) inclusive.

D_{KQZYZ} The preferred disassembly for a *ZA* multi-vector operand of single-vector groups is:

- ZA.*T*[W*v*, *offs*, VGx2], when the operand consists of two single-vector groups.
- ZA.*T*[W*v*, *offs*, VGx4], when the operand consists of four single-vector groups.

Where *offs* is in the range 0 to 7 inclusive, and *T* is one of B, H, S, or D.

I_{BYBQL} The mapping between *ZA* multi-vector operands of single-vector groups and 32-bit element *ZA* tile slices when SVL is 256 bits is illustrated in the following diagram:

B1.4.13 SME2 ZT0 register

R_{KHZMV} A PE with FEAT_SME2 has a 512-bit register, *ZT0*, to store a lookup table.

R_{WDJBC} The ZT0 register holds 8-bit, 16-bit, or 32-bit lookup table elements that are stored in the least significant bits of 32-bit table entries. The lowest numbered 32 bits in the register hold table entry 0.

R_{JQXLS} The ZT0 register lookup table can be accessed using fully packed 2-bit or 4-bit indices from a numbered portion of one source Z*n* SVE scalable vector register.

I_{BRRGG} When the ZT0 register lookup table is addressed by 2-bit indices, 4 different table elements (0-3) of a given element size can be accessed. When the lookup table is addressed by 4-bit indices, 16 different table elements (0-15) of a given element size can be accessed.

R_{JKYRB} The indexed 8-bit, 16-bit, or 32-bit table elements are read from the ZT0 register and packed into consecutive or strided elements of an SVE Z vector or Z multi-vector operand.

B1.5 Software control features and EL0

The following sections describe the EL0 view of the software control features:

- Exception handling
- Wait for Interrupt and Wait for Event
- The YIELD instruction
- Application level cache management
- Instructions relating to Debug
- About PSTATE.DIT

B1.5.1 Exception handling

In the Arm architecture, an *exception* causes a change of program flow. Execution of an exception handler starts, at an Exception level higher than EL0, from a defined vector that relates to the exception taken.

Exceptions include:

- Interrupts.
- Memory system aborts.
- Exceptions generated by attempting to execute an instruction that is UNDEFINED.
- System calls.
- Secure monitor or Hypervisor traps.
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in The AArch64 System Level Programmers' Model.

The `SVC` instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a system call to an operating system.

The `BRK` instruction generates a Breakpoint Instruction exception. This provides a mechanism for debugging software using debugger executing on the same PE, see Breakpoint Instruction exceptions.

Note

The `BRK` instruction is supported only in the A64 instruction set. The equivalent instruction in the T32 and A32 instruction sets is `BKPT`.

B1.5.2 Wait for Interrupt and Wait for Event

Issuing a `WFI` instruction indicates that no further execution is required until a WFI wakeup event occurs, see Wait for Interrupt mechanism. This permits entry to a low-power state.

Issuing a `WFE` instruction indicates that no further execution is required until a WFE wakeup event occurs, see Wait for Event. This permits entry to a low-power state.

B1.5.3 The YIELD instruction

The `YIELD` instruction provides a hint that the task performed by a thread is of low importance so that it could yield, see YIELD. This mechanism can be used to improve overall performance in a *Symmetric Multithreading* (SMT) or *Symmetric Multiprocessing* (SMP) system.

Examples of when the `YIELD` instruction might be used include a thread that is sitting in a spin-lock, or where the arbitration priority of the snoop bit in an SMP system is modified. The `YIELD` instruction permits binary compatibility between SMT and SMP systems.

The `YIELD` instruction is a `NOP` hint instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The `YIELD` instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use for future migration to a multiprocessor or multithreading system. Operating systems can use `YIELD` in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.

B1.5.4 Application level cache management

A small number of cache maintenance instructions can be enabled at EL0 from higher levels of privilege using the SCTLR_EL1 System register. Any access from EL0 to an operation without access permission causes the instruction to be trapped.

About the available operations, see Application level access to functionality related to caches.

B1.5.5 Instructions relating to Debug

Exception handling refers to the `BRK` instruction, which generates a Breakpoint Instruction exception. In addition, in AArch64 state and AArch32 state, the `HLT` instruction causes the PE to halt execution and enter Debug state. This provides a mechanism for debugging software using a debugger that is external to the PE, see About External Debug.

Note

In AArch32 state, previous versions of the architecture defined the `DBG` instruction, which could provide a hint to the debug system. This instruction executes as a `NOP`. Arm deprecates the use of the `DBG` instruction.

B1.5.6 About PSTATE.DIT

A *data-independent-time sequence of code* is the sequence of instructions executed from the first instruction executed after a change of PSTATE.DIT from 0 to 1 through the last instruction executed before a change of PSTATE.DIT from 1 to 0, inclusive. Instructions speculatively executed between the change of PSTATE.DIT from 0 to 1 and the change of PSTATE.DIT from 1 to 0 are considered part of the data-independent-time sequence of code.

A *data-independent-time resource* is any of the following:

- A general-purpose register other than the zero register (WZR or XZR).
- A Stack Pointer register.
- A SIMD&FP register.
- If FEAT_SVE or FEAT_SME is implemented, SVE scalable vector register.
- If FEAT_SVE or FEAT_SME is implemented, SVE scalable predicate register.
- If FEAT_SME is implemented, ZA register.
- If FEAT_SME2 is implemented, ZT0 register.
- SPSR_ELx.{N, Z, C, V}.
- PSTATE.{N, Z, C, V}.

Note

The collections of PSTATE.{N, Z, C, V} and SPSR_ELx.{N, Z, C, V} are each considered a single data-independent-time resource.

A *data-independent-time instruction* is an instruction that is required to honor the data-independent timing behaviors described in this section.

A *data-independent-time* value is any of:

- Any given value (V) read from memory by the Explicit Memory Read Effect of a data-independent-time instruction (I1) that is executed within a data-independent-time sequence of code (C), where V is not consumed by any other instruction (I2) for which any of the following apply:
  - I2 is not a data-independent-time instruction.
  - I2 is not executed in C.
  - V is used to form the address or Logical Address Tag of a Memory Effect generated by I2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - If I2 is an SVE instruction (regardless of whether streaming mode is enabled), V is used as the Governing predicate operand for I2.
    - If I2 is an SME instruction, V is used as the Governing predicate operand, slice index register, or vector select register for I2.
- Any given value (V) written to a data-independent-time resource by a data-independent-time instruction (I1) that is executed within a data-independent-time sequence of code (C), where V is not consumed by any other instruction (I2) for which any of the following apply:
    - I2 is not a data-independent-time instruction.
    - I2 is not executed in C.
    - V is used to form the address or Logical Address Tag of a Memory Effect generated by I2.
    - If I2 is an SVE instruction (regardless of whether streaming mode is enabled), V is used as the Governing predicate operand for I2.
    - If I2 is an SME instruction, V is used as the Governing predicate operand, slice index register, or vector select register for I2.
- Any given value (V) read from a data-independent-time resource by a data-independent-time instruction (I1) that is executed within a data-independent-time sequence of code (C) and none of the following apply:
    - V was produced by another instruction (I0) and any of the following apply:
        - I0 is not a data-independent-time instruction.
        - I0 is not executed in C.
    - V is used to form the address or Logical Address Tag of a Memory Effect produced by I1.
    - V is not consumed by any other instruction (I2) for which any of the following apply:
        - I2 is not a data-independent-time instruction.
        - I2 is not executed in C.
        - V is used to form the address or Logical Address Tag of a Memory Effect generated by I2.
        - If I2 is an SVE instruction (regardless of whether streaming mode is enabled), V is used as the Governing predicate operand for I2.
        - If I2 is an SME instruction, V is used as the Governing predicate operand, slice index register, or vector select register for I2.
- Any given value (V) written to memory by the Explicit Memory Write Effect of a data-independent-time instruction (I1) that is executed within a data-independent-time sequence of code (C) and none of the following apply:
    - V was produced by another instruction (I0) and any of the following apply:
        - I0 is not a data-independent-time instruction.
        - I0 is not executed in C.
    - V is used to form the address or Logical Address Tag of a Memory Effect produced by I1.
    - V was sourced from the zero register.
    - V is not consumed by any other instruction (I2) for which any of the following apply:
        - I2 is not a data-independent-time instruction.
        - I2 is not executed in C.
        - V is used to form the address or Logical Address Tag of a Memory Effect generated by I2.
        - If I2 is an SVE instruction (regardless of whether streaming mode is enabled), V is used as the Governing predicate operand for I2.
        - If I2 is an SME instruction, V is used as the Governing predicate operand, slice index register, or vector select register for I2.
- Any given value (V) speculatively read from memory at a Location (L) as the result of executing a data-independent-time sequence of code, where L is not explicitly read by the data-independent-time sequence of code. Examples of this include:
    - Reading additional bytes from memory while reading the bytes required by an Explicit Memory Read Effect.
    - Hardware-generated prefetches.
    - Prefetch memory instructions.

The execution time of a given data-independent-time sequence of code must be independent of all data-independent-time values.

The execution time of a data-independent-time instruction (I1) executed within a data-independent-time sequence of code must be independent of all data-independent-time values consumed or produced by I1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The time to respond to an asynchronous exception taken from within a data-independent-time sequence of code must be independent of all data-independent-time values.

The execution of a data-independent-time sequence of code (C1) must not cause an irreversible change in microarchitectural state of the PE that would permit a sequence of code (C2) that is executed after C1 to determine any data-independent-time value accessed during the execution of C1. For the purposes of this requirement, a data-independent-time value written by an Explicit Memory Write Effect that is held in caches is not considered an irreversible change in microarchitectural state.

The execution of a data-independent-time sequence of code (C1) must not alter the state of PMU counters in a way that allows a sequence of code (C2) that is executed after C1 to determine any data-independent-time value accessed during C1.

Note

In cases where an instruction is architecturally required to only read or write a subset of a data-independent-time resource, the entire data-independent-time resource is considered to have been read or written for the sake of these requirements.

Note

The architecture does not guarantee that the execution time of a data-independent-time sequence of code is independent of data-independent-time values if those values are read from or written to a peripheral.

Note

The classification of a value being a data-independent-time value due to having been read from a memory location (L) by an Explicit Memory Read Effect or written to L by an Explicit Memory Write Effect is based on the particular Effect generated by a data-independent-time instruction executed from within a data-independent-time sequence of code. The value held in L is not itself considered a data-independent-time value. As a result, it is possible for the execution time of a data-independent-time sequence of code to vary based on the value held in L if L is accessed using any of the following:

- Outside the data-independent-time sequence of code, either architecturally or speculatively.
- Within a data-independent-time sequence of code but not as a data-independent-time value.

Note

- The *Operational information* section of an instruction description indicates whether or not that instruction is a data-independent-time instruction. If the *Operational information* section of an instruction description does not mention data-independent-time or if the section does not exist, then the instruction is not a data-independent-time instruction.
- The use of value prediction for data-independent-time values, is not compatible with the requirement that the timing is insensitive to the data value being loaded.
- Arm recommends that the FEAT_PAuth instructions do not have their timing dependent on the key value used in the pointer authentication, regardless of whether the instruction is executed in a data-independent-time sequence of code.
- The architecture makes no statement about the timing properties of any instructions executed outside of a data-independent-time sequence of code. However, it is likely that these instructions have timing that is invariant of the data in many situations.
- For SVE and SME predicated instructions, it is the programmer's responsibility to use a *Governing predicate* that does not reflect the values of the data being operated on.

A corresponding DIT bit is added to PSTATE in AArch64 state, and to CPSR in AArch32 state.

On an exception that is taken from AArch64 state to AArch64 state, PSTATE.DIT is copied to SPSR_ELx.DIT.

On an exception that is taken from AArch32 state to AArch64 state, CPSR.DIT is copied to SPSR_ELx.DIT.

On an exception return from AArch64 state:

- SPSR_ELx.DIT is copied to PSTATE.DIT, when the target Exception level is in AArch64 state.
- SPSR_ELx.DIT is copied to CPSR.DIT, when the target Exception level is in AArch32 state.

PSTATE.DIT can be written and read at all Exception levels.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- PSTATE.DIT is unchanged on entry into Debug state.
- PSTATE.DIT is not guaranteed to have any effect in Debug state.
- Software is advised to ensure that no indirect branch is executed while secret data is held in registers.
- Software is advised to ensure that no direct branches target non-constant-time code while secret data is held in registers.

Chapter B2
The AArch64 Application Level Memory Model

This chapter gives an application level view of the memory model. It contains the following sections:

- About the Arm memory model
- Atomicity in the Arm architecture
- Ordering requirements defined by the formal concurrency model
- Additional ordering requirements outside of the scope of the formal concurrency model
- Restrictions on the effects of speculation
- Memory barriers
- Caches and memory hierarchy
- Alignment support
- Endian support
- Memory types and attributes
- Mismatched memory attributes
- Synchronization and semaphores

Note

In this chapter, System register names usually link to the description of the register in AArch64 System Register Descriptions, for example. SCTLR_EL1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B2.1 About the Arm memory model

The Arm architecture is a weakly ordered memory architecture that permits the observation and completion of memory accesses in a different order from the program order. The following sections of this chapter provide the complete definition of the memory model.

This section contains:

- Address space
- Memory type overview
- SVE memory model
- SME memory model

B2.1.1 Address space

Address calculations are performed using 64-bit registers.

However, supervisory software can configure the top eight address bits for use as a tag, as described in Address tagging. If this is done, address bits[63:56]:

- Are not considered when determining whether the address is valid.
- Are never propagated to the Program Counter.

Supervisory software determines the valid address range. Attempting to access an address that is not valid generates an MMU fault.

Simple sequential execution of instructions might overflow the valid address range. For more information, see Virtual address space overflow.

Memory accesses use the `Mem()` function. This function makes an access of the required type. If supervisory software configures the top eight address bits for use as a tag, the top eight address bits are ignored.

The `AccessType` defines the different access types and attributes.

Note

- The AArch64 System Level Memory Model and The AArch64 Virtual Memory System Architecture include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also include pseudocode descriptions of these operations.
- For information on the pseudocode that relates to memory accesses, see Basic memory access, Unaligned memory access, and Aligned memory access.

B2.1.2 Memory type overview

The Arm architecture provides the following mutually-exclusive memory types:

Normal This is generally used for the majority of memory operations, both read/write and read-only operations.

Device The Arm architecture forbids Speculative reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive Locations.

Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See Gathering.
- They preserve the access order and synchronization requirements for accesses to a single peripheral. See Reordering.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- They indicate whether a write can be acknowledged other than at the end point. See Early Write Acknowledgement.

For more information on Normal memory and Device memory, see Memory types and attributes.

Note

Earlier versions of the Arm architecture defined a single Device memory type and a Strongly-ordered memory type. A *Note* in Device memory describes how these memory types map onto the Armv8 memory types.

B2.1.3 SVE memory model

I_{CZFSY} SVE predicated memory operations have a vector element size and a memory element access size. The vector element size specifies the data that is read from and written to the vector. The memory element access size specifies the amount of data that is read from and written to the memory.

I_{TJQJF} The vector element size and the memory element access size do not need to have the same value.

I_{LGGHH} For each memory element, there is an associated element address.

SVE also affects behavior in the following areas:

- Requirements for single-copy atomicity.
- SVE memory ordering relaxations.
- Load or Store of Single or Multiple registers.
- Endianness in SVE operations.
- SVE loads and stores that access Device memory.

B2.1.4 SME memory model

R_{BQSCG} SME load/store memory accesses are subject to the same rules that govern SVE load/store memory accesses.

I_{WWVYJ} When the PE is in *Streaming SVE mode*, there are relaxations for Advanced SIMD&FP instructions in the following areas:

- Streaming SVE mode memory ordering relaxations.
- Streaming SVE mode loads and stores that access Device memory.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B2.2 Atomicity in the Arm architecture

Atomicity is a feature of memory accesses, described as *atomic* accesses. The Arm architecture description refers to two types of atomicity, *single-copy atomicity* and *multi-copy atomicity*. In the Arm architecture, the atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information, see:

- Requirements for single-copy atomicity.
- Properties of single-copy atomic accesses.
- Multi-copy atomicity.
- Requirements for multi-copy atomicity.
- Concurrent modification and execution of instructions.
- Possible implementation restrictions on using atomic instructions.

For more information about the memory types, see Memory type overview.

B2.2.1 Requirements for single-copy atomicity

For explicit memory effects generated from an Exception level the following rules apply:

- A read that is generated by a load instruction that loads a single general-purpose register and is aligned to the size of the read in the instruction is single-copy atomic.
- A write that is generated by a store instruction that stores a single general-purpose register and is aligned to the size of the write in the instruction is single-copy atomic.
- Reads that are generated by a Load Pair instruction that loads two general-purpose registers and are aligned to the size of the load to each register are treated as two single-copy atomic reads, one for each register being loaded.
- Writes that are generated by a Store pair instruction that stores two general-purpose registers and are aligned to the size of the store of each register are treated as two single-copy atomic writes, one for each register being stored.
- Load-Exclusive Pair instructions of two 32-bit quantities and Store-Exclusive Pair instructions of 32-bit quantities are single-copy atomic.
- When the Store-Exclusive of a Load-Exclusive/Store-Exclusive pair instruction using two 64-bit quantities succeeds, it causes a single-copy atomic update of the entire memory location being updated.

  Note

  To atomically load two 64-bit quantities, perform a Load-Exclusive pair/Store-Exclusive pair sequence of reading and writing the same value for which the Store-Exclusive pair succeeds, and use the read values from the Load-Exclusive pair.

- Where translation table walks generate a read of a translation table entry, this read is single-copy atomic.
- For the atomicity of instruction fetches, see Concurrent modification and execution of instructions.
- Reads to SIMD and floating-point registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being loaded are treated as single-copy atomic reads.
- Writes from SIMD and floating-point registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being stored are treated as single-copy atomic writes.
- Element or Structure Reads to SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the element being loaded, have each element treated as a single-copy atomic read.
- Element or Structure Writes from SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the element being stored, have each element treated as a single-copy atomic store.
- Reads to SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit reads.
- Writes from SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit writes.
- If FEAT_LS64WB is implemented, accesses to two 128-bit SIMD and floating-point registers by an LDP (SIMD&FP) or STP (SIMD&FP) instruction are treated as one single-copy atomic 256-bit access when both the following are true:
  - The access is 32-byte aligned in memory.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— The access is to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory.

- SVE predicated load and store instructions have the same single-copy atomicity guarantees as the SIMD load and store instructions for 64-bit or smaller elements.
- An SVE predicated load or store of a 128-bit element that is 64-bit aligned is treated as a pair of 64-bit single-copy atomic accesses.
- SVE unpredicated load and store instructions are performed as a sequence of byte accesses.
- SVE unpredicated load and store instructions do not guarantee that any access larger than a byte will be performed as a single-copy atomic access.
- When FEAT_LS64 is implemented, a single-copy atomic load of a 64-byte value that is 64-byte aligned in memory is treated as an atomic 64-byte read from the target address.
- When FEAT_LS64 is implemented, a single-copy atomic store of a 64-byte value that is 64-byte aligned in memory is treated as an atomic 64-byte write to the target address.
- For unaligned memory accesses, the single-copy atomicity is described in Alignment of data accesses.
- The read and write generated by an Atomic instruction is single-copy atomic at the overall size of the data access.

It is architecturally forbidden for a single-copy-atomic Memory Effect to lose its single-copy-atomic properties due to caching. For example, the writeback of a cache line that was dirtied by a 64-bit single-copy-atomic Explicit Write Effect must not be performed in such a way that an Observer could observe part but not all of the 64 bits.

All other memory accesses are regarded as streams of accesses to bytes, and no atomicity between accesses to different bytes is ensured by the architecture.

All accesses to any byte are single-copy atomic.

Note

In AArch64 state, no memory accesses from a `DC ZVA` have single-copy atomicity of any quantity greater than individual bytes.

If, according to these rules, an instruction is executed as a sequence of accesses, exceptions, including interrupts, can be taken during that sequence, regardless of the memory type being accessed. If any of these exceptions are returned from using their preferred return address, the instruction that generated the sequence of accesses is re-executed, and so any access performed before the exception was taken is repeated. See also Taking an asynchronous exception during a multi-access load or store.

Note

The exception behavior for these multiple access instructions means that they are not suitable for use for writes to memory for the purpose of software synchronization.

B2.2.1.1 Changes to single-copy atomicity in Armv8.4

In addition to the single-copy atomicity requirements listed above:

Instructions that are introduced in FEAT_LRCPC, FEAT_LRCPC2, or FEAT_LRCPC3 are single-copy atomic when all of the following conditions are true:

- All bytes being accessed are within the same 16-byte quantity aligned to 16 bytes.
- Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

If FEAT_LSE2 is implemented, all loads and stores are single-copy atomic when all of the following conditions are true:

- Accesses are unaligned to their data size but all bytes being accessed are within a 16-byte quantity that is aligned to 16 bytes.
- Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

If FEAT_LSE2 is implemented, `LDP`, `LDNP`, and `STP` instructions that load or store two 64-bit registers are single-copy atomic when all of the following conditions are true:

- The overall memory access is aligned to 16 bytes.
- Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_LSE2 is implemented, `LDP`, `LDNP`, and `STP` instructions that access fewer than 16 bytes are single-copy atomic when all of the following conditions are true:

- All bytes being accessed are within a 16-byte quantity aligned to 16 bytes.
- Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

B2.2.2 Properties of single-copy atomic accesses

A memory access instruction that is single-copy atomic has the following properties:

1. For a pair of overlapping single-copy atomic store instructions, all of the overlapping writes generated by one of the stores are Coherence-after the corresponding overlapping writes generated by the other store.
2. For a single-copy atomic load instruction L_1 that overlaps a single-copy atomic store instruction S_2, if one of the overlapping reads generated by L_1 Reads-from one of the overlapping writes generated by S_2, then none of the overlapping writes generated by S_2 are Coherence-after the corresponding overlapping reads generated by L_1.

For more information, see Ordering requirements defined by the formal concurrency model.

B2.2.3 Multi-copy atomicity

In a multiprocessing system, writes to a memory location are *multi-copy atomic* if the following conditions are both true:

- All writes to the same location are *serialized*, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

Note

Writes that are not coherent are not multi-copy atomic.

B2.2.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory, writes are not required to be multi-copy atomic.

The Arm memory model is Other-multi-copy atomic. For more information, see External visibility requirement.

B2.2.5 Concurrent modification and execution of instructions (CMODX)

The Arm architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction behaving like any possible sequence of instructions executable at the same Exception level. However, the behavior is more restricted if both the instruction before and the instruction after modification are one of `B`, `B.cond`, `BL`, `BRK`, `CB<cc>`, `CBB<cc>`, `CBH<cc>`, `CBNZ`, `CBZ`, `HVC`, `ISB`, `NOP`, `SMC`, `SVC`, `TBNZ`, `TBZ`, `TRCIT`, or `UDF`.

The more restricted behavior is that the architecture guarantees that the behavior of the instruction that is being concurrently modified and executed is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

When the cases of the more restricted behavior do not apply, to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

1. No PE must be executing an instruction when another PE is modifying that instruction.
2. To ensure that the modified instructions are observable, a PE that is writing the instructions must issue the following sequence of instructions and operations:

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; enter this code with <Wt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Xn.
        STR Wt, [Xn]
        DC CVAU, Xn                 ; Clean data cache by VA to point of unification (PoU)
        DSB ISH                     ; Ensure visibility of the data cleaned from cache
        IC IVAU, Xn                 ; Invalidate instruction cache by VA to PoU
        DSB ISH
```

Note

- The `DC CVAU` operation is not required if the area of memory is either Non-cacheable or Write-Through Cacheable.
- If the contents of physical memory differ between the mappings, changing the mapping of VAs to PAs can cause the instructions to be concurrently modified by one PE and executed by another PE. If the modifications affect instructions other than those listed as being acceptable for modification, synchronization must be used to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
- In a multiprocessor system, the DC CVAU and IC IVAU are broadcast to all PEs within the Inner Shareable domain of the PE running this sequence.

3. When the modified instructions are observable, each PE that is executing the modified instructions must execute an `ISB` or perform a context synchronization event to ensure execution of the modified instructions:

```
        ISB                             ; Synchronize fetched instruction stream
```

Note

For the purposes of CMODX behavior, it is not considered a modification of an instruction at a Location L if a Memory Write Effect E_2 writes the same value to L that was written by the latest Memory Write Effect E_1 earlier in the coherence order for L than E_2.

For more information about the required synchronization operation, see Synchronization and coherency issues between data and instruction accesses.

For information about memory accesses caused by instruction fetches, see Ordering relations.

B2.2.6 Possible implementation restrictions on using atomic instructions

In some implementations, and for some memory types, the properties of atomicity can be met only by functionality outside the PE. Some system implementations might not support atomic instructions for all regions of the memory. In particular, this can apply to:

- Any type of memory in the system that does not support hardware cache coherency.
- Device, Non-cacheable memory, or memory that is treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such implementations, it is defined by the system:

- Whether the atomic instructions are atomic in regard to other agents that access memory.
- If the atomic instructions are atomic in regard to other agents that access memory, which address ranges or memory types this applies to.

An implementation can choose which memory type is treated as Non-cacheable.

The memory types for which it is architecturally guaranteed that the atomic instructions will be atomic are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory.

The architecture only requires that Conventional memory that is mapped in this way supports this functionality.

If the atomic instructions are not atomic in regard to other agents that access memory, then performing an atomic instruction to such a location can have one or more of the following effects:

- The instruction generates a synchronous External abort.
- The instruction generates a System Error interrupt.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data Abort Fault status code of ESR_ELx.DFSC = `110101`.

  For the EL1&0 translation regime, if the atomic instruction is not supported because of the memory type that is defined in the first stage of translation, or the second stage of translation is not enabled, then this exception is a first stage abort and is taken to EL1. Otherwise, the exception is a second stage abort and is taken to EL2.
- The instruction is treated as a `NOP`.
- The instructions are performed, but there is no guarantee that the memory accesses were performed atomically in regard to other agents that access memory. In this case, the instruction might also generate a System Error interrupt.

A system implementation might support atomic floating-point memory operation instructions on different regions of Device and Non-cacheable memory from those supported by other atomic instructions.

B2.3 Ordering requirements defined by the formal concurrency model

The material presented in the current section corresponds to what is described in the formal concurrency model. The definitions of relations, including but not limited to Dependency-ordered-before, Barrier-ordered-before, or Atomic-ordered-before, are automatically transliterated from the formal concurrency model.

The Arm memory model introduces a number of relations which are as follows:

- *Intrinsic relations*; For example, Intrinsic Data Dependencies, Intrinsic Control Dependencies, Intrinsic Order Dependencies and Translation-intrinsically-before are hardware requirements which stem from the instruction semantics.
- *After relations*; For example, Coherence-after and TLBI-after are relations which happen to be oriented that way in a specific execution, but could be oriented the other way in a different execution.
- *Observation relations*; For example, Explicit-Observed-by and TLBI-Observed-by build on *After relations* to describe an execution.
- *Ordered relations*; For example, Ordered-before and TLBI-ordered-before are architectural requirements which must be respected by hardware in all executions.

This section describes observation and ordering in the Arm memory model. It contains the following subsections:

- Basic definitions
- Intrinsic Dependency relations
- Tag-check-intrinsically-before
- Translation-intrinsically-before
- Fetch-intrinsically-before
- Dependency relations
- Ordering relations
- Observation relations
- Definition of an Architecturally Allowed Execution
- Alternative formulations of the External visibility requirement for Explicit Memory Effects

For more information about endpoint ordering of memory accesses, see Reordering.

In the Arm memory model, the Shareability memory attribute indicates the degree to which hardware must ensure memory coherency between a set of observers. See Memory types and attributes.

The Arm architecture defines additional memory attributes and associated behaviors, which are defined in the system level section of this Manual. See:

- The AArch64 System Level Memory Model.
- The AArch64 Virtual Memory System Architecture.

See also Mismatched memory attributes.

The formal memory model described in this section covers much, but not all, of the memory system functionality. In particular the following are in scope:

- Ordering requirements for instructions that explicitly access memory (for example: `LDR`, `STR`, `SWP`, etc.).
  - This includes the ordering requirements between any two Explicit Memory Effects where:
    - The Explicit Memory Effects are to the same Location either from the same or different PEs.
    - One or both of the Explicit Memory Effects are generated by an atomic instruction.
    - A barrier instruction is in program order between the Explicit Memory Effects.
    - There is a dependency between the Explicit Memory Effects.
  - And excludes cases where:
    - At least one of the Explicit Memory Effects is generated by SVE instructions.
    - At least one of the Explicit Memory Effects is generated by SME instructions.
    - At least one of the Explicit Memory Effects is generated by instructions added by FEAT_MOPS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Ordering requirements relating to the Virtual Memory System Architecture:
  - This includes:
    - Implicit TTD Memory Read Effects.
    - Implicit TTD Memory Write Effects when FEAT_HAF or FEAT_HAFDBS is implemented.
    - MMU Fault Effects that cause Data Abort exceptions.
  - This excludes:
    - Any Effects relating to address translation instructions.
    - Any Effects relating to address translation for instruction fetch.
    - The ordering requirements between Implicit TTD Memory Effects that belong to different levels or stages of translation.
    - The ordering requirements relating to FEAT_HDBSS.
    - The ordering requirements relating to FEAT_HACDBS.
- Ordering requirements relating to tag checks when FEAT_MTE2 is implemented. This includes:
  - Implicit Tag Memory Read Effects generated by tag checked instructions.
  - Explicit Tag Memory Effects generated by tag load, tag store, tag and data store, and bulk allocation tag access instructions.
  - TagCheck Fault Effects generated by tag checked instructions.
- Ordering requirements relating to instruction fetch. This includes:
  - Implicit Instruction Memory Read Effects generated as a result of instruction fetch.
  - DC CVAU Effects.
  - IC Effects.
  - Undefined Instruction Fault Effects.

Note

Arm is in the process of formalizing many features of the memory system architecture, but this work is not complete at this time. The following items are not in scope:

- Ordering requirements relating to the Event Register.
- Ordering requirements relating to the Exclusives monitor.
- Endpoint arrival of memory accesses.
- Interactions between memory accesses and peripherals.
- Ordering requirements relating to asynchronous exceptions and error exceptions.
- Ordering requirements relating to the generic interrupt controller.
- Ordering requirements for direct and indirect System register reads and writes.
- Ordering requirements relating to FEAT_GCS.
- Ordering requirements relating to FEAT_SPE.
- Ordering requirements relating to FEAT_TRBE.
- Ordering requirements relating to FEAT_RME.
- Ordering requirements relating to RAS PE architecture.
- Ordering requirements of DC Effects generated by `DC` instructions other than the `DC CVAU, Xt` instruction.

These will be addressed progressively in future versions of the Arm architecture, but until then, the required behaviors are described less formally in the prose and pseudocode of the Arm ARM.

For the purposes of the memory model, all Effects generated due to execution of an instruction are considered to be generated by the PE on which the instruction is executed. The list of all Effects of an instruction in the scope of the Arm Memory Model is further presented in Effects.

In this section Ordering requirements defined by the formal concurrency model, all of the following are assumed:

- One of the following applies:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— All PEs are part of the same Inner Shareable domain and all Memory Effects are to Inner Shareable or Outer Shareable memory as long as no TLB invalidations nor their corresponding `DSB` specify the Non-shareable domain.

— All PEs are part of the same Outer Shareable domain and all Memory Effects are to Outer Shareable memory as long as no TLB invalidations nor their corresponding `DSB` specify the Non-shareable domain or the Inner Shareable domain.

— All PEs are part of the Full System domain and all Memory Effects are to Normal, Inner Non-cacheable, Outer Non-cacheable memory or all Memory Effects are to Normal, Inner Write-Through, Outer Write-Through memory or all Memory Effects are to Device memory as long as all barriers specify the Full System domain and there are no TLB invalidations.

- All Memory Effects are to Normal, Inner Write-Back, Outer Write-Back memory. Behaviors in Ordering requirements defined by the formal concurrency model also apply to Memory Effects to memory with attributes other than Normal, Inner Write-Back, Outer Write-Back (for example, Device or Inner Write-Through, Outer Write-Through) as long as the behavior of the instruction which generated the Memory Effect is guaranteed for the memory type. For example, atomic instructions are only guaranteed to be atomic for Normal, Inner Write-Back, Outer Write-Back, Shareable memory. Memory Effects to memory with attributes other than Normal, Inner Write-Back, Outer Write-Back may require additional ordering behaviors than specified in Ordering requirements defined by the formal concurrency model. Such additional behaviors are described in Memory types and attributes.
- All Memory Effects to a given Location are not using mismatched memory attributes as described in Mismatched memory attributes.

B2.3.1 Basic definitions

The Arm memory model provides a set of definitions that are used to construct conditions on the permitted sequences of accesses to memory.

Location

A *Location* is a Memory Location or a Tag Location. A *Memory Location* is a byte of data that is associated with an address in the physical address space. A *Tag Location* is a 4-bit MTE Allocation Tag that is associated with an address in the physical address space.

Effects

The *Effects* of an instruction can be:

- Register Effects.
- Memory Effects.
- Explicit Memory Effects.
- Implicit TTD Memory Effects.
- Hardware Update Effects.
- Tag Memory Effects.
- Implicit Instruction Memory Read Effects.
- Barrier Effects.
- Instruction Fetch Barrier Effects.
- Conditional Branching, and Intrinsic Branching Effects.
- Fault Effects, Exception Entry, and Exception Return Effects.
- TLBI Effects, Completed TLBI Effects and Invalidation Scopes.
- TLBUncacheable Effects.
- DC CVAU Effects.
- IC Effects, Completed IC Effects.
- Empty Effects.

Program order

An Effect E_1 of an instruction I_1 appears in program order before an Effect E_2 of an instruction I_2 if and only if I_1 occurs before I_2 in the order specified by the program. Each Effect generated by an instruction has a unique Effect identifier that characterizes it among the Effects generated by the same instruction.

Register Effects

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The *Register Effects* of an instruction are register reads or register writes of that instruction. Register Effects only pertain to:

- General purpose registers from R0 to R30, excluding the zero register.
- SVE registers.
- SIMD/FP registers.
- PSTATE.NZCV.
- Direct reads from System registers that are readable.
- Direct writes to System registers that are writable.
- Direct reads from Special-purpose registers that are readable.
- Direct writes to Special-purpose registers that are writable.

For an instruction that accesses registers, a *Register Read Effect* is generated for each register read by the instruction and a *Register Write Effect* is generated for each register written by the instruction. An instruction may generate both Register Read and Write Effects.

Memory Effects

The *Memory Effects* of an instruction are the Read or Write Effects from memory of that instruction. For an instruction that accesses memory, a *Memory Read Effect* is generated for each Location read from by the instruction and a *Memory Write Effect* is generated for each Location written to by the instruction. An instruction can generate both Memory Read and Write Effects.

Explicit Memory Effects

An *Explicit Memory Effect* is a Memory Read or Memory Write Effect that is generated by one of the following:

- A load instruction, store instruction, atomic instruction, Tag and Data store instruction, `DC ZVA`, `DC GZVA`, or `STZGM`; to access the Memory Location(s) addressed by any of the following from the instruction:
  - The `Xn|SP` operand, plus any applicable offset.
  - The `PC` plus the offset specified by the `<label>` argument.
- A Tag load instruction, Tag store instruction, Tag and Data store instruction, Bulk Allocation tag access instruction, `DC GZVA`, or `DC GVA`; to access the Tag Location(s) addressed by the `Xn|SP` operand, plus any applicable offset, of the instruction.
- A Memory Copy or Memory Set instruction; to access the Memory Location(s) addressed by the `Xs` or `Xd` operand of the instruction, including all of the bytes within the range specified by the `Xn` operand of the instruction.
- A Memory Set with tag setting instruction; to access the Tag Location(s) addressed by the `Xs` or `Xd` operand of the instruction, including all of the Allocation tags within the range specified by the `Xn` operand of the instruction.
- An `MRS` or `MSR` instruction that is transformed into a Memory Effect due to FEAT_NV2; to access the Memory Locations addressed by VNCR_EL2 plus the offset for the specified register.

Note

Prefetch memory instructions do not generate any Explicit Memory Effects.

Implicit TTD Memory Effects

Implicit Translation Table Descriptor Memory Effects (Implicit TTD Memory Effects) are Memory Read or Write Effects to translation table descriptors caused by address translation, including the hardware updates for the Access Flag or the Dirty State of a TTD.

Hardware Update Effects

Hardware Update Effects are Implicit TTD Memory Write Effects that correspond to writes modifying the Access Flag or the Dirty State of a TTD.

For more information on Hardware Updates of the Access Flag or Dirty State, see Hardware management of the Access flag and Hardware management of the dirty state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

A Hardware Update Effect for the Access Flag may occur even in the absence of corresponding architecturally executed instructions, in which case the Hardware Update Effect is considered autonomous. Autonomous Hardware Update Effects are not constrained by the ordering relations that apply to the Hardware Update Effects of architecturally executed instructions.

Tag Memory Effects

Tag Memory Effects are a subset of Memory Effects. A Tag Memory Effect refers to a Memory Read or Write Effect to a Tag Location. For example:

- `LDG` and `LDGM` instructions generate an Explicit Tag Memory Read Effect for their read from a Tag Location.
- `STG`, `STGM`, `STGP`, `DC GZVA`, and `DC GVA` instructions generate an Explicit Tag Memory Write Effect for their write to a Tag Location.
- A Tag Checked memory access generates an Implicit Tag Memory Read Effect for its read of a Tag Location, as well as an Explicit Data Memory Effect.

Implicit Instruction Memory Read Effects

An *Implicit Instruction Memory Read Effect* refers to a Memory Read Effect generated as a result of an instruction fetch.

Barrier Effects

Barrier instructions generate *Barrier Effects*. In this chapter, the resulting Effect is named after the instruction. Therefore, an ISB instruction generates an ISB Effect, a DMB instruction generates a DMB Effect, and a DSB instruction generates a DSB Effect.

The following conventions are used when referring to DMB Effects:

- A DMB FULL Effect is generated by a DMB instruction with neither a LD nor ST qualifier.
- A DMB LD Effect is generated by a DMB instruction with the LD qualifier.
- A DMB ST Effect is generated by a DMB instruction with the ST qualifier.

The following conventions are used when referring to DSB Effects:

- A DSB FULL Effect is generated by a DSB instruction with neither a LD nor ST qualifier.
- A DSB LD Effect is generated by a DSB instruction with the LD qualifier.
- A DSB ST Effect is generated by a DSB instruction with the ST qualifier.

Instruction Fetch Barrier Effects

An *Instruction Fetch Barrier Effect* (IFBE) is generated by any of the following:

- A Context Synchronization event.
- An exception entry to ELx, regardless of the value of SCTLR_ELx.EIS, due to an exception generated for any reason other than any of the following:
  - `SVC` instruction execution that is not trapped.
  - `HVC` instruction execution that is not disabled.
  - `SMC` instruction execution that is not trapped or disabled.
  - `BKPT` instruction execution.
  - `BRK` instruction execution.

Note

- If FEAT_ExS is not implemented, or if FEAT_ExS is implemented and the SCTLR_ELx.EOS field is 1, an Exception Return effect is an IFBE due to it being a Context Synchronization event.
- If FEAT_ExS is not implemented, or if FEAT_ExS is implemented and the SCTLR_ELx.EIS field is 1, the Exception entry effects due to the exceptions excluded above are IFBEs due to being Context Synchronization events.

Conditional Branching, and Intrinsic Branching Effects

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Branching Effects are generated when a choice is made between two possible paths in the execution flow. Branching Effects represent such decision points.

Conditional Branching Effects are generated by Conditional branch instructions, when as a consequence of evaluating a condition a choice potentially affecting the execution flow of other subsequent instructions is made.

Intrinsic Branching Effects due to a translation occur when, as a consequence of reading a TTD, a choice is made between raising a fault (for example, if the descriptor is invalid) or performing a physical access. *Intrinsic Branching Effects* represent such decision points.

Intrinsic Branching Effects due to tag checking occur when, as a consequence of reading a tag, a choice is made between raising a fault (that is, due to a failed tag check) or performing a physical access. *Intrinsic Branching Effects* represent such decision points.

Intrinsic Branching Effects due to instruction fetch occur when, as a consequence of reading and decoding an instruction, a choice is made between raising a fault (for example, as a result of fetching an illegal instruction) or proceeding to execute the valid instruction. *Intrinsic Branching Effects* represent such decision points.

Note

Conditional Selection instructions and Compare-and-Swap instructions generate *Intrinsic Branching Effects*.

Fault Effects, Exception Entry, and Exception Return Effects

An instruction that encounters a fault generates a Fault Effect. An instruction that encounters a fault leading to a synchronous exception generates a Fault Effect that is also an *Exception Entry Effect*, for example as a result of reading an invalid TTD or fetching an illegal instruction.

An ERET instruction generates an *Exception Return Effect.*

A Fault Effect generated by the MMU is called an *MMU Fault Effect*. See MMU fault types for a full list of faults generated by the MMU.

A Fault Effect generated by a failed Tag Check is called a *TagCheck Fault Effect*.

Note

- An instruction that encounters an asynchronous Tag Check Fault generates a TagCheck Fault Effect that is not an Exception Entry Effect.
- An instruction that encounters a synchronous Tag Check Fault generates a TagCheck Fault Effect that is also an Exception Entry Effect.

TLBI Effects, Completed TLBI Effects and Invalidation Scopes

TLBI Effects are generated by TLBI instructions.

A TLBI Effect E_1 is a *Completed TLBI Effect* if E_1 appears in program order before a DSB FULL Effect.

The *Invalidation scope* of a TLBI Effect is a set Memory Effects. For a Virtual Address *x*, a Memory Read or Write Effect to the TTD of x is in the Invalidation Scope of a TLBI Effect if *x* is in the scope of the TLBI instruction. For the full description of the scope of TLBI instructions, see TLB maintenance instruction scope.

TLBUncacheable Effects

An MMU Fault Effect is TLBUncacheable if it is one of:

- A Translation Fault Effect.
- An Access Flag Fault Effect.
- An Address Size Fault Effect.
- A synchronous External Abort on translation table walk, such that it cannot be determined whether the TTD would otherwise generate a Translation Fault, Access Flag Fault, or Address Size Fault effect.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

A Permission Fault Effect is not TLBUncacheable.

DC CVAU Effects

DC CVAU Effects are generated by DC CVAU instructions.

IC Effects, Completed IC Effects

IC Effects are generated by IC IALLUIS, IC IALLU or IC IVAU instructions. An IC Effect E_1 is a *Completed IC Effect* if E_1 appears in program order before a DSB FULL Effect.

Empty Effects

Empty Effects are generated by instructions where a decision point, represented by a Branching Effect, leads to no further action resulting from that decision. For example, when FEAT_MTE_ASYNC is implemented and Tag Check Faults are reported asynchronously, a successful tag comparison generates an Empty Effect instead of a TagCheck Fault Effect.

Low-order Bits

The Low-order Bits of an address are the bits that remain unchanged in the translation process of an input address to an output address. The number of low-order bits that remain unchanged depends on the translation granule size.

Same Low-order Bits

Two Effects E_1 and E_2 have the Same Low-order Bits if the Low-order Bits of the address of E_1 and the Low-order Bits of the address of E_2 match.

Note

The address associated with an MMU Fault Effect is the faulting address as indicated in FAR_ELx.

Effects with a valid Physical Address

An Effect E_1 is an Effect with a valid Physical Address if one of the following applies:

- E_1 is a Memory Effect.
- E_1 is a DC Effect.
- E_1 is an IC Effect.

Note

In situations where accessing a Physical Address generates an MMU fault, the PE does not generate the corresponding Memory Effect or DC Effect or IC Effect.

Same Location

An Effect E_1 and an Effect E_2 are to the *Same Location* if one of the following applies:

- All of the following apply:
  - E_1 is an Effect with a valid Physical Address.
  - It is not the case that E_1 is a Tag Memory Effect.
  - E_1 and E_2 are to the same Physical Address.
  - E_2 is an Effect with a valid Physical Address.
  - It is not the case that E_2 is a Tag Memory Effect.
- All of the following apply:
  - E_1 is a Tag Memory Effect.
  - E_1 and E_2 are to the same Physical Address.
  - E_2 is a Tag Memory Effect.

Same Cache Line

An Effect E_1 and an Effect E_2 are to the *Same Cache Line* if:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- E_1 and E_2 are Memory Effects or DC CVAU Effects or IC Effects.
- E_1 and E_2 are to PAs that are on the Same Cache Line as follows from section Cache identification.

Successful Read-Modify-Write pair

Two Effects E_1 and E_2 form a *Successful Read-Modify-Write* pair if all of the following apply:

- E_1 is a Memory Read Effect.
- E_2 is a Memory Write Effect.
- E_1 and E_2 are to the Same Location.
- One of the following applies:
  - — E_1 and E_2 are generated by the same atomic instruction.
  - — E_1 and E_2 are generated by the same successful Load-Exclusive/Store-Exclusive instruction pair.

Reads-from-memory

The *Reads-from-memory* relation couples Memory Read and Write Effects to the same Location so that each Memory Read Effect is paired with exactly one Memory Write Effect in the execution of a program. A Memory Read Effect E_2 Reads-from-memory a Memory Write Effect E_1, if and only if E_1 and E_2 are to the same location and E_2 takes its data from E_1.

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- E_2 is an Explicit Memory Write Effect.
- E_1 appears in program order before E_2.
- E_1 and E_2 are to the Same Location.

then it is not the case that E_1 Reads-from-memory E_2.

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- E_2 is an Explicit Memory Write Effect.
- E_1 and E_2 form a successful Read-Modify-Write pair.

then it is not the case that E_1 Reads-from-memory E_2.

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Implicit Tag Memory Read Effect.
- E_2 is an Explicit Memory Write Effect.
- E_1 appears in program order before E_2.
- E_1 and E_2 are to the Same Location.

then it is not the case that E_1 Reads-from-memory E_2.

Coherence order

There is a per-location *Coherence order* relation that provides a total order over all Memory Write Effects to that Location, starting with a notional Memory Write Effect of the initial value. The Coherence order of a Location represents the order in which Memory Write Effects to the Location arrive at memory.

Local register read successor

An Effect E_2 is a *Local register read successor* of an Effect E_1 if all of the following apply:

- E_1 is a Register Write Effect.
- E_1 appears in program order before E_2.
- E_1 and E_2 are to the same Register.
- It is not the case that all of the following apply:
  - — E_1 appears in program order before E_3.
  - — E_1 and E_3 are to the same Register.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - E_3 is a Register Write Effect.
    - E_3 appears in program order before E_2.
    - E_3 and E_2 are to the same Register.
- E_2 is a Register Read Effect.

Local memory read successor

An Effect E_2 is a *Local memory read successor* of an Effect E_1 if all of the following apply:

- E_1 is a Memory Write Effect.
- E_1 appears in program order before E_2.
- E_1 and E_2 are to the Same Location.
- E_2 is a Memory Read Effect.
- There is no Memory Write Effect E_3 to the Same Location as E_1 such that E_1 appears in program order before E_3 and E_3 appears in program order before E_2.

Local memory write successor

An Effect E_2 is a *Local memory write successor* of an Effect E_1 if one of the following applies:

- All of the following apply:
    - One of the following applies:
        - E_1 is an Explicit Memory Effect.
        - E_1 is an Implicit Tag Memory Read Effect.
    - E_1 appears in program order before E_2.
    - E_1 and E_2 are to the Same Location.
    - E_2 is an Explicit Memory Write Effect.
- All of the following apply:
    - E_1 is an Implicit TTD Memory Read Effect.
    - E_1 appears in program order before E_2.
    - E_1 and E_2 are to the Same Location.
    - One of the following applies:
        - E_2 is an Explicit Memory Write Effect.
        - E_2 is a Hardware Update Effect.

Coherence-before, Coherence-after

A Memory Write Effect E_1 is *Coherence-before* a Memory Write Effect E_2 to the same Location if E_1 is sequenced before E_2 in the Coherence order for the Location.

A Memory Read Effect E_1 is *Coherence-before* a Memory Write Effect E_2 to the same Location if E_1 Reads-from-memory a Memory Write Effect E_3 and E_3 is Coherence-before E_2.

An Effect E_2 is *Coherence-after* an Effect E_1 if E_1 is *Coherence-before* E_2.

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Explicit Memory Write Effect.
- E_2 is an Explicit Memory Write Effect.
- E_1 appears in program order before E_2.
- E_1 and E_2 are to the Same Location.

then it is not the case that E_2 is Coherence-before E_1.

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Explicit Memory Write Effect.
- E_2 is an Explicit Memory Read Effect.
- E_1 appears in program order before E_2.
- E_1 and E_2 are to the Same Location.

then it is not the case that E_2 is Coherence-before E_1.

For two Effects E_1 and E_2 if all of the following apply:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- E_1 is an Explicit Memory Write Effect.
- E_2 is an Implicit Tag Memory Read Effect.
- E_1 appears in program order before E_2.
- E_1 and E_2 are to the Same Location.

then it is not the case that E_2 is Coherence-before E_1.

TLBI-before, TLBI-after

For two Effects E_1 and E_2, if and only if all of the following applies:

- E_1 is a Completed TLBI Effect.
- E_2 is an Implicit TTD Memory Read Effect.
- E_2 is in the Invalidation Scope of E_1.

then one and only one of the following applies:

- E_1 is *TLBI-after* E_2 (equivalently E_2 is *TLBI-before* E_1), or
- E_2 is *TLBI-after* E_1 (equivalently E_1 is *TLBI-before* E_2).

Note

The TLBI-after relation enumerates all possible pairs (E_1,E_2) where E_1 is a TLBI Effect and E_2 is an Implicit TTD Memory Read Effect such that E_2 is in the Invalidation Scope of E_1, and the TLBI-after relation is asymmetric.

DC-before, DC-after

For two Effects E_1 and E_2, if all of the following applies:

- E_1 is a DC CVAU Effect.
- E_2 is an Explicit Memory Write Effect.
- E_1 and E_2 are to the Same Cache Line.

then one of the following applies:

- E_1 is *DC-after* E_2 (equivalently E_2 is *DC-before* E_1), or
- E_2 is *DC-after* E_1 (equivalently E_1 is *DC-before* E_2).

Note

The DC-after relation enumerates all possible pairs (E_1, E_2) where E_1 is a DC CVAU Effect and E_2 is an Explicit Memory Write Effect such that E_1 and E_2 are to the Same Cache Line, and the relation DC-after is asymmetric.

IC-before, IC-after

For two Effects E_1 and E_2, if and only if all of the following applies:

- E_1 is a completed IC Effect.
- E_2 is an Implicit Instruction Memory Read Effect.
- E_1 and E_2 are to the Same Cache Line.

then one and only one of the following applies:

- E_1 is *IC-after* E_2 (equivalently E_2 is *IC-before* E_1), or
- E_2 is *IC-after* E_1 (equivalently E_1 is *IC-before* E_2).

Note

The IC-after relation enumerates all possible pairs (E_1,E_2) where E_1 is a completed IC Effect and E_2 is an Implicit Instruction Memory Read Effect such that E_1 and E_2 are to the Same Cache Line, and the relation IC-after is asymmetric.

Single-copy-atomic grouping

A *single-copy-atomic grouping* gathers Explicit Memory Effects generated by the same instruction when the architecture requires the Explicit Memory Effects to be single-copy atomic as defined in Requirements for single-copy atomicity. For example, an aligned STRH instruction generates two Explicit Memory Write Effects that are in the same single-copy-atomic grouping.

Atomicity of Successful Read-Modify-Write pair

For two Effects E_1 and E_2 if all of the following apply:

- E_1 and E_2 form a successful Read-Modify-Write pair.
- There is an Explicit Memory Write Effect E_3.
- It is not the case that all of the following apply:
  - E_1 is an Explicit Memory Effect.
  - E_1 and E_3 are from the same Processing Element.
  - E_2 is an Explicit Memory Effect.
  - E_2 and E_3 are from the same Processing Element.

then it is not the case that E_1 is Coherence-before E_3 and E_3 is Coherence-before E_2.

B2.3.2 Intrinsic Dependency relations

Intrinsic Dependencies are as follows:

Intrinsic Data Dependency

There is an *Intrinsic Data Dependency* from an Effect E_1 to an Effect E_2 if and only if all the following apply:

- It is not the case that E_1 is an Intrinsic Branching Effect.
- E_1 and E_2 are generated by the same instruction `I`.
- The instruction semantics for that instruction `I` indicate that the value produced by E_1 is consumed by E_2.

Note

This applies even in cases where the Intrinsic Data Dependency might be perceived to be a false dependency.

Intrinsic Control Dependency

There is an *Intrinsic Control Dependency* from an Effect E_1 to an Effect E_2 if and only if all the following apply:

- E_1 is an Intrinsic Branching Effect.
- E_1 and E_2 are generated by the same instruction `I`.
- The instruction semantics for that instruction `I` indicate that the generation of E_2 is conditional and based on the determination of E_1.

Intrinsic Order Dependency

There is an *Intrinsic Order Dependency* from an Effect E_1 to an Effect E_2 if and only if all the following apply:

- E_1 is a Memory Effect.
- E_1 and E_2 are generated by the same instruction `I`.
- The instruction semantics for that instruction `I` indicate that E_1 is generated before E_2.
- It is not the case that there is an Intrinsic Data Dependency from E_1 to E_2.
- It is not the case that there is an Intrinsic Control Dependency from E_1 to E_2.
- E_2 is a Memory Effect.

In the following, instructions whose Intrinsic dependencies are special cases that arose during the formalization of the memory model are listed. This does not preclude the existence of other special cases in the future.

Non-Confidential

B2.3.2.1 Conditional Selection instructions

The following applies to the Effects generated by `CSEL` X_d,X_n,X_m, cond

When the condition `cond` is true all of the following apply:

- Dt_1: There is an Intrinsic Data Dependency from the Register Read Effect of `PSTATE.NZCV` to the Intrinsic Branching Effect corresponding to the condition `cond`.
- Ct_1: There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks the condition `cond` to the Register Read Effect of X_n.
- Dt_2: There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Register Write Effect of X_d.

When the condition `cond` is false all of the following apply:

- Df_1: There is an Intrinsic Data Dependency from the Register Read Effect of `PSTATE.NZCV` to the Intrinsic Branching Effect corresponding to the condition `cond`.
- Cf_1: There is an Intrinsic Control Dependency from the Intrinsic Branching Effect corresponding to the condition `cond` to the Register Read Effect of X_m.
- Df_1: There is an Intrinsic Data Dependency from the Register Read Effect of X_m to the Register Write Effect of X_d.

B2.3.2.2 Compare-and-Swap instructions

The following apply to the Effects generated by `CAS` X_s,X_t,[X_n]:

When the value of the Memory Location x addressed by X_n is not equal to the value of X_s one of the following applies:

- D_1: There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Read Effect of the Memory Location x addressed by X_n.
- D_2: There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s.
- D_3: There is an Intrinsic Data Dependency from the Register Read Effect of X_s to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s.
- Df_1: There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Register Write Effect of X_s.

When the value of the Memory Location x addressed by X_n is equal to the value of X_s one of the following applies:

- All of the following apply:
  - — D_1: There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Read Effect of the Memory Location x addressed by X_n.
  - — D_2: There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s.
  - — D_3: There is an Intrinsic Data Dependency from the Register Read Effect of X_s to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s.
  - — Ds_1: There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Write Effect of the Memory Location x addressed by X_n.
  - — Ds_2: There is an Intrinsic Data Dependency from Register Read Effect X_t to the Explicit Memory Write Effect of the Memory Location x addressed by X_n.
  - — Cs_1: There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s to the Explicit Memory Write Effect of the Memory Location x addressed by X_n.
  - — Ds_{31}: There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Register Write Effect of X_s.
- All of the following apply:
  - — D_1: There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Read Effect of the Memory Location x addressed by X_n.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— D_2: There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s.

— D_3: There is an Intrinsic Data Dependency from the Register Read Effect of X_s to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s.

— Ds_1: There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Write Effect of the Memory Location x addressed by X_n.

— Ds_2: There is an Intrinsic Data Dependency from the Register Read Effect of X_t to the Explicit Memory Write Effect of the Memory Location x addressed by X_n.

— Cs_1: There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s to the Explicit Memory Write Effect of the Memory Location x addressed by X_n.

— Ds_3: There is an Intrinsic Data Dependency from Register Read Effect X_s to the Register Write Effect of X_s.

— Cs_2: There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s to the Register Write Effect of X_s.

B2.3.2.3 Swap instructions

All of the following apply to the Effects generated by the `SWP` X_s, X_t,[X_n] instruction:

- D_1: There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Read Effect of the Memory Location x addressed by X_n.
- D_2: There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Write Effect of the Memory Location x addressed by X_n.
- O_1: There is an Intrinsic Order Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Explicit Memory Write Effect of the Memory Location x addressed by X_n.
- D_3: There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Register Write Effect of X_t.
- D_4: There is an Intrinsic Data Dependency from the Register Read Effect of X_s, to the Explicit Memory Write Effect of the Memory Location x addressed by X_n.

B2.3.2.4 Branch with Link to Register instructions

All of the following apply to the Effects generated by the `BLR` X_n instruction:

- D_1: There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Branching Effect of the instruction.

B2.3.2.5 MTE Checked instructions

If FEAT_MTE2 is implemented, a Checked `LDR` X_t,[X_n] instruction has the following additional dependencies:

When Tag Check Faults are configured to raise a Synchronous Exception one of the following applies:

- If the Logical Address Tag is equal to the Allocation tag, all of the following apply:
  — Dst_1: There is an Intrinsic Data Dependency from the Implicit Tag Memory Read Effect of the Tag Location x of the Memory Location x addressed by X_n to the Intrinsic Branching Effect which checks whether the Allocation Tag of x is equal to the Logical Address Tag in X_n.
  — Cst_1: There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks whether the Allocation Tag of x is equal to the Logical Address Tag in X_n to the Explicit Memory Read Effect of the Memory Location x addressed by X_n.
- If the Logical Address Tag is not equal to the Allocation tag, all of the following apply:
  — Dsf_1: There is an Intrinsic Data Dependency from the Implicit Tag Memory Read Effect of the Tag Location x of the Memory Location x addressed by X_n to the Intrinsic Branching Effect which checks whether the Allocation Tag of x is equal to the Logical Address Tag in X_n.
  — Csf_1: There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks whether the Allocation Tag of x is equal to the Logical Address Tag in X_n to the TagCheck Fault Effect.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When Tag Check Faults are configured to not raise a Synchronous Exception one of the following applies:

- If the Logical Address Tag is equal to the Allocation tag, all of the following apply:
  - — Dat_1: There is an Intrinsic Data Dependency from the Implicit Tag Memory Read Effect of the Tag Location x of the Memory Location x addressed by X_n to the Intrinsic Branching Effect which checks whether the Allocation Tag of x is equal to the Logical Address Tag in X_n.
  - — Cat_1: There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks whether the Allocation Tag of x is equal to the Logical Address Tag in X_n to the empty Effect.
- If the Logical Address Tag is not equal to the Allocation tag, all of the following apply:
  - — Daf_1: There is an Intrinsic Data Dependency from the Implicit Tag Memory Read Effect of the Tag Location x of the Memory Location x addressed by X_n to the Intrinsic Branching Effect which checks whether the Allocation Tag of x is equal to the Logical Address Tag in X_n.
  - — Caf_1: There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks whether the Allocation Tag of x is equal to the Logical Address Tag in X_n to the TagCheck Fault Effect.

B2.3.3 Tag-check-intrinsically-before

Tag-check-before

An Effect E_1 is *Tag-check-before* an Effect E_2 if all of the following apply:

- E_1 is an Implicit Tag Memory Read Effect.
- There is an Intrinsic Data Dependency from E_1 to E_3.
- E_3 is a Branching Effect.
- There is an Intrinsic Control Dependency from E_3 to E_2.
- One of the following applies:
  - — E_2 is an Explicit Memory Effect.
  - — E_2 is a TagCheck Fault Effect.

Tag-check-intrinsically-before

An Effect E_1 is *Tag-check-intrinsically-before* an Effect E_2 if all of the following apply:

- E_1 is Tag-check-before E_2.
- It is not the case that E_2 is an Explicit Memory Read Effect.

B2.3.4 Translation-intrinsically-before

An Effect E_1 is *Translation-intrinsically-before* an Effect E_2 if all of the following apply:

- E_1 is an Implicit TTD Memory Read Effect.
- There is an Intrinsic Data Dependency from E_1 to E_3.
- E_3 is a Branching Effect.
- There is an Intrinsic Control Dependency from E_3 to E_2.
- One of the following applies:
  - — E_2 is an Explicit Memory Effect.
  - — E_2 is an MMU Fault Effect.

B2.3.5 Fetch-intrinsically-before

An Effect E_1 is *Fetch-intrinsically-before* an Effect E_2 if all of the following apply:

- E_1 is an Implicit Instruction Memory Read Effect.
- There is an Intrinsic Data Dependency from E_1 to E_3.
- E_3 is a Branching Effect.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- One of the following applies:
  - — There is an Intrinsic Control Dependency from E_3 to E_2.
  - — All of the following apply:
    - — There is an Intrinsic Control Dependency from E_3 to E_4.
    - — There is an Intrinsic Data Dependency from E_4 to E_2.

B2.3.6 Dependency relations

Dependency through registers and memory

There is a *Dependency through registers and memory* from an Effect E_1 to an Effect E_2 if one of the following applies:

- All of the following apply:
  - — It is not the case that E_1 is generated by a Store-Exclusive instruction as part of a successful Load-Exclusive/Store-Exclusive pair.
  - — E_2 is a Local register read successor of E_1.
- E_2 is a Local memory read successor of E_1.
- There is an Intrinsic Data Dependency from E_1 to E_2.
- All of the following apply:
  - — There is a Dependency through registers and memory from E_1 to E_3.
  - — There is a Dependency through registers and memory from E_3 to E_2.

Data dependency

There is a *Data dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Dependency through registers and memory from E_1 to E_3.
- E_1 appears in program order before E_3.
- E_3 is a Register Read Effect.
- There is an Intrinsic Data Dependency from E_3 to E_2.
- The semantics of the instruction that generates E_3 and E_2 indicate that the value produced by E_3 is consumed in the calculation of the data value written by E_2.
- E_2 is an Explicit Memory Write Effect.

Address dependency

There is an *Address dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Dependency through registers and memory from E_1 to E_3.
- E_1 appears in program order before E_3.
- E_3 is a Register Read Effect.
- There is an Intrinsic Data Dependency from E_3 to E_2.
- The semantics of the instruction that generates E_3 and E_2 indicate that the value produced by E_3 is consumed in the calculation of the address of the Location of E_2.
- One of the following applies:
  - — E_2 is an Explicit Memory Effect.
  - — E_2 is an Implicit Tag Memory Read Effect.
  - — E_2 is an Implicit TTD Memory Read Effect.
  - — E_2 is a Hardware Update Effect.
  - — E_2 is a TLBI Effect.
  - — E_2 is a DC CVAU Effect.
  - — E_2 is an IC IVAU Effect.

Control dependency

There is a *Control dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- E_1 is an Explicit Memory Read Effect.
- There is a Dependency through registers and memory from E_1 to E_3.
- E_1 appears in program order before E_3.
- E_3 is a Register Read Effect.
- There is an Intrinsic Data Dependency from E_3 to E_4.
- E_4 is a Conditional Branching Effect.
- E_4 appears in program order before E_2.

Pick dependency through registers and memory

There is a *Pick dependency through registers and memory* from an Effect E_1 to an Effect E_2 if one of the following applies:

- There is a Dependency through registers and memory from E_1 to E_2.
- There is an Intrinsic Control Dependency from E_1 to E_2.
- All of the following apply:
  - — There is a Pick dependency through registers and memory from E_1 to E_3.
  - — There is a Pick dependency through registers and memory from E_3 to E_2.

Pick Basic dependency

There is a *Pick Basic dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Pick dependency through registers and memory from E_1 to E_2.

Pick Data dependency

There is a *Pick Data dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Pick dependency through registers and memory from E_1 to E_3.
- E_1 appears in program order before E_3.
- E_3 is a Register Read Effect.
- One of the following applies:
  - — There is an Intrinsic Data Dependency from E_3 to E_2.
  - — All of the following apply:
    - — There is an Intrinsic Data Dependency from E_3 to E_4.
    - — There is an Intrinsic Control Dependency from E_4 to E_2.
- The semantics of the instruction that generates E_3 and E_2 indicate that the value produced by E_3 is consumed in the calculation of the data value written by E_2.
- E_2 is an Explicit Memory Write Effect.

Pick Address dependency

There is a *Pick Address dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Pick dependency through registers and memory from E_1 to E_3.
- E_1 appears in program order before E_3.
- E_3 is a Register Read Effect.
- There is an Intrinsic Data Dependency from E_3 to E_2.
- The semantics of the instruction that generates E_3 and E_2 indicate that the value produced by E_3 is consumed in the calculation of the address of the Location of E_2.
- One of the following applies:
  - — E_2 is an Explicit Memory Effect.
  - — E_2 is an Implicit Tag Memory Read Effect.
  - — E_2 is an Implicit TTD Memory Read Effect.
  - — E_2 is a Hardware Update Effect.
  - — E_2 is a TLBI Effect.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- — E_2 is a DC CVAU Effect.
- — E_2 is an IC IVAU Effect.

Pick Control dependency

There is a *Pick Control dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Pick dependency through registers and memory from E_1 to E_3.
- E_1 appears in program order before E_3.
- E_3 is a Register Read Effect.
- There is an Intrinsic Data Dependency from E_3 to E_4.
- E_4 is a Conditional Branching Effect.
- E_4 appears in program order before E_2.

Pick dependency

There is a *Pick dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- One of the following applies:
  - — There is a Pick Basic dependency from E_1 to E_2.
  - — There is a Pick Address dependency from E_1 to E_2.
  - — There is a Pick Data dependency from E_1 to E_2.
  - — There is a Pick Control dependency from E_1 to E_2.
- It is not the case that E_1 and E_2 are generated by the same instruction.

B2.3.7 Ordering relations

Explicit-hazard-ordered-before

An Effect E_1 is *Explicit-hazard-ordered-before* an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- E_1 appears in program order before E_3.
- E_1 and E_3 are to the Same Location.
- E_3 is an Explicit Memory Read Effect.
- One of the following applies:
  - — E_3 belongs to the same single-copy-atomic grouping as E_4.
  - — E_3 and E_4 are the same Effect.
- E_4 is an Explicit Memory Read Effect.
- E_4 is Coherence-before E_5.
- E_4 and E_5 are from different Processing Elements.
- One of the following applies:
  - — E_5 is an Explicit Memory Write Effect.
  - — E_5 is a Hardware Update Effect.
- One of the following applies:
  - — E_5 belongs to the same single-copy-atomic grouping as E_2.
  - — E_5 and E_2 are the same Effect.
- One of the following applies:
  - — E_2 is an Explicit Memory Write Effect.
  - — E_2 is a Hardware Update Effect.

Note

The Explicit-hazard-ordered-before relation does not apply when either E_1 or E_2 or both are generated by SVE instructions.

TTD-read-ordered-before

An Effect E_1 is *TTD-read-ordered-before* an Effect E_2 if one of the following applies:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- All of the following apply:
  - E_1 is TLBI-before E_3.
  - E_3 is a TLBI Effect.
  - E_3 is DSB-ordered-before E_2.
- All of the following apply:
  - E_1 is TLBI-before E_3.
  - E_3 is a TLBI Effect.
  - E_3 is Instruction-fetch-barrier-ordered-before E_2.

TLBI-ordered-before

An Effect E_1 is *TLBI-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is TTD-read-ordered-before E_2.
- All of the following apply:
  - E_3 is Translation-intrinsically-before E_1.
  - E_3 is TTD-read-ordered-before E_2.
  - E_3 and E_2 are from different Processing Elements.
- All of the following apply:
  - E_1 is an Implicit TTD Memory Read Effect.
  - E_1 is Translation-intrinsically-before E_4.
  - E_4 and E_5 have the Same Low-order Bits.
  - E_4 appears in program order before E_5.
  - E_3 is Translation-intrinsically-before E_5.
  - E_3 is an Implicit TTD Memory Read Effect.
  - E_1 and E_3 are generated in the same translation context.
  - E_3 is TTD-read-ordered-before E_2.
  - E_3 and E_2 are from different Processing Elements.

Note

The clause of TLBI-ordered-before which refers to “Same Low-order Bits” applies in cases where an instruction I_1 which generates E_1 and E_4 appears in program order before an instruction I_2 which generates E_3 and E_5, and I_1 and I_2 access overlapping bytes in memory.

Instruction-read-ordered-before

An Effect E_1 is *Instruction-read-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
  - E_1 is IC-before E_3.
  - E_3 is an IC Effect.
  - E_3 is DSB-ordered-before E_2.
- All of the following apply:
  - E_1 is IC-before E_3.
  - E_3 is an IC Effect.
  - E_3 is Instruction-fetch-barrier-ordered-before E_2.
- All of the following apply:
  - The Effective value of CTR_EL0.DIC is 1.
  - E_1 is Coherence-before E_2.

IC-ordered-before

An Effect E_1 is *IC-ordered-before* an Effect E_2 if all of the following apply:

- E_1 is an Implicit Instruction Memory Read Effect.
- E_1 appears in program order before E_3.
- E_3 is an Implicit Instruction Memory Read Effect.
- E_3 is Instruction-read-ordered-before E_2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Hazard-ordered-before

An Effect E_1 is *Hazard-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Explicit-hazard-ordered-before E_2.
- E_1 is TLBI-ordered-before E_2.
- E_1 is IC-ordered-before E_2.

ETS-ordered-before

An Effect E_1 is *ETS-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
  - FEAT_ETS2 is implemented.
  - E_1 is an Explicit Memory Effect.
  - E_1 appears in program order before E_3.
  - E_3 is a TLBUncacheable Fault Effect.
  - E_2 is Translation-intrinsically-before E_3.
  - E_2 is an Implicit TTD Memory Read Effect.
- All of the following apply:
  - FEAT_ETS3 is implemented.
  - E_1 is an Explicit Memory Effect.
  - E_1 appears in program order before E_3.
  - E_3 is an MMU Fault Effect.
  - E_2 is Translation-intrinsically-before E_3.
  - E_2 is an Implicit TTD Memory Read Effect.
- All of the following apply:
  - FEAT_ETS3 is implemented.
  - E_1 is an Explicit Memory Effect.
  - E_1 appears in program order before E_3.
  - E_3 is a TagCheck Fault Effect that generates a synchronous exception.
  - E_2 is Tag-check-intrinsically-before E_3.
  - E_2 is an Implicit Tag Memory Read Effect.

Note

The ETS-ordered-before relation does not apply when E_1 is generated by an Advanced SIMD, floating-point, SVE, or SME instruction. It also does not apply when E_2 is an Implicit TTD Memory Read Effect generated for an instruction fetch.

Fetch-ordered-before

An Effect E_1 is *Fetch-ordered-before* an Effect E_2 if all of the following apply:

- E_1 is an Implicit Instruction Memory Read Effect.
- E_1 appears in program order before E_2.
- It is not the case that E_2 is an Implicit Instruction Memory Read Effect.

Same-Cache-Line-ordered-before

An Effect E_1 is *Same-Cache-Line-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
  - E_1 is an Explicit Memory Effect.
  - E_1 appears in program order before E_2.
  - E_1 and E_2 are to the Same Cache Line.
  - E_2 is a DC CVAU Effect.
- All of the following apply:
  - E_1 is a DC CVAU Effect.
  - E_1 appears in program order before E_2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- — E_1 and E_2 are to the Same Cache Line.
- — E_2 is an Explicit Memory Effect.

- All of the following apply:
  - — E_1 is a DC CVAU Effect.
  - — E_1 appears in program order before E_2.
  - — E_1 and E_2 are to the Same Cache Line.
  - — E_2 is a DC CVAU Effect.

DSB-ordered-before

An Effect E_1 is *DSB-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
  - — One of the following applies:
    - — E_1 is a Memory Effect.
    - — E_1 is a DC CVAU Effect.
    - — E_1 is an IC Effect.
    - — E_1 is a TLBI Effect.
  - — E_1 appears in program order before E_3.
  - — E_3 is a DSB FULL Effect.
  - — E_3 appears in program order before E_2.
  - — It is not the case that one of the following applies:
    - — E_2 is an Implicit TTD Memory Effect.
    - — E_2 is an Implicit Instruction Memory Read Effect.
- All of the following apply:
  - — FEAT_ETS2 is implemented.
  - — One of the following applies:
    - — E_1 is a Memory Effect.
    - — E_1 is a DC CVAU Effect.
    - — E_1 is an IC Effect.
    - — E_1 is a TLBI Effect.
  - — E_1 appears in program order before E_3.
  - — E_3 is a DSB FULL Effect.
  - — E_3 appears in program order before E_2.
  - — E_2 is an Implicit TTD Memory Effect.
- All of the following apply:
  - — One of the following applies:
    - — All of the following apply:
      - · E_1 is an Explicit Memory Read Effect.
      - · It is not the case that E_1 is generated by an atomic instruction whose destination register is WZR or XZR.
    - — E_1 is an Implicit Tag Memory Read Effect.
  - — E_1 appears in program order before E_3.
  - — E_3 is a DSB LD Effect.
  - — E_3 appears in program order before E_2.
  - — It is not the case that one of the following applies:
    - — E_2 is an Implicit TTD Memory Effect.
    - — E_2 is an Implicit Instruction Memory Read Effect.
- All of the following apply:
  - — FEAT_ETS2 is implemented.
  - — E_1 is an Explicit Memory Read Effect.
  - — It is not the case that E_1 is generated by an atomic instruction whose destination register is WZR or XZR.
  - — E_1 appears in program order before E_3.
  - — E_3 is a DSB LD Effect.
  - — E_3 appears in program order before E_2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - E_2 is an Implicit TTD Memory Effect.
- All of the following apply:
    - E_1 is an Explicit Memory Write Effect.
    - E_1 appears in program order before E_3.
    - E_3 is a DSB ST Effect.
    - E_3 appears in program order before E_2.
    - It is not the case that one of the following applies:
        - E_2 is an Implicit TTD Memory Effect.
        - E_2 is an Implicit Instruction Memory Read Effect.
- All of the following apply:
    - FEAT_ETS2 is implemented.
    - E_1 is an Explicit Memory Write Effect.
    - E_1 appears in program order before E_3.
    - E_3 is a DSB ST Effect.
    - E_3 appears in program order before E_2.
    - E_2 is an Implicit TTD Memory Effect.

Note

Regardless of whether FEAT_ETS2 is implemented, the DSB-ordered-before relation does not apply when E_2 is an Implicit TTD Memory Read Effect generated for an instruction fetch.

Instruction-fetch-barrier-ordered-before

An Effect E_1 is *Instruction-fetch-barrier-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
    - E_1 is an Explicit Memory Read Effect.
    - There is a Control dependency from E_1 to E_3.
    - E_3 is an Instruction Fetch Barrier Effect.
    - E_3 appears in program order before E_2.
- All of the following apply:
    - E_1 is an Explicit Memory Read Effect.
    - There is a Pick Control dependency from E_1 to E_3.
    - E_3 is an Instruction Fetch Barrier Effect.
    - E_3 appears in program order before E_2.
- All of the following apply:
    - E_1 is an Explicit Memory Read Effect.
    - There is an Address dependency from E_1 to E_3.
    - E_3 is an Explicit Memory Effect.
    - E_3 appears in program order before E_4.
    - E_4 is an Instruction Fetch Barrier Effect.
    - E_4 appears in program order before E_2.
- All of the following apply:
    - E_1 is an Explicit Memory Read Effect.
    - There is a Pick Address dependency from E_1 to E_3.
    - E_3 is an Explicit Memory Effect.
    - E_3 appears in program order before E_4.
    - E_4 is an Instruction Fetch Barrier Effect.
    - E_4 appears in program order before E_2.
- All of the following apply:
    - E_1 is an Explicit Memory Read Effect.
    - There is a Pick Address dependency from E_1 to E_3.
    - One of the following applies:
        - E_3 is Tag-check-intrinsically-before E_4.
        - E_3 is Translation-intrinsically-before E_4.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - E_4 is an Instruction Fetch Barrier Effect.
    - E_4 appears in program order before E_2.
  - All of the following apply:
    - E_1 is DSB-ordered-before E_3.
    - E_3 is an Instruction Fetch Barrier Effect.
    - E_3 appears in program order before E_2.
  - All of the following apply:
    - E_1 is an Implicit TTD Memory Read Effect.
    - E_1 is Translation-intrinsically-before E_3.
    - E_3 is an Instruction Fetch Barrier Effect.
    - E_3 appears in program order before E_2.
  - All of the following apply:
    - E_1 is an Implicit Tag Memory Read Effect.
    - E_1 is Tag-check-intrinsically-before E_3.
    - E_3 is an Instruction Fetch Barrier Effect.
    - E_3 appears in program order before E_2.
  - All of the following apply:
    - E_1 is an Implicit TTD Memory Read Effect.
    - E_1 is Translation-intrinsically-before E_3.
    - E_3 is an Explicit Memory Effect.
    - E_3 appears in program order before E_4.
    - E_4 is an Instruction Fetch Barrier Effect.
    - E_4 appears in program order before E_2.
  - All of the following apply:
    - E_1 is an Implicit Tag Memory Read Effect.
    - E_1 is Tag-check-before E_3.
    - E_3 is an Explicit Memory Effect.
    - E_3 appears in program order before E_4.
    - E_4 is an Instruction Fetch Barrier Effect.
    - E_4 appears in program order before E_2.

Dependency-ordered-before

An Effect E_1 is *Dependency-ordered-before* an Effect E_2 if one of the following applies:

- There is an Address dependency from E_1 to E_2.
- There is a Data dependency from E_1 to E_2.
- All of the following apply:
  - There is a Control dependency from E_1 to E_2.
  - One of the following applies:
    - E_2 is an Explicit Memory Write Effect.
    - E_2 is a Hardware Update Effect.
    - E_2 is a TLBI Effect.
    - E_2 is a DC CVAU Effect.
    - E_2 is an IC Effect.
- All of the following apply:
  - There is an Address dependency from E_1 to E_3.
  - E_3 is an Explicit Memory Effect.
  - E_3 appears in program order before E_2.
  - One of the following applies:
    - E_2 is an Explicit Memory Write Effect.
    - E_2 is a Hardware Update Effect.
- All of the following apply:
  - There is an Address dependency from E_1 to E_3.
  - E_3 is an Explicit Memory Effect.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - E_2 is a Local memory read successor of E_3.
    - One of the following applies:
        - E_2 is an Explicit Memory Read Effect.
        - E_2 is an Implicit Tag Memory Read Effect.
- All of the following apply:
    - There is a Data dependency from E_1 to E_3.
    - E_3 is an Explicit Memory Effect.
    - E_2 is a Local memory read successor of E_3.
    - One of the following applies:
        - E_2 is an Explicit Memory Read Effect.
        - E_2 is an Implicit Tag Memory Read Effect.
- All of the following apply:
    - E_1 is an Implicit TTD Memory Read Effect.
    - E_1 is Translation-intrinsically-before E_3.
    - E_3 is an Explicit Memory Effect.
    - E_3 appears in program order before E_2.
    - One of the following applies:
        - E_2 is an Explicit Memory Write Effect.
        - E_2 is a Hardware Update Effect.
- All of the following apply:
    - E_1 is an Implicit Tag Memory Read Effect.
    - E_1 is Tag-check-before E_3.
    - E_3 is an Explicit Memory Effect.
    - E_3 appears in program order before E_2.
    - One of the following applies:
        - E_2 is an Explicit Memory Write Effect.
        - E_2 is a Hardware Update Effect.

Intrinsically-ordered-before

An Effect E_1 is *Intrinsically-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Tag-check-intrinsically-before E_2.
- E_1 is Translation-intrinsically-before E_2.
- E_1 is Fetch-intrinsically-before E_2.
- All of the following apply:
    - E_1 is an Explicit Memory Effect.
    - There is an Intrinsic Order Dependency from E_1 to E_2.
    - E_2 is an Explicit Memory Effect.

Pick-ordered-before

An Effect E_1 is *Pick-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
    - There is a Pick Address dependency from E_1 to E_2.
    - One of the following applies:
        - E_2 is an Explicit Memory Write Effect.
        - E_2 is a Hardware Update Effect.
        - E_2 is a TLBI Effect.
        - E_2 is a DC CVAU Effect.
        - E_2 is an IC Effect.
- There is a Pick Data dependency from E_1 to E_2.
- All of the following apply:
    - There is a Pick Control dependency from E_1 to E_2.
    - One of the following applies:
        - E_2 is an Explicit Memory Write Effect.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

        - E_2 is a Hardware Update Effect.
        - E_2 is a TLBI Effect.
        - E_2 is a DC CVAU Effect.
        - E_2 is an IC Effect.
- All of the following apply:
    - There is a Pick Address dependency from E_1 to E_3.
    - E_3 is an Explicit Memory Effect.
    - E_3 appears in program order before E_2.
    - One of the following applies:
        - E_2 is an Explicit Memory Write Effect.
        - E_2 is a Hardware Update Effect.

Atomic-ordered-before

E_1 and E_2 form a successful Read-Modify-Write pair if and only if E_1 and E_2 are generated by the same atomic instruction or the same successful Load-Exclusive/Store-Exclusive instruction pair to the Same Location.

An Effect E_1 is *Atomic-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
    - E_1 is an Explicit Memory Effect.
    - E_1 and E_2 form a successful Read-Modify-Write pair.
    - E_2 is an Explicit Memory Effect.
- All of the following apply:
    - E_1 is an Explicit Memory Effect.
    - E_1 and E_3 form a successful Read-Modify-Write pair.
    - E_2 is a Local memory read successor of E_3.
    - One of the following applies:
        - E_2 is an Explicit Memory Read Effect with Acquire semantics.
        - E_2 is an Explicit Memory Read Effect with AcquirePC semantics.
- All of the following apply:
    - E_1 is an Implicit TTD Memory Read Effect.
    - E_1 and E_2 form a successful Read-Modify-Write pair.
    - E_2 is a Hardware Update Effect.

Barrier-ordered-before

An Effect E_1 is *Barrier-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
    - One of the following applies:
        - E_1 is an Explicit Memory Effect.
        - E_1 is an Implicit Tag Memory Read Effect.
    - E_1 appears in program order before E_3.
    - E_3 is a DMB FULL Effect.
    - E_3 appears in program order before E_2.
    - One of the following applies:
        - E_2 is an Explicit Memory Effect.
        - E_2 is an Implicit Tag Memory Read Effect.
        - E_2 is an MMU Fault Effect.
- All of the following apply:
    - E_1 is an Explicit Memory Effect.
    - E_1 appears in program order before E_3.
    - E_3 is a DMB FULL Effect.
    - E_3 appears in program order before E_2.
    - E_2 is a DC CVAU Effect.
- All of the following apply:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- — E_1 is a DC CVAU Effect.
- — E_1 appears in program order before E_3.
- — E_3 is a DMB FULL Effect.
- — E_3 appears in program order before E_2.
- — E_2 is an Explicit Memory Effect.

- All of the following apply:
  - — E_1 is a DC CVAU Effect.
  - — E_1 appears in program order before E_3.
  - — E_3 is a DMB FULL Effect.
  - — E_3 appears in program order before E_2.
  - — E_2 is a DC CVAU Effect.
- All of the following apply:
  - — One of the following applies:
    - — All of the following apply:
      - · E_1 is an Explicit Effect.
      - · E_1 is a Memory Read Effect.
      - · It is not the case that E_1 is generated by an atomic instruction whose destination register is WZR or XZR.
    - — E_1 is an Implicit Tag Memory Read Effect.
  - — E_1 appears in program order before E_3.
  - — E_3 is a DMB LD Effect.
  - — E_3 appears in program order before E_2.
  - — One of the following applies:
    - — E_2 is an Explicit Memory Effect.
    - — E_2 is an Implicit Tag Memory Read Effect.
    - — E_2 is an MMU Fault Effect.
- All of the following apply:
  - — E_1 is an Explicit Memory Write Effect.
  - — E_1 appears in program order before E_3.
  - — E_3 is a DMB ST Effect.
  - — E_3 appears in program order before E_2.
  - — One of the following applies:
    - — E_2 is an Explicit Memory Write Effect.
    - — E_2 is an MMU Fault Effect.
- All of the following apply:
  - — E_1 is an Explicit Memory Write Effect with Release semantics.
  - — E_3 and E_1 are generated by an atomic instruction.
  - — E_3 is an Explicit Memory Read Effect with Acquire semantics.
  - — E_1 appears in program order before E_2.
  - — One of the following applies:
    - — E_2 is an Explicit Memory Effect.
    - — E_2 is an Implicit Tag Memory Read Effect.
    - — E_2 is an MMU Fault Effect.
- All of the following apply:
  - — E_1 is an Explicit Memory Write Effect with Release semantics.
  - — E_1 appears in program order before E_2.
  - — E_2 is an Explicit Memory Read Effect with Acquire semantics.
- All of the following apply:
  - — One of the following applies:
    - — E_1 is an Explicit Memory Read Effect with Acquire semantics.
    - — E_1 is an Explicit Memory Read Effect with AcquirePC semantics.
  - — E_1 appears in program order before E_2.
  - — One of the following applies:
    - — E_2 is an Explicit Memory Effect.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - E_2 is an Implicit Tag Memory Read Effect.
    - E_2 is an MMU Fault Effect.
- All of the following apply:
  - One of the following applies:
    - E_1 is an Explicit Memory Effect.
    - E_1 is an Implicit Tag Memory Read Effect.
  - E_1 appears in program order before E_2.
  - E_2 is an Explicit Memory Write Effect with Release semantics.

Locally-ordered-before

An Effect E_1 is *Locally-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Intrinsically-ordered-before E_2.
- E_1 is ETS-ordered-before E_2.
- E_1 is Fetch-ordered-before E_2.
- E_1 is Same-Cache-Line-ordered-before E_2.
- E_1 is DSB-ordered-before E_2.
- E_1 is Instruction-fetch-barrier-ordered-before E_2.
- E_2 is a Local memory write successor of E_1.
- All of the following apply:
  - E_3 is a Local memory write successor of E_1.
  - E_3 belongs to the same single-copy-atomic grouping as E_2.
- E_1 is Dependency-ordered-before E_2.
- E_1 is Pick-ordered-before E_2.
- E_1 is Atomic-ordered-before E_2.
- E_1 is Barrier-ordered-before E_2.
- All of the following apply:
  - E_1 is Locally-ordered-before E_3.
  - E_3 is Locally-ordered-before E_2.

Pick-locally-ordered-before

An Effect E_1 is *Pick-locally-ordered-before* an Effect E_2 if all of the following apply:

- There is a Pick dependency from E_1 to E_3.
- E_3 is Locally-ordered-before E_2.
- E_2 is an Explicit Memory Write Effect.

Locally-hardware-required-ordered-before

An Effect E_1 is *Locally-hardware-required-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Locally-ordered-before E_2.
- E_1 is Pick-locally-ordered-before E_2.
- All of the following apply:
  - E_1 is Locally-hardware-required-ordered-before E_3.
  - E_3 is Locally-hardware-required-ordered-before E_2.

Hardware-required-ordered-before

An Effect E_1 is *Hardware-required-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Locally-hardware-required-ordered-before E_2.
- E_1 is Hazard-ordered-before E_2.

B2.3.8 Observation relations

Explicit-Observed-by

An Effect E_1 is *Explicit-Observed-by* an Effect E_2 if one of the following applies:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- All of the following apply:
  - E_1 is an Explicit Memory Effect.
  - E_2 Reads-from-memory E_1.
  - E_1 and E_2 are from different Processing Elements.
  - E_2 is an Explicit Memory Effect.
- All of the following apply:
  - E_1 is an Explicit Memory Effect.
  - E_1 is Coherence-before E_2.
  - E_1 and E_2 are from different Processing Elements.
  - E_2 is an Explicit Memory Effect.

Tag-Observed-by

An Effect E_1 is *Tag-Observed-by* an Effect E_2 if one of the following applies:

- All of the following apply:
  - E_1 is an Explicit Memory Write Effect.
  - E_2 Reads-from-memory E_1.
  - E_1 and E_2 are from different Processing Elements.
  - E_2 is an Implicit Tag Memory Read Effect.
- All of the following apply:
  - E_1 is an Implicit Tag Memory Read Effect.
  - E_1 is Coherence-before E_2.
  - E_1 and E_2 are from different Processing Elements.
  - E_2 is an Explicit Memory Write Effect.

TLBUncacheable-coherence-before

An Effect E_1 is *TLBUncacheable-coherence-before* an Effect E_2 if all of the following apply:

- E_1 is an Implicit TTD Memory Read Effect.
- E_1 is Translation-intrinsically-before E_3.
- E_3 is a TLBUncacheable Fault Effect.
- E_1 is Coherence-before E_2.
- One of the following applies:
  - E_2 is an Explicit Memory Write Effect.
  - E_2 is a Hardware Update Effect.

Hardware-Update-coherence-before

An Effect E_1 is *Hardware-Update-coherence-before* an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- E_1 is Coherence-before E_2.
- E_2 is a Hardware Update Effect.

TLBI-coherence-before

An Effect E_1 is *TLBI-coherence-before* an Effect E_2 if all of the following apply:

- E_1 is a TLBI Effect.
- E_1 is TLBI-before E_3.
- E_3 is an Implicit TTD Memory Read Effect.
- E_3 is Coherence-before E_2.
- E_2 is a Memory Write Effect.

TTD-Observed-by

An Effect E_1 is *TTD-Observed-by* an Effect E_2 if one of the following applies:

- All of the following apply:
  - E_1 is an Implicit TTD Memory Effect.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - E_2 Reads-from-memory E_1.
- All of the following apply:
  - E_2 Reads-from-memory E_1.
  - E_2 is an Implicit TTD Memory Effect.
- E_1 is TLBUncacheable-coherence-before E_2.
- E_1 is Hardware-Update-coherence-before E_2.
- All of the following apply:
  - E_1 is a Hardware Update Effect.
  - E_1 is Coherence-before E_2.
  - E_2 is a Memory Write Effect.
- All of the following apply:
  - E_1 is a Memory Write Effect.
  - E_1 is Coherence-before E_2.
  - E_2 is a Hardware Update Effect.
- E_1 is TLBI-coherence-before E_2.

IC-Coherence-before

An Effect E_1 is *IC-coherence-before* an Effect E_2 if one of the following applies:

- All of the following apply:
  - The Effective value of CTR_EL0.DIC is 0.
  - The Effective value of CTR_EL0.IDC is 0.
  - E_1 is an IC Effect.
  - E_1 is IC-before E_3.
  - E_3 is an Implicit Instruction Memory Read Effect.
  - E_3 is Coherence-before E_4.
  - E_4 is a Memory Write Effect.
  - E_4 is DC-before E_2.
  - E_2 is a DC CVAU Effect.
- All of the following apply:
  - The Effective value of CTR_EL0.DIC is 0.
  - The Effective value of CTR_EL0.IDC is 1.
  - E_1 is an IC Effect.
  - E_1 is IC-before E_3.
  - E_3 is an Implicit Instruction Memory Read Effect.
  - E_3 is Coherence-before E_2.
  - E_2 is a Memory Write Effect.
- All of the following apply:
  - The Effective value of CTR_EL0.DIC is 1.
  - The Effective value of CTR_EL0.IDC is 1.
  - E_1 is an Implicit Instruction Memory Read Effect.
  - E_1 is Coherence-before E_2.
  - E_2 is a Memory Write Effect.

Instruction-Observed-by

An Effect E_1 is *Instruction-Observed-by* an Effect E_2 if one of the following applies:

- All of the following apply:
  - E_2 Reads-from-memory E_1.
  - E_2 is an Implicit Instruction Memory Read Effect.
- E_1 is IC-before E_2.
- All of the following apply:
  - E_1 is a DC CVAU Effect.
  - E_1 is DC-before E_2.
  - E_2 is a Memory Write Effect.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- All of the following apply:
  - E_1 is a Memory Write Effect.
  - E_1 is DC-before E_2.
  - E_2 is a DC CVAU Effect.
- E_1 is IC-coherence-before E_2.

Observed-by

An Effect E_1 is *Observed-by* an Effect E_2 if one of the following applies:

- E_1 is Explicit-Observed-by either E_2 or an Effect which belongs to the same single-copy-atomic grouping as E_2.
- E_1 is Tag-Observed-by either E_2 or an Effect which belongs to the same single-copy-atomic grouping as E_2.
- E_1 is TTD-Observed-by E_2.
- E_1 is Instruction-Observed-by E_2.

B2.3.9 Definition of an Architecturally Allowed Execution

An Architecturally Allowed Execution must satisfy the *External visibility requirement*, which is formulated in terms of an ordering relation called *Ordered-before*. An execution that does not satisfy the external visibility requirement is an Architecturally Forbidden Execution.

Ordered-before

An Effect E_1 is *Ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Hardware-required-ordered-before E_2.
- E_1 is Observed-by E_2.
- All of the following apply:
  - E_1 is Ordered-before E_3.
  - E_3 is Ordered-before E_2.

External visibility requirement

The external visibility requirement is defined as follows: an Architecturally Allowed Execution must not exhibit a cycle in the Ordered-before relation.

In particular, for an Effect E_1 that is Ordered-before an Effect E_2, the External visibility requirement requires that E_2 is not Observed-by E_1.

B2.3.10 Alternative formulations of the External visibility requirement for Explicit Memory Effects

B2.3.10.1 Additional ordering relations

Single-copy-atomic-ordered-before

A Memory Read Effect E_1 is *single-copy-atomic-ordered-before* another Memory Read Effect E_2 if all the following apply:

- E_1 belongs to the same single-copy-atomic grouping as E_2.
- E_1 Reads-from-memory a Memory Write Effect E_3.
- E_1 and E_3 are from different Processing Elements.
- E_2 Reads-from-memory a Memory Write Effect E_4.
- E_2 and E_4 are from the same Processing Element.

B2.3.10.2 External completion requirement for Explicit Memory Effects

The *External completion requirement for Explicit Memory Effects* is an alternative way of formulating the External visibility requirement, in the context of Explicit Memory Effects only.

The Completes-before order is a total order that corresponds to the order in which Memory Effects complete within the system. Effects E_1 and E_2 constitute a single entry in the Completes-before order, if any of the following applies:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- All of the following apply:
  - E_1 is a Memory Write Effect.
  - E_2 is a Memory Write Effect.
  - E_1 belongs to the same single-copy-atomic grouping as E_2.
- All of the following apply:
  - E_1 is a Memory Read Effect.
  - E_2 is a Memory Read Effect.
  - E_1 belongs to the same single-copy-atomic grouping as E_2.
  - E_1 Reads-from-memory a Memory Write Effect E_3.
  - E_1 and E_3 are from different Processing Elements.
  - E_2 Reads-from-memory a Memory Write Effect E_4.
  - E_2 and E_4 are from different Processing Elements.
- All of the following apply:
  - E_1 is a Memory Read Effect.
  - E_2 is a Memory Read Effect.
  - E_1 belongs to the same single-copy-atomic grouping as E_2.
  - E_1 Reads-from-memory a Memory Write Effect E_3.
  - E_1 and E_3 are from the same Processing Element.
  - E_2 Reads-from-memory a Memory Write Effect E_4.
  - E_2 and E_4 are from the same Processing Element.
  - E_3 belongs to the same single-copy-atomic grouping as E_4.

All other Memory Read Effects constitute distinct entries in the Completes-before order.

Completes-before

A Memory Read or Write Effect E_1 completes-before a Memory Read or Write Effect E_2 if E_1 appears in the *Completes-before* order before E_2.

Deriving Reads-from-memory and Coherence order from the Completes-before order

The Reads-from-memory relation can be derived from the Completes-before order by specifying which Memory Write Effect every Memory Read Effect gets its value from. Specifically, for a Memory Read Effect E_1 one of the following must apply:

- If all of the following apply:
  - There is a Memory Write Effect E_2.
  - E_1 is a Local memory read successor of E_2.
  - E_1 Completes-before E_2.
  - There is no Memory Write Effect E_3 to the Same Location in the Completes-before order between E_2 and an Explicit Memory Read Effect E_4 to the Same Location that appears in program order before E_1.

  then it must be that E_1 Reads-from-memory E_2.
- If all of the following apply:
  - There is a Memory Write Effect E_2 (possibly representing the writing of the initial value to the Location).
  - E_2 and E_1 are to the Same Location.
  - E_2 Completes-before E_1.
  - It is not the case that E_2 Completes-before a Memory Write Effect E_3 and E_1 is the Local memory read successor of E_3.
  - There is no Memory Write Effect E_4 to the Same Location in the Completes-before order between E_2 and E_1.
  - There is no Memory Write Effect E_5 to the Same Location in the Completes-before order between E_2 and a Memory Read Effect E_6 to the Same Location that appears in program order before E_1.

  then it must be that E_1 Reads-from-memory E_2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The Coherence order can be derived from the Completes-before order by letting the Coherence order of Memory Write Effects to a memory location be the order in which those Memory Write Effects appear in the Completes-before order. The final value of each memory location is therefore determined by the final Memory Write Effect to each Location in the Completes-before order. If no such Memory Write Effect exists for a given Location, the final value is the initial value of that Location.

External completion requirement for Explicit Memory Effects

The External completion requirement for Explicit Memory Effects requires that an Memory Effect E_1 Completes-before a Memory Effect E_2 if any of the following statements are true:

- E_1 is Locally-hardware-required-ordered-before E_2.
- E_1 is a Memory Read Effect, E_2 is a Memory Read Effect, and E_1 is single-copy-atomic-ordered-before E_2.

B2.3.10.3 External global completion requirement for Explicit Memory Effects

The *External global completion requirement for Explicit Memory Effects* is an alternative way of formulating the External visibility requirement, in the context of Explicit Memory Effects only.

The Globally-completes-before order is a total order that corresponds to the order in which Memory Effects complete within the system. Effects E_1 and E_2 constitute a single entry in the Globally-completes-before order, if any of the following applies:

- All of the following apply:
  - E_1 is a Memory Write Effect.
  - E_2 is a Memory Write Effect.
  - E_1 belongs to the same single-copy-atomic grouping as E_2.
- All of the following apply:
  - E_1 is a Memory Read Effect.
  - E_2 is a Memory Read Effect.
  - E_1 belongs to the same single-copy-atomic grouping as E_2.
  - E_1 Reads-from-memory a Memory Write Effect E_3.
  - E_1 and E_3 are from different Processing Elements.
  - E_2 Reads-from-memory a Memory Write Effect E_4.
  - E_2 and E_4 are from different Processing Elements.
- All of the following apply:
  - E_1 is a Memory Read Effect.
  - E_2 is a Memory Read Effect.
  - E_1 belongs to the same single-copy-atomic grouping as E_2.
  - E_1 Reads-from-memory a Memory Write Effect E_3.
  - E_1 and E_3 are from the same Processing Element.
  - E_2 Reads-from-memory a Memory Write Effect E_4.
  - E_2 and E_4 are from the same Processing Element.
  - E_3 belongs to the same single-copy-atomic grouping as E_4.

All other Memory Read Effects constitute distinct entries in the Globally-completes-before order.

Globally-completes-before

A Memory Read or Write Effect E_1 *Globally-completes-before* a Memory Read or Write Effect E_2 if E_1 appears in the Globally-completes-before order before E_2.

Deriving Reads-from-memory and Coherence order from the Globally-completes-before order

The Reads-from-memory relation can be derived from the Globally-completes-before order by specifying which Memory Write Effect every Memory Read Effect gets its value from. Specifically, for a Memory Read Effect E_1 it must be that if all of the following applies:

- There is Memory Write Effect E_2 (possibly representing the writing of the initial value to the Location).

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- E_2 Globally-completes-before E_1.
- E_1 and E_2 are to the Same Location.
- There is no Memory Write Effect E_3 to the Same Location in the Globally-completes-before order between E_2 and E_1.
- There is no Memory Write Effect E_4 to the Same Location in the Globally-completes-before order between E_2 and an Explicit Memory Read Effect E_5 to the Same Location that appears in program order before E_1.

then it must be that E_1 Reads-from-memory E_2.

The Coherence order can be derived from the Globally-completes-before order by letting the Coherence order of Memory Write Effects to a memory location be the order in which those Memory Write Effects appear in the Globally-completes-before order. The final value of each memory location is therefore determined by the final Memory Write Effect to each Location in the Globally-completes-before order. If no such Memory Write Effect exists for a given Location, the final value is the initial value of that Location.

External global completion requirement

The External global completion requirement requires that a Memory Effect E_1 Globally-completes-before a Memory Effect E_2 if any of the following statements are true:

- E_1 is Locally-hardware-required-ordered-before E_2 and one of the following applies:
  - — E_1 is a Memory Write Effect.
  - — E_1 is a Memory Read Effect, and one of the following applies:
    - — E_1 Reads-from-memory a Memory Write Effect E_3, and E_1 and E_3 are from different Processing Elements, or.
    - — E_1 Reads-from-memory a Memory Write Effect E_3, E_1, and E_3 are from the same Processing Element, and E_3 is Locally-hardware-required-ordered-before E_2.
- E_1 is a Memory Read Effect, E_2 is a Memory Read Effect, and E_1 is single-copy-atomic-ordered before E_2.

B2.4 Additional ordering requirements outside of the scope of the formal concurrency model

The following sections present ordering rules which have been architected but not yet formalized. As a consequence they do not appear in the formal concurrency model, nor in the corresponding transliteration in Ordering requirements defined by the formal concurrency model. They will be integrated into Ordering requirements defined by the formal concurrency model in due course.

B2.4.1 Completion and endpoint ordering

For all memory, the completion rules are defined as:

- A Memory Read effect E_1 to a Location is complete for a shareability domain when all of the following are true:
  - Any Memory Write Effect to the same Location by an observer within the shareability domain will be Coherence-after E_1.
  - All Implicit TTD Memory Read Effects associated with E_1 are complete for that shareability domain.
- A Memory Write effect E_1 to a Location is complete for a shareability domain when all of the following are true:
  - Any Memory Write Effect to the same Location by an observer within the shareability domain will be Coherence-after E_1.
  - Any Memory Read Effect to the same Location by an observer within the shareability domain will be such that either Reads-from E_1 or Reads-from a Memory Write effect that is Coherence-after E_1.
  - All Implicit TTD Memory Read Effects associated with E_1 are complete for that shareability domain.
- An Implicit TTD Memory Read Effect is complete for a shareability domain when the memory accesses associated with the Implicit TTD Memory Read Effect, including Hardware Update Effects, are complete for that shareability domain, and the TLB is updated.
- A cache maintenance instruction is complete for a shareability domain when the memory effects of the instruction are complete for that shareability domain, and Implicit TTD Memory Read Effects that arise from the instruction are complete for that shareability domain.
- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.

The completion of any cache or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the `DSB` operation that is required to guarantee visibility of the maintenance instruction.

Additionally, for Device-nGnRnE memory, a read or write of a Location in a Memory-mapped peripheral that exhibits side effects is complete only when the read or write both:

- Can begin to affect the state of the Memory-mapped peripheral.
- Can trigger all associated side effects, whether they affect other peripheral devices, PEs, or memory.

Interaction between observers in a system is not restricted to communication through shared variables in coherent memory. For example, an observer could configure an interrupt controller to raise an interrupt on another observer as a form of message passing. These interactions typically involve an additional agent, which defines the instruction sequence that is required to establish communication links between different observers. When these forms of interaction are used in conjunction with shared variables, a `DSB` instruction can be used to enforce ordering between them.

Note

This requirement for Device-nGnRnE memory is consistent with the memory access having reached the peripheral endpoint.

Note

These completion rules mean that, for example, a cache maintenance instruction that operates by VA to the PoC completes only after memory at the PoC has been updated.

B2.4.1.1 Peripherals

This section defines a Memory-mapped peripheral and the total order of reads and writes to a peripheral which is defined as the Peripheral arrival order:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Memory-mapped peripheral

A *Memory-mapped peripheral* occupies a memory region of IMPLEMENTATION DEFINED size and can be accessed using load and store instructions. Memory effects to a Memory-mapped peripheral can have side effects, such as causing the peripheral to perform an action. Values that are read from addresses within a Memory-mapped peripheral might not correspond to the last data value written to those addresses. As such, Memory effects to a Memory-mapped peripheral might not appear in the Reads-from or Coherence order relations.

Peripheral arrival order

The *Peripheral arrival order* of a Memory-mapped peripheral is a total order on all Memory Read Effects and Memory Write Effects to that peripheral.

A Memory effect E_1 is inserted in the Peripheral arrival order for a peripheral before a Memory effect E_2, if E_1 and E_2 are to the same peripheral and any of the following applies:

- All of the following apply:
  - E_1 is to Device memory with the non-Reordering attribute.
  - E_2 is to Device memory with the non-Reordering attribute.
  - Any of the following applies:
    - FEAT_XS is not implemented.
    - All of the following apply:
      - FEAT_XS is implemented.
      - E_1 has the XS attribute.
      - E_2 has the XS attribute.
    - All of the following apply:
      - FEAT_XS is implemented.
      - E_1 does not have the XS attribute.
      - E_2 does not have the XS attribute.
  - E_1 appears in program order before E_2.
- All of the following apply:
  - E_1 is to Device memory with the non-Gathering attribute.
  - E_2 is to Device memory with the non-Gathering attribute.
  - E_1 is Ordered-before E_2.
- All of the following apply:
  - Any of the following applies:
    - E_1 is to Device memory.
    - E_1 is to Non-cacheable Normal memory.
  - Any of the following applies:
    - E_2 is to Device memory.
    - E_2 is to Non-cacheable Normal memory.
  - E_1 is Barrier-ordered-before E_2.

Otherwise, exactly one of the following applies:

- E_1 and E_2 are gathered into a single transaction and appear as one Effect in the Peripheral arrival order for the peripheral.
- E_1 is inserted in the Peripheral arrival order for the peripheral before E_2.
- E_2 is inserted in the Peripheral arrival order for the peripheral before E_1.

Gathering is permitted, but not required if none of the following apply:

- E_1 is to Device memory with the non-Gathering attribute.
- E_1 is generated by an `ST64BV` or `ST64BV0` instruction.
- All of the following apply:
  - E_1 is generated by an `ST64B` instruction.
  - E_1 appears in program order before E_2.
  - E_2 is a Memory Write Effect.
- E_2 is to Device memory with the non-Gathering attribute.
- E_2 is generated by an `ST64BV` or `ST64BV0` instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

When FEAT_XS is implemented, if E_1 and E_2 are to Device-nGnRE memory or to Device-nGnRnE memory and E_1 and E_2 are within the same Memory-mapped peripheral, but E_1 and E_2 use different XS attributes, the order of arrival at the endpoint is not defined by the architecture.

Out-of-band-ordered-before

An Effect E_1 is *Out-of-band-ordered-before* an Effect E_2 if and only if all of the following apply:

- E_1 is a Memory Effect.
- Any of the following applies:
  - E_1 is DSB-ordered-before E_3.
  - E_1 is Instruction-fetch-barrier-ordered-before E_3.
- There is an IMPLEMENTATION DEFINED instruction sequence beginning with E_3 indirectly leading to the generation of E_2.
- E_2 is a Memory Effect.

If an Effect E_1 is Out-of-band-ordered-before an Effect E_2, then E_1 is Ordered-before E_2.

Note

Arm expects that, in most systems with early acknowledgments, those acknowledgments will come from a point at or after the point that establishes global visibility. This is expected in such systems to enable the acknowledgments to be used as part of the mechanisms to implement the ordering requirements of the Arm memory model.

B2.4.2 Metadata Dependencies

I_{YRYHC} The execution of the following instructions create ordering relations for the purposes of the Arm memory model:

- `IRG`.
- `PACDA`.
- `PACDB`.
- `AUTDA`.
- `AUTDB`

R_{TVHSL} If FEAT_MTE is implemented, the execution of an `IRG Xd,Xn,Xm` instruction creates:

- A Dependency through registers and memory from the Register Read Effect of Xn to Register Write Effect of Xd.
- If Allocation Tag Access is not prevented for the current Exception level, a Dependency through registers and memory from the Register Read Effect of Xm to Register Write Effect of Xd.

R_{MSWTM} If FEAT_PAuth is implemented, the execution of a `PACDA Xd,Xn` instruction creates:

- A Dependency through registers and memory from the Register Read Effect of Xd to Register Write Effect of Xd.
- If authentication using the APDAKey_EL1 key is enabled, a Dependency through registers and memory from the Register Read Effect of Xn to Register Write Effect of Xd.

R_{JMNSC} If FEAT_FPAC is implemented, the execution of a `PACDB Xd,Xn` instruction creates:

- A Dependency through registers and memory from the Register Read Effect of Xd to Register Write Effect of Xd.
- If authentication using the APDBKey_EL1 key is enabled, a Dependency through registers and memory from the Register Read Effect of Xn to Register Write Effect of Xd.

R_{XYRJT} If FEAT_FPAC is implemented, the execution of an `AUTDA Xd,Xn` instruction creates:

- If authentication using the APDAKey_EL1 key is enabled, a Pick dependency through registers and memory from the Register Read Effect of Xn to Register Write Effect of Xd.
- A Dependency through registers and memory from the Register Read Effect of Xd to Register Write Effect of Xd.

R_{SPBZX} If FEAT_FPAC is implemented, the execution of an `AUTDB Xd,Xn` instruction creates:

- If authentication using the APDBKey_EL1 key is enabled, a Pick dependency through registers and memory from the Register Read Effect of Xn to Register Write Effect of Xd.
- A Dependency through registers and memory from the Register Read Effect of Xd to Register Write Effect of Xd.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B2.4.3 Limited ordering regions

FEAT_LOR introduces *limited ordering regions* (LORegions), which allow large systems to perform special load-acquire and store-release instructions that provide order between the memory accesses to a region of the PA map as observed by a set of observers.

LORegions are defined in the Non-secure physical address space. LORegions cannot be defined in the Secure, Realm, or Root physical address spaces.

This feature is supported in AArch64 state only.

B2.4.3.1 Specification of the LORegions

The LORegions are defined in the Non-secure physical memory map using a set of LORegion descriptors. The number of LORegion descriptors is IMPLEMENTATION DEFINED, and can be discovered by reading the LORID_EL1 register.

Each LORegion descriptor consists of:

- A tuple of the following values:
  - A Start Address.
  - An End Address.
  - An LORegion Number.
- Valid bit which indicates whether that LORegion descriptor is valid.

A memory location lies within the LORegion identified by the LORegion Number if the PA lies between the Start Address and the End Address, inclusive. The Start Address must be defined to be aligned to 64KB and the End Address must be defined as the top byte of a 64KB block of memory.

It is permitted for multiple LORegion descriptors with non-overlapping address ranges to be configured with the same LORegion Number.

The LORegion descriptors are programmed using the LORSA_EL1, LOREA_EL1, LORN_EL1, and LORC_EL1 registers in the System register space. These registers describe only memory addresses in the Non-secure memory map. These registers are UNDEFINED if accessed when SCR_EL3.NS == 0.

If a LoadLOAcquire or a StoreLORelease does not match with any LORegion, then:

- The LoadLOAcquire will behave as a Load-Acquire, and will be ordered in the same way with respect to all accesses, independent of their LORegions.
- The StoreLORelease will behave as a Store-Release, and will be ordered in the same way with respect to all accesses, independent of their LORegions.

Note

If no LORegions are implemented, then the LoadLOAcquire and StoreLORelease will therefore behave as a Load-Acquire and Store-Release.

B2.4.4 SVE memory ordering relaxations

I_{CTNGV} The Arm memory model is relaxed for reads and writes generated by SVE load and store instructions.

R_{QLJPC} When two reads generated by SVE vector load instructions have an address dependency, the dependency does not contribute to the dependency-ordered-before relation.

R_{YMBMZ} When a pair of reads access the same location, and at least one of the reads is generated by an SVE load instruction, for a given observer, the hazard-ordered-before relation does not apply to the pair of reads.

R_{CJHWV} When a single SVE vector store instruction generates multiple writes to the same location, the instruction ensures that these writes appear in the coherence order for that location, in order of increasing vector element number. No other ordering restrictions apply to memory effects generated by the same SVE store instruction.

R_{LVXTJ} If a single SVE load instruction generates multiple reads, the order in which the reads for different elements and registers appear is not architecturally defined.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{VMDYZ} If an address dependency exists between two Read Memory and an SVE non-temporal vector load instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, the memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

I_{CCWGN} For any SVE load or store instruction that generates multiple single-copy atomic accesses to Normal or Device memory, there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic memory element access sizes.

B2.4.5 Streaming SVE mode memory ordering relaxations

R_{HBBTV} If a pair of memory reads access the same location, and at least one of the reads is generated by an Advanced SIMD&FP load instruction, for a given observer, the hazard-ordered-before relation does not apply to the pair of reads when the PE is in *Streaming SVE mode* and FEAT_SME_FA64 is not implemented or not enabled at the current Exception level.

See also:

- Streaming SVE mode.

B2.4.6 Ordering rules for GCS

I_{QNKNL} If FEAT_GCS is implemented, see Guarded Control Stack data accesses for relevant ordering rules.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B2.5 Restrictions on the effects of speculation

A *permitted-speculative-next-PC* is one of:

- For any instruction that is neither an Unconditional branch (immediate) nor an exception generating instruction, the PC plus four.
- For any instruction, an exception vector associated with a synchronous exception generated from the current Exception level.
- For a direct branch, the PC plus the offset contained in the immediate field of the opcode.
- For an indirect branch, any address.
- An exception vector associated with an asynchronous exception taken from the current Exception level.

A *permitted-speculatively-executed-instruction* is the speculative execution of an instruction at a permitted-speculative-next-PC where that PC was generated from one of the following:

- An architecturally executed instruction.
- A permitted-speculatively-executed-instruction.
- An asynchronous exception.

The Arm architecture places certain restrictions on the effects of speculation. These are:

- Each load from a Location (L) using memory attributes (M) after an exception return that is a Context Synchronization event will not speculatively read an entry from earlier in the coherence order for L being loaded from other than the entry generated by the latest store to L using memory attributes M before the exception exit.
- Each load from a Location (L) using memory attributes (M) after an exception entry that is a Context Synchronization event will not speculatively read an entry from earlier in the coherence order for L being loaded from other than the entry generated by the latest store to L using memory attributes M before the exception entry.
- When data is loaded under speculation with a Translation fault, it cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence.
- A speculative Explicit Memory Read Effect generated by an instruction (I_2) running in a hardware-defined context ($context_2$) will not speculatively read data from a speculative Explicit Memory Write Effect generated by an instruction (I_1) running in a different hardware-defined context ($context_1$) if I_1 generates an MMU fault Effect instead of the Explicit Memory Write Effect.
- When data is loaded under speculation with a GPC fault, it cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence, and the execution timing of any other instructions in the speculative sequence is not a function of the data loaded under speculation.
- When stage 2 translation is enabled and a stage 1 translation table entry is loaded under speculation with a GPC fault, the output address or Next-level table address from the entry cannot be used to form an address to be used by other fetches in the translation table walk.
- Granule protection checks apply to speculative instruction fetch and speculative execution. Any instruction fetched under speculation with a GPC fault:
  - Cannot cause an update to any architectural or microarchitectural state as a result of speculative execution of the instruction, where the update of the state is dependent on the content of the instruction.
  - Cannot be stored in a cache that is not affected by `DC PAPA` operations.
- If GPCCR_EL3.GPCP == 0, data from a translation table walk for which the granule protection check for the address being accessed has not been architecturally resolved can not be used to form an address for a subsequent read access or for generating syndrome information, until the granule protection check has passed.

  Note

  Permitting read accesses to locations for which the granule protection check has not been architecturally resolved means the GPT does not protect non-idempotent locations from these speculative read operations.

- When data is loaded under speculation from a location that does not have a valid translation for the translation regime being speculated in, the data cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When data is loaded as a result of speculative accesses made after `TLBI` + `DSB` + `ERET` using a translation that was invalidated by the TLBI, the data cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence. The execution timing of any other instructions in the speculative sequence is not a function of the data loaded.
- Changes to System registers must not occur speculatively in a way that can affect a speculative memory access that can cause a change to the microarchitectural state.
- Changes to Special-purpose registers can occur speculatively.
- Accesses to Device memory are subject to many restrictions on the effects of Speculation. See Device memory.
- Execute-never controls apply to speculative instruction fetching. See Effects on instruction execution permissions and restrictions on instruction fetch.
- When writing new instructions to memory, there is no requirement for an `SB` instruction to prevent speculative execution of the old code. See Instruction cache maintenance instructions.
- Write speculation that is visible to other observers is prohibited for all memory types.
- A load will not speculatively read data from any store that appears in program order after the load itself.
- From Armv9.4, an instruction (I_1) that is not a permitted-speculatively-executed-instruction must not speculatively perform any function, other than being fetched, decoded or performing any side effects resulting from being fetched or decoded, that alters the microarchitectural state of the system in such a way that some other architecturally executed code (code2) can determine any architectural state, except for any architectural state accessed by I_1 as part of I_1 being fetched and decoded, that could not be determined had I_1 not speculatively executed.

  When an architectural or speculative Explicit Memory Write Effect (E_1) to a Location (A_1) is properly synchronized such that a subsequent architectural or speculative instruction fetch (I_1) from A_1 is required to observe E_1, the permitted-speculative-next-PC generated from I_1 is permitted to be generated from the opcode before or after the modification of A_1 by E_1.

Note

The prohibition of using data loaded under speculation with faults to form addresses, condition codes or SVE predicate values does not prohibit the use of value predicted data from such locations for such purposes, so long as the training of the data value prediction was from the hardware defined context that is using the prediction. A consequence of this is that training of value prediction cannot be based on data loaded under speculation with a translation or Permission fault.

B2.5.1 AArch64 Speculative Store Bypass Safe

When FEAT_SSBS is implemented, PSTATE.SSBS is a control that can be set by software to indicate whether hardware is permitted to use, in a manner that is potentially speculatively exploitable, a speculative value in a register that has been loaded from memory using a load instruction that speculatively read the location being loaded from, where the entry that is speculatively read is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

A speculative value in a register is used in a potentially speculatively exploitable manner if it is used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence or if the execution timing of any other instructions in the speculative sequence is a function of the data loaded under speculation.

When the value of PSTATE.SSBS is 0, hardware is not permitted to use speculative register values in a potentially speculatively exploitable manner if the speculative read that loads the register is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

Setting PSTATE.SSBS to 0 is deprecated for performance reasons.

When the value of PSTATE.SSBS is 1, hardware is permitted to use speculative register values in a potentially speculatively exploitable manner if the speculative read that loads the register is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- If speculation is permitted, then cache timing side channels can lead to addresses being derived using reads of address values that have been speculatively loaded from memory to a register.
- Before the introduction of FEAT_SSBS, the control bit SPSR_ELx.SSBS was RES0, and therefore software written without awareness of FEAT_SSBS is expected to program it to 0. This means that PSTATE.SSBS will not be set, so the PE will not be permitted to use speculative loads with outstanding memory disambiguation issues for any subsequent speculative memory accesses if there is any possibility of those subsequent memory accesses creating a cache timing side channel.

B2.5.2 Definition of exploitative control of speculative execution

The execution of some code (code1) can exploitatively control speculative execution of some other code (code2) if all of the following apply:

- The actions of code1 can influence, in a manner that is not hard-to-determine, the prediction of multi-bit values that determine speculative execution of code2 to cause an irreversible change to the microarchitectural state of the PE that is indicative of some architectural state accessible to the execution context of code2.
- code1 has control in determining the choice of the architectural state that the irreversible change to the microarchitectural state is indicative of.
- The irreversible changes to the microarchitectural state of the PE can be measured by code executing in an execution context other than that of code2 to allow the retrieval of the architectural state in a manner that is not hard-to-determine.

Note

Eviction of entries from one context by another context is not considered exploitative control as long as eviction does not result in other forms of prediction that could be exploitatively controlled.

B2.5.3 Definition of predictive leakage to speculative execution

The execution of some code (code1) can predictively leak to some other code (code2) if all of the following apply:

- The execution of code1 influences, in a manner that is not hard-to-determine, the predictive microarchitectural structures of the implementation that predict multi-bit values, not binary choices, to behave in a way that is indicative of some architectural state accessible to the execution context of code1.
- The predictive microarchitectural structures of the implementation impact the timing of the speculative execution of code2 in a way that enables code2 to recover the architectural state in a manner that is not hard-to-determine.
- Code1 and code2 are not collaborating to communicate using the mechanisms in the previous two bullets.

Note

Mechanisms to prevent the influence and the state recovery being “not hard-to-determine” are left open to implementations. Examples could include the complete separation of prediction resources, or the isolation of the predictions using a cryptographic or pseudo-random mechanism to separate each context.
Eviction of entries from predictive microarchitectural structures associated with one context (code2) caused by another context (code1) is considered predictive leakage if it enables code2 to recover some architectural state from code1.

B2.5.4 Restrictions on the effects of speculation from Armv8.5

Note

If SCR_EL3.EEL2 is changed, in order to remove all VMID tagging from Secure EL1 and Secure EL0 entries, each prediction resource should be invalidated by software for:

- Secure EL0 for all ASID and VMID values.
- Secure EL1 for all VMID values.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Further restrictions on speculation are introduced by some additional architectural features as described here.

FEAT_CSV3 introduces these restrictions:

- An attempt to access data under speculation, where the data is inaccessible given the current state of the PE cannot be used to alter the architectural or microarchitectural state in a manner that allows the value of the inaccessible data to be recovered by code architecturally executed through means such as measuring the timing of code. This restriction applies to any of the following cases which make the data inaccessible:
  - Reading from a Location with a Permission or Domain fault.
  - Directly reading from a System register or Special-purpose register that is not architecturally readable.
  - Reading from a SIMD&FP register, SVE register, or SME register that is not accessible due to traps configured by a more privileged Exception level.
  - Indirectly reading from a System register containing a Pointer Authentication Key for which the corresponding Pointer Authentication instructions are disabled.

  Note

  The current state of the PE is defined as the Exception level, values of all Special-purpose registers, and values of all System registers under which the hardware attempts to access the data, which may be on the speculative execution path. If on the speculative execution path, the hardware must respect any changes to the PE state that occur on the speculative path, respecting the same rules that would be required if executing on the non-speculative path. Note that the sequence of instructions on the speculative path may not be the same sequence of instructions that would occur on the non-speculative path as the hardware control flow predictions could cause the two sequences to differ.

  Note

  The following is a list of examples in which use of the inaccessible data could lead to recovery of the value of the inaccessible data:

  - To form an address, generate condition codes, or generate SVE predicate values to be used in the speculative sequence.
  - To form the register value used for the comparison of a compare-and-branch, test-and-branch, or compare-and-swap instruction in the speculative sequence. Note that this is to cover conditional instructions that do not use condition codes to determine their outcomes.
  - By prediction mechanisms such as Cache Prefetch or Data Value predictions.
  - As an input to an instruction in the speculative sequence where the execution timing of the instruction is dependent on the data value.
  - To form or influence a value recorded by the Statistical Profiling Unit or the trace unit.

  Note

  It is permissible for a value of zero to be produced by the load or register read and consumed by an instruction newer than the load in the speculative sequence even if the value of zero results in different execution timing compared to nonzero values.

  Note

  As the effects of speculation are not architecturally visible, this restriction requires that the effect of any speculation cannot give rise to side channels that will leak the values of memory locations, System registers, or Special-purpose registers to a level of privilege that would otherwise not be able to determine those values.

- The value of Allocation tags loaded under speculation as the result of a Tag checked access with a NoTagAccess fault or to Untagged memory cannot influence the execution of the instruction causing the Tag checked access or other instructions in the speculative sequence.

FEAT_CSV2, FEAT_CSV2_1p1, FEAT_CSV2_1p2, FEAT_CSV2_2 and FEAT_CSV2_3 introduce a range of additional restrictions.

If FEAT_CSV2 is implemented:

- Code running in one hardware-defined context (context1) cannot either exploitatively control, or predictively leak to, the speculative execution of code in a different hardware-defined context (context2), as a result of the behavior of any of the following resources:
  - Branch target prediction based on the branch targets used in context1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - This applies to both direct and indirect branches, including return instructions, but excludes the prediction of the direction of a conditional branch.
- Branch type prediction based on the branch types used in context1, when the hardware predicts a branch of a given type to be a different type of branch, and the type of the branch is used to exploitatively control target prediction of indirect branches within context2. *Branch type* is used to distinguish between:
    - Not a branch, direct branch, indirect branch, and branch and link (or call).
- Data Value predictions based on data value from execution in context1.

Note

`PSTATE.{N, Z, C, V}` values from context1 are not considered a data value for this purpose.

- Virtual address-based cache prefetch predictions generated as a result of execution in context1, based on, or causing dereference of, data values from memory.
- Address predictions based on addresses used in context1.
    - This includes any form of memory disambiguation prediction or data forwarding based on partial address match.
- Any other prediction mechanisms, other than Branch, Data Value, Cache Prefetch predictions, or Address predictions.

In this definition, the hardware-defined context is determined by:

- The Exception level.
- The Security state.
- When executing at EL1, if EL2 is implemented and enabled in the current Security state, the VMID.
- When executing at EL0, whether the EL1&0 or the EL2&0 translation regime is in use.
- When executing at EL0 and using the EL1&0 translation regime, the *address space identifier* (ASID) and, if EL2 is implemented and enabled in the current Security state, the VMID.
- When executing at EL0 and using the EL2&0 translation regime, the ASID.

If FEAT_CSV2_2 is implemented, then SCXTNUM_ELx is also part of the hardware-defined context.

For unprivileged accesses generated by unprivileged memory access instructions, the hardware-defined context associated with the data addresses and data values of the unprivileged accesses is determined as if the access was generated by an instruction executed at EL0.

If either FEAT_CSV2_1p1 or FEAT_CSV2_3 is implemented, code running in one hardware-defined context (context1) cannot either exploitatively control, or predictively leak to, the speculative execution of code in a different hardware-defined context (context2) as a result of the behavior of any prediction mechanism based on the branch history used in context1.

If FEAT_CSV2_1p1 is implemented, branch or data values trained from one instruction address cannot exploitatively control, or predictively leak to, the speculative execution of code from a different address.

If FEAT_CSV2_1p2 is implemented, the SCXTNUM_ELx register is implemented, but is not part of the hardware-defined context.

B2.5.5 Restrictions on the effects of speculation from Armv9.5

If FEAT_BTI is implemented:

- Branches predicted or executed under speculation into a Guarded Page that land on instructions other than the intended BTI instructions are also guarded against speculative execution of those instructions.

B2.5.6 Branch history

If FEAT_CLRBHB is not implemented, then the architecture does not define any branch history maintenance instructions for AArch64 state.

When FEAT_CLRBHB is implemented, the `CLRBHB` instruction is available. When the `CLRBHB` instruction is executed, the branch history is cleared for the current context to the extent that branch history information created before the `CLRBHB` instruction cannot be used by code before the `CLRBHB` instruction to exploitatively control the execution of any code in the current context appearing in program order after the instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_ECBHB is implemented, the branch history information created in a context before an exception entry to a higher Exception level using AArch64 cannot be used by code before that exception entry to exploitatively control the execution of any code in a different context after the exception entry.

Note

FEAT_CLRBHB and FEAT_ECBHB restrict the use of the branch history to prevent exploitative control. These restrictions apply only to prediction resources that are protected by FEAT_CSV2.

B2.5.7 Execution, data prediction and prefetching restriction System instructions

When FEAT_SPECRES is implemented alone or alongside FEAT_SPECRES2, the System instructions listed in A64 System instructions for prediction restriction prevent predictions based on information gathered from earlier execution within a particular execution context (CTX), from affecting the later speculative execution within that CTX, to the extent that the speculative execution is observable through side-channels.

The prediction restriction System instructions being used by a particular CTX apply to:

- All control flow prediction resources that predict execution addresses.
- Data value prediction.
- Cache allocation prediction.

For these System instructions, the CTX is defined by:

- The Security state.
- The Exception level.
- When executing at EL1, if EL2 is implemented and enabled in the current Security state, the VMID.
- When executing at EL0, whether the EL1&0 or the EL2&0 translation regime is in use.
- When executing at EL0 when using the EL1&0 translation regime, the ASID and, if EL2 is implemented and enabled in the current Security state, the VMID.
- When executing at EL0 when using the EL2&0 translation regime, the ASID.

Note

- The data value prediction applies to all prediction resources that use some form of training to speculate data values as part of an execution.
- The cache allocation applies to all instruction and data caches, and TLB prefetching hardware used by the executing PE that applies to the supplied context.

The context information is passed as a register argument, and is restricted so that:

- Execution of the System instruction at EL0 only applies to the current hardware defined context.
- Execution of the System instruction at EL1only applies to the current VMID and Security state, and does not apply to EL2 or EL3.
- Execution of the System instruction at EL2 can only apply to the current Security state, and does not apply to EL3.

If the System instruction is specified to apply to a combination of Security state and Exception level that is not implemented, or an Exception level which is higher than the Exception level that the System instruction is executed at, then the System instruction is treated as a `NOP`.

When the System instruction is complete and synchronized, no predictions of the restricted type for the affected context are influenced by the execution of the program before the System instruction in a manner that can be observed by the use of any side channels.

Note

- Prediction restriction System instructions do not require the invalidation of prediction structures so long as the behavior described for completion is met by an implementation.
- Prediction restriction System instructions are permitted to invalidate more prediction information than is defined by the supplied execution context.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

These System instructions are guaranteed to be complete following a DSB that covers both read and write behavior on the same PE that executed the original instruction. A subsequent Context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

In AArch64 state, EL0 access to the System instructions is controlled by:

- When the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, SCTLR_EL1.EnRCTX.
- When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, SCTLR_EL2.EnRCTX.

Note

If SCR_EL3.EEL2 is changed, in order to remove all VMID tagging from Secure EL1 and Secure EL0 entries, each prediction resource should be invalidated for:

- Secure EL0 for all ASID and VMID values.
- Secure EL1 for all VMID values.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B2.6 Memory barriers

Memory barrier is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring load/store instructions. The memory barriers defined by the Arm architecture provide a range of functionality, including:

- Ordering of load/store instructions.
- Completion of load/store instructions.
- Context synchronization.

The following subsections describe the Arm memory barrier instructions:

- Instruction Synchronization Barrier
- Data Memory Barrier
- Speculation Barrier
- Consumption of Speculative Data Barrier
- Speculative Store Bypass Barrier
- Profiling Synchronization Barrier
- Physical Speculative Store Bypass Barrier
- Trace Synchronization Barrier
- Data Synchronization Barrier
- Load-Acquire, Load-AcquirePC, and Store-Release
- LoadLOAcquire, StoreLORelease
- Guarded Control Stack Barrier

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are available only when software execution is at EL1 or higher.

`DMB` and `DSB` instructions affect reads and writes to the memory system generated by load/store instructions and data or unified cache maintenance instructions being executed by the PE.

B2.6.1 Instruction Synchronization Barrier

An `ISB` instruction ensures that all instructions that come after the `ISB` instruction in program order are fetched from the cache or memory after the `ISB` instruction has completed. Using an `ISB` ensures that the effects of context-changing operations executed before the `ISB` are visible to the instructions fetched after the `ISB` instruction. Examples of context-changing operations that require the insertion of an `ISB` instruction to ensure the effects of the operation are visible to instructions fetched after the `ISB` instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to System registers.

Any context-changing operations appearing in program order after the `ISB` instruction take effect only after the `ISB` has been executed.

The pseudocode function for the operation of an `ISB` is `InstructionSynchronizationBarrier()`.

See also Memory barriers.

B2.6.2 Data Memory Barrier

The `DMB` instruction is a memory barrier instruction that ensures the relative order of memory accesses before the barrier with memory accesses after the barrier. The `DMB` instruction does not ensure the completion of any of the memory accesses for which it ensures relative order.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The full definition of the DMB instruction is covered formally in the Ordering requirements defined by the formal concurrency model and this introduction to the DMB instruction is not intended to contradict that section.

The basic principle of a DMB instruction is to introduce order between memory accesses that are specified to be affected by the DMB options supplied as arguments to the DMB instruction. The DMB instruction ensures that all affected memory accesses by the PE executing the DMB instruction that appear in program order before the DMB instruction and those which originate from a different PE, to the extent required by the DMB options, which have been observed by the PE before the DMB instruction is executed, are observed by each PE, to the extent required by the DMB options, before any affected memory accesses that appear in program order after the DMB instruction are observed by that PE.

The use of a DMB instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The DMB instruction affects only memory accesses and the operation of data cache and unified cache maintenance instructions, see A64 Cache maintenance instructions. It has no effect on the ordering of any other instructions executing on the PE.

The pseudocode function for the operation of a DMB instruction is `DataMemoryBarrier()`.

B2.6.3 Speculation Barrier

An SB instruction is a memory barrier that prevents speculative execution of instructions until after the barrier has completed when those instructions could be observed through side-channels.

Until the barrier completes, the speculative execution of any instruction appearing later in the program order than the barrier cannot be performed to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation. An example is speculative allocation into any caching structure where the allocation of that entry could indicate any data value present in memory or in the registers.

- Cannot be performed to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be performed when predicting that a instruction that could generate an exception does not generate an exception.

The speculative execution of an SB instruction cannot be as a result of any of the following:

- Control flow speculation.
- Data value speculation.
- Can be as a result of predicting that an instruction that could generate an exception does not generate an exception.

An SB instruction can complete when all of the following apply:

- It is known that it is not speculative, or it is speculative only as a result of either:
  - Speculating that an instruction that could generate an exception does not generate an exception.
  - Speculating past the point in the Execution stream where a precise asynchronous exception is taken.
- All the data values generated by instructions appearing in program order before the SB instruction are architecturally resolved, and so are not speculative.

Note

The SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched, so long as the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after the SB instruction.

B2.6.4 Consumption of Speculative Data Barrier

The CSDB instruction is a memory barrier instruction that controls speculative execution arising from data value prediction.

Any instruction, other than a branch instruction, that appears in program order after the CSDB cannot be speculatively executed using the results of any of the following predictions if those predictions come from instructions that appear in program order before the CSDB and have not been architecturally resolved:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Data value predictions of any instructions.
- `PSTATE.{N, Z, C, V}` predictions of any instructions other than conditional branch instructions appearing in program order before the `CSDB` that have not been architecturally resolved.
- Predictions of SVE predication state for any SVE instructions.

Note

For purposes of the definition of CSDB, `PSTATE.{N, Z, C, V}` and SVE predication state are not considered data values. This definition permits:

- Control flow speculation before and after the `CSDB` instruction.
- Speculative execution of conditional data processing instructions after the `CSDB` instruction, unless they use the results of data value, SVE predication state, or `PSTATE.{N, Z, C, V}` predictions of instructions appearing in program order before the `CSDB` instruction that have not been architecturally resolved.

B2.6.5 Speculative Store Bypass Barrier

The `SSBB` instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the `SSBB` instruction, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - — The store is to the same location as the load.
  - — The store uses the same virtual address as the load.
  - — The store appears in program order before the `SSBB` instruction.

B2.6.6 Profiling Synchronization Barrier

The `PSB` instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following `DSB` instruction completes when the writes to the profiling buffer have completed.

If the Statistical Profiling Extension is not implemented, this instruction executes as a `NOP`.

B2.6.7 Physical Speculative Store Bypass Barrier

The `PSSBB` instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the `PSSBB` instruction, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - — The store is to the same location as the load.
  - — The store appears in program order before the `PSSBB` instruction.

Note

The effect of this barrier applies to accesses to the same location even if they are accessed with different virtual addresses and from different Exception levels.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B2.6.8 Trace Synchronization Barrier

The TSB instruction is a barrier instruction that preserves the relative order of accesses to System registers due to trace operations and other accesses to the same registers.

A trace operation is an operation of the trace unit generating trace for an instruction when FEAT_TRF is implemented and enabled.

A TSB instruction is not required to execute in program order with respect to other instructions. This includes being reordered with respect to other trace instructions. One or more Context synchronization events are required to ensure that TSB instruction is executed in the necessary order.

If trace is generated between a Context synchronization event and a TSB operation, these trace operations may be reordered with respect to the TSB operation, and therefore may not be synchronized.

The following situations are synchronized using a TSB operation:

- A direct write B to a System register is ordered after an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all of the following are true:
  - A is executed in program order before a Context synchronization event C.
  - C appears in program order before a TSB operation T.
  - B is executed in program order after T.
- A direct read B of a System register is ordered after an indirect write to the same register by a trace operation of a traced instruction A if all the following are true:
  - A is executed in program order before a Context synchronization event C1.
  - C1 appears in program order before TSB operation T.
  - T is executed in program order before a second Context synchronization event C2.
  - B is executed in program order after C2.

A TSB operation is not needed to ensure a direct write B to a System register is ordered before an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all the following are true:

- A is executed in program order after a Context synchronization event C.
- B is executed in program order before C.

If FEAT_TRBE is implemented, the requirements in this section are extended.

See Synchronization and the Trace Buffer Unit.

The pseudocode function for the operation of a TSB instruction is `TraceSynchronizationBarrier()`.

B2.6.9 Data Synchronization Barrier

A DSB instruction is a memory barrier that ensures that memory accesses that occur before the DSB instruction have completed before the completion of the DSB instruction. In doing this, it acts as a stronger barrier than a DMB and all ordering that is created by a DMB with specific options is also generated by a DSB with the same options.

Execution of a DSB instruction:

- At EL2 ensures that any memory accesses caused by Speculative translation table walks from the EL1&0 translation regime have been observed.
- At EL3 ensures that any memory accesses caused by speculative translation table walks from the EL2, EL1&0 or EL2&0 translation regimes have been observed.

For more information, see Out-of-context translation regimes.

A DSB instruction executed by a PE completes when all of the following are complete for the set of observers in the required shareability domain:

- If the required access types of the DSB is reads, all of the following:
  - All Explicit Memory Read Effects generated by instructions in program order before the DSB.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - If FEAT_GCS is implemented, all GCS Memory Read Effects that appear in program order before a GCSB instruction that appears in program order before the DSB.
  - If FEAT_MTE2 is implemented, all Implicit Tag Memory Read Effects generated by instructions in program order before the DSB.
- If the required access types of the DSB is writes, all of the following:
  - All Explicit Memory Write Effects generated by instructions in program order before the DSB.
  - If FEAT_GCS is implemented, all GCS Memory Write Effects that appear in program order before a GCSB instruction that appears in program order before the DSB.
- If the required access types of the DSB is reads and writes, all of the following:
  - All Explicit Memory Effects generated by instructions in program order before the DSB.
  - All Implicit TTD Memory Effects generated by instructions in program order before the DSB.
  - All Implicit Instruction Memory Read Effects generated by instructions in program order before the DSB.
  - All cache maintenance instructions in program order before the DSB.
  - If FEAT_MTE2 is implemented, all Implicit Tag Memory Read Effects generated by instructions in program order before the DSB.
  - If FEAT_SPMU is implemented, all Direct System Register Write Effects to a System PMU register generated by instructions in program order before the DSB.
  - If FEAT_SPE is implemented, all PSB CSYNC instructions in program order before the DSB.
  - If FEAT_XS is implemented and the DSB has the nXS qualifier, all of the following:
    - All TLBInXS maintenance operations generated by AArch64 TLB maintenance instructions with the nXS qualifier in program order before the DSB.
    - If HCRX_EL2.FnXS is 1, all TLBInXS maintenance operations generated by AArch32 or AArch64 TLB maintenance instructions executed at EL1 in program order before the DSB.
  - If FEAT_XS is not implemented or the DSB does not have the nXS qualifier, all of the following:
    - All TLBI maintenance operations generated by TLB maintenance instructions in program order before the DSB.
  - If FEAT_HDBSS is implemented and the DSB is executed at EL2 or EL3, all HDBSS Memory Write Effects generated by instructions in program order before the DSB.
  - If FEAT_TRBE is implemented, all TSB CSYNC instructions in program order before the DSB.
  - All CFP RCTX, COSP RCTX, CPP RCTX, DVP RCTX instructions in program order before the DSB.
  - If FEAT_MTE_ASYNC is implemented, all Indirect System Register Write Effects to the Tag Fault Status Register accessible at ELx generated by instructions in program order before the DSB.
  - If FEAT_GCS is implemented, all GCS Memory Effects that appear in program order before a GCSB instruction that appears in program order before the DSB.

In addition, no instruction that appears in program order after the DSB instruction can alter any state of the system or perform any part of its functionality until the DSB completes other than:

- Being fetched from memory and decoded, or any change to architectural or microarchitectural state resulting from being fetched or decoded.
- Indirectly or directly reading any of the following, so long as the reading of these resources does not cause a change in architectural state:
  - General-purpose registers
  - SIMD&FP registers
  - The Stack Pointer register
  - The Program Counter
  - If FEAT_SVE or FEAT_SME is implemented, SVE scalable vector registers or SVE predicate registers
  - If FEAT_SVE is implemented, the First Fault Register
  - If FEAT_SME is implemented, the ZA storage
  - If FEAT_SME2 is implemented, the ZT0 register
  - Special-purpose registers
  - System registers other than CNTPCTSS_EL0 and CNTVCTSS_EL0
- If FEAT_ETS2 is not implemented, translating any virtual addresses of instructions that generate Explicit Memory Effects.

If FEAT_MTE_ASYNC is implemented, on completion of a DSB instruction with the LD qualifier, or neither the LD nor ST qualifier, all updates to TFSR_ELx.TFy or TFSRE0_EL1.TFy due to Tag Check Faults caused by accesses generated by

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

instructions occurring in program order before the DSB will be complete. For more information on FEAT_MTE_ASYNC, see The Memory Tagging Extension.

When FEAT_XS is implemented and HCRX_EL2.FnXS is 1, an AArch64 DSB instruction executed at EL1 or EL0 behaves in the same way as the corresponding DSB instruction with the nXS qualifier executed at EL1 or EL0.

A DSB instruction ordered after a direct write to a System PMU register does not complete until all observers observe the direct write. A Context synchronization event is required to create the order between the direct write and the DSB instruction.

If FEAT_TRBE is implemented, the requirements in this section are extended. See Trace synchronization and memory barriers.

The pseudocode function for the operation of a DSB is DataSynchronizationBarrier().

See also:

- Memory barriers.
- Ordering and completion of TLB maintenance instructions.

B2.6.9.1 Maintenance scope of the data synchronization barrier operations

A DSB instruction that applies to both reads and writes takes an argument that specifies its maintenance scope. The maintenance scope indicates the subset of TLB invalidate (TLBI) instructions, TLB invalidate pair (TLBIP) instructions, and Instruction cache maintenance (IC) instructions that are covered by this DSB, for one of:

- Outer Shareable domain.
- Inner Shareable domain.
- Non-shareable domain.

When a DSB instruction that applies to both reads and writes is used to ensure completion of TLB maintenance instructions or Instruction cache (IC) instructions, all of the following apply:

- A DSB NSH is sufficient to ensure completion of TLB maintenance instructions or IC instructions that apply to a single PE.
- A DSB ISH is sufficient to ensure completion of TLB maintenance instructions or IC instructions that apply to PEs in the same Inner Shareable domain.
- A DSB OSH is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Outer Shareable domain.

B2.6.10 Load-Acquire, Load-AcquirePC, and Store-Release

Arm provides a set of instructions with Acquire semantics for loads, and Release semantics for stores. These instructions support the *Release Consistency sequentially consistent* (RCsc) model. The architecture also provides optional support for Load-AcquirePC instructions with AcquirePC semantics. The combination of Load-AcquirePC and Store-Release can be used to support the weaker *Release Consistency processor consistent* (RCpc) model.

The full definitions of the Load-Acquire and Load-AcquirePC instructions are covered formally in the Ordering requirements defined by the formal concurrency model. This introduction to the Load-Acquire and Load-AcquirePC instructions is not intended to contradict that section.

The basic principle of both Load-Acquire and Load-AcquirePC instructions is to introduce order between:

- The memory access generated by the Load-Acquire or Load-AcquirePC instruction.
- The memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction, such that the memory access generated by the Load-Acquire or Load-AcquirePC instruction is observed by each PE to the extent that the PE is required to observe the access coherently, before any of the memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction are observed by that PE to the extent that the PE is required to observe the accesses coherently.

The use of a Load-Acquire or Load-AcquirePC instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The full definition of the Store-Release instruction is covered formally in the Ordering requirements defined by the formal concurrency model and this introduction to the Store-Release instruction is not intended to contradict that section.

The basic principle of a Store-Release instruction is to introduce order between the following:

- A set of memory accesses, RWx, that are generated by the PE executing the Store-Release instruction and that appear in program order before the Store-Release instruction, together with those that originate from a different PE to the extent that the PE is required to observe them coherently, observed by the PE before executing the Store-release.
- The memory access generated by the Store-Release (Wrel), such that all of the memory accesses, RWx, are observed by each PE to the extent that the PE is required to observe those accesses coherently, before Wrel is observed by that PE to the extent that the PE is required to observe that access coherently.

The use of a Store-Release instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

Where a Load-Acquire appears in program order after a Store-Release, the memory access generated by the Store-Release instruction is observed by each PE to the extent that PE is required to observe the access coherently, before the memory access generated by the Load-Acquire instruction is observed by that PE, to the extent that the PE is required to observe the access coherently. This does not apply when a Store-Release instruction appears in program order before a Load-AcquirePC instruction.

In addition, the use of a Load-Acquire, Load-AcquirePC or a Store-Release instruction on accesses to a Memory-mapped peripheral introduces order between the Memory effects of the instructions that access that peripheral, as described in the definition of Peripheral arrival order.

Load-Acquire, Load-AcquirePC and Store-Release, other than Load-Acquire Exclusive Pair and Store-Release-Exclusive Pair, access only a single data element.

Load-Acquire Exclusive Pair and Store-Release Exclusive Pair access two data elements.

A Store-Release Exclusive instruction has the release semantics only if the store is successful.

Note

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
  - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
  - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.
- The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit `DMB` instruction.

B2.6.11 LoadLOAcquire, StoreLORelease

For each PE, the Non-secure physical memory map is divided into a set of LORegions using a table that is held within the PE. Any PA in the Non-secure memory map can be a member of one LORegion. If a PA is assigned to more than one LORegion, then an implementation might treat it as if it has been assigned to fewer LORegions than that have been specified. If a PA is not in the Non-secure physical memory map, then that PA cannot be a member of any LORegion. For more information, see Limited ordering regions.

FEAT_LOR provides a set of instructions with Acquire semantics for loads, and Release semantics for stores that apply in relation to the defined LORegions. The new variants of the Load-Acquire and Store-Release instructions are LoadLOAcquire and StoreLORelease. See LoadLOAcquire/StoreLORelease.

For all memory types, these instructions have the following ordering requirements:

- LoadLOAcquire has the same semantics as Load-Acquire except that the memory accesses affected lie within the same LORegion as the address of the memory access generated by the LoadLOAcquire instruction. See Load-Acquire, Load-AcquirePC, and Store-Release.
- StoreLORelease has the same semantics as Store-Release except that the memory accesses affected lie within the same LORegion as the address of the memory access generated by the StoreLORelease instruction. See Load-Acquire, Load-AcquirePC, and Store-Release.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In addition, for accesses to Memory-mapped peripherals:

- LoadLOAcquire has the same semantics as Load-Acquire except that the affected Memory effects of instructions that access the peripheral lie within the same LORegion as the address of the memory access generated by the LoadLOAcquire instruction. See Load-Acquire, Load-AcquirePC, and Store-Release.
- StoreLORelease has the same semantics as Store-Release except that the affected Memory effects of instructions that access the peripheral lie within the same LORegion as the address of the memory access generated by the StoreLORelease instruction. See Load-Acquire, Load-AcquirePC, and Store-Release.

Note

The LoadLOAcquire/StoreLORelease instructions can remove the requirement to use the explicit `DMB` instruction.

B2.6.12 Guarded Control Stack Barrier

The `GCSB` instruction is a barrier instruction that generates a GCSB event. The GCSB event applies ordering requirements between general load/store accesses and Guarded Control Stack data accesses. For more information, see Guarded Control Stack data access behaviors.

If FEAT_GCS is not implemented, this instruction executes as a `NOP`.

B2.7 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. The Arm architecture defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- Introduction to caches
- Memory hierarchy
- Application level access to functionality related to caches
- Implication of caches for the application programmer
- Prefetching into cache

B2.7.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a *tag*.
- The associated data.

Caches increase the average speed of a memory access. Caching takes account of two principles of locality:

Spatial locality

An access to one Location is likely to be followed by accesses to adjacent Locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a *cache line*. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a *cache hit*, and other accesses are called *cache misses*.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. The Arm architecture permits different cache topologies and access policies, provided they comply with the memory coherency model described in this Manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

B2.7.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an Armv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure B2-1 shows an example of such a system in an Armv8-A system that supports virtual addressing.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure B2-1 Multiple levels of cache in a memory hierarchy

Note

In this Manual, in a hierarchical memory system, Level 1 refers to the level closest to the processing element, as shown in Figure B2-1.

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches that are located at the levels closest to the main memory. Memory coherency for cache topologies can be defined using the conceptual points Point of Unification (PoU), Point of Coherency (PoC), Point of Persistence (PoP), and Point of Deep Persistence (PoDP).

For more information, including the definitions of PoU, PoC, PoP, and PoDP, see About cache maintenance in AArch64 state.

If FEAT_MTE2 is implemented, the behavior of cache maintenance instructions is modified. For more information, see Allocation Tags.

B2.7.2.1 The cacheability and shareability memory attributes

Cacheability and shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

Cacheability This attribute defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.

Shareability This attribute defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about Cacheability and Shareability, see Memory types and attributes.

B2.7.3 Application level access to functionality related to caches

As indicated in About the Application level programmers' model, the application level corresponds to execution at EL0. The architecture defines a set of cache maintenance instructions that software can use to manage cache coherency. Software executing at a higher Exception level can enable use of some of this functionality from EL0, as follows:

When the value of SCTLR_EL1.UCI is 1

Software executing at EL0 can access:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The data cache maintenance instructions, `DC CVAU`, `DC CVAC`, `DC CVAP`, `DC CVADP`, and `DC CIVAC`. See The data cache maintenance instruction (DC).
- The instruction cache maintenance instruction `IC IVAU`. See The instruction cache maintenance instruction (IC).

Attempted execution of these instructions might generate a Permission fault as described in Permission fault.

When the value of SCTLR_EL1.UCT is 1

Software executing at EL0 can access the cache type register. See CTR_EL0.

When the value of SCTLR_EL1.DZE is 1

Software executing at EL0 can access the data cache zero instruction `DC ZVA`. See Data cache zero instruction.

The SCTLR_EL1.{UCI, UCT, DZE} control fields are accessible only by software executing at EL1 or higher.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the controls {UCI, UCT and DZE} are found in SCTLR_EL2.

This functionality is UNDEFINED at EL0 when the value of the corresponding SCTLR_EL1 control field is 0.

B2.7.4 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

B2.7.4.1 Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  - Using Non-cacheable or Write-Through memory.
  - Not enabling caches in the system.
- By using cache maintenance instructions to manage the coherency issues in software. See Application level access to functionality related to caches.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see Non-shareable Normal memory and Shareable, Inner Shareable, and Outer Shareable Normal memory.

Note

The performance of these hardware coherency mechanisms is highly IMPLEMENTATION SPECIFIC. In some implementations, the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Not all these mechanisms are directly available to software operating at EL0 and might involve interaction with software operating at a higher Exception level.

B2.7.4.2 Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last Context Synchronization event on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being refetched from memory. In the absence of a Context Synchronization event, there is no limit on the number of times such an instruction might be executed without being refetched from memory.

The behaviors for coherency between memory and instruction fetches is discoverable from the CTR_EL0.{IDC, DIC} bits. A write has been made coherent with an instruction fetch of a shareability domain when:

CTR_EL0.{DIC, IDC} == {0, 0} The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {0, 1} The write is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {1, 1} The write is complete for the shareability domain.

Note

Microarchitecturally, this means that these situations cannot both be true in an implementation:

- After delays in fetching from memory, the instruction queue can have entries written into it out of order.
- For an implementation:
  - When CTR_EL0.DIC == 0, if there is an outstanding entry in the instruction queue, then later entries in the instruction queue are not impacted by the IC IVAU instructions of a different core.
  - When CTR_EL0.DIC == 1, if there is a write to the location that is held in the queue when there is an outstanding entry in the instruction queue for an older entry, then the instruction queue does not have entries invalidated from it.

The full definition of the ordering implications of CTR_EL0.{DIC, IDC} is covered formally in the Ordering requirements defined by the formal concurrency model and the information in this section is not intended to contradict that section.

B2.7.5 Prefetching into cache

The Arm architecture provides memory system hints `PRFM`, `PRFUM`, `RPRFM`, `LDNP`, and `STNP` that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring the data or instruction locations into caches.

The Prefetch instructions are hints, and so implementations can treat them as `NOP`s without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous External abort, which is taken using an SError exception. For more information, see ISS encoding for an exception from a Data Abort.

`PrefetchHint {}` defines the prefetch hint types.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The `Hint_Prefetch()` function signals to the memory system that memory accesses of the type `hint` to or from the specified `address` are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as prefetching the specified address into one or more caches as indicated by the innermost cache level `target` and non-temporal hint `stream`.

For more information on `PRFM`, `PRFUM`, `RPRFM`, and load/store instructions that provide hints to the memory system, see Prefetch memory and Load/store SIMD and floating-point non-temporal pair. For more information on `SVE PRF*` instructions that provide hints to the memory system, see Predicated non-contiguous element accesses.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B2.8 Alignment support

This section describes alignment support. It contains the following subsections:

- Instruction alignment
- Alignment of data accesses

B2.8.1 Instruction alignment

A64 instructions must be word-aligned.

Attempting to fetch an instruction from a misaligned location results in a PC alignment fault. See PC alignment checking.

B2.8.2 Alignment of data accesses

When instructions that load or store single or multiple registers are executed, if the value of SCTLR_ELx.A applicable to the current Exception level is 1, an Alignment fault is generated if any of the following apply:

- For Load-Exclusive, Store-Exclusive, and Atomic instructions, the address that is accessed is not aligned to the overall access size.
- For all other instructions, the address that is accessed is not aligned to the size of the data element being accessed.

If FEAT_LSE2 is implemented, Load-Acquire/Store-Release instructions without exclusive or atomic behavior generate an Alignment fault if all of the following apply:

- Not all bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes.
- The value of SCTLR_ELx.nAA applicable to the current Exception level is 0.

For an unaligned access to any type of Device memory:

- If the memory location cannot support unaligned accesses then an Alignment fault is generated.
- If the memory location supports unaligned accesses, then it is IMPLEMENTATION DEFINED whether the access generates an Alignment fault if the location would not generate an Alignment fault if the same access were made to Normal memory.

B2.8.2.1 Unaligned accesses to Normal memory

The behavior of unaligned accesses to Normal memory is dependent on all of the following:

- The instruction causing the memory access.
- The memory attributes of the accessed memory.
- The value of SCTLR_ELx.{A, nAA}.
- Whether or not FEAT_LSE2 is implemented.

B2.8.2.1.1 Load or Store of Single or Multiple registers

For all instructions that load or store single or multiple registers, but not Load-Exclusive, Store-Exclusive, Load-Acquire/Store-Release, Atomic, and `SETG*` Memory Copy and Memory Set instructions, if the address that is accessed is not aligned to the size of the data element being accessed, then:

When the value of SCTLR_ELx.A applicable to the current Exception level is 1, an Alignment fault is generated.

When the value of SCTLR_ELx.A applicable to the current Exception level is 0:

- An unaligned access is performed.
- If FEAT_LSE2 is not implemented, the access is not guaranteed to be single-copy atomic except at the byte access level.
- If FEAT_LSE2 is implemented:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, the memory access is single-copy atomic. For `LDNP`, `LDP`, or `STP` instructions, the entire memory access will be single-copy atomic.

— If all the bytes of the memory accessed do not lie within a 16-byte quantity aligned to 16 bytes, or the access is not to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, the access is not guaranteed to be single-copy atomic except at the byte access level.

For these instructions, the definition of an unaligned access is based on the size of the accessed elements, not the overall size of the memory access. This affects SIMD and SVE element and structure loads and stores, and also load/store pair instructions.

For predicated SVE vector element and structure load or store instructions, alignment checks are based on the memory element access size, not on the vector element size.

For predicated SVE vector element and structure load or store instructions, *Inactive elements* cannot cause an Alignment fault.

For unpredicated SVE vector register load or store instructions, the base address is checked for 16-byte alignment.

For unpredicated SVE predicate register load or store instructions, the base address is checked for 2-byte alignment.

B2.8.2.1.2 Load-Exclusive/ Store-Exclusive and Atomic instructions

If FEAT_LSE2 is not implemented and the value of SCTLR_ELx.A applicable to the current Exception level is 0, Load-Exclusive/Store-Exclusive and Atomic instructions, including those with acquire or release semantics, generate an alignment fault when the address being accessed is not aligned to the overall size of the access.

If FEAT_LSE2 is implemented, then:

- If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, an unaligned access is performed.
- If all the bytes of the memory access do not lie within a 16-byte quantity aligned to 16-bytes, or the memory access is not to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, then it is a CONSTRAINED UNPREDICTABLE choice of either of the following:
  — An unaligned access is performed meeting all of the semantics of the instruction.
  — An Alignment fault is generated.

Where memory access is performed, then it is single-copy atomic.

For these instructions, the definition of an unaligned access is based on the overall access size.

If FEAT_LS64 is implemented, when a single-copy atomic 64-byte instruction accesses a memory location that is not aligned to 64 bytes, an Alignment fault always occurs, regardless of the value of SCTLR_ELx.A.

If FEAT_THE is implemented, Read-Check-Write instructions, `RCW`, and Read-Check-Write Software instructions, `RCWS`, generate an Alignment fault if the address being accessed is not aligned to the overall access size regardless of the value of SCTLR_ELx.A.

B2.8.2.1.3 Non-atomic Load-Acquire/Store-Release instructions

For Load-Acquire/Store-Release instructions that do not have exclusive or atomic behaviors, when the address being accessed is not aligned to the size of the data element being accessed and the value of SCTLR_ELx.A applicable to the current Exception level is 0:

If FEAT_LSE2 is not implemented, then these instructions generate an Alignment fault.

If FEAT_LSE2 is implemented, then:

- If the memory access is not to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, then it is a CONSTRAINED UNPREDICTABLE choice of either of the following:
  — An unaligned access is performed which is not guaranteed to be single-copy atomic except at the byte access level.
  — An Alignment fault is generated.
- If all of the bytes of the memory access do not lie within a 16-byte quantity aligned to 16 bytes and SCTLR_ELx.nAA applicable to the current Exception level is 1, then an unaligned access is performed which is not guaranteed to be single-copy atomic except at the byte access level.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In this case, when an access is performed it meets all the semantics of the instruction, but the architecture does not define the order of the different transactions of the access defined by the single instructions relative to each other.

- If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, an unaligned access meeting all the semantics of the instruction is performed.

Note

- Unaligned accesses typically take additional cycles to complete compared to a naturally-aligned access.
- An operation that is not single-copy atomic above the byte level can abort on any memory access that it makes and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the page boundary.

B2.8.2.1.4 Memory Copy and Memory Set instructions

For `SETG*` instructions:

- There is an alignment check regardless of the value of SCTLR_ELx.A.
- If Xn is not a multiple of 16, an Alignment fault is generated.
- If Xd is not aligned to a multiple of 16, an Alignment fault is generated.

For more information, see the individual `SETG*` instruction descriptions.

Non-Confidential

B2.9 Endian support

General description of endianness in the Arm architecture describes the relationship between endianness and memory addressing in the Arm architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- Instruction endianness.
- Data endianness.
- Endianness of memory-mapped peripherals.

B2.9.1 General description of endianness in the Arm architecture

This section describes only memory addressing and the effects of endianness for data elements up to quadwords of 128 bits. However, this description can be extended to apply to larger data elements.

For an address A, Figure B2-2 shows, for big-endian and little-endian memory systems, the relationship between:

- The quadword at address A.
- The doubleword at address A and A+8.
- The words at addresses A, A+4, A+8, and A+12.
- The halfwords at addresses A, A+2, A+4, A+6, A+8, A+10, A+12, and A+14.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, A+7, A+8, A+9, A+10, A+11, A+12, A+13, A+14, and A+15.

The terms in Figure B2-2 have the following definitions:

B_A Byte at address A.

HW_A Halfword at address A.

MSByte Most significant byte.

LSByte Least significant byte.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure B2-2 Endianness relationships

The big-endian and little-endian mapping schemes determine the order in which the bytes of a quadword, doubleword, word, or halfword are interpreted. For example, a load of a word from address `0x1000` always results in an access to the bytes at memory locations `0x1000`, `0x1001`, `0x1002`, and `0x1003`. The endianness mapping scheme determines the significance of these 4 bytes.

B2.9.2 Instruction endianness

A64 instructions have a fixed length of 32 bits and are always little-endian.

B2.9.3 Data endianness

SCTLR_EL1.E0E, configurable at EL1 or higher, determines the data endianness for execution at EL0. When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the control is from SCTLR_EL2.E0E.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for SIMD element and data structure loads and stores. For more information, see Endianness in SIMD operations.

Note

This means the Armv8 architecture introduces a requirement for 128-bit endian conversions.

B2.9.3.1 Instructions to reverse bytes in a general-purpose register, a SIMD and floating-point register, or an SVE scalable vector register

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table B2-1 shows the instructions that provide this functionality:

Table B2-1 Byte reversal instructions

Function	Instructions	Notes
Reverse bytes in 32-bit word or words[a]	REV32	For use with general-purpose registers
Reverse bytes in whole register	REV	For use with general-purpose registers
Reverse bytes in 16-bit halfwords	REV16	For use with general-purpose registers
Reverse elements in doublewords, vector	REV64	For use with SIMD and floating-point registers
Reverse elements in words, vector	REV32	For use with SIMD and floating-point registers
Reverse elements in halfwords, vector	REV16	For use with SIMD and floating-point registers
Reverse bytes/halfwords/words within elements, predicated	REVB, REVH, REVW	For use with SVE scalable vector registers

a. Can operate on multiple words.

B2.9.3.2 Endianness in SIMD operations

SIMD element load/store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used to load and store data correctly in both big-endian and little-endian systems.

For example:

```
LD1 {V0.4H}, [X1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure B2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

Figure B2-3 SIMD byte order example

The `BigEndian()` pseudocode function determines the current endianness of the data.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The `BigEndianReverse()` pseudocode function reverses the endianness of a bitstring.

The `BigEndian()` and `BigEndianReverse()` functions are defined in A-profile Architecture Pseudocode.

B2.9.3.3 Endianness in SVE operations

R_{VDGQK} Rules on byte and element order of SIMD load and store instructions apply to SVE load and store instructions.

I_{RFQJP} Additional rules apply to the data endianness of memory accesses performed by SVE load and store instructions.

R_{CNKCL} For predicated SVE vector element and structure load and store instructions, an endianness conversion is performed using the memory element access size. The size of the vector element is not used in endianness conversion.

R_{QHXPL} For unpredicated SVE vector register load and store instructions, the vector byte elements are transferred in increasing element number order without any endianness conversion.

R_{RWLXY} For unpredicated SVE predicate register load and store instructions, each 8 bits from the predicate are transferred as a byte in increasing element number order without any endianness conversion.

R_{YGSBQ} When an SVE load instruction is executed, endianness conversion occurs before any sign-extension or zero-extension into a vector element.

R_{KYRQW} When an SVE store instruction is executed, endianness conversion occurs after any truncation from the vector element to the memory element access size.

B2.9.4 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the Arm architecture must be little-endian.

Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a Cross Trigger Interface, see About the External Debug Registers.
- The memory-mapped register interface to the system level implementation of the Generic Timer, see System Level Implementation of the Generic Timer.
- A memory-mapped register interface to the Performance Monitors, see Recommended External Interface to the Performance Monitors.
- A memory-mapped register interface to the Activity Monitors, see Recommended External Interface to the Activity Monitors.
- A memory-mapped register interface to the Memory System Resource Partitioning and Monitoring architecture (MPAM), see the *Arm® Memory System Resource Partitioning and Monitoring (MPAM) System Component Specification (ARM IHI 0099).*
- Memory-mapped register interfaces to an Arm Generic Interface Controller, see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3 and version 4.*
- The memory-mapped register interface to an Arm trace component. See, for example, the *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4.*

B2.10 Memory types and attributes

The ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- Normal memory
- Device memory
- Memory access restrictions

B2.10.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform Speculative data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- An Explicit Memory Write Effect to a memory location with the Normal attribute completes in finite time.
- Explicit Memory Write Effects to a memory location with the Normal memory type that is either Non-cacheable or Write-Through cacheable for both the Inner and Outer Cacheability must reach the endpoint for that location in the memory system in finite time. Two writes to the same location, where at least one is using the Normal memory type, might be merged before they reach the endpoint unless there is an ordered-before relationship between the two writes. For the purposes of this requirement, the endpoint for a location in Conventional memory is the PoC.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register load/store instructions. See Multi-register loads and stores that access Normal memory.
- Where a load or store instruction performs a sequence of memory accesses, as opposed to one single-copy atomic access as defined in the rules for single-copy atomicity, these accesses might occur multiple times as a result of executing the load or store instruction.

Note

Write speculation that is visible to other observers is prohibited for all memory types.

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.
- Normal memory allows speculative reads and may be affected by intermediate buffering and forwarding of data. If non-idempotent memory locations are mapped as Normal memory, the following may occur:
  - Memory accesses return UNKNOWN values.
  - UNPREDICTABLE effects on memory-mapped peripherals.
- An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For accesses to Normal memory, a `DMB` instruction is required to ensure the required ordering.

The following sections describe the other attributes for Normal memory:

- Shareable Normal memory.
- Non-shareable Normal memory.
- Cacheability attributes for Normal memory.

See also:

- Multi-register loads and stores that access Normal memory.
- Atomicity in the Arm architecture.
- Memory barriers.
- Concurrent modification and execution of instructions.

B2.10.1.1 Shareable Normal memory

A Normal memory location has a Shareability attribute that is one of:

- Inner Shareable, meaning it applies across the Inner Shareable shareability domain.
- Outer Shareable, meaning it applies across both the Inner Shareable and the Outer Shareable shareability domains.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, which hardware must enforce. They do not affect the coherency requirements of instruction fetches, see Synchronization and coherency issues between data and instruction accesses.

Note

- System designers can use the shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different processing elements.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

B2.10.1.1.1 Shareable, Inner Shareable, and Outer Shareable Normal memory

The Arm architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is a member of only a single Inner Shareability domain.
- Each observer is a member of only a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
- The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The details of the use of the shareability attributes are system-specific. Example B2-1 shows how they might be used.

Example B2-1 Use of shareability attributes

In an example implementation, a particular subsystem with two clusters of PEs has the system requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, and is therefore running an independent operating system or hypervisor, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable shareability domain.

For shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

B2.10.1.2 Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

B2.10.1.3 Cacheability attributes for Normal memory

Each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Back Cacheable.
- Write-Through.
- Non-cacheable.

Also, for Write-Back Cacheable and Write-Through Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

For more information, see Cacheability, cache allocation hints, and cache transient hints.

A memory location can be marked as having different cacheability attributes, for example when using aliases in a VA to PA mapping:

- If the attributes differ only in the cache allocation hint, this does not affect the behavior of accesses to that location.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For other cases, see Mismatched memory attributes.

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the shareability domain of a region of memory. In some cases, the use of Write-Through or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through memory:

- A completed write to a memory location that is Non-cacheable or Write-Through for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.
- A completed write to a memory location that is Non-cacheable or Write-Through for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.
- For accesses to Normal memory that is Non-cacheable or Write-Through, a `DMB` instruction introduces a Barrier-ordered-before relation on all accesses to a single peripheral or block of memory that is of IMPLEMENTATION DEFINED size. For more information, see Ordering relations.

Note

Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the Arm architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the *inner* and the *outer* cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner Cacheability attributes can lie outside a cache that is controlled by the Outer Cacheability attributes.
- An implementation might not have any outer cache.

Example B2-2, Example B2-3, and Example B2-4 describe the possible ways of implementing a system with three levels of cache, *level 1* (L1) to *level 3* (L3).

Note

- L1 cache is the level closest to the PE, see Memory hierarchy.
- When managing coherency, system designs must consider both the Inner and Outer Cacheability attributes, as well as the shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example B2-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner Cacheability attribute applied to L1 and L2 cache.
- The Outer Cacheability attribute applied to L3 cache.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example B2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner Cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer Cacheability attribute.

Example B2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner Cacheability attribute applied to L1 cache.
- The Outer Cacheability attribute applied to L2 and L3 cache.

B2.10.1.4 Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store one or more SVE or Advanced SIMD&FP registers from an Exception level, there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

B2.10.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for Armv8 Device memory are:

Gathering Identified as G or nG, see Gathering.

Reordering Identified as R or nR, see Reordering.

Early Write Acknowledgement

Identified as E or nE, see Early Write Acknowledgement.

The Armv8 Device memory types are:

Device-nGnRnE Device non-Gathering, non-Reordering, No Early Write Acknowledgement.

Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.

Device-nGnRE Device non-Gathering, non-Reordering, Early Write Acknowledgement.

Equivalent to the Device memory type in earlier versions of the architecture.

Device-nGRE Device non-Gathering, Reordering, Early Write Acknowledgement.

Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.

Device-GRE Device Gathering, Reordering, Early Write Acknowledgement.

Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that Speculative accesses to Device-GRE memory is forbidden.

Collectively these are referred to as *any Device memory type*. Going down the list, the memory types are described as getting *weaker*; conversely the going up the list the memory types are described as getting *stronger*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.
- The architecture does not require an implementation to distinguish between each of these memory types and Arm recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

  The following exceptions to this apply:
  - Reads generated by the SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.
  - For reads, including hardware speculation, that are performed by an SVE unpredicated load instruction, all of the following are true:
    - For any 64-byte window aligned to 64 bytes containing at least 1 byte that is explicitly accessed by the instruction, any byte in the window can be accessed by the instruction.
    - All bytes accessed by the instruction will be in a 64-byte window aligned to 64 bytes containing at least 1 byte that is explicitly accessed by the instruction.
  - For reads, including hardware speculation, that are performed by an SVE predicated load instruction that is not a non-temporal load, all of the following are true:
    - For any 64-byte window aligned to 64 bytes containing at least 1 byte that is explicitly accessed by an *Active element* of the instruction, any byte in the window can be accessed by the instruction.
    - All bytes accessed by the instruction will be in a 64-byte window aligned to 64 bytes that contains at least 1 byte that is explicitly accessed by an *Active element* of the instruction.
  - For reads, including hardware speculation, that are performed by an SVE predicated non-temporal load instruction from memory locations with the Gathering attributes, all of the following are true:
    - For any 128-byte window aligned to 128 bytes containing at least 1 byte that is explicitly accessed by an *Active element* of the instruction, any byte in the window can be accessed by the instruction.
    - All bytes accessed by the instruction are in a 128-byte window aligned to 128 bytes that contains at least 1 byte that is explicitly accessed by an *Active element* of the instruction.
  - The architecture permits a Memory Copy and Memory Set `CPY*` instruction to perform speculative reads of any memory location, even those marked as Device, within a 64-byte quantity, aligned to 64 bytes, of a location that is within the range [Xs] to [Xs+Xn-1].
  - For Device memory with the Gathering attribute, reads generated by the `LDNP` instructions are permitted to access bytes that are not explicitly accessed by the instruction, provided that the bytes accessed are in a 128-byte window, aligned to 128-bytes, that contains at least one byte that is explicitly accessed by the instruction.
  - Where a load or store instruction performs a sequence of memory accesses, as opposed to one single-copy atomic access as defined in the rules for single-copy atomicity, these accesses might occur multiple times as a result of executing the load or store instruction. See Properties of single-copy atomic accesses.
  - An LDRAA or LDRAB instruction that fails the pointer authentication check and loads from a location in Device memory is permitted to cause one read access to that location if all of the other requirements for accessing that Device location are met.

  Note

  - An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception, the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program defines only a single access. For this reason, Arm strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.
  - Write speculation that is visible to other observers is prohibited for all memory types.

- An Explicit Memory Write Effect to a memory location with any Device memory type completes in finite time.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If a value that would be returned from a read of a memory location with the Device memory type changes without an explicit Memory Write effect by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.
- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.
- A memory location with any Device memory attribute cannot be allocated into a cache.
- Explicit Memory Write Effects to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Two Explicit Memory Write Effects of Device memory type to the same location might be merged before they reach the endpoint, unless both Explicit Memory Write Effects have the non-Gathering attribute or there is an ordered-before relationship between the two Explicit Memory Write Effects.
- For accesses to any Device memory type, a `DMB` instruction introduces a Barrier-ordered-before relation on all accesses to a single peripheral or block of memory that is of IMPLEMENTATION DEFINED size. For more information, see Ordering relations.
- If a memory location is not capable of supporting unaligned memory accesses, then an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.
- If a memory location is capable of supporting unaligned memory accesses, and such a memory location is marked as Device, then it is IMPLEMENTATION DEFINED whether an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.
- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as execute-never for all Exception levels.

  Note

  This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as execute-never for all Exception levels is a programming error.

Note

In the EL1&0 translation regime in systems where HCR_EL2.TGE == 1 and HCR_EL2.DC == 0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes ESR_EL2.ISS[24] to be 0.

See also Memory access restrictions.

The memory types for translation table walks cannot be defined as any Device memory type within the TCR_ELx. For the EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the HCR_EL2.PTW bit is 1, a stage 2 Permission fault is generated if a first stage translation table walk is made to any Device memory type.

Note

In general, making a translation table walk to any Device memory type is the result of a programming error.

For an instruction fetch from a memory location with the Device attribute that is not marked as execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

B2.10.2.1 Gathering

In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

Note

This also applies to writebacks from the cache, whether caused by a Natural eviction or as a result of a cache maintenance instruction.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All accesses occur at their single-copy atomic sizes, except that there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by multi-register load/store instructions that generate more than one single-copy atomic access. See Multi-register loads and stores that access Device memory.

Gathering between two accesses, where one access is barrier-ordered-before the other access, is not permitted.

Gathering between memory accesses generated by Memory Copy and Memory Set instructions is always permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

Note

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  - The accesses are not separated by a `DMB` or `DSB` barrier that affects both of the accesses.
  - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
  - The accesses are not generated by a Store-Release instruction.
- The Arm architecture defines only programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the non-Gathering attribute.

An implementation is not permitted to perform an access with the non-Gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

B2.10.2.2 Reordering

In the Device memory attribute:

R Indicates that the location has the Reordering attribute. Accesses to the location can be reordered within the same rules that apply to accesses to Normal Non-cacheable memory. All memory types with the Reordering attribute have the same ordering rules as accesses to Normal Non-cacheable memory, see Ordering relations.

nR Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Some interconnect fabrics, such as PCIe, perform very limited reordering, which is not important for the software usage. It is outside the scope of the Arm architecture to prohibit the use of a non-Reordering memory type with these interconnects.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the `DMB` instruction.
- The Arm architecture defines only programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.
- The non-Reordering property is only required by the architecture to apply the order of arrival of accesses to a single memory-mapped peripheral of an IMPLEMENTATION DEFINED size, and is not required to have an impact on the order of observation of memory accesses to SDRAM. For this reason, there is no effect of the non-Reordering attribute on the ordering relations between accesses to different locations described in Ordering relations as part of the formal definition of the memory model. It does have an effect on the Peripheral arrival order described in Peripheral arrival order.
- If the same memory location is mapped with different aliases, and different attribute values, these are a type of mismatched attribute. The different attributes could be:
  - A different Reordering attribute value.
  - A different Device memory attribute value.
  - When FEAT_XS is implemented, a different XS attribute value.

For information about the effects of accessing memory with mismatched attributes, see Mismatched memory attributes.

An implementation:

- Is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.
- Is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses to one physical address with the non-Reordering attribute and accesses to a different physical address with the Reordering attribute.
- Access to one physical address with the non-Reordering attribute and access to a different physical address to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

The non-Reordering attribute has no effect on the ordering of cache maintenance instructions, even if the memory location specified in the instruction has the non-Reordering attribute.

The non-Reordering attribute has no effect on the memory accesses caused by Memory Copy and Memory Set instructions.

B2.10.2.3 Early Write Acknowledgement

In the Device memory attribute:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E Indicates that the location has the Early Write Acknowledgement attribute.

nE Indicates that the location has the No Early Write Acknowledgement attribute.

If the No Early Write Acknowledgement attribute is assigned for a Device memory location:

- For memory system endpoints where the system architecture in which the PE is operating requires that acknowledgment of a write comes from the endpoint, it is guaranteed that:
  - Only the endpoint of the write access returns a write acknowledgment of the access.
  - No earlier point in the memory system returns a write acknowledgment.
- For memory system endpoints where the system architecture in which the PE is operating does not require that acknowledgment of a write comes from the endpoint, the acknowledgment of a write is not required to come from the endpoint.

Note

A write with the No Early Write Acknowledgement attribute assigned for a Device memory location is not expected to generate an abort in any situation where the equivalent write to the same location without the No Early Write Acknowledgement attribute assigned does not generate an abort.

This means that a `DSB` barrier instruction, executed by the PE that performed the write to the No Early Write Acknowledgement Location, completes only after the write has reached its endpoint in the memory system if that is required by the system architecture.

Peripherals are an example of system endpoints that require that the acknowledgment of a write comes from the endpoint.

Note

- The Early Write Acknowledgement attribute only affects where the endpoint acknowledgment is returned from, and does not affect the ordering of arrival at the endpoint between accesses, which is determined by either the Device Reordering attribute, or the use of barriers to create order.
- The areas of the physical memory map for which write acknowledgment from the endpoint is required is outside the scope of the Arm Architecture definition and must be defined as part of the system architecture in which the PE is operating. In particular, regions of memory handled as PCIe configuration writes are expected to support write acknowledgment from the endpoint.
- Arm recognizes that not all areas of a physical memory map will be capable of supporting write acknowledgment from the endpoint. In particular, Arm expects that regions of memory handled as posted writes under PCIe will not support write acknowledgment from the endpoint.
- For maximum software compatibility, Arm strongly recommends that all peripherals for which standard software drivers expect that the use of a `DSB` instruction will determine that a write has reached its endpoint are placed in areas of the physical memory map that support write acknowledgment from the endpoint.

B2.10.2.4 Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register and generate more than one single-copy atomic access for that load or store, there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by these load or store instructions.

For all instructions that load or store one or more Advanced SIMD&FP or SVE registers, and generate more than one single-copy atomic access for that load or store, there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by these load or store instructions, even for access to any type of Device memory.

The architecture permits that the non-speculative execution of an instruction that loads or stores more than one general-purpose or SIMD and floating-point register might result in repeated accesses to the same address, even if the resulting accesses are to any type of Device memory.

B2.10.2.5 SVE loads and stores that access Device memory

RXLLJZ All rules applying to Device memory accesses by Advanced SIMD and floating-point load and store instructions apply to Device memory access by SVE load and store instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{YHWJT} Additional rules apply to Device memory access by SVE load and store instructions.

R_{NYMWH} When an SVE vector prefetch instruction is executed, any resulting Read Memory is guaranteed not to access Device memory.

R_{SBHLD} When an SVE Non-fault vector load is executed, or when any element from a First-fault load except the *First active element* attempts to access Device memory, the resulting Read Memory will not access Device memory.

R_{TMVNR} When an SVE Non-fault vector load instruction is executed, an attempt by any *Active element* to access Device memory behaves as follows:

- If the location is in Conventional memory, it is IMPLEMENTATION DEFINED whether it is suppressed and reported in the FFR.
- Otherwise, it is suppressed and reported in the FFR.

R_{SFBKQ} When an SVE First-fault vector load instruction is executed, any Read Memory performed for the *First active element* can access Device memory.

R_{BHNQN} When an SVE First-fault vector load instruction is executed, an attempt by any *Active element* other than the *First active element* to access Device memory behaves as follows:

- If the location is in Conventional memory, it is IMPLEMENTATION DEFINED whether it is suppressed and reported in the FFR.
- Otherwise, it is suppressed and reported in the FFR.

R_{QBLMZ} Any access to Device memory performed by an SVE load or store instruction is relaxed such that it might behave as if:

- The memory has the Gathering attribute, regardless of the configured value of the nG attribute.
- The memory has the Reordering attribute, regardless of the configured value of the nR attribute.
- The memory has the Early Acknowledgment attribute, regardless of the configured value of the nE attribute.

Whether attributes are classified as mismatched is determined strictly by the memory attributes derived from the translation table entry.

B2.10.2.6 Streaming SVE mode loads and stores that access Device memory

R_{XHFBX} When the PE is in *Streaming SVE mode* and FEAT_SME_FA64 is not implemented or not enabled at the current Exception level, any access to Device memory performed by an Advanced SIMD&FP load/store instruction is relaxed such that it might behave as if:

- The Gathering attribute is 1, regardless of the configured value of the nG attribute.
- The Reordering attribute is 1, regardless of the configured value of the nR attribute.
- The Early Acknowledgement attribute is 1, regardless of the configured value of the nE attribute.

Whether attributes are classified as mismatched is determined strictly by the memory attributes derived from the translation table entry.

See also:

- Streaming SVE mode.

B2.10.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For two explicit Memory Read effects to any two adjacent bytes in memory, *p* and *p+1*, generated by the same instruction, and for two explicit Memory Write effects to any two adjacent bytes in memory, *p* and *p+1*, that are generated by the same instruction:
  - The bytes *p* and *p+1* must have the same memory type and Shareability attributes, otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an `LD1`, `ST1`, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
  - Except for possible differences in the cache allocation hints, Arm deprecates having different cacheability attributes for bytes *p* and *p+1*.

  For the permitted CONSTRAINED UNPREDICTABLE behavior, see Crossing a page boundary with different memory types or Shareability attributes.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the accesses of an instruction that causes multiple accesses to any type of Device memory cross an address boundary that corresponds to the smallest implemented translation granule, then behavior is CONSTRAINED UNPREDICTABLE, and Crossing a peripheral boundary with a Device access describes the permitted behaviors. For this reason, it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.

  Note

  — The boundary referred to is between two Device memory regions that are both of the size of the smallest implemented translation granule and aligned to the size of the smallest implemented translation granule.

  — This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.

  — Arm expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.

Non-Confidential

B2.11 Mismatched memory attributes

Memory attributes are controlled by privileged software. For more information, see The AArch64 Virtual Memory System Architecture.

Physical memory locations are accessed with *mismatched attributes* if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type: Device-nGnRnE, Device-nGnRE, Device-nGRE, Device-GRE or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.
- When FEAT_XS is implemented, XS attribute.

Collectively these are referred to as memory attributes.

If FEAT_MTE2 is implemented, accesses to a location which use a common definition of the memory attributes but the Tagged attribute of that location differs do not cause a mismatched access to occur.

If FEAT_MTE_PERM is implemented, the NoTagAccess attribute does not factor into the determination of mismatched attributes.

Note

In this document, the terms *location* and *memory location* refer to any byte within the current coherency granule and are used interchangeably.

When a memory Location is accessed with mismatched attributes, the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory Location might be lost. This means:
  - A read of the memory Location by one agent might not return the value most recently written to that memory Location by the same agent.
  - Multiple writes to the memory Location by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory Location.
- There might be a loss of properties derived from the memory type, as described in later bullets in this section.
- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory Location do not use consistent memory attributes, the Exclusives monitor state becomes UNKNOWN.
- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of Speculative read accesses.
- Prohibition on Gathering.
- Prohibition on reordering.

For the following situations, when a physical memory Location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. Any agent that reads that memory Location using the same common definition of the Memory type, Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:
   - All writes are performed to an alias of the memory Location that uses the same definition of the Memory type, Shareability and Cacheability attributes.
   - Either:
     - All writes are performed to an alias of the memory Location that has Inner Cacheability and Outer Cacheability attributes both as Non-cacheable or Write-Through.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— All aliases to a memory Location use a definition of the Shareability attributes that encompasses all the agents with permission to access the Location.

2. The possible software-visible effects caused by mismatched attributes for a memory Location are defined more precisely if all of the mismatched attributes define the memory Location as one of:
   - Any Device memory type.
   - Any Normal, Inner Non-cacheable or Write-Through, Outer Non-cacheable or Write-Through memory.

   In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:
   - Possible loss of properties derived from the memory type when multiple agents attempt to access the memory Location.
   - Possible reordering of memory transactions to the same memory Location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting `DMB` barrier instructions between accesses to the same memory Location that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory location all assign the same shareability attribute to a Location that has a cacheable attribute, any loss of uniprocessor semantics, ordering, or coherency within a shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable Locations between agents in different shareability domains. This means:
   - Before writing to a cacheable Location not using the Write-Back attribute, software must invalidate, or clean, a Location from the caches if any agent might have written to the Location with the Write-Back attribute. This avoids the possibility of overwriting the Location with stale data.
   - After writing to a cacheable Location with the Write-Back attribute, software must clean the Location from the caches, to make the write visible to external memory. A cache writeback caused by this cache maintenance must preserve the single-copy atomicity of the write, as described in Requirements for single-copy atomicity.
   - Before reading the Location with a cacheable attribute, software must invalidate, or clean and invalidate, the Location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.
   - Executing a `DMB` barrier instruction between any accesses to the same cacheable Location that use different attributes.

   In all cases:
   - Location refers to any byte within the current coherency granule.
   - A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
   - In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see Ordering and completion of data and instruction cache instructions.

   Note

   With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same Location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

2. If the mismatched attributes for a Location mean that multiple cacheable accesses to the Location might be made with different shareability attributes, then uniprocessor semantics, ordering, and coherency are guaranteed only if:
   - Software running on a PE cleans and invalidates a Location from cache before and after each read or write to that Location by that PE.
   - A `DMB` barrier is placed between any accesses to the same memory Location that use different attributes.

   Note

   The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a Location, and the accesses from the different agents have different memory attributes associated with the Location, the Exclusives monitor state becomes UNKNOWN.

Arm strongly recommends that software does not use mismatched attributes for aliases of the same Location. An implementation might not optimize the performance of a system that uses mismatched aliases.

Note

- As described in Non-cacheable accesses and instruction caches, a non-cacheable access is permitted to be cached in an instruction cache, despite the fact that a non-cacheable access is not permitted to be cached in a unified cache.

  Despite this, when cacheable and non-cacheable aliases exist for memory which is executable, these must be treated as mismatched aliases to avoid coherency issues from the data or unified caches that might hold entries that will be brought into the instruction caches.

- Loss of single-copy atomicity behavior is not one of the possible software-visible effects caused by mismatched attributes. For more information about single-copy atomicity, see Requirements for single-copy atomicity.

B2.12 Synchronization and semaphores

Armv8 provides non-blocking synchronization of shared memory, using *synchronization primitives*. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal memory and to any type of Device memory.

Note

Use of the Armv8 synchronization primitives scales for multiprocessing system designs.

Table B2-2 shows the synchronization primitives and the associated `CLREX` instruction.

Table B2-2 Synchronization primitives and associated instruction, A64 instruction set

Transaction size	Additional semantics	Load-Exclusive[a]	Store-Exclusive[a]	Other[a]
Byte	-	`LDXRB`	`STXRB`	-
	Load-Acquire/Store-Release	`LDAXRB`	`STLXRB`	-
Halfword	-	`LDXRH`	`STXRH`	-
	Load-Acquire/Store-Release	`LDAXRH`	`STLXRH`	-
Register[b]	-	`LDXR`	`STXR`	-
	Load-Acquire/Store-Release	`LDAXR`	`STLXR`	-
Pair[b]	-	`LDXP`	`STXP`	-
	Load-Acquire/Store-Release	`LDAXP`	`STLXP`	-
None	Clear-Exclusive	-	-	`CLREX`

a. Instruction in the A64 instruction set.

b. A register instruction operates on a doubleword if accessing an X register, or on a word if accessing a W register A pair instruction operates on two doublewords if access X registers, or on two words if accessing W registers.

Except for the row showing the `CLREX` instruction, the two instructions in a single row are a Load-Exclusive/Store-Exclusive instruction pair. The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address *x* is:

- The Load-Exclusive instruction reads a value from memory address *x*.
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address *x* only if no other observer, process, or thread has performed a more recent store to address *x*. The Store-Exclusive instruction returns a status bit that indicates whether the Write Memory succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see Marking and the size of the marked memory block. A Store-Exclusive instruction to any address in the marked block clears the marking.

Note

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- Exclusive access instructions and Non-shareable memory locations.
- Exclusive access instructions and Shareable memory locations.
- Marking and the size of the marked memory block.
- Context switch support.
- Load-Exclusive and Store-Exclusive instruction usage restrictions.
- Use of WFE and SEV instructions by spin-locks.

Non-Confidential

B2.12.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the shareability attribute is Non-shareable, the exclusive access instructions rely on a *local Exclusives monitor*, or *local monitor*, that marks the address of the Explicit Memory Read effect generated by any Load-Exclusive instruction executed by the PE.

A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Explicit Memory Write effect of the Store-Exclusive instruction is the same as the address that has been marked in the monitor due to the execution of an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - If the store took place, the status value is 0.
  - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

When an Exclusives monitor is in the Exclusive Access state, the monitor is *set*.

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

When an Exclusives monitor is in the Open Access state, the monitor is *clear*.

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a PA that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a PA that is marked as Exclusive Access by its local monitor, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked PA causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the PA to be marked.

Figure B2-4 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: `LoadExcl` represents any Load-Exclusive instruction
`StoreExcl` represents any Store-Exclusive instruction
`Store` represents any other store instruction.

Any `LoadExcl` operation updates the marked address to the most significant bits of the address `x` used for the operation.

Figure B2-4 Local monitor state machine diagram

For more information about marking, see Marking and the size of the marked memory block.

Note

For the local monitor state machine, as shown in Figure B2-4:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any PA, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the `Store` or `StoreExcl` is from another observer.

B2.12.1.1 Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure B2-4.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure B2-4.
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure B2-4 must not indefinitely delay forward progress of execution.

B2.12.2 Exclusive access instructions and Shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.

For shareable memory locations, exclusive access instructions rely on:

- A *local monitor* for each PE in the system, which marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in Exclusive access instructions and Non-shareable memory locations,

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:

— Updating memory.

— Returning a status value of 0.

The local monitor can ignore accesses from other PEs in the system.

- A *global monitor* that marks a PA as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:

  — Can hold at least one marked block.

  — Maintains a state machine for each marked block it can hold.

  Note

  For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, see Load-Exclusive and Store-Exclusive instruction usage restrictions.

Note

The global monitor can either reside within the PE, or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this Manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

If FEAT_MTE2 is implemented, it is IMPLEMENTATION DEFINED whether explicit accesses to Allocation Tags are monitored by a global monitor. For more information, see The Memory Tagging Extension.

Note

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all Arm PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport's Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global Exclusives monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory.

The architecture only requires that Conventional memory mapped in this way supports this functionality.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive or a Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an External abort.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Data Abort Fault status code of ESR_ELx.DFSC = `110101`.

  If the IMPLEMENTATION DEFINED MMU fault is generated for the EL1&0 translation regime then:

  — If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.

  — Otherwise, the fault is a second stage fault and the exception is taken to EL2.

  The priority of this fault is IMPLEMENTATION DEFINED.
- The instruction is treated as a `NOP`.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN. In this case, if the store exclusive instruction is a store exclusive pair of 64-bit quantities, then the two quantities being stored might not be stored atomically.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by Arm PEs is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

B2.12.2.1 Operation of the global Exclusives monitor

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the PA of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other PA that has been marked by the requesting PE.

Note

The global monitor supports only a single outstanding exclusive access to shareable memory per PE.

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the PA accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:

  — A status value of 0 is returned to a register to acknowledge the successful store.

  — The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.

  — If the address accessed is marked for exclusive access in the global monitor state machine for any other PE, then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:

  — A status value of 1 is returned to a register to indicate that the store failed.

  — The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different PA is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:

  — If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.

  — If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means that it responds to:

- Accesses generated by PE(n).

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Accesses generated by the other observers in the shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

A global monitor:

- In the Exclusive Access state is *set*.
- In the Open Access state is *clear*.

B2.12.2.1.1 Clear global monitor event

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see Mechanisms for entering a low-power state.

Figure B2-5 shows the state machine for PE(n) in a global monitor.

‡`StoreExcl`(Marked_address,!n) clears the monitor only if the `StoreExcl` updates memory
Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: `LoadExcl` represents any Load-Exclusive instruction
`StoreExcl` represents any Store-Exclusive instruction
`Store` represents any other store instruction.

Any `LoadExcl` operation updates the marked address to the most significant bits of the address x used for the operation.

Figure B2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking, see Marking and the size of the marked memory block.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

For the global monitor state machine, as shown in Figure B2-5:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure B2-5 shows only how the operations by (!n) cause state transitions of the state machine for PE(n).
- A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.
- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a `CLREX` instruction causes the global monitor to transition from Exclusive Access to Open Access state.
- It is IMPLEMENTATION DEFINED:
  - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

B2.12.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size 2^a bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the *Exclusives reservation granule*. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4-512 words.

Note

This definition means that the Exclusives reservation granule is:

- 4 words in an implementation where *a* is 4.
- 512 words in an implementation where *a* is 11.

For example, in an implementation where *a* is 4, a successful `LDXRB` of address `0x341B4` defines a marked block using bits[47:4] of the address. This means that the four words of memory from `0x341B0` to `0x341BF` are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see CTR_EL0. Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

B2.12.4 Context switch support

An exception return clears the local monitor. As a result, performing a `CLREX` instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

B2.12.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a `LDXP`/`STXP` pair or a `LDXR`/`STXR` pair, executed as part of a loop that contains only a single Load-Exclusive and Store-Exclusive pair. To

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

support different implementations of these functions, software must follow the notes and restrictions given here.

The following notes describe the use of a `LoadExcl`/`StoreExcl` instruction pair, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table B2-2. In this context, a `LoadExcl`/`StoreExcl` pair comprises two instructions in the same thread of execution:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the `IsExclusiveLocal()` function. If the target VA of a `StoreExcl` is different from the VA of the preceding `LoadExcl` instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The `StoreExcl` either passes or fails, the status value returned by the `StoreExcl` is UNKNOWN, and the states of the local and global monitors for that PE are UNKNOWN.

    Note

    This means the `StoreExcl` might pass for some instances of a `LoadExcl`/`StoreExcl` pair with mismatched addresses, and fail for other instances of a `LoadExcl`/`StoreExcl` pair with mismatched addresses.

  - The data at the address accessed by the `LoadExcl`, and at the address accessed by the `StoreExcl`, is UNKNOWN.

  This means software can rely on a `LoadExcl`/`StoreExcl` pair to eventually succeed only if the `LoadExcl` and the `StoreExcl` are executed with the same VA.
- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a `StoreExcl` instruction is the same as the transaction size of the preceding `LoadExcl` instruction executed in that thread. If the transaction size of a `StoreExcl` instruction is different from the preceding `LoadExcl` instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The `StoreExcl` either passes or fails, and the status value returned by the `StoreExcl` is UNKNOWN.

    Note

    This means the `StoreExcl` might pass for some instances of a `LoadExcl`/`StoreExcl` pair with mismatched transaction sizes, and fail for other instances of a `LoadExcl`/`StoreExcl` pair with mismatched transaction sizes.

  - The block of data of the size of the larger of the transaction sizes used by the `LoadExcl`/`StoreExcl` pair at the address accessed by the `LoadExcl`/`StoreExcl` pair, is UNKNOWN.

  This means software can rely on a `LoadExcl`/`StoreExcl` pair to eventually succeed only if the `LoadExcl` and the `StoreExcl` have the same transaction size.
- An implementation of the `LoadExcl` and `StoreExcl` instructions can require that, in any thread of execution, the `StoreExcl` instruction accesses the same number of registers as the preceding `LoadExcl` instruction executed in that thread. If the `StoreExcl` instruction accesses a different number of registers than the preceding `LoadExcl` instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. As a result, software can rely on an `LoadExcl/StoreExcl` pair to eventually succeed only if they access the same number of registers. For more information, see CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers.
- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the Tag Checked property of a memory access due to a `StoreExcl` instruction is the same as the Tag Checked property of a memory access by the preceding `LoadExcl` instruction, unless FEAT_MTE_STORE_ONLY is implemented and the preceding `LoadExcl` is not Tag Checked only due to Store-only Tag Checking being enabled. If the Tag Checked property of memory accesses due to a `LoadExcl`/`StoreExcl` pair in the same thread of execution is not compatible, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The `StoreExcl` either passes or fails, and the status value returned by the `StoreExcl` is UNKNOWN.

    Note

    This means the `StoreExcl` might pass for some instances of such a `LoadExcl`/`StoreExcl` pair, and fail for other instances of such a `LoadExcl`/`StoreExcl` pair.

  - The data at the address accessed by the `LoadExcl`/`StoreExcl` pair is UNKNOWN.

  This means software can rely on a `LoadExcl`/`StoreExcl` pair to eventually succeed only if the memory is accessed with a compatible Tag Checked property.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_LSE is not implemented, `LoadExcl`/`StoreExcl` loops are guaranteed to make forward progress only if, for any `LoadExcl`/`StoreExcl` loop within a single thread of execution, the software meets all of the following conditions. If FEAT_LSE is implemented, software can maximize the likelihood that `LoadExcl`/`StoreExcl` loops make forward progress, for any `LoadExcl`/`StoreExcl` loop within a single thread of execution, by meeting all of the following conditions:

  1 Between the Load-Exclusive and the Store-Exclusive, there are no explicit memory effects, software prefetches, direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, `ISB` barriers, `WFE*` instructions, `WFI*` instructions, `YIELD` instructions, `CLREX` instructions, entry to or exit from Debug state, indirect branches, or Branch with Link instructions.

  2 Between the Store-Exclusive returning a failing result and the retry of the corresponding Load-Exclusive:

  — There are no stores or `PRFM` or `RPRFM` instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive. This includes VA aliases to those addresses.

  — There are no loads or prefetches to any address within the Exclusives reservation granule accessed by the Store-Exclusive that use a different VA alias to that address.

  — There are no other Store-Exclusive instructions to any other address.

  — There are no direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, indirect branches, or Branch with Link instructions.

  — All loads and stores are to a block of contiguous virtual memory of not more than 512 bytes in size.

  The Exclusives monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the Exclusives monitor. However, it is permissible for the `LoadExcl`/`StoreExcl` loop not to make forward progress if a different thread is repeatedly doing any of the following in a tight loop:

  — Performing stores to a PA covered by the Exclusives monitor.

  — Prefetching with intent to write to a PA covered by the Exclusives monitor.

  — Executing data cache clean, data cache invalidate, or data cache clean and invalidate instructions to a PA covered by the Exclusives monitor.

  — Executing instruction cache invalidate all instructions.

  — Executing instruction cache invalidate by VA instructions to a PA covered by the Exclusives monitor.

  — Executing TLB maintenance to a PA covered by the Exclusives monitor.

- Implementations can benefit from keeping the `LoadExcl` and `StoreExcl` operations close together in a single thread of execution. This minimizes the likelihood of the Exclusives monitor state being cleared between the `LoadExcl` instruction and the `StoreExcl` instruction. Therefore, for best performance, Arm strongly recommends a limit of 128 bytes between `LoadExcl` and `StoreExcl` instructions in a single thread of execution.

- The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, Arm recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusives reservation granule. This is a performance guideline rather than a functional requirement.

- After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN.

- For the memory location accessed by a `LoadExcl`/`StoreExcl` pair, if the memory attributes for a `StoreExcl` instruction are different from the memory attributes for the preceding `LoadExcl` instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. Where this occurs because the translation of the accessed address changes between the `LoadExcl` instruction and the `StoreExcl` instruction, the CONSTRAINED UNPREDICTABLE behavior is as follows:

  — The `StoreExcl` either passes or fails, and the status value returned by the `StoreExcl` is UNKNOWN.

  Note

  This means the `StoreExcl` might pass for some instances of a `LoadExcl`/`StoreExcl` pair with changed memory attributes, and fail for other instances of a `LoadExcl`/`StoreExcl` pair with changed memory attributes.

  — The data at the address accessed by the `StoreExcl` is UNKNOWN.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Another bullet point in this list covers the case where the memory attributes of a `LoadExcl`/`StoreExcl` pair differ as a result of using different VAs with different attributes that point to the same PA.

- The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same shareability domain as the PE executing the cache maintenance instruction, as determined by the shareability domain of the address being maintained.

  Note

  Arm strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in one Security state cannot cause a denial of service on a PE in another Security state.

- If the mapping of the VA to PA is changed between the `LoadExcl` instruction and the `StoreExcl` instruction, and the change is performed using a break-before-make sequence as described in Using break-before-make when updating translation table entries, if the `StoreExcl` is performed after another write to the same PA as the `StoreExcl`, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the `StoreExcl` will not pass its monitor check.

  Note

  Arm expects that, in many implementations, either:

  — The TLB invalidation will clear either the local or global monitor.

  — The PA will be checked between the `LoadExcl` and `StoreExcl`.

- The Exclusive Access state for an address accessed by a PE can be lost as a result of a `PRFM PST*` or `RPRFM` instruction to the same PA executed by another PE. This means that a very high rate of repeated `PRFM PST*` or `RPRFM` accesses to a memory location might impede the forward progress of another PE.
- If FEAT_MTE2 is implemented, and if a Tag Unchecked store exclusive instruction would not perform the store and return a status value of 1, it is CONSTRAINED UNPREDICTABLE whether:

  — The instruction is a Tag Checked access,

  — The instruction is an Tag Unchecked access.

  For more information, see The Memory Tagging Extension.

Note

In the event of repeatedly-contending `LoadExcl`/`StoreExcl` instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

B2.12.5.1 CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers

As stated in this section, an implementation can require that the instructions of a Load-Exclusive/Store-Exclusive pair access the same number of registers. In such an implementation, this means behavior is CONSTRAINED UNPREDICTABLE if, in a single thread of execution, either:

- An `LDXP` instruction of two 32-bit quantities is followed by an `STXR` instruction of one 64-bit quantity at the same address.
- An `LDXR` instruction of one 64-bit quantity is followed by an `STXP` instruction of two 32-bit quantities at the same address.

In these cases, the CONSTRAINED UNPREDICTABLE behavior must be one of:

- The `STXP` or `STXR` instruction generates an external Data Abort.
- The `STXP` or `STXR` instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data Abort Fault status code of ESR_ELx.DFSC = `0b110101`.
- The `STXP` or `STXR` instruction always fails, returning a status of 1.
- The `STXP` or `STXR` instruction always passes, returning a status of 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- This STXP or STXR instruction has the same pass or fail behavior that it would have had if the instruction had used the same size and number of registers as the preceding LDXR or LDXP instruction.

B2.12.6 Use of WFE and SEV instructions by spin-locks

Armv8 provides Wait For Event, Send Event, and Send Event Local instructions, WFE, SEV, and SEVL, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in Wait for Event. However, in Armv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

Note

This is equivalent to issuing an SEVL instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an SEV instruction after clearing a spinlock.

Part C

The AArch64 Instruction Set

Chapter C1
The A64 Instruction Set

This chapter describes the A64 instruction set. It contains the following sections:

- About the A64 instruction set
- Structure of the A64 assembler language
- Address generation
- Instruction aliases

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C1.1 About the A64 instruction set

The A64 instruction set is the instruction set supported in the AArch64 Execution state. All A64 instructions have a width of 32 bits.

The following chapters contain alphabetical lists of A64 instructions:

- A64 Base Instruction Descriptions lists all of:
  - Branch instructions, exception generating instructions, system instructions.
  - Load, store, and data-processing instructions associated with the general-purpose registers.
- A64 Advanced SIMD and Floating-point Instruction Descriptions lists the load, store, and data-processing instructions associated with Advanced SIMD and floating-point support.
- SVE Instruction Descriptions lists the load, store, and data-processing instructions associated with SVE support.
- SME Instruction Descriptions lists the load, store, and data-processing instructions associated with SME support.

When an instruction supports more than one syntax, each syntax is an *instruction variant*. Instruction variants can occur because of differences in:

- The size or format of the operands.
- The register file used for the operands.
- The addressing mode used for load/store memory operands.

Instruction variants might also arise as the result of other factors.

Instruction variants are described in the instruction description for the individual instructions.

A64 instruction set encoding describes the A64 encoding structure. A64 instructions have a regular bit encoding structure:

- 5-bit register operand fields at fixed positions within the instruction. For general-purpose register operands, the values 0-30 select one of 31 registers. The value 31 is used as a special case that can:
  - Indicate use of the current stack pointer, when identifying a load/store base register or in a limited set of data-processing instructions. See The stack pointer registers.
  - Indicate the value zero when used as a source register operand.
  - Indicate discarding the result when used as a destination register operand.
- For Advanced SIMD and floating-point register access and SVE scalable vector register access, a 5-bit register operand field selects one of 32 registers of the appropriate type.
- Certain Advanced SIMD, SVE, and SME instructions have a register operand field smaller than 5 bits when specifying an indexed vector element or multi-vector operand, which restricts the number of vector registers that can be accessed by those operands.
- For SME instructions that access ZA tiles, ZA tile slices, or ZA array vectors, see ZA storage.
- Immediate bits that provide constant data-processing values or address offsets are placed in contiguous bit fields. Some calculated values in instruction variants use one or more immediate bit fields together with the secondary encoding bit fields.

All encodings that are not fully defined are described as unallocated. An attempt to execute an unallocated instruction is UNDEFINED, unless the behavior is otherwise defined in this Manual.

C1.2 Structure of the A64 assembler language

The following sections describe the A64 assembler syntax:

- General requirements
- Common syntax terms
- Instruction Mnemonics
- Condition code
- SVE Condition code aliases
- Register names

C1.2.1 General requirements

The letter `W` denotes a general-purpose register holding a 32-bit word, and `X` denotes a general-purpose register holding a 64-bit doubleword.

An A64 assembler recognizes both uppercase and lowercase variants of the instruction mnemonics and register names, but not mixed case variants. An A64 disassembler can output either uppercase or lowercase mnemonics and register names. Program and data labels are case-sensitive.

The A64 assembly language does not require the # character to introduce constant immediate operands, but an assembler must allow immediate values introduced with or without the # character.

In Example C1-1, the sequence // is used as a comment leader and A64 assemblers are encouraged to accept this syntax.

C1.2.2 Common syntax terms

The following syntax terms are used frequently throughout the A64 instruction set description.

`UPPER` Text in upper-case letters is fixed. Text in lower-case letters is variable. This means that register name `Xn` indicates that the `X` is required, followed by a variable register number, for example `X29`.

`< >` Any text enclosed by angle braces, < >, is a value that the user supplies. Subsequent text might supply additional information.

`{ }` Any item enclosed by curly brackets, { }, is optional. A description of the item and how its presence or absence affects the instruction is normally supplied by subsequent text. In some cases curly braces are actual symbols in the syntax, for example when they surround a register list. These cases are called out in the surrounding text.

`[ ]` Any items enclosed by square brackets, [ ], constitute a list of alternative characters. A single one of the characters can be used in that position and the subsequent text describes the meaning of the alternatives. In some case the square brackets are part of the syntax itself, such as addressing modes or vector elements. These cases are called out in the surrounding text.

`a|b` Alternative words are separated by a vertical bar, |, and can be surrounded by parentheses to delimit them. For example, `U(ADD|SUB)W` represents `UADDW` or `USUBW`.

`±` This indicates an optional + or - sign. If neither is used then + is assumed.

`uimmn` An *n*-bit unsigned, positive, immediate value.

`simmn` An *n*-bit two's complement, signed immediate value, where *n* includes the sign bit.

`SP` See Register names.

`Wn` See Register names.

`WSP` See Register names.

`WZR` See Register names.

`Xn` See Register names.

Non-Confidential

XZR	See Register names

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C1.2.3 Instruction Mnemonics

The A64 assembly language overloads instruction mnemonics and distinguishes between the different forms of an instruction based on the operand types. For example, the following `ADD` instructions all have different opcodes. However, the programmer must remember only one mnemonic, as the assembler automatically chooses the correct opcode based on the operands. The disassembler follows the same procedure in reverse.

Example C1-1 ADD instructions with different opcodes

```
ADD W0, W1, W2          // add 32-bit register
ADD X0, X1, X2          // add 64-bit register
ADD X0, X1, W2, SXTW    // add 64-bit extended register
ADD X0, X1, #42         // add 64-bit immediate
```

C1.2.4 Condition code

The A64 ISA has some instructions that set Condition flags or test Condition codes or both. For information about instructions that set the Condition flags or use the condition mnemonics, see Condition flags and related instructions.

Table C1-1 shows the available Condition codes.

Table C1-1 Condition codes

cond	Mnemonic	Meaning (integer)	Meaning (floating-point)[a]	Condition flags
0000	EQ	Equal	Equal	Z == 1
0001	NE	Not equal	Not equal or unordered	Z == 0
0010	CS or HS	Carry set	Greater than, equal, or unordered	C == 1
0011	CC or LO	Carry clear	Less than	C == 0
0100	MI	Minus, negative	Less than	N == 1
0101	PL	Plus, positive or zero	Greater than, equal, or unordered	N == 0
0110	VS	Overflow	Unordered	V == 1
0111	VC	No overflow	Ordered	V == 0
1000	HI	Unsigned higher	Greater than, or unordered	C ==1 && Z == 0
1001	LS	Unsigned lower or same	Less than or equal	!(C ==1 && Z ==0)
1010	GE	Signed greater than or equal	Greater than or equal	N == V
1011	LT	Signed less than	Less than, or unordered	N != V
1100	GT	Signed greater than	Greater than	Z == 0 && N == V
1101	LE	Signed less than or equal	Less than, equal, or unordered	!(Z == 0 && N == V)
1110	AL	Always	Always	Any
1111	NV[b]	Always	Always	Any

a. Unordered means at least one NaN operand.

b. The Condition code `NV` exists only to provide a valid disassembly of the `0b1111` encoding, otherwise its behavior is identical to `AL`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C1.2.5 SVE Condition code aliases

The SVE and SME assembler syntax defines an alternative set of condition code aliases for use with AArch64 conditional instructions, as follows:

Table C1-2 shows the available SVE Condition code aliases.

Table C1-2 SVE Condition codes

cond	Mnemonic	SVE alias	Meaning	Condition flags
0000	EQ	NONE	All *Active elements* were FALSE or there were no *Active elements*.	Z == 1
0001	NE	ANY	An *Active element* was TRUE.	Z == 0
0010	CS or HS	NLAST	The *Last active element* was FALSE or there were no *Active elements*.	C == 1
0011	CC or LO	LAST	The *Last active element* was TRUE.	C == 0
0100	MI	FIRST	The *First active element* was TRUE.	N == 1
0101	PL	NFRST	The *First active element* was FALSE or there were no *Active elements*.	N == 0
0110	VS	-	CTERM comparison failed, but end of partition reached.	V == 1
0111	VC	-	CTERM comparison succeeded, or end of partition not reached.	V == 0
1000	HI		An *Active element* was TRUE, but the *Last active element* was FALSE.	C ==1 && Z == 0
1001	LS	PLAST	The *Last active element* was TRUE, or all *Active elements* were FALSE, or there were no *Active elements*.	C ==0 || Z ==1
1010	GE	TCONT	CTERM termination condition not detected.	N == V
1011	LT	TSTOP	CTERM termination condition detected.	N != V

C1.2.6 Register names

See:

- General-purpose register file and zero register and stack pointer.
- Advanced SIMD and floating-point register file.
- Advanced SIMD and floating-point scalar register names.
- SIMD vector register names.
- SIMD vector element names.
- For SVE register names, see Z0-Z31, P0-P15, and FFR, First Fault Register.
- For SME ZA storage, see ZA array vector access and ZA tile access.
- For SME2 ZT0 storage, see ZT0.

C1.2.6.1 General-purpose register file and zero register and stack pointer

The 31 general-purpose registers in the general-purpose register file are named R0-R30 and encoded in the instruction register fields with values 0-30. In a general-purpose register field the value 31 represents either the current stack pointer or the zero register, depending on the instruction and the operand position.

When the registers are used in a specific instruction variant, they must be qualified to indicate the operand data size, 32 bits or 64 bits, and the data size of the instruction.

When the data size is 32 bits, the lower 32 bits of the register are used and the upper 32 bits are ignored on a read and cleared to zero on a write.

Table C1-3 shows the qualified names for registers, where *n* is a register number 0-30.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C1-3 Naming of general-purpose registers, the zero register, and the stack pointer

Name	Size	Encoding	Description
Wn	32 bits	0-30	General-purpose register 0-30
Xn	64 bits	0-30	General-purpose register 0-30
WZR	32 bits	31	Zero register
XZR	64 bits	31	Zero register
WSP	32 bits	31	Current stack pointer
SP	64 bits	31	Current stack pointer

This list gives more information about the instruction arguments shown in Table C1-3:

- The names Xn and Wn both refer to the same general-purpose register, Rn.
- There is no register named W31 or X31.
- The name SP represents the stack pointer for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as a read or write of the current stack pointer. When instructions do not interpret this operand encoding as the stack pointer, use of the name SP is an error.
- The name WSP represents the current stack pointer in a 32-bit context.
- The name XZR represents the zero register for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as returning zero when read or discarding the result when written. When instructions do not interpret this operand encoding as the zero register, use of the name XZR is an error.
- The name WZR represents the zero register in a 32-bit context.
- The architecture does not define a specific name for general-purpose register R30 to reflect its role as the link register on procedure calls. However, an A64 assembler must always use W30 and X30 for this purpose, and additional software names might be defined as part of the Procedure Call Standard, see *Procedure Call Standard for the Arm 64-bit Architecture*.

C1.2.6.2 Advanced SIMD and floating-point register file

The 32 registers in the Advanced SIMD and floating-point register file, V0-V31, hold floating-point operands for the scalar floating-point instructions, and both scalar and vector operands for the Advanced SIMD instructions. When they are used in a specific instruction form, the names must be further qualified to indicate the data shape, that is the data element size and the number of elements or lanes within the register. A similar requirement is placed on the general-purpose registers. See General-purpose register file and zero register and stack pointer.

Note

The data type is described by the instruction mnemonics that operate on the data. The data type is not described by the register name. The data type is the interpretation of bits within each register or vector element, whether these are integers, floating-point values, polynomials, or cryptographic hashes.

C1.2.6.3 Advanced SIMD and floating-point scalar register names

Advanced SIMD and floating-point instructions that operate on scalar data only access the lower bits of an Advanced SIMD and floating-point register. The unused high bits are ignored on a read and cleared to 0 on a write.

Table C1-4 shows the qualified names for accessing scalar Advanced SIMD and floating-point registers. The letter *n* denotes a register number between 0 and 31.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C1-4 Advanced SIMD and floating-point scalar register names

Size	Name
8 bits	`Bn`
16 bits	`Hn`
32 bits	`Sn`
64 bits	`Dn`
128 bits	`Qn`

C1.2.6.4 SIMD vector register names

If a register holds multiple data elements on which arithmetic is performed in a parallel, SIMD manner, then a qualifier describes the vector shape. The vector shape is the element size and the number of elements or lanes. If the element size in bits multiplied by the number of lanes does not equal 128, then the upper 64 bits of the register are ignored on a read and cleared to zero on a write.

Table C1-5 shows the SIMD vector register names. The letter *n* denotes a register number between 0 and 31.

Table C1-5 SIMD vector register names

Shape	Name
8 bits × 8 lanes	`Vn.8B`
8 bits × 16 lanes	`Vn.16B`
16 bits × 4 lanes	`Vn.4H`
16 bits × 8 lanes	`Vn.8H`
32 bits × 2 lanes	`Vn.2S`
32 bits × 4 lanes	`Vn.4S`
64 bits × 1 lane	`Vn.1D`
64 bits × 2 lanes	`Vn.2D`

C1.2.6.5 SIMD vector element names

Appending a constant, zero-based element index to the register name inside square brackets indicates that a single element from a SIMD and floating-point register is used as a scalar operand. The number of lanes is not represented, as it is not encoded in the instruction and can only be inferred from the index value.

Table C1-6 shows the vector register names and the element index. The letter *i* denotes the element index.

Table C1-6 Vector register names with element index

Size	Name
8 bits	`Vn.B[i]`
16 bits	`Vn.H[i]`
32 bits	`Vn.S[i]`
64 bits	`Vn.D[i]`

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

An assembler must accept a fully qualified SIMD register name if the number of lanes is greater than the index value. See SIMD vector register names. For example, an assembler must accept all of the following forms as the name for the 32-bit element in bits [63:32] of the SIMD and floating-point register V9:

```
V9.S[1]     //standard disassembly
V9.2S[1]    //optional number of lanes
V9.4S[1]    //optional number of lanes
```

Note

The SIMD and floating-point register element name `Vn.S[0]` is not equivalent to the scalar SIMD and floating-point register name `Sn`. Although they represent the same bits in the register, they select different instruction encoding forms, either the vector element or the scalar form.

C1.2.6.5.1 SIMD vector register list

Where an instruction operates on multiple SIMD&FP or SVE registers, for example vector load/store structure and table lookup operations, the registers are specified as a list enclosed by curly braces. This list consists of either a sequence of registers separated by commas, or a register range separated by a hyphen. The registers must be numbered in increasing order, modulo 32, in increments of one. The hyphenated form is preferred for disassembly if there are more than two registers in the list and the register numbers are increasing by 1. The following examples are equivalent representations of a set of four registers `V4` to `V7`, each holding four lanes of 32-bit elements:

```
{ V4.4S - V7.4S }              //standard disassembly
{ V4.4S, V5.4S, V6.4S, V7.4S } //alternative representation
```

C1.2.6.5.2 SIMD vector element list

Registers in a list can also have a vector element form. For example, the `LD4` instruction can load one element into each of four registers, and in this case the index is appended to the list as follows:

```
{ V4.S - V7.S }[3]                //standard disassembly
{ V4.4S, V5.4S, V6.4S, V7.4S }[3]  //alternative with optional number of lanes
```

C1.3 Address generation

The A64 instruction set supports 64-bit virtual addresses (VAs). The valid VA range is determined by the following factors:

- The size of the implemented virtual address space.
- *Memory Management Unit* (MMU) configuration settings.
- *Memory Protection Unit* (MPU) configuration settings.

Limits on the VA size mean that the most significant bits of the virtual address do not hold valid address bits. These unused bits can hold:

- A tag, see Address tagging.
- If FEAT_PAuth is implemented, a Pointer authentication code (PAC), see Pointer authentication.

For more information on memory management and address translation, see The AArch64 Virtual Memory System Architecture.

C1.3.1 Register indexed addressing

The A64 instruction set allows a 64-bit index register to be added to the 64-bit base register, with optional scaling of the index by the access size. Additionally it allows for sign-extension or zero-extension of a 32-bit value within an index register, followed by optional scaling.

C1.3.2 PC-relative addressing

The A64 instruction set has support for position-independent code and data addressing:

- PC-relative literal loads have an offset range of ± 1MB.
- Process state flag and compare based conditional branches have a range of ± 1MB. Test bit conditional branches have a restricted range of ± 32KB.
- Unconditional branches, including branch and link, have a range of ± 128MB.

PC-relative load/store operations, and address generation with a range of ± 4GB can be performed using two instructions.

C1.3.3 Load/store addressing modes

Load/store addressing modes in the A64 instruction set require a 64-bit base address from a general-purpose register X0-X30 or the current stack pointer, `SP`, with an optional immediate or register offset. Table C1-7 shows the assembler syntax for the complete set of load/store addressing modes.

Table C1-7 A64 Load/store addressing modes

Addressing Mode	Offset		
	Immediate	Register	Extended Register
Base register only (no offset)	`[base{, #0}]`	-	-
Base plus offset	`[base{, #imm}]`	`[base, Xm{, LSL #imm}]`	`[base, Wm, (S|U)XT(X|W) {#imm}]`
Pre-indexed	`[base, #imm]!`	-	-
Post-indexed	`[base], #imm`	`[base], Xm`[a]	-
Literal (PC-relative)	`label`	-	-

a. The post-indexed by register offset mode can be used with the SIMD load/store structure instructions described in Load/store Advanced SIMD. Otherwise the post-indexed by register offset mode is not available.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Some types of load/store instruction support only a subset of the load/store addressing modes listed in Table C1-7. Details of the supported modes are as follows:

- Base plus offset addressing means that the address is the value in the 64-bit base register plus an offset.
- Pre-indexed addressing means that the address is the sum of the value in the 64-bit base register and an offset, and the address is then written back to the base register.
- Post-indexed addressing means that the address is the value in the 64-bit base register, and the sum of the address and the offset is then written back to the base register.
- Literal addressing means that the address is the value of the 64-bit program counter for this instruction plus a 19-bit signed word offset. This means that it is a 4 byte aligned address within ±1MB of the address of this instruction with no offset. Literal addressing can be used only for loads of at least 32 bits and for prefetch instructions. The PC cannot be referenced using any other addressing modes. The syntax for labels is specific to individual toolchains.
- An immediate offset can be unsigned or signed, and scaled or unscaled, depending on the type of load/store instruction. When the immediate offset is scaled it is encoded as a multiple of the transfer size, although the assembly language always uses a byte offset, and the assembler or disassembler performs the necessary conversion. The usable byte offsets therefore depend on the type of load/store instruction and the transfer size.

  Table C1-8 shows the offset and the type of load/store instruction.

Table C1-8 Immediate offsets and the type of load/store instruction

Offset bits	Sign	Scaling	Write-Back	Load/store type
0	-	-	-	Exclusive/acquire/release
7	Signed	Scaled	Optional	Register pair
9	Signed	Unscaled	Optional	Single register
12	Unsigned	Scaled	No	Single register

- A register offset means that the offset is the 64 bits from a general-purpose register, Xm, optionally scaled by the transfer size, in bytes, if `LSL #imm` is present and where `imm` must be equal to $\log_2$(transfer_size). The `SXTX` extend/shift option is functionally equivalent to `LSL`, but the `LSL` option is preferred in source code.
- An extended register offset means that offset is the bottom 32 bits from a general-purpose register Wm, sign-extended or zero-extended to 64 bits, and then scaled by the transfer size if so indicated by `#imm`, where imm must be equal to $\log_2$(transfer_size). An assembler must accept Wm or Xm as an extended register offset, but Wm is preferred for disassembly.
- Generating an address lower than the value in the base register requires a negative signed immediate offset or a register offset holding a negative value.
- When stack alignment checking is enabled by system software and the base register is the SP, the current stack pointer must be initially quadword aligned, that is aligned to 16 bytes. Misalignment generates a Stack Alignment fault. The offset does not have to be a multiple of 16 bytes unless the specific load/store instruction requires this. SP cannot be used as a register offset.

C1.3.3.1 Address calculation

General-purpose arithmetic instructions can calculate the result of most addressing modes and write the address to a general-purpose register or, in most cases, to the current stack pointer.

Table C1-9 shows the arithmetic instructions that can calculate addressing modes.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C1-9 Arithmetic instructions to calculate addressing modes

Addressing Form	Offset		
	Immediate	**Register**	**Extended Register**
Base register (no offset)	`MOV Xd|SP, base`	-	-
Base plus offset	`ADD Xd|SP, base, #imm` or `SUB Xd|SP, base, #imm`	`ADD <Xd|SP>, base, Xm{,LSL#imm}`	`ADD <Xd|SP>, base, Wm,(S|U)XT(W|H|B|X) {#imm}`
Pre-indexed	-	-	-
Post-indexed	-	-	-
Literal (PC-relative)	`ADR Xd, label`	-	-

Note

- For the 64-bit base plus register offset form, the `UXTX` mnemonic is an alias for the `LSL` shift option, but `LSL` is preferred for disassembly. Similarly the `SXTX` extend/shift option is functionally equivalent to the `LSL` option, but the `LSL` option is preferred in source code.
- To calculate a base plus immediate offset the `ADD` instructions defined in Arithmetic (immediate) accept an unsigned 12-bit immediate offset, with an optional left shift by 12. This means that a single `ADD` instruction cannot support the full range of byte offsets available to a single register load/store with a scaled 12-bit immediate offset. For example, a quadword `LDR` effectively has a 16-bit byte offset. To calculate an address with a byte offset that requires more than 12 bits it is necessary to use two `ADD` instructions. The following example shows this:

```
ADD Xd, base, #(imm & 0xFFF)
ADD Xd, Xd, #(imm>>12), LSL #12
```

- To calculate a base plus extended register offset, the `ADD` instructions defined in Arithmetic (extended register) provide a superset of the addressing mode that also supports sign-extension or zero-extension of a byte or halfword value with any shift amount between 0 and 4, for example:

```
ADD  Xd, base, Wm, SXTW #3   // Xd = base + (SignExtend(Wm) LSL 3)
ADD  Xd, base, Wm, UXTH #4   // Xd = base + (ZeroExtend(Wm<15:0>) LSL 4)
```

- If the same extended register offset is used by more than one load/store instruction, then, depending on the implementation, it might be more efficient to calculate the extended and scaled intermediate result just once, and then reuse it as a simple register offset. The extend and scale calculation can be performed using the `SBFIZ` and `UBFIZ` bitfield instructions defined in Bitfield move, for example:

```
SBFIZ Xd, Xm, #3, #32   //Xd = "Wm, SXTW #3"
UBFIZ Xd, Xm, #4, #16   //Xd = "Wm, UXTH #4"
```

C1.4 Instruction aliases

Some instructions have an associated *architecture alias* that is used for disassembly of the encoding when the associated conditions are met. Architecture alias instructions are included in the alphabetic lists of instruction types and clearly presented as an alias form in descriptions for the individual instructions.

Chapter C2
About the A64 Instruction Descriptions

This chapter describes the *instruction descriptions* contained in A64 Base Instruction Descriptions, A64 Advanced SIMD and Floating-point Instruction Descriptions, SVE Instruction Descriptions, and SME Instruction Descriptions.

It contains the following sections:

- Understanding the A64 instruction descriptions
- General information about the A64 instruction descriptions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C2.1 Understanding the A64 instruction descriptions

Each instruction description in A64 Base Instruction Descriptions, A64 Advanced SIMD and Floating-point Instruction Descriptions, SVE Instruction Descriptions, and SME Instruction Descriptions has the following content:

1. A title.
2. An introduction to the instruction.
3. The instruction encoding or encodings.
4. Any alias conditions.
5. A list of the assembler symbols for the instruction.
6. Pseudocode describing how the instruction operates.
7. Notes, if applicable.

The following sections describe each of these.

C2.1.1 The title

The title of an instruction description includes the base mnemonic for the instruction.

If different forms of an instruction use the same base mnemonic, each form has its own description. In this case, the title is the mnemonic followed by a short description of the instruction form in parentheses. This is most often used when an operand is an immediate value in one instruction form, but is a register in another form.

For example, in A64 Base Instruction Descriptions there are the following titles for different forms of the `ADD` instruction:

- ADD (extended register).
- ADD (immediate).
- ADD (shifted register).

C2.1.2 An introduction to the instruction

This briefly describes the function of the instruction. The introduction is not a complete description of the instruction, and it is not definitive. If there is any conflict between it and the more detailed information that follows it, the more detailed information takes priority.

C2.1.3 The instruction encoding or encodings

This shows the instruction encoding diagram, or if the instruction has more than one encoding, shows all of the encoding diagrams. Each diagram has a subheading.

For example, for load and store instructions, the subheadings might be:

- Post-index.
- Pre-index.
- Unsigned offset.

Each diagram numbers the bits from 31 to 0. The diagram for an instruction at address *A* shows, from left to right, the bytes at addresses *A*+3, *A*+2, *A*+1, and *A*.

There might be variants of an encoding, if the *assembler syntax prototype* differs depending on the value in one or more of the encoding fields. In this case, each variant has a subheading that describes the variant and shows the distinguishing field value or values in parentheses. For example, in A64 Base Instruction Descriptions there are the following subheadings for variants of the `ADC` instruction encoding:

- 32-bit variant (sf = 0).
- 64-bit variant (sf = 1).

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The assembler syntax prototype for an encoding or variant of an encoding shows how to form a complete assembler source code instruction that assembles to the encoding. Unless otherwise stated, the prototype is also the preferred syntax for a disassembler to disassemble the encoding to. Disassemblers are permitted to omit optional symbols that represent the default value of a field or set of fields, to produce more readable disassembled code, provided that the output re-assembles to the same encoding.

Each encoding diagram, and its associated assembler syntax prototypes, is followed by encoding-specific pseudocode that translates the fields of that encoding into inputs for the encoding-independent pseudocode that describes the operation of the instruction. See Pseudocode describing how the instruction operates.

C2.1.4 Any alias conditions, if applicable

This is an optional part of an instruction description. If included, it describes the set of conditions for which an alternative mnemonic and its associated assembler syntax prototypes are preferred for disassembly by a disassembler. It includes a link to the alias instruction description that defines the alternative syntax. The alias syntax and the original syntax can be used interchangeably in the assembler source code.

Arm recommends that if a disassembler outputs the alias syntax, it consistently outputs the alias syntax.

C2.1.5 A list of the assembler symbols for the instruction

The *Assembler symbols* subsection of the instruction description contains a list of the symbols that the assembler syntax prototype or prototypes use, if any.

In assembler syntax prototypes, the following conventions are used:

`< >` Angle brackets. Any symbol enclosed by these is a name or a value that the user supplies. For each symbol, there is a description of what the symbol represents. The description usually also specifies which encoding field or fields encodes the symbol.

`{ }` Brace brackets. Any symbols enclosed by these are optional. For each optional symbol, there is a description of what the symbol represents and how its presence or absence is encoded.

In some assembler syntax prototypes, some brace brackets are mandatory, for example if they surround a register list. When the use of brace brackets is mandatory, they are separated from other syntax items by one or more spaces.

`#` This usually precedes a numeric constant. All uses of # are optional in A64 assembler source code. Arm recommends that disassemblers output the # where the assembler syntax prototype includes it.

`+/-` This indicates an optional + or - sign. If neither is coded, + is assumed.

Single spaces are used for clarity, to separate syntax items. Where a space is mandatory, the assembler syntax prototype shows two or more consecutive spaces.

Any characters not shown in this conventions list must be coded exactly as shown in the assembler syntax prototype. Apart from brace brackets, the characters shown are used as part of a meta-language to define the architectural assembler syntax for an instruction encoding or alias, but have no architecturally defined significance in the input to an assembler or in the output from a disassembler.

The following symbol conventions are used:

`<Xn>` The 64-bit name of a general-purpose register (X0-X30) or the zero register (XZR).

`<Wn>` The 32-bit name of a general-purpose register (W0-W30) or the zero register (WZR).

`<Xn|SP>` The 64-bit name of a general-purpose register (X0-X30) or the current stack pointer (SP).

`<Wn|WSP>` The 32-bit name of a general-purpose register (W0-W30) or the current stack pointer (WSP).

`<Bn>, <Hn>, <Sn>, <Dn>, <Qn>`

The 8, 16, 32, 64, or 128-bit name of a SIMD and floating-point register in a scalar context, as described in Register names.

`<Vn>` The name of a SIMD and floating-point register in a vector context, as described in Register names.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<Zn>` The name of an SVE scalable vector register, as described in Treatment of SVE scalable vector registers.

`<Pn>` The name of an SVE scalable predicate register, as described in Vector predication.

If the description of a symbol specifies that the symbol is a register, the description might also specify that the range of permitted registers is extended or restricted. It also specifies any differences from the default rules for such fields.

For information about SME conventions, see ZA storage.

Note

Register names provides the A64 register names.

C2.1.6 Pseudocode describing how the instruction operates

The *Operation* subsection of the instruction description contains this pseudocode.

It is encoding-independent pseudocode that provides a precise description of what the instruction does.

Note

For a description of Arm pseudocode and the execution model for an instruction, see *Arm® Architecture Specification Language Reference* (ARM DDI 0626).

C2.1.7 Notes, if applicable

If applicable, other notes about the instruction appear under additional subheadings.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C2.2 General information about the A64 instruction descriptions

This section provides general information about the A64 instruction descriptions. Some of this information also applies to System register descriptions, for example the terms defined in Fixed values in AArch64 instruction and System register descriptions apply to the AArch64 descriptions throughout this Manual. The following subsections provide this information:

- Execution of instructions in Debug state
- Fixed values in AArch64 instruction and System register descriptions
- Modified immediate constants in A64 floating-point instructions

C2.2.1 Execution of instructions in Debug state

In general, except for the instructions described in Debug state, the A64 instruction descriptions do not indicate any differences in the behavior of the instruction if it is executed in Debug state. For this information, see Executing instructions in Debug state.

Note

For many instructions, execution is unchanged in Debug state. Executing instructions in Debug state identifies these instructions.

C2.2.2 Fixed values in AArch64 instruction and System register descriptions

This section summarizes the terms used to describe fixed values in AArch64 register and instruction descriptions. The Glossary gives full descriptions of these terms, and each entry in this section includes a link to the corresponding Glossary entry.

Note

In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the Glossary.

The following terms are used to describe bits or fields with fixed values:

RAZ Read-As-Zero. See Read-As-Zero (RAZ).

In diagrams, a RAZ bit can be shown as 0.

(0), RES0 Reserved, Should-Be-Zero (SBZ) or RES0.

In instruction encoding diagrams, and sometimes in other descriptions, `(0)` indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction executes as if the value of the bit was 0.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either `(0)(0)(0)` or as `(000)`.

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. See the Glossary definition of RES0 for more information.

Note

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES0 fields,

The `(0)` and RES0 descriptions can be applied to bits or bit fields that are read-only, or are write-only. The Glossary definitions cover these cases.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

RAO Read-As-One. See Read-As-One (RAO).

In diagrams, a RAO bit can be shown as 1.

(1), RES1 Reserved, Should-Be-One (SBO) or RES1.

In instruction encoding diagrams, and sometimes in other descriptions, `(1)` indicates an SBO bit. If the bit is set to 0, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction executes as if the value of the bit was 1.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either `(1)(1)(1)` or as `(111)`.

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. See the Glossary definition of *RES1* for more information.

Note

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES1 fields,

The `(1)` and RES1 descriptions can be applied to bits or bit fields that are read-only, or are write-only. The Glossary definitions cover these cases.

C2.2.3 Modified immediate constants in A64 floating-point instructions

Table C2-1 shows the immediate constants available in `FMOV` (scalar, immediate) and `FMOV` (vector, immediate) floating-point instructions.

Table C2-1 A64 Floating-point modified immediate constants

Data type	immediate	Constant[a]
`F16`	abcdefgh	`aBbbcdef gh000000`
`F32`	abcdefgh	`aBbbbbbc defgh000 00000000 00000000`
`F64`	abcdefgh	`aBbbbbbb bbcdefgh 00000000 00000000 00000000 00000000 00000000 00000000`

a. In this column, `B` = NOT(`b`). The bit pattern represents the floating-point number $(-1)^S \times 2^{exp} \times$ mantissa, where S = `UInt(a)`, exp = `UInt(NOT(b):c:d)-3` and mantissa = `(16+UInt(e:f:g:h))/16`.

The immediate value shown in the table is either:

- The value of the `imm8` field for an `FMOV` (scalar, immediate) instruction, see FMOV (scalar, immediate).
- The value obtained by concatenating the `a:b:c:d:e:f:g:h` fields for an `FMOV` (vector, immediate) instruction, see FMOV (vector, immediate).

Table C2-2 shows the floating-point constant values encoded in the `b:c:d:e:f:g:h` fields of the `FMOV` (vector, immediate) instruction.

Chapter C3
A64 Instruction Set Overview

This chapter provides an overview of the A64 instruction set. It contains the following sections:

- Branches, Exception generating, and System instructions
- Loads and stores
- Loads and stores - SVE, SVE2
- Loads and stores - SME, SME2, SVE2p1
- Data processing - immediate
- Data Processing - MTE
- Data processing - register
- Data processing - SIMD and floating-point
- Data processing - SVE
- Data processing - SVE2
- Data processing - SME, SME2

For a structured breakdown of instruction groups by encoding, see A64 Instruction Set Encoding.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.1 Branches, Exception generating, and System instructions

This section describes the branch, exception generating, and System instructions. It contains the following subsections:

- Conditional branch
- Unconditional branch (immediate)
- Unconditional branch (register)
- Direct and indirect branch
- Exception generation and return
- System register instructions
- System instructions
- Hint instructions
- Barriers and CLREX instructions
- Pointer authentication instructions
- Checked Pointer Arithmetic instructions

Note

Software must:

- Use only `BLR` or `BL` to perform a nested subroutine call when that subroutine is expected to return to the immediately following instruction, that is, the instruction with the address of the `BLR` or `BL` instruction incremented by four.
- Use only `RET` to perform a subroutine return, when that subroutine is expected to have been entered by a `BL` or `BLR` instruction.
- Use only `B`, `BR`, or the instructions listed in Table C3-1 to perform a control transfer that is not a subroutine call or subroutine return described in this *Note*.

C3.1.1 Conditional branch

Conditional branches change the flow of execution depending on the following:

- The current state of the Condition flags.
- The result of comparison between 0 and a value or a bit in a general purpose register.
- The result of comparison between values in two general purpose registers.
- The result of comparison between an immediate value and a value in a general purpose register.

See Table C1-1 for a list of the Condition codes that can be used for `cond`.

Table C3-1 shows the Conditional branch instructions.

Table C3-1 Conditional branch instructions

Mnemonic	Instruction	Branch offset range from the PC	See
`B.cond`	Branch conditionally	±1MB	B.cond
`BC.cond`	Branch consistent conditionally		BC.cond

C3.1.2 Unconditional branch (immediate)

Unconditional branch (immediate) instructions change the flow of execution unconditionally by adding an immediate offset with a range of ±128MB to the value of the program counter that fetched the instruction. The BL instruction also writes the address of the sequentially following instruction to general-purpose register, X30.

Table C3-2 shows the Unconditional branch instructions with an immediate branch offset.

Table C3-2 Unconditional branch instructions (immediate)

Mnemonic	Instruction	Immediate branch offset range from the PC	See
B	Branch	±128MB	B
BL	Branch with link		BL

C3.1.3 Unconditional branch (register)

Unconditional branch (register) instructions change the flow of execution unconditionally by setting the program counter to the value in a general-purpose register. The BLR instruction also writes the address of the sequentially following instruction to general-purpose register X30. The RET instruction behaves identically to BR, but provides an additional hint to the PE that this is a return from a subroutine. Table C3-3 shows Unconditional branch instructions that jump directly to an address held in a general-purpose register.

C3.1.5 Exception generation and return

This section describes the following exceptions:

- Exception generating
- Exception return
- Debug state

C3.1.5.1 Exception generating

Table C3-6 shows the Exception generating instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-6 Exception generating instructions

DCPS1	Debug change PE state to EL1	DCPS1
DCPS2	Debug change PE state to EL2	DCPS2
DCPS3	Debug change PE state to EL3	DCPS3
DRPS	Debug restore PE state	DRPS

C3.1.6 System register instructions

For detailed information about the System register instructions, see The A64 System Instruction Class. Table C3-9 shows the System register instructions.

If FEAT_SYSREG128 is implemented, the following instructions are added that allow the PE to move values between a 128-bit System register and two adjacent 64-bit general-purpose registers:

- MRRS.
- MSRR.

- `ESB`, see Error synchronization event.
- `PSB`, see The Statistical Profiling Extension.
- `GCSB`, see Guarded Control Stack data accesses.

C3.1.10 Pointer authentication instructions

FEAT_PAuth adds support for pointer authentication, see Pointer authentication. This functionality includes the A64 instructions described in this section. These instructions fall into two groups, see:

- Basic pointer authentication instructions.
- Combined instructions that include pointer authentication.

C3.1.10.1 Basic pointer authentication instructions

Each of these instructions only performs an operation that supports pointer authentication.

Table C3-14 shows the instructions that add a *Pointer Authentication Code* (PAC) to the address in a register:

Table C3-14 Instructions that add a PAC

Mnemonic	Instruction	See
`PACDA`	Pointer Authentication Code for data address, using key A - PACDA	PACDA, PACDZA - PACDA
`PACDB`	Pointer Authentication Code for data address, using key B - PACDB	PACDB, PACDZB - PACDB
`PACDZA`	Pointer Authentication Code for data address, using key A - PACDZA	PACDA, PACDZA - PACDZA
`PACDZB`	Pointer Authentication Code for data address, using key B - PACDZB	PACDB, PACDZB - PACDZB
`PACGA`	Pointer Authentication Code, using generic key	PACGA
`PACIA`	Pointer Authentication Code for instruction address, using key A - PACIA	PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA - PACIA
`PACIA1716`	Pointer Authentication Code for instruction address, using key A - PACIA1716	PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA - PACIA1716
`PACIA171615`	Pointer Authentication Code for instruction address, using key A	PACIA171615
`PACIASP`	Pointer Authentication Code for instruction address, using key A - PACIASP	PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA - PACIASP
`PACIASPPC`	Pointer Authentication Code for return address, using key A	PACIASPPC
`PACIAZ`	Pointer Authentication Code for instruction address, using key A - PACIAZ	PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA - PACIAZ
`PACIB`	Pointer Authentication Code for instruction address, using key B - PACIB	PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB - PACIB
`PACIB1716`	Pointer Authentication Code for instruction address, using key B - PACIB1716	PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB - PACIB1716

RETAB	Return from subroutine, with pointer authentication - RETAB	RETAA, RETAB - RETAB
RETABSPPC	Return from subroutine, with enhanced pointer authentication using an immediate offset - RETABSPPC	RETAASPPC, RETABSPPC - RETABSPPC
RETABSPPCR	Return from subroutine, with enhanced pointer authentication using a register - RETABSPPCR	RETAASPPCR, RETABSPPCR - RETABSPPCR

C3.1.11 Checked Pointer Arithmetic instructions

FEAT_CPA adds support for Checked Pointer Arithmetic, see Checked Pointer Arithmetic.

If FEAT_CPA is implemented, the instructions shown in Table C3-19 are implemented.

Table C3-19 Checked Pointer Arithmetic instructions

Mnemonic	Instruction	See
ADDPT	Add checked pointer	ADDPT
	Add checked pointer vectors (predicated)	ADDPT (predicated)
	Add checked pointer vectors (unpredicated)	ADDPT (unpredicated)
MADDPT	Multiply-add checked pointer	MADDPT
MADPT	Multiply-add checked pointer vectors to multiplicand	MADPT
MLAPT	Multiply-add checked pointer vectors	MLAPT
MSUBPT	Multiply-subtract checked pointer	MSUBPT

C3.2 Loads and stores

This section describes the load/store instructions. It contains the following subsections:

- Load/store register
- Load/store register (unscaled offset)
- Load/store pair
- Load/store pair unprivileged
- Load/store non-temporal pair
- Load/store non-temporal pair unprivileged
- Load/store unprivileged
- Single-copy atomic 64-byte load/store
- Load-Exclusive/Store-Exclusive
- Load-Exclusive/Store-Exclusive unprivileged
- Load-Acquire/Store-Release
- Load-Acquire/Store-Release unprivileged
- LoadLOAcquire/StoreLORelease
- Load/store scalar SIMD and floating-point
- Load/store Advanced SIMD
- Prefetch memory
- Atomic instructions
- Memory Tagging instructions
- Memory Copy and Memory Set instructions

The requirements for the alignment of data memory accesses are strict. For more information, see Alignment of data accesses.

The additional control bits SCTLR_ELx.SA and SCTLR_EL1.SA0 control whether the stack pointer must be quadword aligned when used as a base register. See SP alignment checking. Using a misaligned stack pointer generates an SP alignment fault exception.

Note

In some cases, load/store instructions can lead to CONSTRAINED UNPREDICTABLE behavior. See AArch64 CONSTRAINED UNPREDICTABLE behaviors.

C3.2.1 Load/store register

The load/store register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset, optionally scaled.
- Base plus a 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

See also Load/store addressing modes.

If a Load instruction specifies writeback and the register being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a `NOP`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction performs the load using the specified addressing mode and the base register becomes UNKNOWN. In addition, if an exception occurs during the execution of such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store instruction performs a writeback and the register that is stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction performs the store to the designated register using the specified addressing mode, but the value stored is UNKNOWN.

Table C3-20 shows the load/store register instructions.

Table C3-20 Load/store register instructions

Mnemonic	Instruction	See
`LDR`	Load register (immediate)	LDR (immediate)
	Load register (literal)	LDR (literal)
	Load register (register)	LDR (register)
`LDRB`	Load register byte (immediate)	LDRB (immediate)
	Load register byte (register)	LDRB (register)
`LDRH`	Load register halfword (immediate)	LDRH (immediate)
	Load register halfword (register)	LDRH (register)
`LDRSB`	Load register signed byte (immediate)	LDRSB (immediate)
	Load register signed byte (register)	LDRSB (register)

	Store register byte (register)	STRB (register)
`STRH`	Store register halfword (immediate)	STRH (immediate)
	Store register halfword (register)	STRH (register)

C3.2.2 Load/store register (unscaled offset)

The load/store register instructions with an unscaled offset support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See Load/store addressing modes.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The load/store register (unscaled offset) instructions are required to disambiguate this instruction class from the load/store register instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset, because that can represent some offset values in the same range.

The ambiguous immediate offsets are byte offsets that are both:

- In the range 0-255, inclusive.
- Naturally aligned to the access size.

Other byte offsets in the range -256 to 255 inclusive are unambiguous. An assembler program translating a load/store instruction, for example `LDR`, is required to encode an unambiguous offset using the unscaled 9-bit offset form, and to encode an ambiguous offset using the scaled 12-bit offset form. A programmer might force the generation of the unscaled 9-bit form by using one of the mnemonics in Table C3-21. Arm recommends that a disassembler outputs all unscaled 9-bit offset forms using one of these mnemonics, but unambiguous offsets can be output using a load/store single register mnemonic, for example, `LDR`.

Table C3-21 shows the load/store register instructions with an unscaled offset.

Table C3-21 Load/store register (unscaled offset) instructions

Mnemonic	Instruction	See
`LDUR`	Load register (unscaled)	LDUR
`LDURB`	Load register byte (unscaled)	LDURB
`LDURH`	Load register halfword (unscaled)	LDURH
`LDURSB`	Load register signed byte (unscaled)	LDURSB
`LDURSH`	Load register signed halfword (unscaled)	LDURSH
`LDURSW`	Load register signed word (unscaled)	LDURSW
`STUR`	Store register (unscaled)	STUR
`STURB`	Store register byte (unscaled)	STURB
`STURH`	Store register halfword (unscaled)	STURH

C3.2.3 Load/store pair

The load/store pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also Load/store addressing modes.

If a Load Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

If a Load Pair instruction specifies writeback and one of the registers being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the base register becomes UNKNOWN. In addition, if an exception occurs during the instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store Pair instruction performs a writeback and one of the registers being stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the stores of the registers indicated by the specified addressing mode, but the value stored for the base register is UNKNOWN.

Table C3-22 shows the load/store pair instructions.

Table C3-22 Load/store pair instructions

Mnemonic	Instruction	See
LDP	Load pair of registers	LDP
LDPSW	Load pair of registers signed word	LDPSW
STP	Store pair of registers	STP

C3.2.4 Load/store pair unprivileged

The Load unprivileged pair and Store unprivileged pair instructions are added as part of the FEAT_LSUI architecture feature. These instructions belong to the class of unprivileged memory access instructions. The privileges of the Explicit Memory Effects generated by these instructions are controlled by PSTATE.UAO. For more information, see PSTATE.UAO.

The load/store unprivileged pair instructions support the following address modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See Load/store addressing modes.

Table C3-23 Load/store unprivileged pair instructions

Mnemonic	Instruction	See
LDTP	Load unprivileged pair of registers	LDTP
STTP	Store unprivileged pair of registers	STTP

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.2.5 Load/store non-temporal pair

The load/store non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See Load/store addressing modes.

The load/store non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be prefetched and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a Load Non-temporal Pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, the memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-Temporal Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-24 shows the load/store non-temporal pair instructions.

Table C3-24 Load/store non-temporal pair instructions

Mnemonic	Instruction	See
`LDNP`	Load pair of registers, with non-temporal hint	LDNP
`STNP`	Store pair of registers, with non-temporal hint	STNP

C3.2.6 Load/store non-temporal pair unprivileged

The load/store non-temporal pair unprivileged instructions are added as part of the FEAT_LSUI architecture feature. These instructions belong to the class of unprivileged memory access instructions. The privileges of the Explicit Memory Effects generated by these instructions are controlled by PSTATE.UAO. For more information, see PSTATE.UAO.

The load/store non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

Table C3-25 Load/store non-temporal pair instructions

Mnemonic	Instruction	See
`LDTNP`	Load unprivileged pair of registers, with non-temporal hint	LDTNP
`STTNP`	Store unprivileged pair of registers, with non-temporal hint	STTNP

Non-Confidential

C3.2.7 Load/store unprivileged

The load/store unprivileged instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See Load/store addressing modes.

The access permissions that apply to accesses made at EL0 apply to the memory accesses made by a load/store unprivileged instruction that is executed either:

- At EL1 when the Effective value of PSTATE.UAO is 0.
- At EL2 when both the Effective value of HCR_EL2.{E2H, TGE} is {1, 1} and the Effective value of PSTATE.UAO is 0.

Otherwise, memory accesses made by a load/store unprivileged instruction are subject to the access permissions that apply to the Exception level at which the instruction is executed. These are the permissions that apply to the corresponding load/store register instruction, see Load/store register.

Note

This means that when the value of PSTATE.UAO is 1 the access permissions for a load/store unprivileged instruction are always the same as those for the corresponding load/store register instruction.

Table C3-26 shows the load/store unprivileged instructions.

Table C3-26 Load-Store unprivileged instructions

Mnemonic	Instruction	See
`LDTR`	Load register (unprivileged)	LDTR
`LDTRB`	Load register byte (unprivileged)	LDTRB
`LDTRH`	Load register halfword (unprivileged)	LDTRH
`LDTRSB`	Load register signed byte (unprivileged)	LDTRSB
`LDTRSH`	Load register signed halfword (unprivileged)	LDTRSH
`LDTRSW`	Load register signed word (unprivileged)	LDTRSW
`STTR`	Store register (unprivileged)	STTR
`STTRB`	Store register byte (unprivileged)	STTRB
`STTRH`	Store register halfword (unprivileged)	STTRH

C3.2.8 Single-copy atomic 64-byte load/store

If FEAT_LS64 is implemented, the following instructions are implemented:

- LD64B.
- ST64B.

If FEAT_LS64_V is implemented, the following instructions are implemented:

- LD64B.
- ST64B.
- ST64BV.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_LS64_ACCDATA is implemented, the following instructions are implemented:

- LD64B.
- ST64B.
- ST64BV.
- ST64BV0.

LD64B and ST64B can only target Device or Normal Non-cacheable memory unless FEAT_LS64WB is implemented.

The single-copy atomic 64-byte load/store instructions support one addressing mode:

- Base register only.

See also Load/store addressing modes.

The memory location accessed by the instructions is required to be aligned on a 64-byte boundary, otherwise an Alignment fault occurs.

If an ST64BV, ST64BV0, or if FEAT_LS64WB is not implemented an LD64B or ST64B, attempts to access a memory type that is not one of the following, then a Data Abort with DFSC code `0b110101` is generated:

- Normal Inner Non-cacheable, Outer Non-cacheable.
- Device-GRE.
- Device-nGRE.
- Device-nGnRE.
- Device-nGnRnE.

It is IMPLEMENTATION DEFINED which of the following approaches is used to provide this check:

- The check is performed at each enabled stage of translation, and the fault is reported for the first stage of translation that provides an inappropriate memory type. In this case, the value of the HCR_EL2.DC bit does not cause accesses generated by the instructions to generate a stage 1 Data abort,
- The check is performed against the resulting memory type after all enabled stages of translation. In this case the fault is reported at the final enabled stage of translation.
- The check is performed against the resulting memory type after all enabled stages of translation. In this case the fault is reported for the first stage of translation that provided an inappropriate memory type. The value of the HCR_EL2.DC bit does not cause accesses generated by the instructions to generate a stage 1 Data abort.

If FEAT_LS64WB is implemented, then LD64B and ST64B are also supported and 64-byte single-copy atomic for Conventional memory that is Inner and Outer Write-Back Cacheable, Shareable. In this case, if an LD64B or ST64B attempts to access:

- A memory region that is Inner and Outer Write-Back Cacheable, Shareable, but the target memory location is not in Conventional memory, then it is IMPLEMENTATION DEFINED whether:
  - A stage 1 Data Abort with DFSC code `0b110101` is generated.
  - The access succeeds but is not guaranteed to be single-copy atomic above the byte level.
- A cacheable type of memory other than Inner and Outer Write-Back Cacheable, Shareable, then it is IMPLEMENTATION DEFINED whether:
  - A stage 1 Data Abort with DFSC code `0b110101` is generated.
  - The access succeeds as a 64-byte single-copy atomic operation.

For behavior when FEAT_LS64WB is implemented and an LD64B or ST64B targets Tagged memory that is Inner and Outer Write-Back Cacheable, Shareable, see Tag Check Faults.

If the target memory location does not support the LD64B or ST64B instructions, then one of the following behaviors occurs:

- A stage 1 Data Abort with DFSC code of `0b110101`, is generated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction performs the memory accesses, but the accesses are not single-copy atomic above the byte level.

If the target memory location does not support the ST64BV or ST64BV0 instructions, then the register specified by <Xs> is set to `0xFFFF_FFFF_FFFF_FFFF`.

Regardless of the memory type:

- The memory access generated by an ST64BV or ST64BV0 instruction is not merged with any accesses.
- The memory access generated by an ST64B instruction is not merged with any accesses generated by store instructions appearing in program order after the instruction.

Table C3-27 shows the single-copy atomic 64-byte load/store instructions.

Table C3-27 Single-copy atomic 64-byte load/store instructions

Mnemonic	Instruction	See
`LD64B`	Single-copy atomic 64-byte load	LD64B

Table C3-29 shows the single-copy atomic 64-byte EL0 store with status result.

Table C3-29 Single-copy atomic 64-byte EL0 store with status result instructions

Mnemonic	Instruction	See
`ST64BV0`	Single-copy atomic 64-byte EL0 store with status result	ST64BV0

C3.2.9 Load-Exclusive/Store-Exclusive

The Load-Exclusive/Store-Exclusive instructions support only one addressing mode:

- Base register with no offset.

See Load/store addressing modes.

The Load-Exclusive instructions mark the physical address being accessed as an exclusive access. This exclusive access mark is checked by the Store-Exclusive instruction, permitting the construction of atomic read-modify-write operations on shared memory variables, semaphores, mutexes, and spinlocks. See Synchronization and semaphores.

If FEAT_LSE2 is not implemented then:.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Load-Exclusive/Store-Exclusive instructions other than Load-Exclusive pair and Store-Exclusive pair require natural alignment, and an unaligned address generates an Alignment fault.
- Memory accesses generated by Load-Exclusive pair or Store-Exclusive pair instructions must be aligned to the size of the pair, otherwise the access generates an Alignment fault.

  For more information on alignment requirements and behaviors, see Load-Exclusive/ Store-Exclusive and Atomic instructions.

When a Store-Exclusive pair succeeds, it causes a single-copy atomic update of the entire memory location being stored to.

Table C3-30 shows the Load-Exclusive/Store-Exclusive instructions.

Table C3-30 Load-Exclusive/Store-Exclusive instructions

LDXRH	Load exclusive register halfword	LDXRH
STXP	Store exclusive pair of registers	STXP
STXR	Store exclusive register	STXR
STXRB	Store exclusive register byte	STXRB
STXRH	Store exclusive register halfword	STXRH

C3.2.10 Load-Exclusive/Store-Exclusive unprivileged

The Load-Exclusive unprivileged and Store-Exclusive unprivileged instructions are added as part of the FEAT_LSUI architecture feature. These instructions belong to the class of unprivileged memory access instructions. The privileges of the Explicit Memory Effects generated by these instructions are controlled by PSTATE.UAO. For more information, see PSTATE.UAO.

The Load-Exclusive/Store-Exclusive unprivileged instructions support only one address mode:

- Base register with no offset.

See Load/store addressing modes.

Table C3-31 Load-exclusive/Store-exclusive unprivileged instructions

Mnemonic	Instruction	See
LDTXR	Load unprivileged exclusive register	LDTXR
STTXR	Store unprivileged exclusive register	STTXR

C3.2.11 Load-Acquire/Store-Release

The Load-Acquire, Load-AcquirePC and Store-Release instructions are added as part of the FEAT_LRCPC, FEAT_LRCPC2, and FEAT_LRCPC3 architecture features.

If FEAT_LSE2 is not implemented, then:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Load-Acquire, Load-AcquirePC, and Store-Release instructions other than Load-Acquire pair and Store-Release pair require natural alignment, and an unaligned address generates an Alignment fault.
- Memory accesses generated by Load-Acquire pair or Store-Release pair instructions must be aligned to the size of the accessed element in the pair, otherwise the access generates an Alignment fault.

For more information on alignment requirements and behaviors, see Non-atomic Load-Acquire/Store-Release instructions.

The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction. For more information about the ordering of Load-Acquire, Load-AcquirePC, and Store-Release, see Load-Acquire, Load-AcquirePC, and Store-Release.

A Store-Release Exclusive instruction has the Release semantics only if the store is successful.

Armv8.1 adds more instructions with load-acquire and store-release mechanisms, see LoadLOAcquire/StoreLORelease.

Table C3-32 shows the Non-exclusive Load-Acquire/Store-Release instructions.

STLLRH	Store LORelease register halfword	STLLRH

C3.2.14 Load/store scalar SIMD and floating-point

The load/store scalar SIMD and floating-point instructions operate on scalar values in the SIMD and floating-point register file as described in Advanced SIMD and floating-point scalar register names. The memory addressing modes available, described in Load/store addressing modes, are identical to the general-purpose register load/store instructions, and like those instructions permit arbitrary address alignment unless strict alignment checking is enabled. However, unlike the load/store instructions that transfer general-purpose registers, load/store scalar SIMD and floating-point instructions make no guarantee of atomicity, even when the address is naturally aligned to the size of the data.

C3.2.14.1 Load/store scalar SIMD and floating-point register

The load/store scalar SIMD and floating-point register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus unscaled 9-bit signed immediate offset.
- Base plus 64-bit register offset, optionally scaled.
- Base plus 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

For more information on the addressing modes, see Load/store addressing modes.

Note

The unscaled 9-bit signed immediate offset address mode requires its own instruction form, see Load/store scalar SIMD and floating-point register (unscaled offset).

Table C3-37 shows the load/store instructions for a single SIMD and floating-point register.

Table C3-37 Load/store single SIMD and floating-point register instructions

Mnemonic	Instruction	See
LDR	Load SIMD&FP register (PC-relative literal)	LDR (literal, SIMD&FP)

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

	Load SIMD&FP register (immediate offset)	LDR (immediate, SIMD&FP)
	Load SIMD&FP register (register offset)	LDR (register, SIMD&FP)
STR	Store SIMD&FP register (immediate offset)	STR (immediate, SIMD&FP)
	Store SIMD&FP register (register offset)	STR (register, SIMD&FP)

C3.2.14.2 Load/store scalar SIMD and floating-point register (unscaled offset)

The load/store scalar SIMD and floating-point register instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See also Load/store addressing modes.

The load/store scalar SIMD and floating-point register (unscaled offset) instructions are required to disambiguate this instruction class from the load/store single SIMD and floating-point instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset. This is similar to the load/store register (unscaled offset) instructions, that disambiguate this instruction class from the load/store register instruction, see Load/store register (unscaled offset).

Table C3-38 shows the load/store SIMD and floating-point register instructions with an unscaled offset.

Table C3-38 Load/store SIMD and floating-point register instructions

Mnemonic	Instruction	See
LDUR	Load SIMD&FP register (unscaled offset)	LDUR (SIMD&FP)
STUR	Store SIMD&FP register (unscaled offset)	STUR (SIMD&FP)

C3.2.14.3 Load/store SIMD and floating-point register pair

The load/store SIMD and floating-point register pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also Load/store addressing modes.

If a Load pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode and the register being loaded takes an UNKNOWN value.

For behavior when FEAT_LS64WB is implemented, see Requirements for single-copy atomicity.

Table C3-39 shows the load/store SIMD and floating-point register pair instructions.

LDP	Load pair of SIMD&FP registers	LDP (SIMD&FP)
STP	Store pair of SIMD&FP registers	STP (SIMD&FP)

C3.2.14.4 Load/store unprivileged SIMD and floating-point register pair

The load/store unprivileged SIMD and floating-point register pair instructions are added as part of the FEAT_LSUI architecture feature. These instructions belong to the class of unprivileged memory access instructions. The privileges of the Explicit Memory Effects generated by these instructions are controlled by PSTATE.UAO. For more information, see PSTATE.UAO.

The load/store unprivileged SIMD and floating-point register pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also Load/store addressing modes.

Table C3-40 Load/store unprivileged SIMD and floating-point register pair instructions

Mnemonic	Instruction	See
LDTP	Load unprivileged pair of SIMD&FP registers	LDTP (SIMD&FP)
STTP	Store unprivileged pair of SIMD&FP registers	STTP (SIMD&FP)

C3.2.14.5 Load/store SIMD and floating-point non-temporal pair

The load/store SIMD and floating-point non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See also Load/store addressing modes.

The load/store non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be prefetched and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a load non-temporal pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, those memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a load non-temporal pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

LDTNP	Load unprivileged pair of SIMD&FP registers, with non-temporal hint	LDTNP (SIMD&FP)
STTNP	Store unprivileged pair of SIMD&FP registers, with non-temporal hint	STTNP (SIMD&FP)

C3.2.15 Load/store Advanced SIMD

The Advanced SIMD load/store structure instructions support the following addressing modes:

- Base register only.
- Post-indexed by a 64-bit register.
- Post-indexed by an immediate, equal to the number of bytes transferred.

Load/store vector instructions, like other load/store instructions, allow any address alignment, unless strict alignment checking is enabled. If strict alignment checking is enabled, then alignment checking to the size of the element is performed. However, unlike the load/store instructions that transfer general-purpose registers, the load/store vector instructions do not guarantee atomicity, even when the address is naturally aligned to the size of the element.

C3.2.15.1 Load/store structures

Table C3-43 shows the load/store structure instructions. A post-increment immediate offset, if present, must be 8, 16, 24, 32, 48, or 64, depending on the number of elements transferred.

Table C3-43 Load/store multiple structures instructions

Mnemonic	Instruction	See
LD1	Load multiple single-element structures to one, two, three, or four registers	LD1 (multiple structures)

C3.2.15.2 Load single structure and replicate

Table C3-44 shows the Load single structure and replicate instructions. A post-increment immediate offset, if present, must be 1, 2, 3, 4, 6, 8, 12, 16, 24, or 32, depending on the number of elements transferred.

Table C3-44 Load single structure and replicate instructions

Mnemonic	Instruction	See
`LD1R`	Load one single-element structure and replicate to all lanes (of one register)	LD1R
`LD2R`	Load single 2-element structure and replicate to all lanes of two registers	LD2R
`LD3R`	Load single 3-element structure and replicate to all lanes of three registers	LD3R
`LD4R`	Load single 4-element structure and replicate to all lanes of four registers	LD4R

Mnemonic	Instruction	See
`LDAP1`	Load-acquire RCpc one single-element structure to one lane of one register	LDAP1 (SIMD&FP)
`LDAPUR`	Load-acquire RCpc SIMD&FP register (unscaled offset)	LDAPUR (SIMD&FP)
`STL1`	Store-release a single-element structure from one lane of one register	STL1 (SIMD&FP)
`STLUR`	Store-release SIMD&FP register (unscaled offset)	STLUR (SIMD&FP)

C3.2.16 Prefetch memory

The Prefetch memory instructions support the following addressing modes:

- Base register with no offset.
- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset. This can be optionally scaled by 8-bits, for example `LSL`#3.
- Base plus a 32-bit extended register offset. This can be optionally scaled by 8-bits.
- PC-relative literal.

The Prefetch memory instructions signal to the memory system that memory accesses from a specified address or range of addresses are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory access when they do occur, such as prefetching the specified address or range of addresses into one or more caches. Because these signals are only hints, it is valid for the PE to treat any or all prefetch instructions as a `NOP`.

Because they are hints to the memory system, the operation of a prefetch memory instruction cannot cause a synchronous exception. However, a memory operation performed as a result of one of these memory system hints might in exceptional cases trigger an asynchronous event, and thereby influence the execution of the PE. An example of an asynchronous event that might be triggered is an SError exception.

A prefetch memory instruction can only have an effect on software visible structures as defined in the translation regime of the current Exception level, such as caches and translation lookaside buffers associated with memory locations that can be accessed by reads, writes, or execution.

A `PRFM`, `PRFUM`, or `RPRFM` instruction is guaranteed not to access Device memory.

A `PRFM` or `PRFUM` instruction using a `PLI` hint cannot result in any access that could not be performed by the PE speculatively fetching an instruction. Therefore, if all associated MMUs are disabled, a `PLI` hint can only access memory locations consistent with instruction fetches permitted by The effects of disabling an address translation stage.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Arm recommends that when a `PRFM` or a `PRFUM` instruction describes a particular cache level, then the memory location described at that cache level should be made available at that same cache level, even if the line had previously been at a level of the cache that is closer to the PE than the specified cache level.

Note

For a PRFM PST instruction, this might result in the demotion of a cache line from a level that was closer to the cache.

Table C3-46 shows the Prefetch memory instructions.

Table C3-46 Prefetch memory instructions

Mnemonic	Instruction	See
`PRFM`	Prefetch memory (immediate)	PRFM (immediate)
	Prefetch memory (literal)	PRFM (literal)
	Prefetch memory (register)	PRFM (register)
`PRFUM`	Prefetch memory (unscaled offset)	PRFUM
`RPRFM`	Range prefetch memory	RPRFM

C3.2.17 Atomic instructions

The atomic instructions perform atomic read and write operations on a memory location such that the architecture guarantees that no modification of that memory location by another observer can occur between the read and the write defined by that instruction.

This section describes the following operations:

- Atomic integer memory operations.
- Atomic floating-point memory operations.
- Unprivileged atomic memory operations.
- Swap operations.
- Swap unprivileged.
- Compare and Swap operations.
- Compare and Swap unprivileged.
- Read-Check-Write.

The atomic instructions support only one addressing mode:

- Base register only.

See also Load/store addressing modes.

For the purpose of permission checking, and for watchpoints, all of the Atomic memory operation instructions are treated as performing both a load and a store.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the architecture. The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity. These operations map to the acquire and release definitions, and are counted as Load-Acquire and Store-Release operations respectively.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If mnemonics share an instruction name and the shortest mnemonic (for example, LDADD) has neither acquire nor release semantics, an extension of that mnemonic can indicate the following:

- A: the instruction has acquire semantics. For example, LDADDA.
- AL: the instruction has acquire and release semantics. For example, LDADDAL.
- L: the instruction has release semantics. For example, LDADDL.

C3.2.17.1 Atomic integer memory operations

The address accessed by the 128-bit atomic instructions must be aligned to 128-bits, otherwise the instructions generate an Alignment fault.

For the `LD<OP>` instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

The `ST<OP>` instructions, and `LD<OP>` instructions where the destination register is WZR or XZR, are not regarded as doing a read for the purpose of a `DMB LD` barrier.

For information on alignment requirements and behaviors, see Load-Exclusive/ Store-Exclusive and Atomic instructions.

Table C3-47 Atomic integer memory operation instructions

C3.2.17.3 Unprivileged atomic memory operations

The unprivileged atomic memory operation instructions are added as part of the FEAT_LSUI architecture feature. These instructions belong to the class of unprivileged memory access instructions. The privileges of the Explicit Memory Effects generated by these instructions are controlled by PSTATE.UAO. For more information, see PSTATE.UAO.

The atomic memory operation instructions support only one addressing mode:

- Base register only.

See also Load/store addressing modes.

C3.2.17.4 Swap operations

For the `SWP` instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

If the destination register Rt is WZR or XZR, this is not regarded as doing a read for the purpose of a `DMB LD` barrier.

For information on alignment requirements and behaviors, see Load-Exclusive/ Store-Exclusive and Atomic instructions.

C3.2.17.4.1 Swap unprivileged

The swap unprivileged instructions are added as part of the FEAT_LSUI architecture feature. These instructions belong to the class of unprivileged memory access instructions. The privileges of the Explicit Memory Effects generated by these instructions are controlled by PSTATE.UAO. For more information, see PSTATE.UAO.

The swap unprivileged instructions support only one addressing mode:

- Base register only.

See also Load/store addressing modes.

Mnemonic	Instruction	See
SWPT	Swap unprivileged	SWPT, SWPTA, SWPTAL, SWPTL
SWPTA		
SWPTAL		
SWPTL		

C3.2.17.5 Compare and Swap operations

If FEAT_LSE2 is not implemented then:

- The CAS instructions require natural alignment.
- The CASP instructions require alignment to the total size of the memory being accessed.

If a compare and swap instruction does not perform a store, then the instruction does not have release semantics, regardless of the instruction ordering options.

For the CAS and CASP instructions, the architecture permits that a data read clears any Exclusives monitors associated with that location, even if the compare subsequently fails. If these instructions generate a synchronous Data Abort, the registers which are compared and loaded are restored to the values held in the registers before the instruction was executed.

If the destination register Rs is WZR or XZR, this is not regarded as doing a read for the purpose of a DMB LD barrier.

For more information on alignment requirements and behaviors, see Load-Exclusive/ Store-Exclusive and Atomic instructions.

C3.2.17.6 Read-Check-Write

If FEAT_THE is implemented, then the Read-Check-Write instructions, RCW, and Read-Check-Write Software instructions, RCWS, are provided to conditionally update stage 1 descriptors.

RCW and RCWS instructions update PSTATE.{N, Z, C, V} to {0, 0, 1, 0}, with all of the following exceptions:

- For the compare and swap variants of the RCW and RCWS instructions, if the compare fails, then PSTATE.N is set to 1.
- Otherwise, all of the following apply:
  - If RCW and RCWS instructions fail the RCW checks, then PSTATE.Z is set to 1.
  - If RCWS instructions fail the RCWS checks, then PSTATE.C is set to 0.

If FEAT_D128 is implemented, then RCW and RCWS instructions that operate on 128 bits of data are provided.

If the address is not aligned to the data transfer size, then RCW and RCWS instructions generate an Alignment fault.

The following table shows the RCW and RCWS instructions that operate on 64 bits of data:

C3.2.19 Memory Copy and Memory Set instructions

If FEAT_MOPS is implemented, the `CPY*`, `SETE*`, `SETM*`, and `SETP*` instructions described in this section are implemented. If FEAT_MOPS and FEAT_MTE are implemented, the `SETG*` instructions described in this section are also implemented. Collectively, the instructions described in this section are referred to as *Memory Copy and Memory Set* instructions.

To perform a memory copy or memory set, three instructions - a prologue, then a main, and then an epilogue - are expected to be run in succession, with no instruction appearing in the code between them:

- To perform a memory copy, forward-only: `CPYFP*`, then `CPYFM*`, and then `CPYFE*`.
- To perform a memory copy, forward or backward: `CPYP*`, then `CPYM*`, and then `CPYE*`.
- To perform a memory set with tag setting: `SETGP*`, then `SETGM*`, and then `SETGE*`.
- To perform a memory set without tag setting: `SETP*`, then `SETM*`, and then `SETE*`.

The variant of each instruction is also expected to be the same throughout one of these sequences. For example, `CPYFPWTWN`, `CPYFMWTWN`, `CPYFEWTWN`.

Note

The Memory Copy and Memory Set instructions are expected to be the preferred approach for compilation for performance for any of the following cases:

- The size or alignments of the copy or set operation are not known at compile time.
- The size or alignments of the copy or set operation are known at compile time, but not amenable to the operation being performed using load and store instructions without looping.

Arm recommends that hardware implementations optimize the performance of these cases.

Fetching of a Memory Copy and Memory Set instruction multiple times during its execution is permissible.

The handling of synchronous exceptions generated by Memory Copy and Memory Set instructions is described in ESR_ELx, FAR_ELx, Definition of a precise exception and imprecise exception, and Synchronous exception entry.

The handling of asynchronous exceptions generated by Memory Copy and Memory Set instructions is described in Definition of a precise exception and imprecise exception and Asynchronous exception entry.

Memory Copy and Memory Set exceptions can be generated by execution of Memory Copy and Memory Set instructions restarting on a physical hardware PE implementation that is different from the physical hardware PE implementation that an exception was taken from. For more information, see Memory Copy and Memory Set exceptions.

If an exception is taken during the execution of a Memory Copy and Memory Set instruction, that instruction has not been executed for the purposes of instruction counting, instruction tracing, statistical profiling, or single stepping.

For the purposes of single stepping and performance monitoring, each Memory Copy and Memory Set instruction is regarded as a single instruction that performs a store and, in the case of `CPY*` instructions, also performs a load.

For Memory Copy and Memory Set instructions, the following are not architecturally defined:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The size of the memory transactions they create.
- The order between accesses to different addresses.

The `CPY*` instructions are guaranteed to make forward progress if none of the following leaf level translation table entries fault:

- The source leaf level translation table entry used to translate the address encoded in `Xs`.
- If the range of remaining source addresses, encoded in `Xs` and `Xn`, crosses a page boundary:
  - The next leaf level translation table entry, as determined by the copy direction, adjacent to the source leaf level translation table entry used to translate the address encoded in `Xs`.
- The destination leaf level translation table entry used to translate the address encoded in `Xd`.
- If the range of remaining destination addresses, encoded in `Xd` and `Xn`, crosses a page boundary:
  - The next leaf level translation table entry, as determined by the copy direction, adjacent to the destination leaf level translation table entry used to translate the address encoded in `Xd`.

The `SET*` instructions are guaranteed to make forward progress if none of the following leaf level translation table entries fault:

- The destination leaf level translation table entry used to translate the address encoded in `Xd`.
- If the range of remaining addresses, encoded in `Xd` and `Xn`, crosses a page boundary:
  - The next leaf level translation table entry adjacent to the destination leaf level translation table entry used to translate the address encoded in `Xd`.

Note

For a `CPY*` instruction, destination address, source address and copy size are encoded in `Xd`, `Xs` and `Xn` depending on the Option and Direction chosen by the implementation.
For a `SET*` instruction, destination address and set size are encoded in `Xd` and `Xn` depending on the Option and Direction chosen by the implementation.
A PE can ensure that the forward progress described in this section can be achieved by ensuring that, when an MMU fault is encountered, all bytes leading up to the fault have been operated on and the operand registers have been updated.
A PE should not report MMU faults other than for the leaf level translation table entries described in this section.

Table C3-60 shows the memory copy, forward-only instructions.

C3.3 Loads and stores - SVE, SVE2

SVE vector load and store instructions transfer data in memory to or from elements of one or more vector or predicate transfer registers. SVE also includes vector prefetch instructions that provide read and write hints to the memory system. For SVE predicated load, store, and prefetch instructions, the memory element access size and type that is associated with each vector element is specified by a suffix to the instruction mnemonic, independently of the element size of the transfer registers. For example, LD1SH. The following table shows the supported instruction suffixes for SVE load, store, and prefetch instructions:

Instruction suffix	Memory element access size and type
B	Unsigned byte
H	Unsigned halfword or half-precision floating-point
W	Unsigned word or single-precision floating-point
D	Unsigned doubleword or double-precision floating-point
SB	Signed byte
SH	Signed halfword
SW	Signed word

The element size of the transfer registers is always greater than or equal to the memory element access size. When the element size of the transfer registers is strictly greater than the memory element access size, then these are referred to as unpacked data accesses. In the case of unpacked data accesses:

- For load instructions, each element access is sign-extended or zero-extended to fill the vector element, according to its memory element access size and type.
- For store instructions, each vector element is truncated to the memory element access size.

Where the vector element size and the memory element access size are the same, then these are referred to as packed data accesses. Signed access types are not supported for packed data accesses. Packed and unpacked access sizes and types relate to the vector element size of the transfer registers, as defined in the following table:

Vector element	Packed access suffix	Unpacked access suffixes
.B	B	-
.H	H	B, SB
.S	W	H, SH, B, SB
.D	D	W, SW, H, SH, B, SB

For gather-load and scatter-store instructions, the vector element size can only be .S or .D. This means that any non-contiguous memory element access of less than a word is unpacked. Non-contiguous memory element accesses of a word can be either packed or unpacked, depending on the vector element size.

Load, store, and prefetch instructions consist of the following:

- Predicated single vector contiguous element accesses.
- Predicated multiple vector contiguous structure load/store.
- Predicated non-contiguous element accesses.
- Predicated replicating element loads.
- Unpredicated vector register load/store.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Unpredicated predicate register load/store.
- Non-temporal gather/scatter.

All predicated load instructions zero the Inactive elements of the destination vector, except for Non-fault loads and First-fault loads when the corresponding FFR element is FALSE. When this happens, the content of the corresponding destination vector element is CONSTRAINED UNPREDICTABLE, as described in rule R_{NGFTJ}.

Prefetch instructions provide hints to hardware and do not change architectural state. Therefore, a *Governing predicate* for a prefetch instruction provides an additional hint which indicates the memory locations to be prefetched. Prefetch instructions require a prefetch operation specifier. SVE prefetch instructions support all of the prefetch operations except for the PLI prefetch operand types.

Load, store, and prefetch instructions that multiply a scalar index register or an index vector element by the memory element access size specify a shift type, followed by a shift amount in bits. The shift type can be one of `LSL`, `SXTW`, or `UXTW`. The shift amount is always Log_2 of the memory element access size, in bytes. The shift amount defaults to zero when the memory element access size is a byte, and the shift size can be omitted. The shift type of `LSL` must be omitted if the shift amount is omitted.

When included as part of the assembler syntax for an instruction, `MUL VL` indicates that the specified immediate index value is multiplied by the size of the addressed vector or predicate in memory, measured in bytes, irrespective of predication. For a detailed description of the meaning of this assembler syntax for each instruction, see the appropriate subsection below. When used in pseudocode, the symbol `VL` represents the vector length, measured in bits.

SVE load, store, and prefetch instructions do not support pre-indexed or post-indexed addressing.

C3.3.1 Predicated single vector contiguous element accesses

Predicated contiguous load and store instructions access memory locations starting from an address that is defined by a scalar base register plus either:

- A scalar index register.
- An immediate index value that is in the range -8 to 7, inclusive. This defaults to zero if omitted.

The predicated contiguous load and store instructions have two supporting addressing modes:

- Scalar base plus immediate index.
- Scalar base plus scalar index.

Predicated contiguous prefetch instructions address memory locations in a similar manner, with the index being either:

- A scalar index register.
- An immediate index value that is in the range of -32 to 31, inclusive. This defaults to zero if omitted.

For predicated contiguous load and store SVE instructions:

- The immediate index value is a vector index, not an element index. The immediate index value is multiplied by the number of vector elements, irrespective of predication, and then multiplied by the memory element access size in bytes. The resulting offset is incremented following each element access by the memory element access size.
- The scalar index register value is multiplied by the memory element access size in bytes. The index value is incremented by one after each element access, but the scalar index register is not updated by the instruction.
- When alignment checking is enabled for loads and stores, the value of the base address register must be aligned to the memory element access size.

	Contiguous store non-temporal words from vector (scalar index)	STNT1W (scalar plus scalar, single register)

C3.3.2 Predicated multiple vector contiguous structure load/store

Predicated multiple vector contiguous structure load/store instructions are defined by a scalar base register plus either:

- A scalar index register.
- An immediate index that is a multiple of N, in the range -8×N to 7×N, inclusive. This defaults to zero if omitted.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The predicated contiguous structure load and store instructions have two supporting addressing modes:

- Scalar base plus immediate index.
- Scalar base plus scalar index.

For the predicated multiple vector contiguous structure load/store SVE instructions:

- The immediate index value is a vector index, not an element index. The immediate index value is multiplied by the number of vector elements, irrespective of predication, and then multiplied by the memory element access size in bytes. The resulting offset is incremented following each element access by the memory element access size.
- The scalar index register value is multiplied by the memory element access size in bytes. Following each element access, the index value is incremented by one but the instruction does not update the scalar index register.
- Each predicate element applies to a single structure in memory, or equivalently to the same element number within each of the two, three, or four transferred vector registers.
- These instructions support packed data accesses only.
- When alignment checking is enabled for loads and stores, the base address must be aligned to the element access size.

C3.3.3 Predicated non-contiguous element accesses

Predicated non-contiguous element accesses address non-contiguous memory locations that are specified by either:

- A scalar base register plus a vector of indices or offsets.
- A vector of base addresses plus an immediate byte offset. The immediate byte offset is a multiple of the memory element access size, in the range 0 to 31 times the memory element access size, inclusive, and defaults to zero if omitted.

The predicated non-contiguous element accesses have two supporting addressing modes:

- Scalar base plus 64-bit vector index.
- Scalar base plus 32-bit vector index.
- Vector base plus immediate offset.

For this group of SVE instructions:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Vector registers used as part of the address must specify a vector element size of 32 bits or 64 bits, .S or .D. For load and store instructions, the transfer register must specify the same vector element size.
- If the index vector register contains 32-bit index values then the lowest 32 bits of each index vector element can either be zero-extended or sign-extended to 64 bits.
- For load and store instructions, the index vector elements are then optionally multiplied by the memory element access size, in bytes, if a shift amount is specified. For prefetch instructions, the index vector elements are always multiplied by the memory element access size, in bytes.
- When alignment checking is enabled for loads and stores, the calculated virtual address of each element must be aligned to the memory element access size.

C3.3.4 Predicated replicating element loads

The load and replicate instructions read one or more contiguous memory locations starting from an address that is defined by a scalar base register plus either:

- A scalar index register.
- An immediate byte offset.

The predicated contiguous load and store instructions have two supporting addressing modes:

- Scalar base plus immediate offset.
- Scalar base plus scalar index.

This defaults to zero if omitted. For predicated replicating element load SVE instructions:

- When alignment checking is enabled, the base address must be aligned to the memory element access size.

Table C3-69 Predicated replicating element loads

LD1RW	Load and broadcast unsigned word to vector	LD1RW

C3.3.5 Unpredicated vector register load/store

The unpredicated vector register load, LDR, and store, STR, instructions transfer a single vector register from or to memory locations that are specified by a scalar base register plus an immediate index value that is in the range -256 to 255, inclusive. The immediate index value defaults to zero if omitted.

The unpredicated vector register load/store instructions have one supporting addressing mode:

- Scalar base plus immediate index.

For the unpredicated vector register load/store SVE instructions:

- The immediate index value is a vector index, not an element index. The immediate index value is multiplied by the current vector register length in bytes.
- The data transfer is performed as a contiguous stream of byte accesses in ascending element order, without endianness conversion.
- When alignment checking is enabled for loads and stores, the base address must be 16-byte aligned.

Table C3-70 Unpredicated vector register load/store

Mnemonic	Instruction	See
LDR	Load vector register	LDR (vector)
STR	Store vector register	STR (vector)

Non-Confidential

C3.3.6 Unpredicated predicate register load/store

The unpredicated predicate register load, LDR, and store, STR, instructions transfer a single predicate register from or to memory locations that are specified by a scalar base register plus an immediate index value that is in the range -256 to 255, inclusive. The immediate index value defaults to zero if omitted.

The unpredicated predicate register load/store instructions have one supporting addressing mode:

- Scalar base plus immediate index.

For unpredicated predicate register load/store SVE instructions:

- The immediate index value is a predicate index, not an element index. The immediate index value is multiplied by the current predicate register length, in bytes.
- The data transfer is performed as a contiguous stream of byte accesses, each byte containing 8 consecutive predicate bits, in ascending bit and element order, without endian conversion.
- When alignment checking is enabled for loads and stores, the base address must be 2-byte aligned.

Table C3-71 Unpredicated predicate register load/store

Mnemonic	Instruction	See
`LDR`	Load predicate register	LDR (predicate)
`STR`	Store predicate register	STR (predicate)

C3.3.7 Non-temporal gather/scatter

The non-temporal gather load and scatter store instructions provide a hint to the memory system that the data structure being accessed has a low reuse frequency. The memory system can use the hint to avoid retaining the data or evicting more frequently-used data from the caches.

These instructions support a single addressing mode consisting of 64-bit or 32-bit vector base addresses plus an unscaled 64-bit scalar offset that defaults to the zero register, XZR. Other addressing modes can be constructed using extra instructions.

Table C3-72 Non-temporal gather load and scatter store instructions

Mnemonic	Instruction	See

C3.4 Loads and stores - SME, SME2, SVE2p1

The following subsections describe the SME, SME2 and SVE2p1 loads and stores:

- Array vector/table load and store.
- Consecutive multi-vector loads and stores.
- SVE2.1 quadword loads and stores.

C3.4.1 Array vector/table load and store

These instructions transfer data between the ZA array vector or the ZT0 registers and memory.

These instructions are performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte.

Table C3-73 SME array vector/table load and store

Mnemonic	Instruction	See
`LDR`	Load ZA array vector	LDR (array vector)
	Load ZT0 register	LDR (table)
`STR`	Store ZA array vector	STR (array vector)
	Store ZT0 register	STR (table)

C3.4.2 Contiguous multi-vector loads and stores

C3.4.2.1 Consecutive multi-vector loads and stores

Multi-vector load and store instructions that transfer data between memory and consecutive SVE vector registers.

Table C3-74 Consecutive multi-vector load and store instructions

Mnemonic	Instruction	See
`LD1B`	Contiguous load of bytes to multiple consecutive vectors (immediate index)	LD1B (scalar plus immediate, consecutive registers)
	Contiguous load of bytes to multiple consecutive vectors (scalar index)	LD1B (scalar plus scalar, consecutive registers)

C3.4.2.3 Tile slice multi-vector loads and stores

Tile slice load and store instructions transfer bytes between a tile slice and memory.

Table C3-76 Tile slice multi-vector load and store instructions

Mnemonic	Instruction	See
LD1B	Contiguous load of bytes to 8-bit element ZA tile slice	LD1B (scalar plus scalar, tile slice)
LD1D	Contiguous load of doublewords to 64-bit element ZA tile slice	LD1D (scalar plus scalar, tile slice)
LD1H	Contiguous load of halfwords to 16-bit element ZA tile slice	LD1H (scalar plus scalar, tile slice)
LD1Q	Contiguous load of quadwords to 128-bit element ZA tile slice	LD1Q
LD1W	Contiguous load of words to 32-bit element ZA tile slice	LD1W (scalar plus scalar, tile slice)
ST1B	Contiguous store of bytes from 8-bit element ZA tile slice	ST1B (scalar plus scalar, tile slice)
ST1D	Contiguous store of doublewords from 64-bit element ZA tile slice	ST1D (scalar plus scalar, tile slice)
ST1H	Contiguous store of halfwords from 16-bit element ZA tile slice	ST1H (scalar plus scalar, tile slice)
ST1Q	Contiguous store of quadwords from 128-bit element ZA tile slice	ST1Q
ST1W	Contiguous store of words from 32-bit element ZA tile slice	ST1W (scalar plus scalar, tile slice)

C3.4.3 SVE2.1 quadword loads and stores

C3.4.3.1 Contiguous quadword loads and stores

Contiguous load or store to/from elements of a vector register from/to the memory address generated by a scalar base and an immediate index, which is multiplied and added to the base address, or a scalar index, which is added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

C3.5 Data processing - immediate

This section describes the instruction groups for data processing with immediate operands. It contains the following subsections:

- Arithmetic (immediate)
- Integer minimum and maximum (immediate)
- Logical (immediate)
- Move (wide immediate)
- Move (immediate)
- PC-relative address calculation
- Bitfield move
- Bitfield insert and extract
- Extract register
- Shift (immediate)
- Sign-extend and Zero-extend

C3.5.1 Arithmetic (immediate)

The Arithmetic (immediate) instructions accept a 12-bit unsigned immediate value, optionally shifted left by 12 bits.

The Arithmetic (immediate) instructions that do not set Condition flags can read from and write to the current stack pointer. The flag setting instructions can read from the stack pointer, but they cannot write to it.

Table C3-80 shows the Arithmetic instructions with an immediate offset.

Table C3-80 Arithmetic instructions with an immediate

Mnemonic	Instruction	See
`ADD`	Add immediate value	ADD (immediate)
`ADDS`	Add immediate value, setting flags	ADDS (immediate)
`CMN`	Compare negative (immediate)	CMN (immediate)
`CMP`	Compare (immediate)	CMP (immediate)
`SUB`	Subtract immediate value	SUB (immediate)
`SUBS`	Subtract immediate value, setting flags	SUBS (immediate)

C3.5.2 Integer minimum and maximum (immediate)

The Integer maximum and minimum (immediate) instructions determine the maximum/minimum of the source register value and immediate.

These instructions are only present when FEAT_CSSC is implemented.

Table C3-81 shows the Integer maximum and minimum (immediate) instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-81 Integer maximum and minimum (immediate) instructions

Mnemonic	Instruction	See
SMAX	Signed maximum (immediate)	SMAX (immediate)
SMIN	Signed minimum (immediate)	SMIN (immediate)
UMAX	Unsigned maximum (immediate)	UMAX (immediate)
UMIN	Unsigned minimum (immediate)	UMIN (immediate)

C3.5.3 Logical (immediate)

The Logical (immediate) instructions accept a bitmask immediate value that is a 32-bit pattern or a 64-bit pattern viewed as a vector of identical elements of size e = 2, 4, 8, 16, 32 or, 64 bits. Each element contains the same sub-pattern, that is a single run of 1 to (e - 1) nonzero bits from bit 0 followed by zero bits, then rotated by 0 to (e - 1) bits. This mechanism can generate 5334 unique 64-bit patterns as 2667 pairs of pattern and their bitwise inverse.

Note

Values that consist of only zeros or only ones cannot be described in this way.

The Logical (immediate) instructions that do not set the Condition flags can write to the current stack pointer, for example to align the stack pointer in a function prologue.

Note

Apart from `ANDS` and its `TST` alias, Logical (immediate) instructions do not set the Condition flags. However, the final results of a bitwise operation can be tested by a `CBZ`, `CBNZ`, `TBZ`, or `TBNZ` conditional branch.

Table C3-82 shows the Logical immediate instructions.

Table C3-82 Logical immediate instructions

Mnemonic	Instruction	See
AND	Bitwise AND (immediate)	AND (immediate)
ANDS	Bitwise AND (immediate), setting flags	ANDS (immediate)
EOR	Bitwise exclusive-OR (immediate)	EOR (immediate)
ORR	Bitwise OR (immediate)	ORR (immediate)
TST	Test bits (immediate)	TST (immediate)

C3.5.4 Move (wide immediate)

The Move (wide immediate) instructions insert a 16-bit immediate, or inverted immediate, into a 16-bit aligned position in the destination register. The value of the other bits in the destination register depends on the variant used. The optional shift amount can be any multiple of 16 that is smaller than the register size.

Table C3-83 shows the Move (wide immediate) instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-83 Move (wide immediate) instructions

Mnemonic	Instruction	See
MOVK	Move wide with keep	MOVK
MOVN	Move wide with NOT	MOVN
MOVZ	Move wide with zero	MOVZ

C3.5.5 Move (immediate)

The Move (immediate) instructions are aliases for a single MOVZ, MOVN, or ORR (immediate with zero register), instruction to load an immediate value into the destination register. An assembler must permit a signed or unsigned immediate, as long as its binary representation can be generated using one of these instructions, and an assembler error results if the immediate cannot be generated in this way. On disassembly, it is unspecified whether the immediate is output as a signed or an unsigned value.

If there is a choice between the MOVZ, MOVN, and ORR instruction to encode the immediate, then an assembler must prefer MOVZ to MOVN, and MOVZ or MOVN to ORR, to ensure reversibility. A disassembler must output ORR (immediate with zero register) MOVZ, and MOVN, as a MOV mnemonic except that the underlying instruction must be used when:

- ORR has an immediate that can be generated by a MOVZ or MOVN instruction.
- A MOVN instruction has an immediate that can be encoded by MOVZ.
- MOVZ #0 or MOVN #0 have a shift amount other than LSL #0.

Table C3-84 shows the Move (immediate) instructions.

Table C3-84 Move (immediate) instructions

Mnemonic	Instruction	See
MOV	Move bitmask immediate value	MOV (bitmask immediate)
	Move inverted wide immediate value	MOV (inverted wide immediate)
	Move wide immediate value	MOV (wide immediate)

C3.5.6 PC-relative address calculation

The ADR instruction adds a signed, 21-bit immediate to the value of the program counter that fetched this instruction, and then writes the result to a general-purpose register. This permits the calculation of any byte address within ±1MB of the current PC.

The ADRP instruction shifts a signed, 21-bit immediate left by 12 bits, adds it to the value of the program counter with the bottom 12 bits cleared to zero, and then writes the result to a general-purpose register. This permits the calculation of the address at a 4KB aligned memory region. In conjunction with an ADD (immediate) instruction, or a load/store instruction with a 12-bit immediate offset, this allows for the calculation of, or access to, any address within ±4GB of the current PC.

Note

The term *page* used in the ADRP description is short-hand for the 4KB memory region, and is not related to the virtual memory translation granule size.

Table C3-85 shows the instructions used for PC-relative address calculations are as follows:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-85 PC-relative address calculation instructions

Mnemonic	Instruction	See
ADR	Form PC-relative address	ADR
ADRP	Form PC-relative address to 4KB page	ADRP

C3.5.7 Bitfield move

The Bitfield move instructions copy a field of constant width from bit 0 in the source register to a constant bit position in the destination register, or from a constant bit position in the source register to bit 0 in the destination register. The remaining bits in the destination register are set as follows:

- For BFM, the remaining bits are unchanged.
- For UBFM the lower bits, if any, and upper bits, if any, are set to zero.
- For SBFM, the lower bits, if any, are set to zero, and the upper bits, if any, are set to a copy of the most-significant bit in the copied field.

Table C3-86 shows the Bitfield move instructions.

Table C3-86 Bitfield move instructions

Mnemonic	Instruction	See
BFM	Bitfield move	BFM
SBFM	Signed bitfield move	SBFM
UBFM	Unsigned bitfield move	UBFM

C3.5.8 Bitfield insert and extract

The Bitfield insert and extract instructions are implemented as aliases of the Bitfield move instructions. Table C3-87 shows the Bitfield insert and extract aliases.

Table C3-87 Bitfield insert and extract instructions

Mnemonic	Instruction	See
BFC	Bitfield clear	BFC

UBFX	Unsigned bitfield extract	UBFX

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.5.9 Extract register

Depending on the register width of the operands, the Extract register instruction copies a 32-bit or 64-bit field from a constant bit position within a double-width value formed by the concatenation of a pair of source registers to a destination register.

Table C3-88 shows the Extract (immediate) instructions.

Table C3-88 Extract register instructions

Mnemonic	Instruction	See
EXTR	Extract register	EXTR

C3.5.10 Shift (immediate)

Shifts and rotates by a constant amount are implemented as aliases of the Bitfield move or Extract register instructions. The shift or rotate amount must be in the range 0 to one less than the register width of the instruction, inclusive.

Table C3-89 shows the aliases that can be used as immediate shift and rotate instructions.

Table C3-89 Aliases for immediate shift and rotate instructions

C3.7 Data processing - register

This section describes the instruction groups for data processing with all register operands. It contains the following subsections:

- Arithmetic (shifted register)
- Arithmetic (extended register)
- Arithmetic with carry
- Integer maximum and minimum (register)
- Flag manipulation instructions
- Logical (shifted register)
- Move (register)
- Absolute value
- Shift (register)
- Multiply and divide
- CRC32
- Bit operation
- Conditional select
- Conditional comparison

C3.7.1 Arithmetic (shifted register)

The Arithmetic (shifted register) instructions apply an optional shift operator to the second source register value before performing the arithmetic operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators `LSL`, `ASR`, and `LSR` accept an immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator implies `LSL #0`, which means that there is no shift. A disassembler must not output `LSL #0`. However, a disassembler must output all other shifts by zero.

The current stack pointer, SP or WSP, cannot be used with this class of instructions. See Arithmetic (extended register) for arithmetic instructions that can operate on the current stack pointer.

Table C3-93 shows the Arithmetic (shifted register) instructions.

Table C3-93 Arithmetic (shifted register) instructions

Mnemonic	Instruction	See
`ADD`	Add optionally-shifted register	ADD (shifted register)
`ADDS`	Add optionally-shifted register, setting flags	ADDS (shifted register)
`CMN`	Compare negative (shifted register)	CMN (shifted register)
`CMP`	Compare (shifted register)	CMP (shifted register)
`NEG`	Negate (shifted register)	NEG (shifted register)
`NEGS`	Negate, setting flags	NEGS
`SUB`	Subtract optionally-shifted register	SUB (shifted register)
`SUBS`	Subtract optionally-shifted register, setting flags	SUBS (shifted register)

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.7.2 Arithmetic (extended register)

The extended register instructions provide an optional sign-extension or zero-extension of a portion of the second source register value, followed by an optional left shift by a constant amount of 1-4, inclusive.

The extended shift is described by the mandatory extend operator `SXTB`, `SXTH`, `SXTW`, `UXTB`, `UXTH`, or `UXTW` . This is followed by an optional left shift amount. If the shift amount is not specified, the default shift amount is zero. A disassembler must not output a shift amount of zero.

For 64-bit instruction forms, the additional operators `UXTX` and `SXTX` use all 64 bits of the second source register with an optional shift. In that case, Arm recommends `UXTX` as the operator. If and only if at least one register is SP, Arm recommends use of the `LSL` operator name, rather than `UXTX`, and when the shift amount is also zero then both the operator and the shift amount can be omitted. `UXTW` and `SXTW` both use all 32 bits of the second source register with an optional shift. In that case Arm recommends `UXTW` as the operator. If and only if at least one register is WSP, Arm recommends use of the `LSL` operator name, rather than `UXTW`, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

For 32-bit instruction forms, the operators `UXTW` and `SXTW` both use all 32 bits of the second source register with an optional shift. In that case, Arm recommends `UXTW` as the operator. If and only if at least one register is WSP, Arm recommends use of the `LSL` operator name, rather than `UXTW`, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

The non-flag setting variants of the extended register instruction permit the use of the current stack pointer as either the destination register and the first source register. The flag setting variants only permit the stack pointer to be used as the first source register.

In the 64-bit form of these instructions, the final register operand is written as `Wm` for all except the `UXTX`/`LSL` and `SXTX` extend operators. For example:

```
CMP X4, W5, SXTW
ADD X1, X2, W3, UXTB #2
SUB SP, SP, X1              // SUB SP, SP, X1, UXTX #0
```

Table C3-94 shows the Arithmetic (extended register) instructions.

Table C3-94 Arithmetic (extended register) instructions

Mnemonic	Instruction	See
`ADD`	Add extended and scaled register	ADD (extended register)
`ADDS`	Add extended and scaled register, setting flags	ADDS (extended register)
`CMN`	Compare negative (extended register)	CMN (extended register)
`CMP`	Compare (extended register)	CMP (extended register)
`SUB`	Subtract extended and scaled register	SUB (extended register)
`SUBS`	Subtract extended and scaled register, setting flags	SUBS (extended register)

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.7.3 Arithmetic with carry

The Arithmetic with carry instructions accept two source registers, with the carry flag as an additional input to the calculation. They do not support shifting of the second source register.

Table C3-95 shows the Arithmetic with carry instructions

Table C3-95 Arithmetic with carry instructions

Mnemonic	Instruction	See
`ADC`	Add with carry	ADC
`ADCS`	Add with carry, setting flags	ADCS
`NGC`	Negate with carry	NGC
`NGCS`	Negate with carry, setting flags	NGCS
`SBC`	Subtract with carry	SBC
`SBCS`	Subtract with carry, setting flags	SBCS

C3.7.4 Integer maximum and minimum (register)

The Integer maximum and minimum (register) instructions determine the maximum/minimum of the two source register values.

These instructions are only present when FEAT_CSSC is implemented.

Table C3-96 shows the Integer maximum and minimum (register) instructions.

Table C3-96 Integer maximum and minimum (register) instructions

Mnemonic	Instruction	See
`SMAX`	Signed maximum (register)	SMAX (register)
`SMIN`	Signed minimum (register)	SMIN (register)
`UMAX`	Unsigned maximum (register)	UMAX (register)
`UMIN`	Unsigned minimum (register)	UMIN (register)

C3.7.5 Flag manipulation instructions

The Flag manipulation instructions set the value of the NZCV condition flags directly.

The instructions `SETF8` and `SETF16` accept one source register and set the NZV condition flags based on the value of the input register. The instruction `RMIF` accepts one source register and two immediate values, rotating the first source register using the first immediate value and setting the NZCV condition flags masked by the second immediate value.

The instructions `AXFLAG` and `XAFLAG` convert PSTATE condition flags between a form representing the result of an Arm floating-point scalar compare instruction and an alternative representation required by some software. See Table C6-1 for more information.

Table C3-97 shows the Flag manipulation instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-97 Flag manipulation instructions

Mnemonic	Instruction	See
AXFLAG	Convert floating-point condition flags from Arm to external format	AXFLAG
CFINV	Invert carry flag	CFINV
RMIF	Rotate, mask insert flags	RMIF
SETF16	Evaluation of 8-bit or 16-bit flag values - SETF16	SETF8, SETF16 - SETF16
SETF8	Evaluation of 8-bit or 16-bit flag values - SETF8	SETF8, SETF16 - SETF8
XAFLAG	Convert floating-point condition flags from external format to Arm format	XAFLAG

C3.7.6 Logical (shifted register)

The Logical (shifted register) instructions apply an optional shift operator to the second source register value before performing the main operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators `LSL`, `ASR`, `LSR`, and `ROR` accept a constant immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator and amount implies `LSL #0`, which means that there is no shift. A disassembler must not output `LSL #0`. However, a disassembler must output all other shifts by zero.

Note

Apart from `ANDS`, `TST`, and `BICS`, the logical instructions do not set the Condition flags, but the final result of a bit operation can usually directly control a `CBZ`, `CBNZ`, `TBZ`, or `TBNZ` conditional branch.

Table C3-98 shows the Logical (shifted register) instructions.

Table C3-98 Logical (shifted register) instructions

Mnemonic	Instruction	See
AND	Bitwise AND (shifted register)	AND (shifted register)
ANDS	Bitwise AND (shifted register), setting flags	ANDS (shifted register)
BIC	Bitwise bit clear (shifted register)	BIC (shifted register)
BICS	Bitwise bit clear (shifted register), setting flags	BICS (shifted register)
EON	Bitwise exclusive-OR NOT (shifted register)	EON (shifted register)
EOR	Bitwise exclusive-OR (shifted register)	EOR (shifted register)
MVN	Bitwise NOT	MVN
ORN	Bitwise OR NOT (shifted register)	ORN (shifted register)
ORR	Bitwise OR (shifted register)	ORR (shifted register)
TST	Test (shifted register)	TST (shifted register)

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.7.7 Move (register)

The Move (register) instructions are aliases for other data processing instructions. They copy a value from a general-purpose register to another general-purpose register or the current stack pointer, or from the current stack pointer to a general-purpose register.

Table C3-99 MOV register instructions

Mnemonic	Instruction	See
MOV	Move register value	MOV (register)
	Move register value to or from SP	MOV (to/from SP)

C3.7.8 Absolute value

The Absolute value instruction is only present when FEAT_CSSC is implemented.

Table C3-100 shows the Absolute value instruction.

Table C3-100 Absolute value instruction

Mnemonic	Instruction	See
ABS	Absolute value	ABS

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.7.9 Shift (register)

In the Shift (register) instructions, the shift amount is the positive value in the second source register modulo the register size. The register width of the instruction controls whether the new bits are fed into the result on a right shift or rotate at bit[63] or bit[31].

Table C3-101 shows the Shift (register) instructions.

Table C3-101 Shift (register) instructions

Mnemonic	Instruction	See
ASRV	Arithmetic shift right variable	ASRV
LSLV	Logical shift left variable	LSLV
LSRV	Logical shift right variable	LSRV
RORV	Rotate right variable	RORV

However, the Shift (register) instructions have a preferred set of aliases that match the shift immediate aliases described in Shift (immediate).

Table C3-102 shows the aliases for Shift (register) instructions.

Table C3-102 Aliases for Variable shift instructions

Mnemonic	Instruction	See
ASR	Arithmetic shift right (register)	ASR (register)
LSL	Logical shift left (register)	LSL (register)
LSR	Logical shift right (register)	LSR (register)
ROR	Rotate right (register)	ROR (register)

C3.7.10 Multiply and divide

This section describes the instructions used for integer multiplication and division. It contains the following subsections:

- Multiply
- Divide

C3.7.10.1 Multiply

The Multiply instructions write to a single 32-bit or 64-bit destination register, and are built around the fundamental four operand multiply-add and multiply-subtract operation, together with 32-bit to 64-bit widening variants. A 64-bit to 128-bit widening multiple can be constructed with two instructions, using SMULH or UMULH to generate the upper 64 bits. Table C3-103 shows the Multiply instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-103 Multiply integer instructions

Mnemonic	Instruction	See
MADD	Multiply-add	MADD
MNEG	Multiply-negate	MNEG
MSUB	Multiply-subtract	MSUB
MUL	Multiply	MUL
SMADDL	Signed multiply-add long	SMADDL
SMNEGL	Signed multiply-negate long	SMNEGL
SMSUBL	Signed multiply-subtract long	SMSUBL
SMULH	Signed multiply high	SMULH
SMULL	Signed multiply long	SMULL (32-bit)
UMADDL	Unsigned multiply-add long	UMADDL
UMNEGL	Unsigned multiply-negate long	UMNEGL
UMSUBL	Unsigned multiply-subtract long	UMSUBL
UMULH	Unsigned multiply high	UMULH
UMULL	Unsigned multiply long	UMULL (32-bit)

C3.7.10.2 Divide

The Divide instructions calculate the quotient of a division, rounded towards zero. The remainder can then be calculated as (numerator - (quotient × denominator)), using the `MSUB` instruction.

If a signed integer division (`INT_MIN / -1`) is performed where `INT_MIN` is the most negative integer value representable in the selected register size, then the result overflows the signed integer range. No indication of this overflow is produced and the result that is written to the destination register is `INT_MIN`.

A division by zero results in a zero being written to the destination register, without any indication that the division by zero occurred.

Table C3-104 shows the Divide instructions.

Table C3-104 Divide instructions

Mnemonic	Instruction	See
SDIV	Signed divide	SDIV (quotient)
UDIV	Unsigned divide	UDIV (quotient)

C3.7.11 CRC32

The `CRC32` instructions operate on the general-purpose register file to update a 32-bit CRC value from an input value comprising 1, 2, 4, or 8 bytes. There are two different classes of `CRC` instructions, `CRC32`, and `CRC32C`, that support two commonly used 32-bit polynomials, known as CRC-32 and CRC-32C.

To fit with common usage, the bit order of the values is reversed as part of the operation.

When bits[19:16] of ID_AA64ISAR0_EL1 are set to `0b0001`, the `CRC` instructions are implemented.

These instructions are optional in an Armv8.0 implementation.

All implementations of Armv8.1 architecture and later are required to implement the `CRC32` instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-105 shows the CRC instructions.

Table C3-105 CRC32 instructions

Mnemonic	Instruction	See
CRC32B	CRC32 checksum - CRC32B	CRC32B, CRC32H, CRC32W, CRC32X - CRC32B
CRC32CB	CRC32C checksum - CRC32CB	CRC32CB, CRC32CH, CRC32CW, CRC32CX - CRC32CB
CRC32CH	CRC32C checksum - CRC32CH	CRC32CB, CRC32CH, CRC32CW, CRC32CX - CRC32CH
CRC32CW	CRC32C checksum - CRC32CW	CRC32CB, CRC32CH, CRC32CW, CRC32CX - CRC32CW
CRC32CX	CRC32C checksum - CRC32CX	CRC32CB, CRC32CH, CRC32CW, CRC32CX - CRC32CX
CRC32H	CRC32 checksum - CRC32H	CRC32B, CRC32H, CRC32W, CRC32X - CRC32H
CRC32W	CRC32 checksum - CRC32W	CRC32B, CRC32H, CRC32W, CRC32X - CRC32W
CRC32X	CRC32 checksum - CRC32X	CRC32B, CRC32H, CRC32W, CRC32X - CRC32X

C3.7.12 Bit operation

The CNT and CTZ instructions are only present when FEAT_CSSC is implemented.

Table C3-106 shows the Bit operation instructions.

Table C3-106 Bit operation instructions

Mnemonic	Instruction	See
CLS	Count leading sign bits	CLS
CLZ	Count leading zeros	CLZ
CNT	Count bits	CNT
CTZ	Count trailing zeros	CTZ
RBIT	Reverse bits	RBIT
REV	Reverse bytes	REV
REV16	Reverse bytes in 16-bit halfwords	REV16
REV32	Reverse bytes in 32-bit words	REV32
REV64	Reverse bytes	REV64

C3.7.13 Conditional select

The Conditional select instructions select between the first or second source register, depending on the current state of the Condition flags. When the named condition is true, the first source register is selected and its value is copied without modification to the destination register. When the condition is false the second source register is selected and its value might be optionally inverted, negated, or incremented by one, before writing to the destination register.

Other useful conditional set and conditional unary operations are implemented as aliases of the four Conditional select instructions.

Table C3-107 shows the Conditional select instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-107 Conditional select instructions

CSETM	Conditional set mask	CSETM
CSINC	Conditional select increment	CSINC
CSINV	Conditional select invert	CSINV
CSNEG	Conditional select negation	CSNEG

C3.7.14 Conditional comparison

The Conditional comparison instructions provide a conditional select for the NZCV Condition flags, setting the flags to the result of an arithmetic comparison of its two source register values if the named input condition is true, or to an immediate value if the input condition is false. There are register and immediate forms. The immediate form compares the source register to a small 5-bit unsigned value.

Table C3-108 shows the Conditional comparison instructions.

C3.8 Data processing - SIMD and floating-point

This section describes the instruction groups for data processing with SIMD and floating-point register operands.

Common features of SIMD instructions gives general information about SIMD instructions.

The following subsections describe the scalar floating-point data processing instructions:

- Floating-point move (register).
- Floating-point move (immediate).
- Floating-point conversion.
- Floating-point round to integral value.
- Floating-point multiply-add.
- Floating-point arithmetic (one source).
- Floating-point arithmetic (two sources).
- Floating-point minimum and maximum.
- Floating-point comparison.
- Floating-point conditional select.

The following subsections describe the SIMD data processing instructions:

- SIMD move.
- SIMD arithmetic.
- SIMD compare.
- SIMD widening and narrowing arithmetic.
- SIMD unary arithmetic.
- SIMD by element arithmetic.
- SIMD permute.
- SIMD immediate.
- SIMD shift (immediate).
- SIMD conversions.
- SIMD reduce (across vector lanes).
- SIMD pairwise arithmetic.
- SIMD matrix multiply-accumulate.
- SIMD dot product.
- SIMD table lookup.
- SIMD complex number arithmetic instructions.
- SIMD BFloat16.
- SIMD multiply-accumulate.
- The Cryptographic Extension in AArch64 state.

For information about the floating-point exceptions, see Floating-point exceptions and exception traps.

C3.8.1 Common features of SIMD instructions

A number of SIMD instructions come in three forms:

Wide Indicated by the suffix *W*. The element width of the destination register and the first source operand is double that of the second source operand.

Long Indicated by the suffix *L*. The element width of the destination register is double that of both source operands.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Narrow Indicated by the suffix *N*. The element width of the destination register is half that of both source operands.

In addition, each vector form of the instruction is part of a pair, with a second and upper part suffix of *2*, to identify the variant of the instruction:

- Where a SIMD operation widens or lengthens a 64-bit vector to a 128-bit vector, the instruction provides a second part operation that can extract the source from the upper 64 bits of the source registers.
- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the instruction provides a second-part operation that can pack the result of a second operation into the upper part of the same destination register.

Note

This is referred to as a *lane set specifier*.

C3.8.2 Floating-point move (register)

The Floating-point move (register) instructions copy a scalar floating-point value from one register to another register without performing any conversion.

Some of the Floating-point move (register) instructions overlap with the functionality provided by the Advanced SIMD instructions `DUP`, `INS`, and `UMOV`. However, Arm recommends using the `FMOV` instructions when operating on scalar floating-point data to avoid the creation of scalar floating-point code that depends on the availability of the Advanced SIMD instruction set.

Table C3-109 shows the Floating-point move (register) instructions.

Table C3-109 Floating-point move (register) instructions

Mnemonic	Instruction	See
`FMOV`	Floating-point move register without conversion	FMOV (register)
	Floating-point move to or from general-purpose register without conversion	FMOV (general)

C3.8.3 Floating-point move (immediate)

The Floating-point move (immediate) instructions convert a small constant immediate floating-point value into a half-precision, single-precision, or double-precision scalar floating-point value in a SIMD and floating-point register.

The floating-point constant can be specified either in decimal notation, such as 12.0 or -1.2e1, or as a string beginning with `0x` followed by a hexadecimal representation of the IEEE 754 half-precision, single-precision, or double-precision encoding. Arm recommends that a disassembler uses the decimal notation, provided that this displays the value precisely.

Note

When FEAT_FP16 is not implemented, the only half-precision instructions that are supported are floating-point conversions between half-precision, single-precision, and double-precision.

The floating-point value must be expressible as ($\pm n/16 \times 2^r$), where n is an integer in the range $16 \leq n \leq 31$ and r is an integer in the range of $-3 \leq r \leq 4$, that is a normalized binary floating-point encoding with one sign bit, four bits of fraction, and a 3-bit exponent.

Table C3-110 shows the Floating-point move (immediate) instruction:

Non-Confidential

Table C3-110 Floating-point move (immediate) instruction

Mnemonic	Instruction	See
FMOV	Floating-point move immediate (scalar)	FMOV (scalar, immediate)

C3.8.4 Floating-point conversion

The following subsections describe the conversion of floating-point values:

- Convert floating-point precision
- Convert from floating-point single-precision to BFloat16
- Convert from floating-point to integer or fixed-point
- Convert from integer or fixed-point to floating-point

C3.8.4.1 Convert floating-point precision

These instructions convert a floating-point scalar with one precision to a floating-point scalar with a different precision, using the current rounding mode as specified by FPCR.RMode.

Table C3-111 shows the Floating-point precision conversion instruction.

Table C3-111 Floating-point precision conversion instruction

Mnemonic	Instruction	See
FCVT	Floating-point convert precision (scalar)	FCVT

C3.8.4.2 Convert from floating-point single-precision to BFloat16

The BFCVT instruction is provided by FEAT_BF16. This instruction converts a single-precision floating-point input to BFloat16 format, honoring the FPCR rounding mode controls to give a more accurate conversion than simply removing the bottom 16 bits of the input.

Table C3-112 shows this instruction.

Table C3-112 Floating-point single-precision to BFloat16 conversion instruction

Mnemonic	Instruction	See
BFCVT	Single-precision convert to BFloat16 (scalar)	BFCVT

C3.8.4.3 Convert from floating-point to integer or fixed-point

Floating-point to integer or fixed-point conversion is supported by the following instruction variants:

- Scalar instruction variant, which converts a floating-point value in a SIMD and floating-point source register to an integer or fixed-point value in a general-purpose destination register.
- Scalar SIMD&FP instruction variant, which converts a floating-point value in a SIMD and floating-point source register to an integer value in a SIMD and floating-point destination register.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For a fixed-point value, a final immediate operand indicates that the general-purpose register holds a fixed-point number and `fbits` indicates the number of bits after the binary point. `fbits` is in the range 1- 32 inclusive for a 32-bit general-purpose register name, and 1-64 inclusive for a 64-bit general-purpose register name.

Table C3-113 shows the floating-point to integer or fixed-point conversion instructions.

	Floating-point convert to unsigned integer, rounding toward zero (vector)	FCVTZU (vector, integer)
`FJCVTZS`	Floating-point JavaScript convert to signed fixed-point, rounding toward zero	FJCVTZS

C3.8.4.4 Convert from integer or fixed-point to floating-point

The integer or fixed-point to floating-point conversion is supported by the following instruction variants:

- Scalar instruction variant, which converts an integer or fixed-point value in a general-purpose register to a floating-point value in a SIMD and floating-point destination register.
- Scalar SIMD&FP variant, which converts an integer value in a SIMD and floating-point source register to a floating-point value in a SIMD and floating-point destination register.

For a fixed-point value, a final immediate operand indicates that the general-purpose register holds a fixed-point number and `fbits` indicates the number of bits after the binary point. `fbits` is in the range 1- 32 inclusive for a 32-bit general-purpose register name, and 1-64 inclusive for a 64-bit general-purpose register name.

UCVTF	Unsigned fixed-point convert to floating-point (scalar)	UCVTF (scalar, fixed-point)
	Unsigned integer convert to floating-point (scalar)	UCVTF (scalar, integer)
	Unsigned integer convert to floating-point (vector)	UCVTF (vector, integer)

C3.8.5 Floating-point round to integral value

The following subsections describe instructions which round a floating-point number to an integral valued floating-point number in the same format:

- Floating-point round to an integer of the same size as the register
- Floating-point round to 32-bit or 64-bit integer

C3.8.5.1 Floating-point round to an integer of the same size as the register

The following instructions round a floating-point value to an integer floating-point value of the same size.

For these instructions:

- A zero input gives a zero result with the same sign.
- An infinite input gives an infinite result with the same sign.
- A NaN is propagated as in normal floating-point arithmetic.

These instructions can cause floating-point exceptions, for more information see Floating-point exceptions and exception traps.

Table C3-115 shows the Floating-point round to integer instructions.

Table C3-115 Floating-point round to integer instructions

C3.8.5.2 Floating-point round to 32-bit or 64-bit integer

The following instructions are present if FEAT_FRINTTS is implemented, The instructions round to a value that fits in a 32-bit integer or a 64-bit integer size, and use either round towards zero or the ambient rounding model.

These instructions can cause floating-point exceptions, for more information see Floating-point exceptions and exception traps.

Table C3-116 shows the Floating-point round to 32-bit or 64-bit integer instructions.

Table C3-116 Floating-point round to integer instructions

Mnemonic	Instruction	See

`FMUL`	Floating-point multiply (scalar)	FMUL (scalar)
`FNMUL`	Floating-point multiply-negate (scalar)	FNMUL (scalar)
`FSUB`	Floating-point subtract (scalar)	FSUB (scalar)

C3.8.9 Floating-point minimum and maximum

The `FPMin(x,y)` and `FPMax(x,y)` operations return a quiet NaN when either *x* or *y* is NaN.

As described in Flushing denormalized numbers to zero, if flushing denormalized inputs to zero is enabled, denormal operands are flushed to zero before comparison, and if the result of the comparison is the flushed value, then a zero value is returned. Where both *x* and *y* are zero, or denormal values flushed to zero, with different signs, then +0.0 is returned by `FPMax()` and -0.0 by `FPMin()`.

The `FPMinNum(x,y)` and `FPMaxNum(x,y)` operations follow the IEEE 754-2008 standard and return the numerical operand when one operand is numerical and the other a quiet NaN. Apart from this additional handling of a single quiet NaN, the result is then identical to `FPMin(x,y)` and `FPMax(x,y)`.

Table C3-120 shows the Floating-point instructions that can perform floating-point minimum and maximum operations.

Table C3-120 Floating-point minimum and maximum instructions

Mnemonic	Instruction	See
`FMAX`	Floating-point maximum (scalar)	FMAX (scalar)
`FMAXNM`	Floating-point maximum number (scalar)	FMAXNM (scalar)
`FMIN`	Floating-point minimum (scalar)	FMIN (scalar)
`FMINNM`	Floating-point minimum number (scalar)	FMINNM (scalar)

C3.8.10 Floating-point comparison

These instructions set the NZCV Condition flags in PSTATE, based on the result of a comparison of two operands. If the floating-point comparisons are *unordered*, where one or both operands are a form of NaN, the C and V bits are set to 1 and the N and Z bits are cleared to 0.

Note

The NZCV flags in the FPSR are associated with AArch32 state. The A64 floating-point comparison instructions do not change the Condition flags in the FPSR.

For the conditional Floating-point comparison instructions, if the condition is TRUE, the flags are updated to the result of the comparison, otherwise the flags are updated to the immediate value that is defined in the instruction encoding.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The quiet compare instructions generate an Invalid Operation floating-point exception if either of the source operands is a signaling NaN. The signaling compare instructions generate an Invalid Operation floating-point exception if either of the source operands is any type of NaN.

Note

If FEAT_FlagM2 is implemented, instructions AXFLAG and XAFLAG convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format. See FEAT_FlagM for more information.

Table C3-121 shows the Floating-point comparison instructions.

C3.8.14 SIMD compare

The SIMD compare instructions compare vector or scalar elements according to the specified condition and set the destination vector element to all ones if the condition holds, or to zero if the condition does not hold.

Note

Some of the comparisons, such as LS, LE, LO, and LT, can be made by reversing the operands and using the opposite comparison, HS, GE, HI, or GT.

Table C3-125 shows that SIMD compare instructions.

Table C3-125 SIMD compare instructions

	Unsigned integer convert to floating-point (vector)	UCVTF (vector, integer)

C3.8.21.3 FP8 floating-point conversion

Convert each floating-point element of the source vector while scaling the value, and place the results in the corresponding elements of the destination vector.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For instructions that convert other floating-point formats to FP8 formats, each input element is scaled by adding the value specified in FPMR.NSCALE to its unbounded exponent during the conversion.

For instructions that convert FP8 formats to other floating-point formats, each input element is scaled by subtracting the value specified in FPMR.LSCALE or FPMR.LSCALE2 from its unbounded exponent during the conversion.

For more information, see the instruction descriptions.

Table C3-134 shows the SIMD FP8 floating-point conversion instructions.

Table C3-134 SIMD FP8 floating-point conversion instructions

SMINP	Signed minimum pairwise	SMINP
UMAXP	Unsigned maximum pairwise	UMAXP
UMINP	Unsigned minimum pairwise	UMINP

C3.8.24 SIMD dot product

C3.8.24.1 Integer dot product

FEAT_DotProd provides SIMD instructions that perform the dot product of the four 8-bit subelements of the 32-bit elements of one vector with the four 8-bit subelements of a second vector. It provides two forms of the instructions, each with signed and unsigned versions:

Vector form The dot product is calculated for each element of the first vector with the corresponding element of the second vector.

Indexed form The dot product is calculated for each element of the first vector with the element of the second vector that is indicated by the index argument to the instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

That is, a single element from the second vector is used, and the dot product is calculated between each element of the first vector and this single element from the second vector.

Table C3-137 shows the SIMD integer dot product instructions.

Table C3-137 SIMD integer dot product instructions

Mnemonic	Instruction	See
SDOT	Dot product signed arithmetic (vector)	SDOT (vector)
	Dot product signed arithmetic (vector, by element)	SDOT (by element)
SUDOT	Dot product with signed and unsigned integers (vector, by element)[a]	SUDOT (by element)
UDOT	Dot product unsigned arithmetic (vector)	UDOT (vector)
	Dot product unsigned arithmetic (vector, by element)	UDOT (by element)
USDOT	Dot product with unsigned and signed integers (vector)[a]	USDOT (vector)
	Dot product with unsigned and signed integers (vector, by element)[a]	USDOT (by element)

a. This instruction is supported when FEAT_I8MM is implemented.

C3.8.24.2 FP8 floating-point dot product

The FP8 floating-point dot product instructions accumulate the dot product of two or four adjacent FP8 source elements into half-precision or single-precision destination elements. They generate a fused, downscaled sum-of-products and accumulate into each destination element, without intermediate rounding.

For these instructions, the unbounded intermediate sum-of-products is scaled by subtracting the value specified in FPMR.LSCALE from its unbounded exponent. For more information, see the instruction descriptions.

Table C3-138 shows these instructions.

Table C3-138 SIMD FP8 floating-point dot product instructions

Mnemonic	Instruction	See
FDOT	8-bit floating-point dot product to half-precision (vector)	FDOT (8-bit floating-point to half-precision, vector)
	8-bit floating-point dot product to half-precision (vector, by element)	FDOT (8-bit floating-point to half-precision, by element)
	8-bit floating-point dot product to single-precision (vector)	FDOT (8-bit floating-point to single-precision, vector)
	8-bit floating-point dot product to single-precision (vector, by element)	FDOT (8-bit floating-point to single-precision, by element)

C3.8.25 SIMD matrix multiply-accumulate

C3.8.25.1 Integer matrix multiply-accumulate

The integer matrix multiply-accumulate instructions are implemented by FEAT_I8MM.

The source and destination vectors of this instruction are organized as follows:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In the first source vector, a 2x8 matrix of 8-bit integers in row-by-row order.
- In the second source vector, an 8x2 matrix of 8-bit integers in column-by-column order.
- In the destination vector, a 2x2 matrix of 32-bit integers in row-by-row order.

One matrix multiplication is performed per vector and accumulated into the destination vector.

Table C3-139 shows these instructions.

Table C3-139 SIMD integer matrix multiply-accumulate instructions

Mnemonic	Instruction	See
`SMMLA`	Signed 8-bit integer matrix multiply-accumulate to 32-bit integer (vector)	SMMLA (vector)
`UMMLA`	Unsigned 8-bit integer matrix multiply-accumulate to 32-bit integer (vector)	UMMLA (vector)
`USMMLA`	Unsigned and signed 8-bit integer matrix multiply-accumulate to 32-bit integer (vector)	USMMLA (vector)

C3.8.25.2 FP8 matrix multiply-accumulate

The FP8 `FMMLA` (widening, 8-bit floating-point to single-precision) instruction is implemented by FEAT_F8F32MM. The source and destination vectors of this instruction are organized as follows:

- In the first source vector, a 2x8 matrix of 8-bit floating-point values in row-by-row order.
- In the second source vector, an 8x2 matrix of 8-bit floating-point values in column-by-column order.
- In the destination vector, a 2x2 matrix of single-precision values in row-by-row order.

One matrix multiplication is performed per vector and accumulated into the destination vector.

The FP8 `FMMLA` (widening, 8-bit floating-point to half-precision) instruction is implemented by FEAT_F8F16MM. This instruction delimits each source and destination vector into 64-bit segments. The 64-bit segments are organized as follows:

- In the first source vector, a 2x4 matrix of 8-bit floating-point values in row-by-row order.
- In the second source vector, a 4x2 matrix of 8-bit floating-point values in column-by-column order.
- In the destination vector, a 2x2 matrix of half-precision values in row-by-row order.

One matrix multiplication is performed per vector segment and accumulated into the destination vector segment.

These instructions generate a fused, downscaled sum-of-products and accumulate into each destination element, without intermediate rounding.

For these instructions, the intermediate sum of products is downscaled by subtracting the value in FPMR.LSCALE from its unbounded exponent. For more information, see the instruction descriptions.

Table C3-140 SIMD FP8 matrix multiply-accumulate instructions

Mnemonic	Instruction	See
`FMMLA`	8-bit floating-point matrix multiply-accumulate to half-precision	FMMLA (widening, 8-bit floating-point to half-precision)
	8-bit floating-point matrix multiply-accumulate to single-precision	FMMLA (widening, 8-bit floating-point to single-precision)

C3.8.26 SIMD table lookup

C3.8.26.1 Table vector lookup

Table C3-141 shows the SIMD table vector lookup instructions.

Table C3-141 SIMD table vector lookup instructions

Mnemonic	Instruction	See
TBL	Table vector lookup	TBL
TBX	Table vector lookup extension	TBX

C3.8.26.2 Lookup table using 2-bit or 4-bit indices

Copy indexed elements from the first source vector(s) to the destination vector, using packed indices from a portion of the second source vector.

Table C3-142 shows the SIMD lookup table instructions.

Table C3-142 SIMD lookup table using 2-bit or 4-bit indices instructions

Mnemonic	Instruction	See
LUTI2	Lookup table read with 2-bit indices	LUTI2
LUTI4	Lookup table read with 4-bit indices	LUTI4

C3.8.27 SIMD complex number arithmetic instructions

FEAT_FCMA provides SIMD instructions that perform arithmetic on complex numbers held in element pairs in vector registers, where the less significant element of the pair contains the real component and the more significant element contains the imaginary component.

These instructions provide double-precision and single-precision versions. If FEAT_FP16 is implemented they also provide half-precision versions, otherwise the half-precision encodings are UNDEFINED.

Table C3-143 shows the FEAT_FCMA SIMD instructions.

Table C3-143 SIMD complex number arithmetic instructions

Mnemonic	Instruction	See
FCADD	Floating-point complex add	FCADD
FCMLA	Floating-point complex multiply accumulate	FCMLA
	Floating-point complex multiply accumulate (by element)	FCMLA (by element)

A pair of FCMLA instructions can be used to perform a complex number multiplication. This is demonstrated in Complex multiplication.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.8.28 SIMD multiply-accumulate

C3.8.28.1 Floating-point fused multiply-accumulate

The SIMD floating-point fused multiply-accumulate instructions multiply the vector elements in the first source SIMD&FP register by the corresponding value in the second source SIMD&FP register, and accumulate or subtract the product in the vector elements of the destination SIMD&FP register.

Table C3-144 shows these instructions.

Table C3-144 SIMD floating-point fused multiply-accumulate instructions

Mnemonic	Instruction	See
FMLA	Floating-point fused multiply-add to accumulator (vector)	FMLA (vector)
FMLAL	Floating-point fused multiply-add long to accumulator (vector) - FMLAL	FMLAL, FMLAL2 (vector) - FMLAL
FMLAL2	Floating-point fused multiply-add long to accumulator (vector) - FMLAL2	FMLAL, FMLAL2 (vector) - FMLAL2
FMLS	Floating-point fused multiply-subtract from accumulator (vector)	FMLS (vector)
FMLSL	Floating-point fused multiply-subtract long from accumulator (vector) - FMLSL	FMLSL, FMLSL2 (vector) - FMLSL
FMLSL2	Floating-point fused multiply-subtract long from accumulator (vector) - FMLSL2	FMLSL, FMLSL2 (vector) - FMLSL2

C3.8.28.2 FP8 floating-point widening multiply-accumulate

The FP8 floating-point multiply-accumulate instructions widen the 8-bit floating-point elements in the source vectors to half-precision or single-precision format and multiply the corresponding elements.

They generate a fused, downscaled product and accumulate into the corresponding elements of the destination vector, without intermediate rounding.

For these instructions, the unbounded intermediate product is scaled by subtracting the value specified in FPMR.LSCALE from its unbounded exponent. For more information, see the instruction descriptions.

Table C3-145 shows these instructions.

C3.8.29 SIMD BFloat16

If FEAT_BF16 is implemented, the instructions in this section are available.

C3.8.29.1 SIMD BFloat16 floating-point multiply-add

The BFloat16 floating-point multiply-add instructions perform an implicit conversion of the bottom (even-numbered) or top (odd-numbered) BFloat16 source elements to IEEE 754 single-precision floating-point format before performing a fused multiply-add without intermediate rounding to the overlapping single-precision destination element. These instructions follow the normal floating-point behaviors that apply to single-precision arithmetic, controlled by the Effective value of the FPCR, and captured in the FPSR cumulative exception bits.

Table C3-146 SIMD BFloat16 floating-point multiply-add instructions

Mnemonic	Instruction	See
BFMLALB	BFloat16 multiply-add to single-precision (by element)	BFMLALB, BFMLALT (by element)
	BFloat16 multiply-add to single-precision (vector)	BFMLALB, BFMLALT (vector)
BFMLALT	BFloat16 multiply-add to single-precision (by element)	BFMLALB, BFMLALT (by element)
	BFloat16 multiply-add to single-precision (vector)	BFMLALB, BFMLALT (vector)

C3.8.29.2 SIMD BFloat16 floating-point dot product

The BFloat16 floating-point dot product instruction, `BFDOT`, performs an implicit conversion of vectors of BFloat16 input values to IEEE 754 single-precision floating-point format.

The BFloat16 dot product instructions delimit their source vectors into pairs of BFloat16 elements.

Mnemonic	Instruction	See
BFDOT	BFloat16 dot product to single-precision (vector)	BFDOT (vector)
	BFloat16 dot product to single-precision (vector, by element)	BFDOT (by element)

C3.8.29.3 SIMD BFloat16 floating-point matrix multiply-accumulate

The BFloat16 floating-point matrix multiply-accumulate instruction, BFMMLA is implemented by FEAT_BF16.

The source and destination vectors of this instruction are organized as follows:

- In the first source vector, a 2x4 matrix of BFloat16 values in row-by-row order.
- In the second source vector, a 4x2 matrix of BFloat16 values in column-by-column order.
- In the destination vector, a 2x2 matrix of single-precision values in row-by-row order.

One matrix multiplication is performed per source vector and accumulated into the corresponding destination vector. This corresponds to accumulating two 2-way BFloat16 widening dot products into each single-precision destination element, following the numeric behaviors described for BFDOT instruction in SIMD BFloat16 floating-point dot product.

Table C3-148 SIMD BFloat16 floating-point matrix multiply instructions

Mnemonic	Instruction	See
BFMMLA	BFloat16 matrix multiply-accumulate to single-precision	BFMMLA (widening)

C3.8.29.4 SIMD BFloat16 floating-point convert

The BFloat16 floating-point convert instructions perform accurately rounded down-conversion of single-precision source vector elements to BFloat16 format.

C3.8.30 The Cryptographic Extension in AArch64 state

C3.8.30.1 The Armv8.0 Cryptographic Extension

The instructions provided by the OPTIONAL Armv8.0 Cryptographic Extension use the SIMD and floating-point register file. For more information about the functions they provide, see:

- *Advanced Encryption Standard (AES)*.
- *Secure Hash Algorithm (SHA)*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- *The Galois/Counter Mode of Operation*.

Table C3-150 shows the Armv8.0 Cryptographic Extension instructions.

Table C3-150 Cryptographic Extension instructions

Mnemonic	Instruction	See
`AESD`	AES single round decryption	AESD
`AESE`	AES single round encryption	AESE
`AESIMC`	AES inverse mix columns	AESIMC
`AESMC`	AES mix columns	AESMC
`PMULL`	Polynomial multiply long	PMULL, PMULL2[a]
`SHA1C`	SHA1 hash update (choose)	SHA1C
`SHA1H`	SHA1 fixed rotate	SHA1H
`SHA1M`	SHA1 hash update (majority)	SHA1M
`SHA1P`	SHA1 hash update (parity)	SHA1P
`SHA1SU0`	SHA1 schedule update 0	SHA1SU0
`SHA1SU1`	SHA1 schedule update 1	SHA1SU1
`SHA256H`	SHA-256 hash update (part 1)	SHA256H
`SHA256H2`	SHA-256 hash update (part 2)	SHA256H2
`SHA256SU0`	SHA-256 schedule update 0	SHA256SU0
`SHA256SU1`	SHA-256 schedule update 1	SHA256SU1

a. The Cryptographic Extension adds the variant of the instruction that operates on two 64-bit polynomials.

C3.8.30.2 Armv8.2 extensions to the Cryptographic Extension

Armv8.2 supports the following OPTIONAL extensions to the Cryptographic Extension:

- FEAT_SHA512, SHA2-512 functionality.
- FEAT_SHA3, SHA3 functionality.
- FEAT_SM3, SM3 functionality.
- FEAT_SM4, SM4 functionality.

C3.8.30.2.1 FEAT_SHA512, SHA2-512 functionality

FEAT_SHA512 provides instructions to accelerate the SHA-2 hash algorithm using a digest that is larger than 256 bits. The relevant standards are SHA-384, SHA-512, SHA-512|224 and SHA-512|256. These are all based on the SHA-512 calculation, and therefore this set of instructions is described as the *SHA512 instructions*.

Implementation of FEAT_SHA512 requires the implementation of the SHA1 and SHA2-256 instructions from the Armv8.0 Cryptographic Extension.

Note

Implementation of FEAT_SHA512 does not require the implementation of the AES instructions, and the 64-bit polynomial variants of the `PMULL` instructions, from the Armv8.0 Cryptographic Extension.

When FEAT_SHA512 is implemented, the value of ID_AA64ISAR0_EL1.SHA2 is `0b0010`, indicating support for the SHA512 instructions.

Table C3-151 shows the FEAT_SHA512 instructions:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-151 FEAT_SHA512 instructions

Mnemonic	Instruction	See
SHA512H	SHA-512 hash update part 1	SHA512H
SHA512H2	SHA-512 hash update part 2	SHA512H2
SHA512SU0	SHA-512 schedule update 0	SHA512SU0
SHA512SU1	SHA-512 schedule update 1	SHA512SU1

Use of the SHA512 instructions shows an example of the use of these instructions to calculate a SHA512 hash iteration. This example code is not part of the architectural definition of these instructions.

C3.8.30.2.2 FEAT_SHA3, SHA3 functionality

FEAT_SHA3 provides instructions to accelerate the SHA-3 hash algorithm. This set of instructions is described as the *SHA3 instructions.*

Note

Implementation of FEAT_SHA3 does not require the implementation of the AES instructions, and the 64-bit polynomial variants of the `PMULL` instructions, from the Armv8.0 Cryptographic Extension.

When FEAT_SHA3 is implemented, the value of ID_AA64ISAR0_EL1.SHA3 is `0b0001`, indicating support for the SHA3 instructions.

Table C3-152 shows the FEAT_SHA3 instructions. The SHA-3 hash algorithm is based on a running digest of 1600 bytes, arranged as a five by five array of 64-bit registers. The Arm acceleration of these instructions is based on mapping the 25 64-bit values into 25 vector registers, with each 64-bit value occupying the same 64-bit element in each vector. A series of transformations is performed on these registers as part of a round of the SHA-3 hash calculation.

The SIMD nature of the vector registers means the acceleration can calculate two parallel SHA3 hash calculations, where one calculation is performed using the zeroth 64-bit element of each vector, and the other calculation is performed using the first 64-bit element of each vector.

To provide acceleration where the SIMD calculation is not required, the instructions provide variants that operate only on the zeroth 64-bit elements. These are provided as a power optimization.

Table C3-152 FEAT_SHA3 instructions

Mnemonic	Instruction	See
BCAX	Bit clear and exclusive-OR	BCAX
EOR3	Three-way exclusive-OR	EOR3
RAX1	Rotate and exclusive-OR	RAX1
XAR	Exclusive-OR and rotate	XAR

Use of the SHA3 instructions shows an example of the use of these instructions to calculate the combined theta, phi, rho and chi operations of a SHA3 iteration. This example code is not part of the architectural definition of these instructions.

C3.8.30.2.3 FEAT_SM3, SM3 functionality

FEAT_SM3 provides instructions to accelerate the SM3 hash algorithm, the standard Chinese hash algorithm. These are described as the *SM3 instructions.*

FEAT_SM3 can be implemented independently of any part of the Armv8.0 Cryptographic Extension, and independently of FEAT_SHA512.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This means that Armv8.2 permits an implementation of the Cryptographic Extension that provides only the FEAT_SM3 functionality.

When FEAT_SM3 is implemented, the value of ID_AA64ISAR0_EL1.SM3 is `0b0001`, indicating support for the SM3 instructions.

Table C3-153 shows the FEAT_SM3 instructions. The SM3 algorithm calculates a digest of 256 bits, which can be held in two vector registers. The SM3 instructions include instructions to accelerate the computation of the hash and the schedule update.

Note

The SM3 instruction names refer to intermediate variables defined as part of the *SM3 Cryptographic Hash Algorithm* specification.

Table C3-153 FEAT_SM3 instructions

Mnemonic	Instruction	See
`SM3PARTW1`	SM3PARTW1	SM3PARTW1
`SM3PARTW2`	SM3PARTW2	SM3PARTW2
`SM3SS1`	SM3SS1	SM3SS1
`SM3TT1A`	SM3TT1A	SM3TT1A
`SM3TT1B`	SM3TT1B	SM3TT1B
`SM3TT2A`	SM3TT2A	SM3TT2A
`SM3TT2B`	SM3TT2B	SM3TT2B

Use of the SM3 instructions shows an example of the use of these instructions to generate an SM3 hash. This example code is not part of the architectural definition of these instructions.

C3.8.30.2.4 FEAT_SM4, SM4 functionality

FEAT_SM4 provides instruction to accelerate the SM4 encryption algorithm, the standard Chinese encryption algorithm. This set of instructions is described as the *SM4 instructions*.

FEAT_SM4 can be implemented independently of any part of the Armv8.0 Cryptographic Extension, and independently of FEAT_SHA3.

Note

This means that Armv8.2 permits an implementation of the Cryptographic Extension that provides only the FEAT_SM4 functionality.

When FEAT_SM4 is implemented, the value of ID_AA64ISAR0_EL1.SM4 is `0b0001`, indicating support for the SM4 instructions.

Table C3-154 shows the FEAT_SM4 instructions. The SM4 algorithm is 128-bit wide block cipher. The `SM4E` instruction accelerates a single round of encryption or decryption, and the `SM4EKEY` instruction accelerates a single round of key generation:

C3.9 Data processing - SVE

The following subsections describe the SVE processing instructions:

- SVE Vector integer operations
- SVE Vector address calculation
- SVE Bitwise logical operations
- SVE Bitwise shift, reverse, and count
- SVE Vector floating-point operations
- Predicate operations
- Loop control
- SVE Move operations
- Index vector generation
- Move prefix
- Reduction operations

C3.9.1 SVE Vector integer operations

C3.9.1.1 SVE Integer arithmetic

For binary operations, the Integer arithmetic instructions perform arithmetic operations on a source vector containing integer element values, and a second source vector of either integer element values or an immediate value.

For ternary operations, these instructions perform arithmetic operations on a source vector containing integer element values, a second source vector of either integer element values or an immediate value, and a third source vector containing integer element values.

Table C3-155 Integer arithmetic instructions

Mnemonic	Instruction	See
ABS	Absolute value (predicated)	ABS
ADD	Add (predicated)	ADD (vectors, predicated)
	Add (unpredicated)	ADD (vectors, unpredicated)
	Add immediate (unpredicated)	ADD (immediate)

C3.9.1.2 SVE Integer dot product

The Integer dot product instructions delimit the source vectors into groups of four 8-bit or 16-bit integer elements. Within each group of four elements, the elements in the first source vector are multiplied by the corresponding elements in the second source vector. The resulting widened products are summed and added to the 32-bit or 64-bit element of the accumulator and destination vector that aligns with the group of four elements in the first source vector.

The indexed forms of these instructions specify a single, numbered, group of four elements within each 128-bit segment of the second source vector as the multiplier for all the groups of four elements within the corresponding 128-bit segment of the first source vector.

Table C3-156 Integer dot product instructions

Mnemonic	Instruction	See
SDOT	Signed integer dot product (four-way)	SDOT (4-way, vectors)
	Signed integer dot product (two-way)	SDOT (2-way, vectors)
	Signed integer dot product by indexed element (four-way)	SDOT (4-way, indexed)
	Signed integer dot product by indexed element (two-way)	SDOT (2-way, indexed)
SUDOT	Signed by unsigned 8-bit integer dot product by indexed element to 32-bit integer	SUDOT
UDOT	Unsigned integer dot product (four-way)	UDOT (4-way, vectors)
	Unsigned integer dot product (two-way)	UDOT (2-way, vectors)
	Unsigned integer dot product by indexed element (four-way)	UDOT (4-way, indexed)
	Unsigned integer dot product by indexed element (two-way)	UDOT (2-way, indexed)
USDOT	Unsigned by signed 8-bit integer dot product by indexed element to 32-bit integer	USDOT (indexed)
	Unsigned by signed 8-bit integer dot product to 32-bit integer	USDOT (vectors)

C3.9.1.3 SVE Integer matrix multiply-accumulate

The Integer matrix multiply-accumulate instructions are implemented by FEAT_I8MM.

The matrix multiply-accumulate instructions delimit source and destination vectors into 128-bit segments. The 128-bit segments are organized as follows:

- In the first source vector, a 2x8 matrix of 8-bit integers in row-by-row order.
- In the second source vector, an 8x2 matrix of 8-bit integers in column-by-column order.
- In the destination vector, a 2x2 matrix of 32-bit integers in row-by-row order.

One matrix multiplication is performed per vector segment and accumulated into the destination vector segment.

Table C3-157 Integer matrix multiply operations

Mnemonic	Instruction	See

C3.9.1.4 SVE Integer comparison

The Integer comparison instructions compare *Active elements* in the first source vector with the corresponding elements in a second vector or with an immediate value. The Boolean result of each comparison is placed in the corresponding element of the destination predicate. *Inactive elements* in the destination predicate register are set to FALSE. All integer comparisons set the N, Z, and C condition flags based on the predicate result, and set the V flag to zero.

The wide element variants of the compare instructions allow a packed vector of narrower elements to be compared with wider 64-bit elements. These instructions treat the second source vector as having a fixed 64-bit doubleword element size and compare each narrow element of the first source vector with the corresponding vertically-aligned wide element of the second source vector. For example, if the first source vector contained 8-bit byte elements, then 8-bit element[0] to element[7] of the first source vector are compared with 64-bit element[0] of the second source vector, 8-bit element[8] to element[15] with 64-bit element[1], and so on. All 64 bits of the wide elements are significant for the comparison, with the narrow elements being sign-extended or zero-extended to 64 bits as appropriate for the type of comparison.

C3.9.2 SVE Vector address calculation

The Vector address calculation instructions calculate vectors of addresses and addresses of vectors. This includes instructions to add a multiple of the current vector length or predicate register length, in bytes, to a general-purpose register.

The ADR instruction is an integer arithmetic operation that is used to calculate a vector of 64-bit or 32-bit addresses.

The ADR destination vector elements are calculated by the addition of the corresponding elements in the source vectors, with an optional sign or zero extension and optional bitwise left shift of 1-3 bits applied to the final operands. This can be considered as the addition of a vector base and a scaled vector index.

The ADR instruction calculates a vector of 32-bit addresses by the addition of a 32-bit base and a scaled 32-bit unsigned index. The ADR instruction calculates a vector of 64-bit addresses by one of:

- Addition of a 64-bit base and a scaled 64-bit unsigned index.
- Addition of a 64-bit base and a scaled, zero-extended 32-bit index.
- Addition of a 64-bit base and a scaled, sign-extended 32-bit index.

Table C3-159 Vector address calculation instructions

	Bitwise exclusive-OR (unpredicated)	EOR (vectors, unpredicated)
	Bitwise exclusive-OR with immediate (unpredicated)	EOR (immediate)
MOV	Move logical bitmask immediate to vector (unpredicated)	MOV
	Move vector register (unpredicated)	MOV (vector, unpredicated)
NOT	Bitwise invert (predicated)	NOT (vector)
ORN	Bitwise inclusive OR with inverted immediate (unpredicated)	ORN (immediate)
ORR	Bitwise inclusive OR (predicated)	ORR (vectors, predicated)
	Bitwise inclusive OR (unpredicated)	ORR (vectors, unpredicated)
	Bitwise inclusive OR with immediate (unpredicated)	ORR (immediate)

C3.9.4 SVE Bitwise shift, reverse, and count

Bitwise shifts, reversals, and counts within vector elements.

Shift counts saturate at the number of bits per element, rather than being used modulo the element size. If modulo behavior is required, then the modulus must be calculated separately.

The wide element variants of the bitwise shift instructions allow a packed vector of narrower elements to be shifted by wider 64-bit shift amounts. These instructions treat the second source vector as having a fixed 64-bit doubleword element size and shift each narrow element of the first source vector by the corresponding vertically-aligned wide element of the second source vector. For example, if the first source vector contained 8-bit byte elements, then 8-bit element[0] to element[7] of the first vector are shifted by 64-bit element[0] of the second source vector, 8-bit element [8] to element[15] by 64-bit element[1], and so on. All 64 bits of the wide shift amount are significant.

Table C3-161 Bitwise shift, reverse, and count instructions

Mnemonic	Instruction	See

C3.9.5.2 SVE Floating-point multiply accumulate

The Floating-point multiply accumulate instructions perform floating-point fused multiply-add or multiply-subtract operations and their negated forms. There are two groups of these instructions, as follows:

- Instructions where the result of the operation is written to the addend register.
  - Supported instructions are: FMLA, FMLS, FNMLA, FNMLS.
- Instructions where the result of the operation is written to the multiplicand register.
  - Supported instructions are: FMAD, FMSB, FNMAD, FNMSB.

Table C3-163 Floating-point multiply accumulate instructions

Mnemonic	Instruction	See
FMLA	Floating-point fused multiply-add (predicated)	FMLA (vectors)
	Floating-point fused multiply-add by indexed element	FMLA (indexed)
FMLS	Floating-point fused multiply-subtract (predicated)	FMLS (vectors)

C3.9.5.3 SVE Floating-point complex arithmetic

The Floating-point complex arithmetic instructions perform arithmetic on vectors containing floating-point complex numbers as interleaved pairs of elements, where the even-numbered elements contain the real components and the odd-numbered elements contain the imaginary components.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The `FCADD` instructions rotate the complex numbers in the second source vector by 90 degrees or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, before adding active pairs of elements to the corresponding elements of the first source vector in a destructive manner.

The `FCMLA` instructions perform a transformation of the operands to allow the creation of multiply-add or multiply-subtract operations on complex numbers by combining two of the instructions. The transformations performed are as follows:

- The complex numbers in the second source vector, considered in polar form, are rotated by 0 degrees or 180 degrees before multiplying by the duplicated real components of the first source vector.
- The complex numbers in the second source vector, considered in polar form, are rotated by 90 degrees or 270 degrees before multiplying by the duplicated imaginary components of the first source vector.

The resulting products are then added to the corresponding components of the destination and addend vector, without intermediate rounding.

Two FCMLA instructions can be used as follows:

```
FCMLA Zda.S, Pg/M, Zn.S, Zm.S, #A
...
FCMLA Zda.S, Pg/M, Zn.S, Zm.S, #B
```

For example, some meaningful combinations of A and B are:

- A=0, B=90. In this case, the two vectors of complex numbers in Zn and Zm are multiplied and the products are added to the complex numbers in Zda.
- A=0, B=270. In this case, the conjugates of the complex numbers in Zn are multiplied by the complex numbers in Zm and the products are added to the complex numbers in Zda.
- A=180, B=270. In this case, the two vectors of complex numbers in Zn and Zm are multiplied and the products are subtracted from the complex numbers in Zda.
- A=180, B=90. In this case, the conjugates of the complex numbers in Zn are multiplied by the complex numbers in Zm and the products are subtracted from the complex numbers in Zda.

Note

The lack of intermediate rounding can give unexpected results in certain cases relative to a traditional sequence of independent multiply, add, and subtract instructions.
In addition, when using these instructions, the behavior of calculations such as ($\infty+\infty i$) multiplied by (0+i) is (NaN+NaNi), rather than the result expected by ISO C, which is complex. The expectation is that these instructions are only used in situations where the effect of differences in the rounding and handling of infinities are not material to the calculation.

C3.9.5.5 SVE Floating-point comparisons

The Floating-point comparison instructions compare active floating-point element values in the first source vector with corresponding elements in the second vector or with the immediate value +0.0. The Boolean result of each comparison is placed in the corresponding element of the destination predicate. *Inactive elements* in the destination predicate register are set to FALSE. Floating-point vector comparisons do not set the condition flags.

C3.9.5.6 SVE Floating-point transcendental acceleration

The Floating-point transcendental instructions accelerate calculations of sine, cosine, and exponential functions for vectors containing floating-point element values.

The trigonometric instructions accelerate the calculation of a polynomial series approximation for the sine and cosine functions. The exponential instruction accelerates the polynomial series calculation of the exponential function.

Table C3-167 Floating-point transcendental instructions

FEXPA	Floating-point exponential accelerator	FEXPA
FTMAD	Floating-point trigonometric multiply-add coefficient	FTMAD
FTSMUL	Floating-point trigonometric starting value	FTSMUL
FTSSEL	Floating-point trigonometric select coefficient	FTSSEL

C3.9.5.7 SVE Floating-point indexed multiples

The Floating-point indexed multiples instructions multiply all floating-point elements within each 128-bit segment of the first source vector by the single numbered element within the corresponding segment of the second source vector.

For the FMLA and FMLS instructions, the products are destructively added or subtracted from the corresponding elements of the addend and destination vector, without intermediate rounding.

Table C3-168 Floating-point indexed multiples instructions

Mnemonic	Instruction	See
FMLA	Floating-point fused multiply-add by indexed element	FMLA (indexed)
FMLS	Floating-point fused multiply-subtract by indexed element	FMLS (indexed)
FMUL	Floating-point multiply by indexed element	FMUL (indexed)

C3.9.5.8 SVE Floating-point matrix multiply-accumulate and companion instructions

The floating-point matrix multiply-accumulate and companion instructions facilitate matrix multiplication calculation.

The matrix multiply-accumulate instructions delimit source and destination vectors into segments. The segments are organized as follows:

- In the first source vector, a 2x2 matrix in row-by-row order.
- In the second source vector, a 2x2 matrix in column-by-column order.
- In the destination vector, a 2x2 matrix in row-by-row order.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

One matrix multiplication is performed per vector segment and accumulated into the destination vector segment. For the double-precision matrix multiply-accumulate instructions, the vector segment length and minimum vector length is 256 bits. Double-precision matrix multiply-accumulate instructions are not supported when the vector length is 128 bits. For the single-precision matrix multiply-accumulate instruction, the vector segment length is 128 bits.

The floating-point matrix multiply-accumulate instructions strictly define the order of accumulations, and the multiplications and additions are not fused, so intermediate rounding is performed after every multiplication and every addition.

The companion instructions support data rearrangements in vector registers as required by the double-precision matrix multiply-accumulate instructions.

The following table shows the floating-point matrix multiplication instructions and companion instructions that are implemented by FEAT_F64MM:

Table C3-169 Floating-point matrix multiply instructions

Mnemonic	Instruction	See
FMMLA	Floating-point matrix multiply-accumulate	FMMLA (non-widening)
LD1ROB	Contiguous load and replicate thirty-two bytes (immediate index)	LD1ROB (scalar plus immediate)

FMMLA	Floating-point matrix multiply-accumulate	FMMLA (non-widening)

C3.9.5.9 SVE BFloat16 floating-point multiply-add

The BFloat16 floating-point multiply-add instructions perform an implicit conversion of the bottom (even-numbered) or top (odd-numbered) BFloat16 source elements to IEEE 754 single-precision floating-point format before performing a fused multiply-add without intermediate rounding to the overlapping single-precision destination element. These instructions follow the normal floating-point behaviors that apply to single-precision arithmetic, controlled by the Effective value of the FPCR, and captured in the FPSR cumulative exception bits.

BFMLSLT	BFloat16 multiply-subtract by indexed element from single-precision (top)	BFMLSLT (indexed)
	BFloat16 multiply-subtract from single-precision (top)	BFMLSLT (vectors)

C3.9.5.10 SVE BFloat16 floating-point dot product

The BFloat16 floating-point dot product instruction, `BFDOT`, performs an implicit conversion of vectors of BFloat16 input values to IEEE 754 single-precision floating-point format.

The BFloat16 dot product instructions delimit their source vectors into pairs of BFloat16 elements.

Table C3-172 SVE BFloat16 floating-point dot product instructions

Mnemonic	Instruction	See
BFDOT	BFloat16 dot product by indexed element to single-precision	BFDOT (indexed)
	BFloat16 dot product to single-precision	BFDOT (vectors)

C3.9.5.11 SVE BFloat16 floating-point matrix multiply-accumulate

The BFloat16 floating-point matrix multiply-accumulate instruction, `BFMMLA`, is implemented by FEAT_BF16.

This instruction delimits the source and destination vectors into 128-bit segments. The 128-bit segments are organized as follows:

- In the first source vector, a 2x4 matrix of BFloat16 values in row-by-row order.
- In the second source vector, a 4x2 matrix of BFloat16 values in column-by-column order.
- In the destination vector, a 2x2 matrix of single-precision values in row-by-row order.

One matrix multiplication is performed per source vector segment and accumulated into the corresponding destination vector segment. This corresponds to accumulating two 2-way BFloat16 widening dot products into each single-precision destination element, following the numeric behaviors described for `BFDOT` instruction in SVE BFloat16 floating-point dot product.

Table C3-173 SVE BFloat16 floating-point matrix multiply instruction

Mnemonic	Instruction	See
BFMMLA	BFloat16 matrix multiply-accumulate to single-precision	BFMMLA (widening)

C3.9.5.12 SVE BFloat16 floating-point convert

The BFloat16 floating-point convert instructions perform accurately rounded down-conversion of IEEE 754 single-precision source vector elements to BFloat16 format.

The BFCVT instruction places its BFloat16 results in the bottom or even-numbered 16-bit elements of the destination vector, and sets the top or odd-numbered elements to zero.

The BFCVTNT instruction places its BFloat16 results in the top or odd-numbered 16-bit elements of the destination vector, leaving the bottom or even-numbered elements unchanged.

These instructions follow the normal floating-point behaviors that apply to single-precision arithmetic, controlled by the Effective value of the FPCR, and captured in the FPSR cumulative exception bits.

Table C3-174 SVE BFloat16 floating-point convert instructions

Mnemonic	Instruction	See
BFCVT	Single-precision convert to BFloat16 (predicated)	BFCVT
BFCVTNT	Single-precision convert to BFloat16 (top, predicated)	BFCVTNT

C3.9.6 Predicate operations

The Predicate instructions perform operations that manipulate the predicate registers.

Some of these instructions are insensitive to the predicate element size and specify an explicit byte element size qualifier, .B, but an assembler must accept any qualifier, or none.

C3.9.6.1 SVE Predicate initialization

The Predicate initialization instructions initialize predicate elements.Predicate elements can be initialized to be FALSE, or to be TRUE when their element number is less than:

- A fixed number of elements from the following range: VL1-VL8, VL16, VL32, VL64, VL128 or VL256.
- The largest power of two elements, POW2.
- The largest multiple of three or four elements, MUL3 or MUL4.
- The number of accessible elements, ALL, which is implicitly a multiple of two.

Unspecified or out of range constraint encodings generate a predicate with values that are all FALSE and do not cause an Undefined Instruction exception.

Table C3-175 Predicate initialization instructions

Mnemonic	Instruction	See
PFALSE	Set all predicate elements to false	PFALSE

Non-Confidential

Mnemonic	Instruction	See
PTRUE	Initialize predicate from named constraint	PTRUE (predicate)
PTRUES	Initialize predicate from named constraint and set the condition flags	PTRUES

C3.9.6.2 SVE Predicate move operations

The Predicate move instructions operate on all bits of the predicate registers, implying a fixed, 1-bit predicate element size. The flag-setting variants set the N, Z, and C condition flags based on the predicate result, and set the V flag to zero. Because these instructions operate with a fixed, 1-bit element size, the *Governing predicate* for the flag-setting variants should be in the canonical form for a predicate element size in order to generate a meaningful set of condition flags for that element size.

Table C3-176 Predicate move instructions

Mnemonic	Instruction	See
MOV	Move predicate (unpredicated)	MOV
	Move predicates (merging)	MOV (predicate, merging)
	Move predicates (zeroing)	MOV (predicate, zeroing)
MOVS	Move predicate (unpredicated), setting the condition flags	MOVS (unpredicated)
	Move predicates (zeroing), setting the condition flags	MOVS (predicated)
SEL	Conditionally select elements from two predicates	SEL (predicates)

C3.9.6.3 SVE Predicate logical operations

The Predicate logical operation instructions perform bitwise logical operations on predicate registers that operate on all bits of the register, implying a fixed, 1-bit predicate element size. The flag-setting variants set the N, Z, and C condition flags based on the predicate result, and set the V flag to zero. Inactive elements in the destination Predicate register are set to zero, except for PTEST which does not specify a destination register. Because these instructions operate with a fixed, 1-bit element size, the *Governing predicate* for the flag-setting variants should be in the canonical form for a predicate element size in order to generate a meaningful set of condition flags for that element size.

ORR	Bitwise inclusive OR predicates	ORR (predicates)
ORRS	Bitwise inclusive OR predicates, setting the condition flags	ORRS
PTEST	Set condition flags for predicate	PTEST

C3.9.6.4 FFR predicate handling

The FFR predicate handling instructions work with SVE First-fault and Non-fault loads using the FFR to determine which elements have been successfully loaded and which remain to be loaded on a subsequent iteration.

The RDFFRS instruction sets the N, Z, and C condition flags based on the predicate result, and sets the V flag to zero. Because these instructions operate with a fixed, 1-bit element size, the *Governing predicate* for the RDFFRS instruction should be in the canonical form for a predicate element size in order to generate a meaningful set of condition flags for that element size.

Table C3-178 FFR predicate handling instructions

Mnemonic	Instruction	See
RDFFR	Read the first-fault register	RDFFR (unpredicated)
	Return predicate of successfully loaded elements	RDFFR (predicated)
RDFFRS	Return predicate of successfully loaded elements, setting the condition flags	RDFFRS
SETFFR	Initialize the first-fault register to all true	SETFFR
WRFFR	Write the first-fault register	WRFFR

C3.9.6.5 Predicate count

The Predicate count instructions count either the number of Active predicate elements that are set to TRUE, or the number of elements implied by a named predicate constraint. The count can be placed in a general-purpose register, or used to increment or decrement a vector or general-purpose register.

Signed or unsigned saturating variants handle cases where, for example, an increment might cause a vectorized scalar loop index to overflow and therefore never satisfy a loop termination condition that compares it with a limit that is close to the maximum integer value.

The named predicate constraint limits the number of elements to:

- A fixed number of elements from the following range: VL1-VL8, VL16, VL32, VL64, VL128 or VL256.
- The largest power of two elements, POW2.
- The largest multiple of three or four elements, MUL3 or MUL4.
- The number of accessible elements, ALL, implicitly a multiple of two.

Unspecified or out of range predicate constraint encodings generate a zero element count and do not cause an Undefined Instruction exception.

UQINCW	Unsigned saturating increment scalar by multiple of 32-bit predicate constraint element count	UQINCW (scalar)
	Unsigned saturating increment vector by multiple of 32-bit predicate constraint element count	UQINCW (vector)

C3.9.7 Loop control

These instructions control counted vector loops and vector loops with data-dependent termination conditions. These instructions create a loop partition predicate with *Active elements* set to TRUE up to the point where the loop should terminate, and FALSE thereafter. Two loop concepts are supported, simple loops and data-dependent loops.

C3.9.7.1 Simple loops

An up-counting `WHILE` instruction that increments the value of the first scalar operand and compares the value with a second, fixed scalar operand. The instruction generates a destination predicate with all of the following characteristics:

- The predicate elements starting from the lowest numbered element are true while the comparison is true.
- The predicate elements thereafter, up to the highest numbered element, are false when the comparison becomes false.

All 32 bits or 64 bits of the scalar operands are significant for the purposes of comparison. The full 32-bit or 64-bit value of the first operand is incremented by 1 for each destination predicate element, irrespective of the element size. The first general-purpose register operand is not updated.

If all of the following occur, a comparison can never fail, resulting in an all-true predicate:

- The comparison includes an equality test.
- The second scalar operand is equal to the maximum integer value of the selected size and type of comparison.

The N, Z, C, and V condition flags are unconditionally set to control a subsequent conditional branch.

Table C3-180 Single loop instructions

Mnemonic	Instruction	See
WHILELE	While incrementing signed scalar less than or equal to scalar	WHILELE (predicate)
WHILELO	While incrementing unsigned scalar lower than scalar	WHILELO (predicate)
WHILELS	While incrementing unsigned scalar lower than or same as scalar	WHILELS (predicate)
WHILELT	While incrementing signed scalar less than scalar	WHILELT (predicate)

C3.9.7.2 Data-independent loops

For data-dependent termination conditions, it is necessary to convert the result of a vector comparison into a loop partition predicate. The new partition truncates the current vector partition immediately before or after the first active TRUE comparison. The N, Z, C, and V condition flags are optionally set to control a subsequent conditional branch.

The `BRKA` instructions set active destination predicate elements to TRUE up to and including the first active TRUE element in their source predicate register, setting subsequent elements to FALSE.

The `BRKB` instructions set active destination predicate elements to TRUE up to but excluding the first active TRUE element in their source predicate register, setting subsequent elements to FALSE.

The `BRKPA` and `BRKPB` instructions propagate the result of a previous `BRKB` or `BRKPB` instruction, by setting their destination predicate register to all FALSE if the *Last active element* of their first source predicate register is not TRUE, but otherwise generate the destination predicate from their second source predicate as described for the `BRKA` and `BRKB` instructions.

The BRKN instructions propagate the result of a previous `BRKB` or `BRKPB` instruction by setting the destination predicate register to all FALSE if the *Last active element* of their first source predicate register is not TRUE, but otherwise leave the destination predicate unchanged. The destination and second source predicate must have been created by another instruction, such as `RDFFR` or `WHILE`.

Table C3-181 Data-independent loop instructions

Mnemonic	Instruction	See
`BRKA`	Break after first true condition	BRKA
`BRKAS`	Break after first true condition, setting the condition flags	BRKAS
`BRKB`	Break before first true condition	BRKB
`BRKBS`	Break before first true condition, setting the condition flags	BRKBS
`BRKN`	Propagate break to next partition	BRKN
`BRKNS`	Propagate break to next partition, setting the condition flags	BRKNS
`BRKPA`	Break after first true condition, propagating from previous partition	BRKPA
`BRKPAS`	Break after first true condition, propagating from previous partition and setting the condition flags	BRKPAS
`BRKPB`	Break before first true condition, propagating from previous partition	BRKPB
`BRKPBS`	Break before first true condition, propagating from previous partition and setting the condition flags	BRKPBS

C3.9.7.3 Serialized operations

The Serialized operation instructions permit *Active elements* within a vector to be processed sequentially without unpacking the vector. The condition flags are unconditionally set to control a subsequent conditional branch.

Table C3-182 Serialized operation instructions

Mnemonic	Instruction	See
`CTERMEQ`	Compare and terminate loop - Equal	CTERMEQ, CTERMNE - Equal
`CTERMNE`	Compare and terminate loop - Not equal	CTERMEQ, CTERMNE - Not equal
`PFIRST`	Set the First active predicate element to true	PFIRST
`PNEXT`	Find next active predicate	PNEXT

C3.9.8 SVE Move operations

C3.9.8.1 Element move and broadcast

The Element move and broadcast instructions copy data from scalar registers, immediate values, and other vectors to all vector elements or only to Active vector elements. The copied data might be in an integer or floating-point format.

Table C3-183 Element move and broadcast instructions

Mnemonic	Instruction	See
CPY	Copy general-purpose register to vector elements (predicated)	CPY (scalar)
	Copy signed integer immediate to vector elements (merging)	CPY (immediate, merging)
	Copy signed integer immediate to vector elements (zeroing)	CPY (immediate, zeroing)
	Copy SIMD&FP scalar register to vector elements (predicated)	CPY (SIMD&FP scalar)
DUP	Broadcast general-purpose register to vector elements (unpredicated)	DUP (scalar)
	Broadcast signed immediate to vector elements (unpredicated)	DUP (immediate)
FCPY	Copy floating-point immediate to vector elements (predicated)	FCPY
FDUP	Broadcast floating-point immediate to vector elements (unpredicated)	FDUP
FMOV	Move floating-point +0.0 to vector elements (predicated)	FMOV (zero, predicated)
	Move floating-point +0.0 to vector elements (unpredicated)	FMOV (zero, unpredicated)
	Move floating-point immediate to vector elements (predicated)	FMOV (immediate, predicated)
	Move floating-point immediate to vector elements (unpredicated)	FMOV (immediate, unpredicated)
MOV	Move general-purpose register to vector elements (predicated)	MOV (scalar, predicated)
	Move general-purpose register to vector elements (unpredicated)	MOV (scalar, unpredicated)
	Move indexed element or SIMD&FP scalar to vector (unpredicated)	MOV (SIMD&FP scalar, unpredicated)
	Move signed immediate to vector elements (unpredicated)	MOV (immediate, unpredicated)
	Move signed integer immediate to vector elements (merging)	MOV (immediate, merging)
	Move signed integer immediate to vector elements (zeroing)	MOV (immediate, zeroing)
	Move SIMD&FP scalar register to vector elements (predicated)	MOV (SIMD&FP scalar, predicated)
	Move vector elements (predicated)	MOV (vector, predicated)
	Move vector register (unpredicated)	MOV (vector, unpredicated)
SEL	Conditionally select elements from two predicates	SEL (predicates)
	Conditionally select elements from two vectors	SEL (vectors)

C3.9.8.2 Element permute and shuffle

The Element permute and shuffle instructions move data between different vector elements, or between vector elements and scalar registers.

These instructions perform the following operations:

- Conditionally extract the *Last active element* of a vector or the following element.
  - The supported instructions are `CLASTA` and `CLASTB`.
- Unconditionally extract the *Last active element* of a vector or the following element.
  - The supported instructions are `LASTA` and `LASTB`.
- Variable permute instructions where the permutation is determined by the values in a predicate register or a table of element index values.
  - The supported instructions are `COMPACT`, `SPLICE`, and `TBL`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Fixed permute instructions where the form of the permutation is encoded in the instruction.
  - The supported instructions are: `DUP`, `EXT`, `INSR`, `REV`, `REVB`, `REVH`, `REVW`, `SUNPKHI`, `SUNPKLO`, `TRN1`, `TRN2`, `UUNPKHI`, `UUNPKLO`, `UZP1`, `UZP2`, `ZIP1`, and `ZIP2`.

Table C3-184 Element permute and shuffle instructions

Mnemonic	Instruction	See
`CLASTA`	Conditionally extract element after last to general-purpose register	CLASTA (scalar)
	Conditionally extract element after last to SIMD&FP scalar register	CLASTA (SIMD&FP scalar)
	Conditionally extract element after last to vector register	CLASTA (vectors)
`CLASTB`	Conditionally extract last element to general-purpose register	CLASTB (scalar)
	Conditionally extract last element to SIMD&FP scalar register	CLASTB (SIMD&FP scalar)
	Conditionally extract last element to vector register	CLASTB (vectors)
`COMPACT`	Copy Active vector elements to lower-numbered elements	COMPACT
`DUP`	Broadcast indexed element to vector (unpredicated)	DUP (indexed)
`EXT`	Extract vector from pair of vectors	EXT
`INSR`	Insert general-purpose register in shifted vector	INSR (scalar)
	Insert SIMD&FP scalar register in shifted vector	INSR (SIMD&FP scalar)
`LASTA`	Extract element after last to general-purpose register	LASTA (scalar)
	Extract element after last to SIMD&FP scalar register	LASTA (SIMD&FP scalar)
`LASTB`	Extract last element to general-purpose register	LASTB (scalar)
`MOV`	Move indexed element or SIMD&FP scalar to vector (unpredicated)	MOV (SIMD&FP scalar, unpredicated)
	Move SIMD&FP scalar register to vector elements (predicated)	MOV (SIMD&FP scalar, predicated)
`REV`	Reverse all elements in a vector (unpredicated)	REV (vector)
`REVB`	Reverse bytes / halfwords / words within elements (predicated)	REVB, REVH, REVW
`REVH`		
`REVW`		
`SPLICE`	Splice two vectors under predicate control	SPLICE
`TBL`	Programmable table lookup in one or two vector table (zeroing)	TBL
`TRN1`	Interleave even or odd elements from two vectors	TRN1, TRN2 (vectors)
`TRN2`		
`UZP1`	Concatenate even or odd elements from two vectors	UZP1, UZP2 (vectors)
`UZP2`		
`ZIP1`	Interleave elements from two half vectors	ZIP1, ZIP2 (vectors)
`ZIP2`		

C3.9.8.3 Unpacking instructions

The Unpacking instructions unpack half of the elements from the source vector register or predicate register, widen the unpacked elements to twice the width, and place the result in the destination register.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-185 Unpacking instructions

Mnemonic	Instruction	See
PUNPKHI	Unpack and widen half of predicate - High half	PUNPKHI, PUNPKLO - High half
PUNPKLO	Unpack and widen half of predicate - Low half	PUNPKHI, PUNPKLO - Low half
SUNPKHI	Signed unpack and extend half of vector - High half	SUNPKHI, SUNPKLO - High half
SUNPKLO	Signed unpack and extend half of vector - Low half	SUNPKHI, SUNPKLO - Low half
UUNPKHI	Unsigned unpack and extend half of vector - High half	UUNPKHI, UUNPKLO - High half
UUNPKLO	Unsigned unpack and extend half of vector - Low half	UUNPKHI, UUNPKLO - Low half

C3.9.8.4 Predicate permute

The Predicate instructions are used to move and permute predicate elements. These instructions generally mirror the fixed vector permutes to allow predicates to follow their data. The permutes move all of the bits in a predicate element, not just the canonical bits.

Table C3-186 Predicate instructions

Mnemonic	Instruction	See
REV	Reverse all elements in a predicate	REV (predicate)
TRN1	Interleave even or odd elements from two predicates - Even	TRN1, TRN2 (predicates) - Even
TRN2	Interleave even or odd elements from two predicates - Odd	TRN1, TRN2 (predicates) - Odd
UZP1	Concatenate even or odd elements from two predicates - Even	UZP1, UZP2 (predicates) - Even
UZP2	Concatenate even or odd elements from two predicates - Odd	UZP1, UZP2 (predicates) - Odd
ZIP1	Interleave elements from two half predicates - Low halves	ZIP1, ZIP2 (predicates) - Low halves
ZIP2	Interleave elements from two half predicates - High halves	ZIP1, ZIP2 (predicates) - High halves

C3.9.9 Index vector generation

The INDEX instruction initializes a vector horizontally by setting its first element to an integer value, and then repeatedly incrementing it by a second integer value to generate the subsequent elements. Each integer value can be specified as a signed immediate or a general-purpose register.

Table C3-187 Index instructions

Mnemonic	Instruction	See
INDEX	Create index starting from and incremented by general-purpose register	INDEX (scalars)
	Create index starting from and incremented by immediate	INDEX (immediates)
	Create index starting from general-purpose register and incremented by immediate	INDEX (scalar, immediate)
	Create index starting from immediate and incremented by general-purpose register	INDEX (immediate, scalar)

C3.9.10 Move prefix

The MOVPRFX (predicated) instruction is a predicated vector move that can be combined with a predicated destructive instruction that immediately follows it, in program order, to create a single constructive operation, or to convert an instruction with merging predication to use zeroing predication.

The MOVPRFX (unpredicated) instruction is an unpredicated vector move that can be combined with a predicated or unpredicated destructive instruction that immediately follows it, in program order, to create a single constructive operation.

The *Operational information* section of an SVE instruction description indicates whether or not an instruction can be predictably prefixed by a MOVPRFX instruction. If the *Operational information* of an *SVE* instruction description does not mention MOVPRFX or if the section does not exist, then the instruction cannot be predictably prefixed by a MOVPRFX instruction.

The prefixed instruction that immediately follows a MOVPRFX instruction in program order must be an implemented SVE instruction that can be predictably prefixed by a MOVPRFX instruction, or an A64 HLT instruction, or an A64 BRK instruction. For an SVE instruction that can be predictably prefixed by a MOVPRFX instruction, all of the following apply:

- The destination register field implicitly specifies one of the source operands, which means that it is a destructive binary or ternary vector operation or unary operation with merging predication, excluding MOVPRFX.
- The destination register is the same as the MOVPRFX destination register.
- The prefixed instruction does not use the MOVPRFX destination register in any of its other source register fields, even if it has a different name but refers to the same architectural register state. For example, Z1, V1, and D1 all refer to the same architectural register.
- If the MOVPRFX instruction is predicated, then the prefixed instruction is predicated using the same *Governing predicate* register, and the maximum encoded element size is the same as the MOVPRFX element size, excluding the fixed-size 64-bit elements of the wide elements form of bitwise shift and integer compare operations.
- If the MOVPRFX instruction is unpredicated, then the prefixed instruction can use any *Governing predicate* register and element size, or it can be unpredicated. A predicated MOVPRFX cannot be used with an unpredicated instruction.

If the instruction that follows a MOVPRFX instruction is not an implemented SVE instruction that can be predictably prefixed by a MOVPRFX instruction, the two instructions behave in one of the following CONSTRAINED UNPREDICTABLE ways:

- Either or both instructions can execute with their individually described effects.
- Either instruction can generate an Undefined Instruction exception.
- Either or both instructions can execute as a NOP.
- The second instruction can execute with an UNKNOWN value for any of its source registers.
- Any register that is written by either or both instructions can be set to an unknown value.
- A control flow instruction that writes the PC can set the PC to an unknown value.

Table C3-188 Move prefix instructions

Mnemonic	Instruction	See
MOVPRFX	Move prefix (predicated)	MOVPRFX (predicated)
	Move prefix (unpredicated)	MOVPRFX (unpredicated)

Unless the combination of a constructive operation with merging predication is specifically required, it is strongly recommended that, for performance reasons, software should prefer to use the zeroing form of predicated MOVPRFX or the unpredicated MOVPRFX instruction.

For more information about how the MOVPRFX instruction is handled by the Performance Monitors extension, see the definitions of Instruction architecturally executed and Operation.

Non-Confidential

C3.9.10.1 MOVPRFX instruction behavior in self-hosted debug

A `MOVPRFX` instruction can legally prefix a `BRK` or `HLT` instruction.

If a hardware breakpoint is programmed with the address of a legal `MOVPRFX` instruction, when any of the following events occur, the hardware breakpoint generates a Breakpoint exception:

- The `MOVPRFX` instruction is committed for execution.
- The combined `MOVPRFX` and Prefixed instruction is committed for execution.

If a hardware breakpoint is programmed with the address of an illegal `MOVPRFX` instruction or a Prefixed instruction, when any of the `MOVPRFX` instruction and Prefixed instruction are committed for execution, it is CONSTRAINED UNPREDICTABLE whether or not the hardware breakpoint generates a Breakpoint exception.

If a single-step is performed for a `MOVPRFX` instruction, it is CONSTRAINED UNPREDICTABLE whether the PE steps over the pair of instructions or steps over only the `MOVPRFX` instruction.

C3.9.11 Reduction operations

C3.9.11.1 Horizontal reductions

The Horizontal reduction instructions perform arithmetic horizontally across *Active elements* of a single source vector and deliver a scalar result.

The floating-point horizontal accumulating sum instruction, `FADDA`, operates strictly in order of increasing element number across a vector, using the scalar destination register as a source for the initial value of the accumulator. This preserves the original program evaluation order where non-associativity is required.

The other floating-point reductions calculate their result using a recursive pair-wise algorithm that does not preserve the original program order, but permits increased parallelism for code that does not require strict order of evaluation.

Integer reductions are fully associative, and the order of evaluation is not specified by the architecture.

Table C3-189 Horizontal reduction instructions

Mnemonic	Instruction	See
`ANDV`	Bitwise AND reduction to scalar	ANDV
`EORV`	Bitwise exclusive-OR reduction to scalar	EORV
`FADDA`	Floating-point add strictly-ordered reduction, accumulating in scalar	FADDA
`FADDV`	Floating-point add recursive reduction to scalar	FADDV
`FMAXNMV`	Floating-point maximum number recursive reduction to scalar	FMAXNMV
`FMAXV`	Floating-point maximum recursive reduction to scalar	FMAXV
`FMINNMV`	Floating-point minimum number recursive reduction to scalar	FMINNMV
`FMINV`	Floating-point minimum recursive reduction to scalar	FMINV
`ORV`	Bitwise inclusive OR reduction to scalar	ORV
`SADDV`	Signed add reduction to scalar	SADDV
`SMAXV`	Signed maximum reduction to scalar	SMAXV
`SMINV`	Signed minimum reduction to scalar	SMINV
`UADDV`	Unsigned add reduction to scalar	UADDV
`UMAXV`	Unsigned maximum reduction to scalar	UMAXV
`UMINV`	Unsigned minimum reduction to scalar	UMINV

C3.10 Data processing - SVE2

The following subsections describe the SVE2 processing instructions:

- Down-counting loops.
- Constructive multiply.
- Uniform DSP operations.
- Widening DSP operations.
- Narrowing DSP operation.
- Unary narrowing operations.
- Non-widening pairwise arithmetic.
- Widening pairwise arithmetic.
- Bitwise ternary logical instructions.
- Large integer arithmetic.
- Multiplication by indexed elements.
- Complex integer arithmetic.
- Conversions.
- Floating-point widening multiply-accumulate.
- Floating-point integer binary logarithm.
- Cross-lane match detect.
- Bit permutation.
- Polynomial arithmetic.
- Vector permutation.
- Table lookup.
- Cryptography support.
- BFloat16 arithmetic.
- BFloat16 minimum/maximum.
- Floating-point adjust exponent.
- Floating-point multiply-accumulate.
- Dot product.
- Floating-point matrix multiply-accumulate.
- Floating-point round.
- Quadword operations.
- Integer shift and convert.
- Predicate element index.
- Multi-vector predication.
- Permute vector.
- Predicate pair loop control.
- Predicate move.
- Predicate select.

C3.10.1 Down-counting loops

A down-counting `WHILE` instruction decrements the value of the first scalar operand and compares the value with a second, fixed scalar operand. The instruction generates a destination predicate with all of the following characteristics:

- The predicate elements starting from the highest-numbered element are true while the comparison remains true.
- The predicate elements thereafter, down to the lowest-numbered element, are false when the comparison becomes false.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All 32 bits or 64 bits of the scalar operands are significant for the purposes of comparison. The full 32-bit or 64-bit value of the first operand is decremented by 1 for each destination predicate element, irrespective of the element size. The first general-purpose register operand is not updated.

If all of the following occur, a comparison can never fail, resulting in an all-true predicate:

- The comparison includes an equality test.
- The second scalar operand is equal to the minimum integer value of the selected size and type of comparison.

Table C3-190 Down counting loop instructions

Mnemonic	Instruction	See
`WHILEGE`	While decrementing signed scalar greater than or equal to scalar	WHILEGE (predicate)
`WHILEGT`	While decrementing signed scalar greater than scalar	WHILEGT (predicate)
`WHILEHI`	While decrementing unsigned scalar higher than scalar	WHILEHI (predicate)
`WHILEHS`	While decrementing unsigned scalar higher than or same as scalar	WHILEHS (predicate)

C3.10.2 Constructive multiply

SVE2 includes the following constructive, three-operand versions of the integer multiply instructions:

Table C3-191 Constructive multiply instructions

Mnemonic	Instruction	See
`MUL`	Multiply (unpredicated)	MUL (vectors, unpredicated)
`SMULH`	Signed multiply returning high half (unpredicated)	SMULH (unpredicated)
`UMULH`	Unsigned multiply returning high half (unpredicated)	UMULH (unpredicated)

C3.10.3 Uniform DSP operations

The uniform DSP instructions are based on AArch64 Advanced SIMD instructions with the same mnemonic. The instructions operate on integer operands and produce results with a uniform element size. The operation of an instruction might include one or more of rounding, halving, saturation, and accumulation.

Table C3-192 Uniform DSP instructions

Mnemonic	Instruction	See
`SABA`	Signed absolute difference and accumulate	SABA
`SHADD`	Signed halving add	SHADD
`SHSUB`	Signed halving subtract	SHSUB
`SHSUBR`	Signed halving subtract reversed	SHSUBR

USRA	Unsigned shift right and accumulate (immediate)	USRA

C3.10.4 Widening DSP operations

The widening DSP instructions are based on AArch64 Advanced SIMD instructions with similar mnemonics. The instructions operate on integer values and produce results that are twice the width of some or all of the inputs. The instructions read the narrow inputs from either the even-numbered (bottom) or odd-numbered (top) source elements and place each result in the double-width destination elements that overlap the narrow source elements.

Table C3-193 Widening DSP instructions

Mnemonic	Instruction	See
SABALB	Signed absolute difference and accumulate long (bottom)	SABALB
SABALT	Signed absolute difference and accumulate long (top)	SABALT
SABDLB	Signed absolute difference long (bottom)	SABDLB

USUBWT	Unsigned subtract wide (top)	USUBWT

C3.10.5 Narrowing DSP operation

The narrowing DSP instructions are based on AArch64 Advanced SIMD instructions with similar mnemonics. The instructions operate on integer values and produce results that are half the width of the inputs. The instructions read wide source elements and place each result in one of the following:

- The overlapped even-numbered (bottom) half-width destination elements. The odd-numbered destination elements are set to zero.
- The overlapped odd-numbered (top) half-width destination elements. The even-numbered destination elements are unchanged, which means that the instructions are implicitly merging operations.

Table C3-194 Narrowing DSP instructions

Mnemonic	Instruction	See

C3.10.6 Unary narrowing operations

The unary narrowing instructions are unpredicated and do not write to the source register. The instructions read elements from the source vector and saturate each value to the half-width destination element size. The instructions place the narrow results in one of the following:

- The overlapped even-numbered (bottom) half-width elements. The odd-numbered elements are set to zero.
- The overlapped odd-numbered (top) half-width elements. The even-numbered elements are unchanged.

Non-saturating (truncating) conversions can be performed using SVE instructions such as shifts, masks, and permutes.

C3.10.7 Non-widening pairwise arithmetic

The non-widening pairwise arithmetic instructions operate on pairs of adjacent elements in each source vector and produce a result element that is the same size as a single input element. The results from the first and second source vectors are interleaved, so that the source and result elements overlap. The result is destructively placed in the first source vector. The AArch64 Advanced SIMD instructions do not interleave the results from the first and second source vectors. Predication applies to the destination vector. The even-numbered predicate elements enable an operation on a pair of elements in the first source vector. The odd-numbered predicate elements enable an operation on a pair of elements in the second source vector. *Inactive elements* in the destination vector register are not modified.

Table C3-196 Non-widening pairwise arithmetic instructions

Mnemonic	Instruction	See

`SMINP`	Signed minimum pairwise	SMINP
`UMAXP`	Unsigned maximum pairwise	UMAXP
`UMINP`	Unsigned minimum pairwise	UMINP

C3.10.8 Widening pairwise arithmetic

The widening pairwise arithmetic instructions operate on pairs of adjacent elements in a single source vector and produce a double-width result element that is accumulated into the destination vector. *Inactive elements* in the destination vector register are not modified.

Table C3-197 Widening pairwise arithmetic instructions

Mnemonic	Instruction	See
`SADALP`	Signed add and accumulate long pairwise	SADALP
`UADALP`	Unsigned add and accumulate long pairwise	UADALP

C3.10.9 Bitwise ternary logical instructions

The bitwise ternary logical instructions enable complex bit processing codes to be accelerated using multiple bitwise logical operations in a shorter instruction sequence. All of the following operations are supported by the bitwise ternary logical instructions:

- The `BCAX` instruction combines a ternary bitwise clear with an exclusive-OR.
- The `EOR3` instruction provides a ternary exclusive-OR.
- The `XAR` instruction combines an exclusive-OR with rotation by a constant amount.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The bitwise select instructions, `BSL`, `BSL1N`, `BSL2N`, and `NBSL`, can be used with other bitwise logical instructions to generate all 256 possible bitwise combinations of three input bits using at most three instructions.

The bitwise ternary logical instructions are unpredicated.

Table C3-198 Bitwise ternary logical instructions

Mnemonic	Instruction	See
`BCAX`	Bitwise clear and exclusive-OR	BCAX
`BSL`	Bitwise select	BSL
`BSL1N`	Bitwise select with first input inverted	BSL1N
`BSL2N`	Bitwise select with second input inverted	BSL2N
`EOR3`	Bitwise exclusive-OR between three vectors	EOR3
`NBSL`	Bitwise inverted select	NBSL
`XAR`	Bitwise exclusive-OR and rotate right by immediate	XAR

C3.10.10 Large integer arithmetic

The large integer arithmetic instructions aid the processing of large integers in vector registers by maintaining multiple carry chains that are interleaved in accumulator vectors.A large integer arithmetic instruction takes as input all of the following:

- Either the even-numbered (bottom) or odd-numbered (top) elements of the first source vector.
- A 1-bit carry input from the least-significant bit of the odd-numbered elements of the second source vector.

The inputs to the instruction are added to or subtracted from the even-numbered elements of the destination and accumulator vector. The 1-bit carry output is placed in the corresponding odd-numbered element of the destination vector.

Table C3-199 Large integer arithmetic instructions

Mnemonic	Instruction	See
`ADCLB`	Add with carry long (bottom)	ADCLB
`ADCLT`	Add with carry long (top)	ADCLT
`SBCLB`	Subtract with carry long (bottom)	SBCLB
`SBCLT`	Subtract with carry long (top)	SBCLT

C3.10.11 Multiplication by indexed elements

The multiplication by indexed elements instructions take all integer elements in each 128-bit vector segment of the first source vector and multiplies them by the indexed element in the corresponding segment of the second source vector.

The products might be destructively added to or subtracted from the corresponding elements of an addend vector.

The second source vector elements are specified using an immediate index that selects the same element position in each 128-bit vector segment. The index range is 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 3 bits depending on the element size.

C3.10.12 Complex integer arithmetic

Complex integer arithmetic instructions operate on signed integer complex numbers in vectors containing the following interleaved element pairs:

- The even-numbered elements contain the real parts of the complex numbers.
- The odd-numbered elements contain the imaginary parts of the complex numbers.

C3.10.12.1 Uniform complex integer arithmetic

The uniform complex integer arithmetic instructions operate on vectors containing integral complex numbers. The instructions operate on complex numbers that are in polar form.

The `CADD` instructions rotate the complex numbers in the second source vector before adding element pairs to the corresponding elements of the first source vector, in a destructive manner. The rotation direction is 90 degrees or 270 degrees from the positive real axis towards the positive imaginary axis.

The `CMLA` instructions transform the operands to enable multiply-add or multiply-subtract operations on complex numbers by combining two of the instructions. The following transformations are done:

- The complex numbers in the second source vector are rotated by 0 degrees or 180 degrees before multiplying by the duplicated real components of the first source vector.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The complex numbers in the second source vector are rotated by 90 degrees or 270 degrees before multiplying by the duplicated imaginary components of the first source vector.

The resulting products are added to the corresponding components of the destination and addend vector.

Two `CMLA` instructions can be used, as follows:

- `CMLA Zda.S, Zn.S, Zm.S, #A`
- `CMLA Zda.S, Zn.S, Zm.S, #B`

Some meaningful combinations of A and B are:

- A=0, B=90. The complex number vectors, Zn and Zm, are multiplied and the products are added to the complex numbers in Zda.
- A=0, B=270. The complex number conjugates in Zn are multiplied by the complex numbers in Zm and the products are added to the complex numbers in Zda.
- A=180, B=270. The two complex number vectors, Zn and Zm, are multiplied and the products are subtracted from the complex numbers in Zda.
- A=180, B=90. The complex number conjugates in Zn are multiplied by the complex numbers in Zm and the products are subtracted from the complex numbers in Zda.

The `CMLA` indexed form uses a single complex number in each 128-bit segment of the second source vector as the multiplier for all complex numbers in the corresponding first source vector segment. The complex numbers in the second source vector are specified using an immediate index that selects the same complex number position in each 128-bit vector segment. The index range is 0 to one less than the number of complex numbers per 128-bit segment, encoded in 1 to 2 bits depending on the complex number size.

Table C3-201 Uniform complex integer arithmetic instructions

	Saturating rounding doubling complex integer multiply-add high by indexed element	SQRDCMLAH (indexed)

C3.10.12.2 Widening complex integer arithmetic

The widening complex integer instructions deinterleave the real and imaginary components of integral complex numbers, and generate complex result components that have a higher numeric precision than the input values. The instructions differ from other complex instructions that process the real and imaginary components of complex numbers and write the complex result components to the destination.

The following instructions are useful when generating the widened components of the result of a complex multiply-add:

- `SQDMLALBT`, the imaginary results.
- `SQDMLSLT`, the real results.
- `SQDMLALB`, the conjugate real results.
- `SQDMLSLBT`, the conjugate imaginary results.

The following instructions are useful when generating the widened components of the result of a complex addition (X + jY) or (X - jY), given complex numbers X and Y:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- `SADDLBT`, the imaginary results when calculating (X + jY) or real values when calculating (X - jY).
- `SSUBLBT`, the real results when calculating (X + jY) or imaginary values when calculating (X - jY).

Table C3-202 Widening complex integer arithmetic instructions

Mnemonic	Instruction	See

`SSUBLBT`	Signed subtract long (bottom - top)	SSUBLBT
`SSUBLTB`	Signed subtract long (top - bottom)	SSUBLTB

C3.10.12.3 Complex integer dot product

The complex integer dot product instructions delimit the source vectors into pairs of 8-bit or 16-bit signed integer complex numbers. The complex numbers in the first source vector are multiplied by the corresponding complex numbers in the second source vector. The wide real or wide imaginary part of the product is accumulated into a 32-bit or 64-bit destination vector element that overlaps all four of the elements that form a pair of complex number values in the first source vector.

Each instruction implicitly deinterleaves the real and imaginary components of their complex number inputs, so that the destination vector accumulates four wide real sums or four wide imaginary sums.

The complex numbers in the second source vector are rotated by 0, 90, 180, or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, considered in polar form, by applying the following transformations before the dot product operations:

- If the rotation is #0, the imaginary parts of the complex numbers in the second source vector are negated. The destination vector accumulates the real parts of a complex dot product.
- If the rotation is #90, the real and imaginary parts of the complex numbers the second source vector are swapped. The destination vector accumulates the imaginary parts of a complex dot product.
- If the rotation is #180, there is no transformation. The destination vector accumulates the real parts of a complex conjugate dot product.
- If the rotation is #270, the real parts of the complex numbers in the second source vector are negated and then swapped with the imaginary parts. The destination vector accumulates the imaginary parts of a complex conjugate dot product.

The indexed form of the instruction selects a single complex number pair within each 128-bit segment of the second source vector to multiply with all complex number pairs within the corresponding 128-bit segment of the first source vector. The complex number pairs within the second source vector are specified using an immediate index which selects the same complex number pair position within each 128-bit vector segment. The index range is from 0 to one less than the number of complex number pairs per 128-bit segment, encoded in 1 or 2 bits depending on the size of the complex number pair.

Each complex number is represented in a vector register as an even and odd pair of elements. The real part is the even-numbered element and the imaginary part is the odd-numbered element.

C3.10.13 Conversions

C3.10.13.1 Floating-point conversions

The floating-point extra conversion instructions convert to and from fully packed vectors of narrower floating-point elements.

The `FCVTLT` instruction converts the top or odd-numbered narrow floating-point vector elements to wider elements of the next higher precision. The conversion is similar to what is done by the widening integer instructions.

The `FCVTNT` and `FCVTXNT` instructions convert wider floating-point vector elements to the top or odd-numbered narrower elements of the next lower precision. The conversion is similar to what is done by the narrowing integer instructions.

The `FCVTXNT` and `FCVTX` instructions convert from double-precision to fully packed half-precision in two narrowing steps, double-precision to single-precision and then single-precision to half-precision. The two-step conversion is done without an intermediate rounding error by using von Neumann rounding, which rounds an inexact mantissa to an odd value.

The SVE `FCVT` instructions implement the corresponding widening and narrowing conversions on the bottom or even-numbered half-width elements.

Table C3-204 Floating-point extra conversion instructions

Mnemonic	Instruction	See
`FCVTLT`	Floating-point widening convert (top, predicated)	FCVTLT
`FCVTNT`	Floating-point narrowing convert (top, predicated)	FCVTNT (predicated)
`FCVTX`	Double-precision convert to single-precision, rounding to odd (predicated)	FCVTX
`FCVTXNT`	Double-precision convert to single-precision, rounding to odd (top, predicated)	FCVTXNT

C3.10.13.2 FP8 floating-point conversions

Convert each floating-point element of the source vector while scaling the value, and place the results in the corresponding elements of the destination vector.

For instructions that convert other floating-point formats to FP8 formats, each input element is scaled by adding the value specified in FPMR.NSCALE to its unbounded exponent during the conversion.

For instructions that convert FP8 formats to other floating-point formats, each input element is scaled by subtracting the value specified in FPMR.LSCALE or FPMR.LSCALE2 from its unbounded exponent during the conversion.

For more information, see the instruction descriptions.

C3.10.14 Multiply-accumulate

C3.10.14.1 Floating-point widening multiply-accumulate

The floating-point widening multiply-accumulate instructions multiply the even-numbered or odd-numbered half-precision elements of the two source vectors and then destructively add or subtract the single-precision intermediate products. Intermediate rounding is not done. The result is placed into the overlapping single-precision elements of the addend vector.

The instructions implicitly convert the half-precision inputs to single-precision and can be used to mitigate the impact of round-off errors when accumulating half-precision floating-point values over many iterations.

The instructions are unpredicated and preserve the multiplier and multiplicand source vectors.

Table C3-206 Floating-point widening multiply-accumulate instructions

	Half-precision multiply-subtract from single-precision (top)	FMLSLT (vectors)

C3.10.14.2 FP8 floating-point widening multiply-accumulate

The FP8 floating-point multiply-accumulate instructions widen the 8-bit floating-point elements in the source vectors to half-precision or single-precision format and multiply the corresponding elements. They generate a fused, downscaled product and accumulate into the corresponding elements of the destination vector, without intermediate rounding.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For these instructions, the unbounded intermediate product is scaled by subtracting the value specified in FPMR.LSCALE from its unbounded exponent. For more information, see the instruction descriptions.

	8-bit floating-point multiply-add to half-precision (top)	FMLALT (vectors, FP8 to FP16)

C3.10.15 Floating-point integer binary logarithm

The floating-point integer binary logarithm instruction returns the signed integer base 2 logarithm of each floating-point input element |x| after normalization.

The instruction produces the unbiased exponent of x used in the representation of the floating-point value. For positive x, x = significand $\times$ $2^{exponent}$.

The integer results are placed in elements of the destination vector, which have the same width as the floating-point input elements:

- If x is normal, the result is the base 2 logarithm of x.
- If x is subnormal, the result corresponds to the normalized representation.
- If x is infinite, the result is $2^{(esize-1)}$-1.
- If x is ±0.0 or NaN, the result is -$2^{(esize-1)}$.

Inactive elements in the destination vector register are not modified.

FAMIN	Floating-point absolute minimum (predicated)	FAMIN

C3.10.17 Cross-lane match detect

This section includes instructions that detect or count matching elements within another vector, or within a 128-bit vector segment.

C3.10.17.1 Vector Histogram Count

The vector histogram count instructions create vector histograms.

- HISTSEG compares each 8-bit byte element in the first source vector with all of the elements in the corresponding 128-bit segment of the second source vector. The instruction counts the matching elements and places the result in the corresponding destination vector element. The instruction is unpredicated.
- HISTCNT compares each active 32-bit or 64-bit element in the first source vector with all elements in the second source vector that have an element number less than or equal to the *Active element* in the first source vector. The number of matching elements is counted and the result is placed in the corresponding destination vector element. *Inactive elements* in the destination vector are set to zero. *Inactive elements* in the second source vector do not cause a match.

Table C3-210 Vector histogram count instructions

Mnemonic	Instruction	See
HISTCNT	Count matching elements in vector	HISTCNT
HISTSEG	Count matching elements in vector segments	HISTSEG

C3.10.17.2 Character match

The character match instructions can be used to scan each 128-bit segment of the second source vector for an 8-bit or 16-bit character string from the first source vector.

The MATCH and NMATCH instructions compare each active 8-bit or 16-bit character in the first source vector with all of the characters in the corresponding 128-bit segment of the second source vector. When the first source character matches any (MATCH) or does not match any (NMATCH) character in the second segment, a true value is placed in the corresponding destination predicate element, otherwise a false value is placed in the destination predicate element. *Inactive elements* in the destination predicate register are set to zero.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The instruction sets the NZC condition flags based on the predicate result, and sets the V flag to zero.

Table C3-211 Character match instructions

Mnemonic	Instruction	See
`MATCH`	Detect any matching elements within quadwords, setting the condition flags	MATCH
`NMATCH`	Detect no matching elements within quadwords, setting the condition flags	NMATCH

C3.10.17.3 Contiguous conflict detection

The contiguous conflict detection instructions check two addresses for a conflict or overlap between address ranges that could result in a loop-carried dependency through memory. The address range has the form [addr,addr+*VL*÷8], where *VL* is the Effective SVE vector length in bits. A conflict can occur when contiguous load and store instructions use these addresses within the same loop iteration.

The instructions generate a predicate with elements that are true when the addresses cannot conflict within the same iteration, and false thereafter. The instructions set the NZC condition flags based on the predicate result, and the V flag is set to zero.

Table C3-212 Contiguous conflict detection instructions

Mnemonic	Instruction	See
`WHILERW`	While free of read-after-write conflicts	WHILERW
`WHILEWR`	While free of write-after-read/write conflicts	WHILEWR

C3.10.18 Bit permutation

The bit permutation instructions are optional. The bit permutation instructions are configured by the ID_AA64ZFR0_EL1.BitPerm bit. The instructions can be used to scatter, gather, or separate a set of bits within each first source vector element under the control of a bit mask or sieve in the corresponding second source vector elements. The instructions are unpredicated.

The `BDEP` instruction scatters the lowest-numbered contiguous bits within each first source vector element to the bit positions that are indicated by nonzero bits in the corresponding mask element of the second source vector. The order of the bits is preserved. The bits corresponding to a zero mask bit are set to zero.

The `BEXT` instruction gathers bits in each first source vector element from the bit positions that are indicated by nonzero bits in the corresponding mask element of the second source vector. The bits are gathered to the lowest-numbered contiguous bits of the corresponding destination element, preserving their order. The remaining higher-numbered bits are set to zero.

The `BGRP` instruction selects bits from each first source vector element and groups them into the corresponding destination element, using a corresponding mask element in the second source vector, as follows:

- The nonzero bits in the mask element select the bit positions from the corresponding first source vector element. The selected bits are gathered into the lowest-numbered contiguous bits of the destination element.
- The zero bits in the mask element select the bit positions from the corresponding first source vector element. The selected bits are gathered into the highest-numbered contiguous bits of the destination element.

The bit order within each group is preserved.

BDEP	Scatter lower bits into positions selected by bitmask	BDEP
BEXT	Gather lower bits from positions selected by bitmask	BEXT
BGRP	Group bits to right or left as selected by bitmask	BGRP

C3.10.19 Polynomial arithmetic

The polynomial arithmetic instructions support polynomial arithmetic over [0, 1], where exclusive-OR takes the place of addition. The instructions can be used in applications such as CRC calculations, AES-GCM, elliptic curve cryptography, Diffie-Hellman key exchange, and others.

The PMUL and widening PMLAL, PMULL, PMULLB, and PMULLT instructions perform polynomial multiplication over [0,1]. PMLAL additionally performs a bitwise exclusive-OR of the multiplication result on the element in the destination vector.

The PMULLB and PMULLT instructions read the source operands from either the even-numbered (bottom) or odd-numbered (top) elements, respectively. The widened results are placed in the double-width destination elements that overlap with the corresponding source elements.

The multi-vector PMLAL and PMULL instructions produce results in two destination vectors. The double-width results calculated from even-numbered source elements are placed in the first destination vector, while the double-width results calculated from odd-numbered source elements are placed in the second destination vector.

The EORBT and EORTB instructions operate on the even-numbered elements of the first source vector register and the odd-numbered elements of the second source vector register. The result is either placed in the even-numbered elements of the destination vector, leaving the odd-numbered elements unchanged, or placed in the odd-numbered elements of the destination vector, leaving the even-numbered elements unchanged.

These instructions are unpredicated.

Table C3-214 Polynomial arithmetic instructions

Mnemonic	Instruction	See
EORBT	Interleaving exclusive-OR (bottom, top)	EORBT
EORTB	Interleaving exclusive-OR (top, bottom)	EORTB
PMLAL	Multi-vector polynomial multiply long and accumulate	PMLAL
PMUL	Polynomial multiply (unpredicated)	PMUL
PMULL	Multi-vector polynomial multiply long	PMULL
PMULLB	Polynomial multiply long (bottom)	PMULLB
PMULLT	Polynomial multiply long (top)	PMULLT

C3.10.20 Vector permutation

The vector concatenation instructions EXT and SPLICE have constructive versions that are introduced in SVE2 that preserve both of the source operands. In the constructive versions of the instruction, only the first source vector register number is encoded, which requires the source vectors to be in consecutively numbered registers (modulo 32).

The EXPAND instruction copies the lowest numbered source vector elements to Active elements of the destination vector, this complements the COMPACT instruction.

For more information see Table C3-184.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-215 Vector permutation instructions

Mnemonic	Instruction	See
COMPACT	Copy Active vector elements to lower-numbered elements	COMPACT
EXPAND	Copy lower-numbered vector elements to Active elements	EXPAND
EXT	Extract vector from pair of vectors	EXT
SPLICE	Splice two vectors under predicate control	SPLICE

C3.10.21 Table lookup

C3.10.21.1 Extended table lookup permute

The SVE2 extended table lookup instructions, TBL and TBX enable the construction of table lookups or programmable vector permutes where the table consists of two or more vector registers.

Because the index values can select any element in a vector, the instructions are not naturally vector length agnostic.

Table C3-216 Extended table lookup instructions

Mnemonic	Instruction	See
TBL	Programmable table lookup in one or two vector table (zeroing)	TBL
TBX	Programmable table lookup in single vector table (merging)	TBX

C3.10.21.2 Lookup table using 2-bit or 4-bit indices

Copy indexed elements from the first source vector(s) to the destination vector, using packed indices from a portion of the second source vector.

Table C3-217 SVE2 lookup table using 2-bit or 4-bit indices instructions

Mnemonic	Instruction	See
LUTI2	Lookup table read with 2-bit indices (8-bit and 16-bit)	LUTI2 (8-bit and 16-bit)
LUTI4	Lookup table read with 4-bit indices (8-bit and 16-bit)	LUTI4 (8-bit and 16-bit)

C3.10.22 Cryptography support

C3.10.22.1 AES-128 instructions

AES-128 is a 128-bit block cipher that is calculated using a combination of linear EOR operations, the use of rotations by fixed values, and a set of 8-bit non-linear substitutions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The AESE, AESMC, and AESEMC instructions accelerate a single encryption round, and the AESD, AESIMC, and AESDIMC instructions accelerate a single decryption round. These instructions read a 16-byte state from a 128-bit segment of the first source vectors, and a round key from a 128-bit segment of the second source vector.

The AES instructions are unpredicated.

Table C3-218 AES-128 instructions

Mnemonic	Instruction	See
AESD	AES single round decryption	AESD (vectors)
	Multi-vector AES single round decryption	AESD (indexed)
AESDIMC	Multi-vector AES single round decryption and inverse mix columns	AESDIMC
AESE	AES single round encryption	AESE (vectors)
	Multi-vector AES single round encryption	AESE (indexed)
AESEMC	Multi-vector AES single round encryption and mix columns	AESEMC
AESIMC	AES inverse mix columns	AESIMC
AESMC	AES mix columns	AESMC

C3.10.22.2 SHA-3 instructions

The SHA-3 instructions accelerate the SHA-3 hash algorithm.

The SHA-3 hash is based on a running digest of 1600 bits, arranged as a five by five array of 64-bit values. The instructions map the 25 64-bit values into 25 vector registers, with each 64-bit value occupying the same 64-bit element in each vector. A series of transformations is done on these registers during a round of the SHA-3 hash calculation.

Two or more parallel SHA-3 hash calculations are combined as a SIMD operation, where one calculation operates on the 0th 64-bit element of each vector, and the other calculation operates on the first 64-bit element of each vector. The SIMD operation is useful for the fast parallel hash algorithm recently introduced into the SHA-3 standard that allows a single input stream to be calculated using multiple SHA-3 hashes in parallel.

The SHA3 instructions are unpredicated.

Table C3-219 SHA-3 instructions

Mnemonic	Instruction	See
RAX1	Bitwise rotate left by 1 and exclusive-OR	RAX1

See also Bitwise ternary logical instructions.

C3.10.22.3 SM4 instructions

SM4 is the standard Chinese symmetric encryption algorithm which can be accelerated using a similar approach to that used for AES.

SM4 is a 128-bit wide block cipher that is calculated using a combination of linear EOR operations, the use of fixed-value rotations, and a set of 8-bit non-linear substitutions.

- The SM4E instruction reads 16 bytes of input data from each 128-bit segment of the first source vector, and four iterations of 32-bit round keys from the corresponding 128-bit segments of the second source vector. Each input data block is encrypted by four rounds in accordance with the SM4 standard, and destructively placed in the corresponding segments of the first source vector.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The `SM4EKEY` instruction reads four rounds of 32-bit input key values from each 128-bit segment of the first source vector, and four rounds of 32-bit constants from the corresponding 128-bit segment of the second source vector. The four rounds of output key values are derived in accordance with the SM4 standard, and placed in the corresponding segments of the destination vector.

The SM4 instructions are unpredicated.

Table C3-220 SM4 instructions

Mnemonic	Instruction	See
`SM4E`	SM4 encryption and decryption	SM4E
`SM4EKEY`	SM4 key updates	SM4EKEY

C3.10.23 BFloat16 arithmetic

C3.10.23.1 Add and subtract

Add or subtract BFloat16 elements of the second source vector from the corresponding elements of the first source vector and destructively place the results in the corresponding elements of the first source vector.

Table C3-221 SVE2 BFloat16 add and subtract instructions

Mnemonic	Instruction	See
`BFADD`	BFloat16 add (predicated)	BFADD (predicated)
	BFloat16 add (unpredicated)	BFADD (unpredicated)
`BFSUB`	BFloat16 subtract (predicated)	BFSUB (predicated)
	BFloat16 subtract (unpredicated)	BFSUB (unpredicated)

C3.10.23.2 Multiply and multiply-accumulate

Multiply all BFloat16 elements of the first source vector by the specified element in the corresponding second source vector and place the results in the corresponding elements of the destination vector. The accumulate instructions add or subtract the result without intermediate rounding from the corresponding elements of the destination vector.

`BFMLA` and `BFMLS` perform a fused multiply-add or multiply-subtract of BFloat16 values without intermediate rounding.

Table C3-222 SVE2 BFloat16 multiply and multiply-accumulate instructions

Mnemonic	Instruction	See
`BFMLA`	BFloat16 fused multiply-add	BFMLA (vectors)
	BFloat16 fused multiply-add by indexed element	BFMLA (indexed)
`BFMLS`	BFloat16 fused multiply-subtract	BFMLS (vectors)
	BFloat16 fused multiply-subtract by indexed element	BFMLS (indexed)

Mnemonic	Instruction	See
BFMUL	BFloat16 multiply (predicated)	BFMUL (vectors, predicated)
	BFloat16 multiply (unpredicated)	BFMUL (vectors, unpredicated)
	BFloat16 multiply by indexed element	BFMUL (indexed)

C3.10.24 BFloat16 minimum/maximum

Determine the maximum or minimum active BFloat16 elements of the second source vector and corresponding elements of the first source vector and destructively place the results in the corresponding elements of the first source vector.

Table C3-223 SVE2 BFloat16 minimum/maximum instructions

Mnemonic	Instruction	See
BFMAX	BFloat16 maximum (predicated)	BFMAX
BFMAXNM	BFloat16 maximum number (predicated)	BFMAXNM
BFMIN	BFloat16 minimum (predicated)	BFMIN
BFMINNM	BFloat16 minimum number (predicated)	BFMINNM

C3.10.25 Floating-point adjust exponent

The SVE2 BFSCALE instruction performs BFloat16 scaling by integer powers of two.

Table C3-224 SVE2 floating-point adjust exponent instructions

Mnemonic	Instruction	See
BFSCALE	BFloat16 adjust exponent (predicated)	BFSCALE

C3.10.26 Clamp to minimum/maximum

Clamp each element in the destination vectors to between the minimum value in the corresponding element of the first source vector and the maximum value in the corresponding element of the second source vector and destructively place the clamped results in the corresponding elements of the destination vector.

C3.10.26.1 Floating-point clamp to minimum/maximum

Table C3-225 SVE2.1 Floating-point clamp to minimum/maximum instructions

Mnemonic	Instruction	See
BFCLAMP	BFloat16 clamp to minimum/maximum number	BFCLAMP
FCLAMP	Floating-point clamp to minimum/maximum number	FCLAMP

Table C3-226 SVE2.1 Integer clamp to minimum/maximum instructions

Mnemonic	Instruction	See
SCLAMP	Signed clamp to minimum/maximum	SCLAMP
UCLAMP	Unsigned clamp to minimum/maximum	UCLAMP

C3.10.27 Dot product

C3.10.27.1 Floating-point dot product

Compute the dot product of a pair of values held in the corresponding elements of the first source vectors multiplied by the corresponding elements of the second source vector. The dot product is then destructively added to the corresponding element of the destination vector.

Table C3-227 SVE2.1 Floating-point dot product instructions

Mnemonic	Instruction	See
FDOT	Half-precision dot product by indexed element to single-precision	FDOT (2-way, indexed, FP16 to FP32)
	Half-precision dot product to single-precision	FDOT (2-way, vectors, FP16 to FP32)

C3.10.27.2 FP8 floating-point dot product

The FP8 floating-point dot product instructions accumulate the dot product of two or four adjacent FP8 source elements into half-precision or single-precision destination elements. They generate a fused, downscaled sum-of-products and accumulate into each destination element, without intermediate rounding.

For these instructions, the unbounded intermediate sum-of-products is scaled by subtracting the value specified in FPMR.LSCALE. For more information, see the instruction descriptions.

Table C3-228 SVE2 FP8 floating-point dot product instructions

Mnemonic	Instruction	See
FDOT	8-bit floating-point dot product by indexed element to half-precision	FDOT (2-way, indexed, FP8 to FP16)
	8-bit floating-point dot product by indexed element to single-precision	FDOT (4-way, indexed)
	8-bit floating-point dot product to half-precision	FDOT (2-way, vectors, FP8 to FP16)
	8-bit floating-point dot product to single-precision	FDOT (4-way, vectors)

C3.10.28 Floating-point matrix multiply-accumulate

C3.10.28.1 Floating-point matrix multiply-accumulate

The `FMMLA` (widening, FP16 to FP32) instruction is implemented by FEAT_SVE_F16F32MM. This instruction delimits each source and destination vector into 128-bit segments. The 128-bit segments are organized as follows:

- In the first source vector, a 2x4 matrix of half-precision values in row-by-row order.
- In the second source vector, a 4x2 matrix of half-precision values in column-by-column order.
- In the destination vector, a 2x2 matrix of single-precision values in row-by-row order.

One matrix multiplication is performed per vector segment and accumulated into the destination vector segment.

The intermediate single-precision sums-of-products are rounded before they are summed, and the intermediate sum is rounded before addition to the single-precision destination elements.

Table C3-229 SVE2 Floating-point matrix multiply-accumulate instructions

Mnemonic	Instruction	See
`FMMLA`	Half-precision matrix multiply-accumulate to single-precision	FMMLA (widening, FP16 to FP32)

C3.10.28.2 FP8 floating-point matrix multiply-accumulate

The FP8 `FMMLA` (widening, FP8 to FP32) instruction is implemented by FEAT_F8F32MM. This instruction delimits each source and destination vector into 128-bit segments. The 128-bit segments are organized as follows:

- In the first source vector, a 2x8 matrix of 8-bit floating-point values in row-by-row order.
- In the second source vector, an 8x2 matrix of 8-bit floating-point values in column-by-column order.
- In the destination vector, a 2x2 matrix of single-precision values in row-by-row order.

One matrix multiplication is performed per vector segment and accumulated into the destination vector segment.

The FP8 `FMMLA` (widening, FP8 to FP16) instruction is implemented by FEAT_F8F16MM. This instruction delimits each source and destination vector into 64-bit segments. The 64-bit segments are organized as follows:

- In the first source vector, a 2x4 matrix of 8-bit floating-point values in row-by-row order.
- In the second source vector, a 4x2 matrix of 8-bit floating-point values in column-by-column order.
- In the destination vector, a 2x2 matrix of half-precision values in row-by-row order.

One matrix multiplication is performed per vector segment and accumulated into the destination vector segment.

These instructions generate a fused, downscaled sum-of-products and accumulate into each destination element, without intermediate rounding. For these instructions, the intermediate sum of products is downscaled by subtracting the value in FPMR.LSCALE from its unbounded exponent. For more information, see the instruction descriptions.

Table C3-230 SVE2 FP8 Floating-point matrix multiply-accumulate instructions

Mnemonic	Instruction	See
`FMMLA`	8-bit floating-point matrix multiply-accumulate to half-precision	FMMLA (widening, FP8 to FP16)

C3.10.29 Floating-point round to integral value

The following instructions round a floating-point value to an integral floating-point value of 32-bit or 64-bit integer size.

These instructions can cause floating-point exceptions, for more information see Floating-point exceptions and exception traps.

Table C3-231 SVE2 Floating-point round to integral value instructions

Mnemonic	Instruction	See
FRINT32X	Floating-point round to 32-bit integer (predicated)	FRINT32X
FRINT32Z	Floating-point round to 32-bit integer, rounding toward zero (predicated)	FRINT32Z
FRINT64X	Floating-point round to 64-bit integer (predicated)	FRINT64X
FRINT64Z	Floating-point round to 64-bit integer, rounding toward zero (predicated)	FRINT64Z

C3.10.30 Quadword operations

C3.10.30.1 Permute within quadwords

In these instructions the same permutation pattern is applied within each quadword.

Table C3-232 SVE2.1 Permute within quadwords instructions

Mnemonic	Instruction	See
DUPQ	Broadcast indexed element within each quadword vector segment (unpredicated)	DUPQ
EXTQ	Extract vector segment from each pair of quadword vector segments	EXTQ
TBLQ	Programmable table lookup within each quadword vector segment (zeroing)	TBLQ
TBXQ	Programmable table lookup within each quadword vector segment (merging)	TBXQ
UZPQ1	Concatenate even elements within each pair of quadword vector segments	UZPQ1
UZPQ2	Concatenate odd elements within each pair of quadword vector segments	UZPQ2
ZIPQ1	Interleave elements from low halves of each pair of quadword vector segments	ZIPQ1
ZIPQ2	Interleave elements from high halves of each pair of quadword vector segments	ZIPQ2

C3.10.30.2 Reduction to quadword

In the reductions to quadwords instructions a full SVE vector is reduced to a single 128-bit vector. The result of the operations is placed into the corresponding element of the 128-bit Advanced SIMD and floating-point destination register.

Table C3-233 SVE2.1 Reduction to quadword instructions

Mnemonic	Instruction	See
ADDQV	Add reduction of quadword vector segments	ADDQV
ANDQV	Bitwise AND reduction of quadword vector segments	ANDQV

SMAXQV	Signed maximum reduction of quadword vector segments	SMAXQV
SMINQV	Signed minimum reduction of quadword vector segments	SMINQV
UMAXQV	Unsigned maximum reduction of quadword vector segments	UMAXQV
UMINQV	Unsigned minimum reduction of quadword vector segments	UMINQV

C3.10.31 Integer shift and convert

Convert or shift the value of each element of the source vectors and place the results in the corresponding destination vector elements.

These are narrowing, interleaving, saturating variants of the integer shift and convert instructions, to avoid write after write dependencies for merging narrowing top instructions.

Table C3-234 SVE2.1 Integer shift and convert instructions

Mnemonic	Instruction	See
SQCVTN	Signed 32-bit integer saturating extract narrow to interleaved 16-bit integer	SQCVTN
SQCVTUN	Signed 32-bit integer saturating extract narrow to interleaved unsigned 16-bit integer	SQCVTUN
SQRSHRN	Signed saturating rounding shift right narrow by immediate to interleaved integer	SQRSHRN
SQRSHRUN	Signed saturating rounding shift right unsigned narrow by immediate and interleave	SQRSHRUN
UQCVTN	Unsigned 32-bit integer saturating extract narrow to interleaved 16-bit integer	UQCVTN
UQRSHRN	Unsigned saturating rounding shift right narrow by immediate to interleaved integer	UQRSHRN

C3.10.32 Predicate element index

Determine the index of the first or last active TRUE predicate element.

Table C3-235 SVE2 Scalar index instructions

Mnemonic	Instruction	See
FIRSTP	Scalar index of first true predicate element (predicated)	FIRSTP
LASTP	Scalar index of last true predicate element (predicated)	LASTP

C3.10.33 Multi-vector predication

Multi-vector predication is required when using the Contiguous multi-vector loads and stores, and also reduces the number of predicate registers and predicate calculations in a loop.

The `WHILE` instructions generate a predicate-as-counter encoding. These instructions have an operand that indicates the number of vectors (2 or 4) to be controlled by this predicate, which determines:

- The maximum value that can be stored in the count.
- The number of elements that are considered *Active* when calculating the *Any Active element* and *Last Active element* SVE condition flags.

`CNTP` has an operand that indicates the limit of the number of elements to be counted. The limit corresponds to the total number of elements in either 2 or 4 vectors.

For more information, see Predicate-as-counter.

Table C3-236 SVE2.1 Multi-vector predication instructions

Mnemonic	Instruction	See
`CNTP`	Set scalar to count from predicate-as-counter	CNTP (predicate as counter)
`PEXT`	Predicate extract from predicate-as-counter	PEXT (predicate)
	Predicate extract pair from predicate-as-counter	PEXT (predicate pair)
`PTRUE`	Initialize predicate-as-counter to all active	PTRUE (predicate as counter)
`WHILEGE`	While decrementing signed scalar greater than or equal to scalar (predicate-as-counter)	WHILEGE (predicate as counter)
`WHILEGT`	While decrementing signed scalar greater than scalar (predicate-as-counter)	WHILEGT (predicate as counter)
`WHILEHI`	While decrementing unsigned scalar higher than scalar (predicate-as-counter)	WHILEHI (predicate as counter)
`WHILEHS`	While decrementing unsigned scalar higher than or same as scalar (predicate-as-counter)	WHILEHS (predicate as counter)
`WHILELE`	While incrementing signed scalar less than or equal to scalar (predicate-as-counter)	WHILELE (predicate as counter)
`WHILELO`	While incrementing unsigned scalar lower than scalar (predicate-as-counter)	WHILELO (predicate as counter)
`WHILELS`	While incrementing unsigned scalar lower than or same as scalar (predicate-as-counter)	WHILELS (predicate as counter)
`WHILELT`	While incrementing signed scalar less than scalar (predicate-as-counter)	WHILELT (predicate as counter)

C3.10.34 Permute vector

This instruction is a fixed permute instruction, which is a doubleword variant of the reverse within elements instructions.

Table C3-237 SVE2.1 Permute vector instruction

Mnemonic	Instruction	See
`REVD`	Reverse 64-bit doublewords in elements (predicated)	REVD

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.10.35 Predicate pair loop control

Generate a pair of predicate registers to simplify loop unrolling.

Table C3-238 SVE2.1 Predicate pair loop control instructions

Mnemonic	Instruction	See
`WHILEGE`	While decrementing signed scalar greater than or equal to scalar (pair of predicates)	WHILEGE (predicate pair)
`WHILEGT`	While decrementing signed scalar greater than scalar (pair of predicates)	WHILEGT (predicate pair)
`WHILEHI`	While decrementing unsigned scalar higher than scalar (pair of predicates)	WHILEHI (predicate pair)
`WHILEHS`	While decrementing unsigned scalar higher than or same as scalar (pair of predicates)	WHILEHS (predicate pair)
`WHILELE`	While incrementing signed scalar less than or equal to scalar (pair of predicates)	WHILELE (predicate pair)
`WHILELO`	While incrementing unsigned scalar lower than scalar (pair of predicates)	WHILELO (predicate pair)
`WHILELS`	While incrementing unsigned scalar lower than or same as scalar (pair of predicates)	WHILELS (predicate pair)
`WHILELT`	While incrementing signed scalar less than scalar (pair of predicates)	WHILELT (predicate pair)

C3.10.36 Predicate move

With the `PMOV` (to predicate) instruction, based on the specified element size and immediate index, the selected bits in a vector register are expanded into a predicate register ready to be used as an SVE governing predicate.

With the `PMOV` (to vector) instruction a portion of a bit array is created and can be stored to memory or further processed in registers.

Table C3-239 SVE2.1 Predicate move instructions

Mnemonic	Instruction	See
`PMOV`	Move predicate from vector	PMOV (to predicate)
	Move predicate to vector	PMOV (to vector)

C3.10.37 Predicate select

`PSEL` places contents of the first source predicate register into a destination register or sets the destination to all-FALSE.

Table C3-240 SVE2.1 Predicate select instruction

Mnemonic	Instruction	See
`PSEL`	Predicate select between predicate register or all-false	PSEL

C3.11 Data processing - SME, SME2

The following subsections describe the SME, SME2, and SME2.1 processing instructions:

- Clamp to minimum/maximum
- Floating-point dot product
- Vertical dot product
- Element concatenate and interleave
- Floating-point conversions
- Floating-point round
- Floating-point adjust exponent
- Lookup table
- Move operations
- Multi-vector arithmetic
- Multi-vector minimum/maximum
- Multi-vector multiply
- Multi-vector multiply-accumulate
- Multi-vector multiply high
- Multi-vector select
- Multi-vector shift and convert
- Outer product
- Quarter-tile outer product
- Structured sparsity outer product
- Stack frame operations
- Unpack and extend
- Zero operations

C3.11.1 Clamp to minimum/maximum

Clamp each element in the destination vectors to between the minimum value in the corresponding element of the first source vector and the maximum value in the corresponding element of the second source vector and destructively place the clamped results in the corresponding elements of the destination vectors.

C3.11.1.1 Floating-point clamp to minimum/maximum

Table C3-241 SME2 Floating-point clamp to minimum/maximum instructions

Mnemonic	Instruction	See
`BFCLAMP`	Multi-vector BFloat16 clamp to minimum/maximum number	BFCLAMP
`FCLAMP`	Multi-vector floating-point clamp to minimum/maximum number	FCLAMP

C3.11.1.2 Integer clamp to minimum/maximum

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-242 SME2 Integer clamp to minimum/maximum instructions

Mnemonic	Instruction	See
SCLAMP	Multi-vector signed clamp to minimum/maximum	SCLAMP
UCLAMP	Multi-vector unsigned clamp to minimum/maximum	UCLAMP

C3.11.2 Floating-point dot product

Compute the dot product of two or four values held in the corresponding elements of the first source vectors and in the corresponding element of the second source vector. The widened dot product is then added to the corresponding element of the ZA single-vector groups.

C3.11.2.1 BFloat16 floating-point dot product

Table C3-243 BFloat16 floating-point dot product instructions

Mnemonic	Instruction	See
BFDOT	Multi-vector BFloat16 dot product by indexed element to single-precision	BFDOT (multiple and indexed vector)
	Multi-vector BFloat16 dot product by vector to single-precision	BFDOT (multiple and single vector)
	Multi-vector BFloat16 dot product to single-precision	BFDOT (multiple vectors)

C3.11.2.2 Floating-point dot product

Table C3-244 SME2 Floating-point Dot product instructions

Mnemonic	Instruction	See
FDOT	Multi-vector half-precision dot product by indexed element to single-precision	FDOT (2-way, multiple and indexed vector, FP16 to FP32)
	Multi-vector half-precision dot product by vector to single-precision	FDOT (2-way, multiple and single vector, FP16 to FP32)
	Multi-vector half-precision dot product to single-precision	FDOT (2-way, multiple vectors, FP16 to FP32)

C3.11.2.3 FP8 floating-point dot product

The FP8 floating-point dot product instructions accumulate the dot product of two or four FP8 source elements into half-precision or single-precision destination elements. They generate a fused, downscaled sum-of-products and accumulate into each destination element, without intermediate rounding.

For these instructions, the unbounded intermediate sum-of-products is scaled by subtracting the value specified in FPMR.LSCALE from its unbounded exponent. For more information, see the instruction descriptions.

C3.11.3 Vertical dot product

Compute the vertical dot product of the corresponding values held in the first source vectors and in the corresponding elements of second source vector. The widened dot product is then added to the corresponding element of the ZA single-vector groups.

C3.11.3.1 BFloat16 vertical dot product

Table C3-247 SME2 BFloat16 floating-point vertical dot product instructions

Mnemonic	Instruction	See
BFVDOT	Multi-vector BFloat16 vertical dot product by indexed element to single-precision	BFVDOT

C3.11.3.2 Floating-point vertical dot product

Table C3-248 SME2 Floating-point vertical dot product instructions

Mnemonic	Instruction	See
FVDOT	Multi-vector half-precision vertical dot product by indexed element to single-precision	FVDOT (FP16 to FP32)

C3.11.3.3 FP8 floating-point vertical dot product

For FP8 vertical dot product instructions, the unbounded intermediate sum-of-products is scaled by subtracting the value specified in FPMR.LSCALE from its unbounded exponent. For more information, see the instruction descriptions.

Table C3-249 SME2 FP8 floating-point vertical dot product instructions

Mnemonic	Instruction	See
FVDOT	Multi-vector 8-bit floating-point vertical dot product by indexed element to half-precision	FVDOT (FP8 to FP16)
FVDOTB	Multi-vector 8-bit floating-point vertical dot product by indexed element to single-precision (bottom)	FVDOTB
FVDOTT	Multi-vector 8-bit floating-point vertical dot product by indexed element to single-precision (top)	FVDOTT

C3.11.3.4 Integer vertical dot product

Table C3-250 SME2 Integer vertical dot product instructions

Mnemonic	Instruction	See
SUVDOT	Multi-vector signed by unsigned 8-bit integer vertical dot product by indexed element to 32-bit integer	SUVDOT

USVDOT	Multi-vector unsigned by signed 8-bit integer vertical dot product by indexed element to 32-bit integer	USVDOT
UVDOT	Multi-vector unsigned 16-bit integer vertical dot product by indexed element to 32-bit integer	UVDOT (2-way)
	Multi-vector unsigned integer vertical dot product by indexed element	UVDOT (4-way)

C3.11.4 Element concatenate and interleave

Join elements from the source vectors and place them in the corresponding elements of the destination vectors.

Table C3-251 SME2 Element concatenate/interleave instructions

Mnemonic	Instruction	See
UZP	Concatenate elements from four vectors	UZP (four registers)
	Concatenate elements from two vectors	UZP (two registers)
ZIP	Interleave elements from four vectors	ZIP (four registers)
	Interleave elements from two vectors	ZIP (two registers)

C3.11.5 Floating-point conversions

Convert each element of the source vectors and place the results in the corresponding elements of the destination vectors.

C3.11.5.1 Floating-point conversions

Table C3-252 SME2 Floating-point conversion instructions

Mnemonic	Instruction	See
FCVT	Multi-vector half-precision convert to single-precision	FCVT (widening)
	Multi-vector single-precision convert to half-precision	FCVT (narrowing, FP32 to FP16)
FCVTL	Multi-vector half-precision convert to deinterleaved single-precision	FCVTL
FCVTN	Multi-vector single-precision convert to interleaved half-precision	FCVTN (FP32 to FP16)
FCVTZS	Multi-vector single-precision convert to signed 32-bit integer, rounding toward zero	FCVTZS
FCVTZU	Multi-vector single-precision convert to unsigned 32-bit integer, rounding toward zero	FCVTZU

C3.11.5.2 BFloat16 floating-point conversions

BFCVTN	Multi-vector single-precision convert to interleaved BFloat16	BFCVTN

C3.11.5.3 FP8 floating-point conversions

Convert each floating-point element of the source vectors while scaling the value, and place the results in the corresponding elements of the destination vector.

For instructions that convert other floating-point formats to FP8 formats, each input element is scaled by adding the value specified in FPMR.NSCALE to its unbounded exponent during the conversion.

For instructions that convert FP8 formats to other floating-point formats, each input element is scaled by subtracting the value specified in FPMR.LSCALE or FPMR.LSCALE2 from its unbounded exponent during the conversion.

For more information, see the instruction descriptions.

Table C3-254 FP8 floating-point conversion instructions

Mnemonic	Instruction	See
BF1CVT	Multi-vector 8-bit floating-point convert to BFloat16 - BF1CVT	BF1CVT, BF2CVT - BF1CVT
BF1CVTL	Multi-vector 8-bit floating-point convert to deinterleaved BFloat16 - BF1CVTL	BF1CVTL, BF2CVTL - BF1CVTL
BF2CVT	Multi-vector 8-bit floating-point convert to BFloat16 - BF2CVT	BF1CVT, BF2CVT - BF2CVT
BF2CVTL	Multi-vector 8-bit floating-point convert to deinterleaved BFloat16 - BF2CVTL	BF1CVTL, BF2CVTL - BF2CVTL
BFCVT	Multi-vector BFloat16 convert to 8-bit floating-point	BFCVT (BFloat16 to 8-bit floating-point)
F1CVT	Multi-vector 8-bit floating-point convert to half-precision - F1CVT	F1CVT, F2CVT - F1CVT
F1CVTL	Multi-vector 8-bit floating-point convert to deinterleaved half-precision - F1CVTL	F1CVTL, F2CVTL - F1CVTL
F2CVT	Multi-vector 8-bit floating-point convert to half-precision - F2CVT	F1CVT, F2CVT - F2CVT
F2CVTL	Multi-vector 8-bit floating-point convert to deinterleaved half-precision - F2CVTL	F1CVTL, F2CVTL - F2CVTL
FCVT	Multi-vector half-precision convert to 8-bit floating-point	FCVT (narrowing, FP16 to FP8)
	Multi-vector single-precision convert to 8-bit floating-point	FCVT (narrowing, FP32 to FP8)
FCVTN	Multi-vector single-precision convert to interleaved 8-bit floating-point	FCVTN (FP32 to FP8)

C3.11.6 Floating-point round

Round each element of the source vectors to an integral floating-point value and place the results in the corresponding elements of the destination vectors.

Table C3-255 SME2 Floating-point round to integral value instructions

Mnemonic	Instruction	See
FRINTA	Multi-vector single-precision round to integral value, to nearest with ties away from zero	FRINTA
FRINTM	Multi-vector single-precision round to integral value, toward minus Infinity	FRINTM
FRINTN	Multi-vector single-precision round to integral value, to nearest with ties to even	FRINTN
FRINTP	Multi-vector single-precision round to integral value, toward plus Infinity	FRINTP

C3.11.7 Floating-point adjust exponent

C3.11.7.1 Floating-point scaling

The FSCALE instructions perform floating-point scaling by integer powers of two.

Table C3-256 SME2 floating-point scaling instructions

Mnemonic	Instruction	See
FSCALE	Multi-vector floating-point adjust exponent	FSCALE (multiple vectors)
	Multi-vector floating-point adjust exponent by vector	FSCALE (multiple and single vector)

C3.11.7.2 BFloat16 scaling

The BFSCALE instructions perform BFloat16 scaling by integer powers of two.

Table C3-257 SME2 BFloat16 scaling instructions

Mnemonic	Instruction	See
BFSCALE	Multi-vector BFloat16 adjust exponent	BFSCALE (multiple vectors)
	Multi-vector BFloat16 adjust exponent by vector	BFSCALE (multiple and single vector)

C3.11.8 Lookup table

Copy elements from ZT0 to the destination vectors using packed indices from a portion of the source vector.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-258 SME2/SME2.1 Lookup table read instructions

Mnemonic	Instruction	See
`LUTI2`	Lookup table read with 2-bit indexes (four registers)	LUTI2 (four registers)
	Lookup table read with 2-bit indexes (single)	LUTI2 (single)
	Lookup table read with 2-bit indexes (two registers)	LUTI2 (two registers)
`LUTI4`	Lookup table read with 4-bit indexes (four registers)	LUTI4 (four registers, 16-bit and 32-bit)
	Lookup table read with 4-bit indexes (single)	LUTI4 (single)
	Lookup table read with 4-bit indexes (two registers)	LUTI4 (two registers)
	Lookup table read with 4-bit indexes and 8-bit elements (four registers)	LUTI4 (four registers, 8-bit)

C3.11.9 Move operations

Move between ZA single-vector groups, vector registers, or individual horizontal or vertical ZA tile slices.

Table C3-259 SME/SME2 Move instructions

Mnemonic	Instruction	See
`MOVA`	Move Z four-vector operand to ZA four-slice operand	MOVA (vector to tile, four registers)
	Move Z four-vector operand to four ZA single-vector groups	MOVA (vector to array, four registers)
	Move Z two-vector operand to ZA two-slice operand	MOVA (vector to tile, two registers)
	Move Z two-vector operand to two ZA single-vector groups	MOVA (vector to array, two registers)
	Move Z vector to ZA tile slice	MOVA (vector to tile, single)
	Move ZA four-slice operand to Z four-vector operand	MOVA (tile to vector, four registers)
	Move ZA tile slice to Z vector	MOVA (tile to vector, single)
	Move ZA two-slice operand to Z two-vector operand	MOVA (tile to vector, two registers)
	Move four ZA single-vector groups to Z four-vector operand	MOVA (array to vector, four registers)
	Move two ZA single-vector groups to Z two-vector operand	MOVA (array to vector, two registers)

C3.11.9.1 Lookup table move

Move 8 bytes between the ZT0 register and a general-purpose register at a specified byte offset.

`MOVT` (vector to table) copies the source vector register to ZT0 at a specified vector length offset.

Table C3-260 SME2 Lookup table move instructions

Mnemonic	Instruction	See
`MOVT`	Move 8 bytes from ZT0 to general-purpose register	MOVT (table to scalar)
	Move 8 bytes from general-purpose register to ZT0	MOVT (scalar to table)
	Move vector register to ZT0	MOVT (vector to table)

Non-Confidential

C3.11.9.2 Move and zero

Move contents of ZA single-vector groups or of consecutive horizontal or vertical slices within a ZA tile to the destination vectors and zero the source contents.

Table C3-261 SME2.1 Move and zero instructions

Mnemonic	Instruction	See
MOVAZ	Move and zero ZA four-slice operand to Z four-vector operand	MOVAZ (tile to vector, four registers)
	Move and zero ZA tile slice to Z vector	MOVAZ (tile to vector, single)
	Move and zero ZA two-slice operand to Z two-vector operand	MOVAZ (tile to vector, two registers)
	Move and zero four ZA single-vector groups to Z four-vector operand	MOVAZ (array to vector, four registers)
	Move and zero two ZA single-vector groups to Z two-vector operand	MOVAZ (array to vector, two registers)

C3.11.10 Multi-vector arithmetic

C3.11.10.1 Add and subtract

Add or subtract vectors from ZA single-vector groups or destructively place results in corresponding elements of the source vectors.

Table C3-262 SME2 Add and subtract instructions

Mnemonic	Instruction	See
ADD	Multi-vector accumulate to ZA array vectors	ADD (to array, array and multiple vectors)
	Multi-vector add by vector to ZA array vectors	ADD (to array, multiple and single vector)
	Multi-vector add by vector to multi-vector	ADD (to vector, multiple vectors)
	Multi-vector add to ZA array vectors	ADD (to array, multiple vectors)
SUB	Multi-vector subtract by vector to ZA array vectors	SUB (to array, multiple and single vector)
	Multi-vector subtract from ZA array vectors	SUB (to array, array and multiple vectors)
	Multi-vector subtract to ZA array vectors	SUB (to array, multiple vectors)

C3.11.10.2 Add vector to array

Add each element of the source vector to the corresponding Active element of each vertical or horizontal slice of a ZA tile.

Table C3-263 SME Add vector to array instructions

Mnemonic	Instruction	See
ADDHA	Add horizontally vector elements to ZA tile	ADDHA
ADDVA	Add vertically vector elements to ZA tile	ADDVA

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.11.10.3 Floating-point add and subtract

Destructively add or subtract all elements of the source vectors from the corresponding elements of the ZA single-vector groups.

Table C3-264 SME2 Floating-point add and subtract instructions

Mnemonic	Instruction	See
BFADD	Multi-vector BFloat16 accumulate to ZA array vectors	BFADD
BFSUB	Multi-vector BFloat16 subtract from ZA array vectors	BFSUB
FADD	Multi-vector floating-point accumulate to ZA array vectors	FADD
FSUB	Multi-vector floating-point subtract from ZA array vectors	FSUB

C3.11.11 Multi-vector minimum/maximum

Determine the minimum or maximum of elements of the second source vector and the corresponding elements of the first source vectors and destructively place the results in the corresponding elements of the first source vectors.

C3.11.11.1 BFloat16 minimum/maximum

These instructions follow the SME2.1 non-widening BFloat16 numerical behaviors corresponding to instructions that place their results in two or four SVE Z vectors. If FEAT_SVE_B16B16 is implemented, these instructions are also implemented.

Table C3-265 SME2.1 BFloat16 minimum/maximum

Mnemonic	Instruction	See
BFMAX	Multi-vector BFloat16 maximum	BFMAX (multiple vectors)
	Multi-vector BFloat16 maximum by vector	BFMAX (multiple and single vector)
BFMAXNM	Multi-vector BFloat16 maximum number	BFMAXNM (multiple vectors)
	Multi-vector BFloat16 maximum number by vector	BFMAXNM (multiple and single vector)
BFMIN	Multi-vector BFloat16 minimum	BFMIN (multiple vectors)

	Multi-vector half-precision multiply-add by vector to single-precision	FMLAL (multiple and single vector, FP16 to FP32)
	Multi-vector half-precision multiply-add to single-precision	FMLAL (multiple vectors, FP16 to FP32)
FMLS	Multi-vector floating-point fused multiply-subtract	FMLS (multiple vectors)
	Multi-vector floating-point fused multiply-subtract by indexed element	FMLS (multiple and indexed vector)
	Multi-vector floating-point fused multiply-subtract by vector	FMLS (multiple and single vector)
FMLSL	Multi-vector half-precision multiply-subtract by indexed element from single-precision	FMLSL (multiple and indexed vector)
	Multi-vector half-precision multiply-subtract by vector from single-precision	FMLSL (multiple and single vector)
	Multi-vector half-precision multiply-subtract from single-precision	FMLSL (multiple vectors)

C3.11.13.3 FP8 floating-point widening multiply-accumulate

The FP8 floating-point multiply-accumulate instructions widen the 8-bit floating-point elements in the source vectors to half-precision or single-precision format and multiply the corresponding elements.

They generate a fused, downscaled product and accumulate into the corresponding elements of the destination vector, without intermediate rounding.

For these instructions, the unbounded intermediate product is scaled by subtracting the value specified in FPMR.LSCALE from its unbounded exponent. For more information, see the instruction descriptions.

Table C3-273 SME2 FP8 floating-point widening multiply-accumulate instructions

Mnemonic	Instruction	See
FMLAL	Multi-vector 8-bit floating-point multiply-add by indexed element to half-precision	FMLAL (multiple and indexed vector, FP8 to FP16)
	Multi-vector 8-bit floating-point multiply-add by vector to half-precision	FMLAL (multiple and single vector, FP8 to FP16)
	Multi-vector 8-bit floating-point multiply-add to half-precision	FMLAL (multiple vectors, FP8 to FP16)

C3.11.14 Multi-vector multiply high

These instructions multiply then double the corresponding elements of the first and second source vectors and destructively place the most significant half of the result in the corresponding elements of the first and second source vectors.

Table C3-275 SME2 Multi-vector multiply high

Mnemonic	Instruction	See
SQDMULH	Multi-vector signed saturating doubling multiply high	SQDMULH (multiple vectors)
	Multi-vector signed saturating doubling multiply high by vector	SQDMULH (multiple and single vector)

C3.11.15 Multi-vector select

Copy into elements of the destination vectors the corresponding elements from the first source vectors where the corresponding predicate elements are TRUE, and from the second source vectors where the corresponding predicate elements are FALSE.

Table C3-276 SME2 Multi-vector select

Mnemonic	Instruction	See
SEL	Multi-vector conditional select	SEL

C3.11.16 Multi-vector shift and convert

Convert or shift the value of each element of the source vectors and place the results in the corresponding destination vector elements.

Table C3-277 SME2 Multi-vector shift and convert instructions

Mnemonic	Instruction	See
SCVTF	Multi-vector signed 32-bit integer convert to single-precision	SCVTF
SQCVT	Multi-vector signed 32-bit integer saturating extract narrow to 16-bit integer	SQCVT (two registers)
	Multi-vector signed saturating extract narrow	SQCVT (four registers)
SQCVTN	Multi-vector signed saturating extract narrow to interleaved integer	SQCVTN
SQCVTU	Multi-vector signed 32-bit integer saturating extract narrow to unsigned 16-bit integer	SQCVTU (two registers)
	Multi-vector signed saturating extract narrow to unsigned integer	SQCVTU (four registers)

	Unsigned integer sum of outer products, accumulating	UMOPA (4-way)
UMOPS	Unsigned 16-bit integer sum of outer products to 32-bit integer, subtracting	UMOPS (2-way)
	Unsigned integer sum of outer products, subtracting	UMOPS (4-way)
USMOPA	Unsigned by signed integer sum of outer products, accumulating	USMOPA (4-way)
USMOPS	Unsigned by signed integer sum of outer products, subtracting	USMOPS

C3.11.18 Quarter-tile outer product

The quarter-tile outer product instructions generate four independent quarter-tile outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors. The resulting quarter-tile outer products are added to or subtracted from the destination ZA tile.

C3.11.18.1 BFloat16 quarter-tile outer product

Table C3-283 SME BFloat16 quarter-tile outer product instructions

Mnemonic	Instruction	See
BFMOP4A	BFloat16 quarter-tile outer product, accumulating	BFMOP4A (non-widening)
	BFloat16 quarter-tile sum of outer products to single-precision, accumulating	BFMOP4A (widening)

SMOP4S	Signed 16-bit integer quarter-tile sum of outer products to 32-bit integer, subtracting	SMOP4S (2-way)
	Signed integer quarter-tile sum of outer products, subtracting	SMOP4S (4-way)
SUMOP4A	Signed by unsigned integer quarter-tile sum of outer products, accumulating	SUMOP4A
SUMOP4S	Signed by unsigned integer quarter-tile sum of outer products, subtracting	SUMOP4S
UMOP4A	Unsigned 16-bit integer quarter-tile sum of outer products to 32-bit integer, accumulating	UMOP4A (2-way)
	Unsigned integer quarter-tile sum of outer products, accumulating	UMOP4A (4-way)
UMOP4S	Unsigned 16-bit integer quarter-tile sum of outer products to 32-bit integer, subtracting	UMOP4S (2-way)
	Unsigned integer quarter-tile sum of outer products, subtracting	UMOP4S (4-way)
USMOP4A	Unsigned by signed integer quarter-tile sum of outer products, accumulating	USMOP4A
USMOP4S	Unsigned by signed integer quarter-tile sum of outer products, subtracting	USMOP4S

C3.11.19 Structured sparsity outer product

The SME structured sparsity outer product instructions accumulate the products or sum-of-products of all elements of the second source vector and selected elements of the first source vectors.

The SME widening structured sparsity outer product instructions widen and multiply a dense matrix by a 2:4 sparse matrix and accumulate to the destination tile. In a 2:4 structured sparsity pattern, two elements are selected per group of four elements, discarding the remaining two elements.

The SME non-widening structured sparsity outer product instructions multiply a dense matrix by a 1:2 sparse matrix and accumulate to the destination tile. In a 1:2 structured sparsity pattern, one element is selected out of a pair of elements, discarding the remaining element.

C3.11.20 Stack frame operations

Multiply the Streaming SVE vector register size in bytes by an immediate and add the result to the destination general-purpose register or current stack pointer. `RDSVL` only places the result in the destination general-purpose register without addition.

Table C3-291 SME Stack frame instructions

Mnemonic	Instruction	See
`ADDSPL`	Add multiple of Streaming SVE predicate register size to scalar register	ADDSPL
`ADDSVL`	Add multiple of Streaming SVE vector register size to scalar register	ADDSVL
`RDSVL`	Read multiple of Streaming SVE vector register size to scalar register	RDSVL

C3.11.21 Unpack and extend

Unpack elements from the source vectors and extend them to place in elements of twice their size within the destination vectors.

Table C3-292 SME2 Unpack and extend instructions

Mnemonic	Instruction	See
`SUNPK`	Unpack and sign-extend multi-vector elements	SUNPK
`UUNPK`	Unpack and zero-extend multi-vector elements	UUNPK

C3.11.22 Zero operations

Set all corresponding bytes or ZA vector groups to zero.

Table C3-293 SME/SME2 Zero instructions

Mnemonic	Instruction	See
`ZERO`	Zero a list of 64-bit element ZA tiles	ZERO (tiles)
	Zero ZT0	ZERO (table)

C3.11.22.1 Zero ZA array vectors

Table C3-294 SME2.1 Zero ZA array vectors instructions

Chapter C4
A64 Instruction Set Encoding

This chapter describes the encoding of the A64 instruction set. It contains the following section:

- A64 instruction set encoding

In this chapter:

- In the decode tables, an entry of x for a field value means the value of the field does not affect the decoding.

Chapter C5
The A64 System Instruction Class

This chapter describes the A64 System instruction class, and the System instruction class encoding space, that is a subset of the System registers encoding space. It contains the following sections:

- The System instruction class encoding space
- Special-purpose registers
- A64 System instructions for cache maintenance
- A64 System instructions for address translation
- A64 System instructions for TLB maintenance
- A64 System instructions for prediction restriction
- A64 System instructions for the Branch Record Buffer Extension
- A64 System instructions for the Trace Extension
- A64 System instructions for the Guarded Control Stack
- A64 System instructions introduced by FEAT_RME_GPC3
- A64 IMPLEMENTATION DEFINED System instructions

See General information about the A64 instruction descriptions for information about entries used in the instruction encoding descriptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C5.1 The System instruction class encoding space

Part of the A64 instruction encoding space is assigned to instructions that access the System register encoding space. These instructions provide:

- Access to *System registers*, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the `CLREX` instruction.
- Architectural hint instructions.

This section describes the general model for accessing this functionality.

Note

- See Fixed values in AArch64 instruction and System register descriptions for information about abbreviations used in the System instruction descriptions.
- In AArch32 state much of this functionality is provided through the System register interface described in The AArch32 System register interface. In AArch64 state, the parameters used to characterize the System register encoding space are `{op0, op1, CRn, CRm, op2}`. These are based on the parameters that characterize the AArch32 System register encoding space, which reflect the original implementation of these registers, as described in Background to the System register interface. There is no particular significance to the naming of these parameters, and no functional distinction between the `opn` parameters and the `CRx` parameters.

Principles of the System instruction class encoding describes some general properties of these encodings. System instruction class encoding overview then describes the top-level encoding of these instructions, and the following sections then describe the next level of the encoding hierarchy of System instructions and Special-purpose registers:

- op0 == `0b00`, architectural hints, barriers and CLREX, and PSTATE access.
- op0 == `0b01`, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack instructions, and FEAT_RME_GPC3 instructions.
- op0 == `0b11`, Moves to and from non-debug System registers and Special-purpose registers.

For the description of the next level of encoding hierarchy of System registers, see:

- Moves to and from debug and trace System registers.
- Moves to and from non-debug System registers, Special-purpose registers.
- Reserved encodings for IMPLEMENTATION DEFINED registers.

C5.1.1 Principles of the System instruction class encoding

An encoding in the System instruction space is identified by a set of arguments,`{op0, op1, CRn, CRm, op2}`. These form an encoding hierarchy, where:

`op0` Defines the top-level division of the encoding space, see System instruction class encoding overview.

`op1` Except for encodings allocated to `HINTE` if FEAT_HINTE is implemented, `op1` identifies the lowest Exception level at which the encoding is accessible, as follows:

Accessible at EL0 `op1` has the value `0b011`.

Accessible at EL1 `op1` has the value `0b000`, `0b001`, or `0b010`. The value is the same as the `op1` value used to access the equivalent AArch32 register.

Accessible at Secure EL1 `op1` has the value `0b111`.

Accessible at EL2 `op1` has the value `0b100` or `0b101`. The value `0b101` is used for the EL12 encodings that access EL1 System registers used when FEAT_VHE is implemented and the Effective value of HCR_EL2.E2H is 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessible at EL3 `op1` has the value `0b110`.

Arm strongly recommends that implementers adopt this use of `op1` when using the IMPLEMENTATION DEFINED regions of the encoding space described in Reserved encodings for IMPLEMENTATION DEFINED registers.

C5.1.2 System instruction class encoding overview

The encoding of the System instruction class describes each instruction as being either:

- A transfer to a System register. This is a System instruction with the semantics of a write.
- A transfer from a System register. This is a System instruction with the semantics of a read.

A System instruction that initiates an operation operates as if it was making a transfer to a register.

In the AArch64 instruction set, the decode structure for the System instruction class is:

31 30 29 28	27 26 25 24	23 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0 1	0 1 0 1	0 0	L	op0	op1	CRn	CRm	op2	Rt

Except for encodings allocated to `HINTE` if FEAT_HINTE is implemented, the value of `L` indicates the transfer direction:

0 Transfer to System register.

1 Transfer from System register.

The `op0` field is the top-level encoding of the System instruction type. Its possible values are:

`0b00` These encodings provide:

- Instructions with an immediate field for accessing PSTATE, the current PE state.
- The architectural hint instructions.
- Barriers and the `CLREX` instruction.

For more information about these encodings, see op0 == `0b00`, architectural hints, barriers and CLREX, and PSTATE access.

`0b01` These encodings provide:

- Cache maintenance instructions.
- TLB maintenance instructions.
- Address translation instructions.
- Prediction restriction instructions.
- BRBE instructions.
- Instrumentation Trace Extension instructions.
- Guarded Control Stack instructions.
- FEAT_RME_GPC3 instructions.

Note

These are equivalent to operations in the AArch32 (`coproc` == `0b1111`) encoding space.

For more information, see op0 == `0b01`, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack instructions, and FEAT_RME_GPC3 instructions.

`0b10` These encodings provide moves to and from:

- Legacy AArch32 System registers for execution environments, to provide access to these registers from higher Exception levels that are using AArch64.
- Debug, PMU, System PMU, and trace registers.

Note

These are equivalent to the registers in the AArch32 (`coproc` == `0b1110`) encoding space.

For more information, see Moves to and from debug and trace System registers.

`0b11` These encodings provide:

- Moves to and from Non-debug System registers. The accessed registers provide system control, and system status information.

  Note

  The accessed registers are equivalent to the registers in the AArch32 (`coproc` == `0b1111`) encoding space.

- Access to Special-purpose registers.

For more information, see Instructions for accessing Special-purpose registers and Instructions for accessing non-debug System registers.

C5.1.2.1 UNDEFINED behaviors

In the System register instruction encoding space, the following principles apply:

- All unallocated encodings are treated as UNDEFINED.
- Encodings with `L` == 1 and `op0` == `0b0x` are UNDEFINED, except for the following:
  - Encodings in the area reserved for IMPLEMENTATION DEFINED use, see Reserved encoding space for IMPLEMENTATION DEFINED instructions.
  - Encodings allocated to `HINTE` if FEAT_HINTE is implemented.

For registers and operations that are accessible from a particular Exception level, any attempt to access those registers from a lower Exception level is UNDEFINED.

If a particular Exception level:

- Defines a register to be RO, then any attempt to write to that register, at that Exception level, is UNDEFINED. This means that any access to that register with `L` == 0 is UNDEFINED.
- Defines a register to be WO, then any attempt to read from that register, at that Exception level, is UNDEFINED. This means that any access to that register with `L` == 1 is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED, but see the recommendation in Principles of the System instruction class encoding.

C5.1.3 op0 == `0b00`, architectural hints, barriers and CLREX, and PSTATE access

The encoding of the `op0` == `0b00` group of instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18 16	15 12	11 8	7 5	4 0
1	1	0	1	0	1	0	1	0	0	L	0	0	op1	CRn	CRm	op2	Rt
											op0						

This encoding is subdivided further by `CRn`:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b0010` See Architectural hint instructions.

`0b0011` See Barriers and CLREX.

`0b0100` See Instructions for accessing the PSTATE fields.

C5.1.3.1 Architectural hint instructions

Within the `op0 == 0b00` encodings, the architectural hint instructions are identified by `CRn` having the value `0b0010`.

If FEAT_HINTE is implemented, the architectural hint encoding space is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	5	4	0
1	1	0	1	0	1	0	1	0	0	L	0	0	imm3		0	0	1	0	imm7	Rt
											op0		op1		CRn				CRm op2	

Otherwise, the architectural hint encoding space is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	5	4	0
1	1	0	1	0	1	0	1	0	0	0	0	0	0	1 1	0	0	1	0	Op<6:0>	1 1 1 1 1
											op0		op1		CRn				CRm op2	Rt

When `(L == 0b0 && imm3 == 0b011 && Rt == 0b11111)`, the value of `op<6:0>` determines the hint instruction, as follows:

`0b0000000` `NOP` instruction.

`0b0000001` `YIELD` instruction.

`0b0000010` `WFE` instruction.

`0b0000011` `WFI` instruction.

`0b0000100` `SEV` instruction.

`0b0000101` `SEVL` instruction.

`0b0000110` `DGH` instruction.

`0b0000111` `XPACD, XPACI, XPACLRI` instruction.

`0b0001000` `PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA` instruction, PACIA1716 variant.

`0b0001010` `PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB` instruction, PACIB1716 variant.

`0b0001100` `AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA` instruction, AUTIA1716 variant.

`0b0001110` `AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB` instruction, AUTIB1716 variant.

`0b0010000` `ESB` instruction.

`0b0010001` `PSB` instruction.

`0b0010010` `TSB` instruction.

`0b0010100` `CSDB` instruction.

`0b0010110` `CLRBHB` instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b0011000` `PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA` instruction, PACIAZ variant.

`0b0011001` `PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA` instruction, PACIASP variant.

`0b0011010` `PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB` instruction, PACIBZ variant.

`0b0011011` `PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB` instruction, PACIBSP variant.

`0b0011100` `AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA` instruction, AUTIAZ variant.

`0b0011101` `AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA` instruction, AUTIASP variant.

`0b0011110` `AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB` instruction, AUTIBZ variant.

`0b0011111` `AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB` instruction, AUTIBSP variant.

`0b0100xx0` `BTI` instruction.

`0b0101000` `CHKFEAT` instruction.

`0b011000x` `STSHH` instruction.

These instructions are described in A64 Base Instruction Descriptions.

Note

- In an implementation without FEAT_HINTE, FEAT_HINTE encodings except `(L == 0b0 && imm3 == 0b011 && Rt == 0b11111)` are UNDEFINED.
- The operations of the A64 instructions for architectural hints are identical to the corresponding T32 and A32 instructions.

For more information about:

- The `WFE`, `WFI`, `SEV`, and `SEVL` instructions, see Mechanisms for entering a low-power state.
- The `YIELD` instruction, see Software control features and EL0.
- The `STSHH` instruction, see Use of the FEAT_PCDPHINT STSHH and PRFM IR (immediate) instructions.

C5.1.3.2 Barriers and CLREX

Within the `op0` == `0b00` encodings, the barriers and `CLREX` instructions are identified by `CRn` having the value `0b0011`. The encoding of these instructions is:

31 30 29 28	27 26 25 24	23 22	21	20 19	18 16	15 12	11 8	7 5	4	0
1 1 0 1	0 1 0 1	0 0	0	0 0	0 1 1	0 0 1 1	CRm	op2	1	1 1 1 1 1
				op0	op1	CRn				Rt

The value of `op2` determines the instruction, as follows:

`0b001` `DSB` instruction, Memory nXS barrier variant.

`0b010` `CLREX` instruction.

`0b100` `DSB` instruction, Memory barrier variant.

`0b101` `DMB` instruction.

`0b110` `ISB` instruction.

`0b111` `SB` instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b000`; `0b011` UNDEFINED.

These instructions are described in A64 Base Instruction Descriptions.

Note

- Instruction encodings for barriers and CLREX are UNDEFINED if bits[4:0] are not set to `0b11111`.
- The operations of the A64 instructions for barriers and `CLREX` are identical to the corresponding T32 and A32 instructions.

For more information about:

- The barrier instructions, see Memory barriers.
- The `CLREX` instruction, see Synchronization and semaphores.

C5.1.3.3 Instructions for accessing the PSTATE fields

Within the `op0` == `0b00` encodings, the instructions that can be used to modify PSTATE fields directly are identified by `CRn` having the value `0b0100`. The encoding of these instructions is shown in Figure C5-1 and Figure C5-2:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15			12	11	8	7	5	4			0
1	1	0	1	0	1	0	1	0	0	0	0	0	op1		0	1	0	0	Imm4		op2		1	1	1	1	1
											op0				CRn				CRm						Rt		

Figure C5-1 Instructions using #Imm4

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15			12	11			8	7	5	4			0
1	1	0	1	0	1	0	1	0	0	0	0	0	op1		0	1	0	0	0	0	0	Imm1	op2		1	1	1	1	1
											op0				CRn				CRm							Rt		

Figure C5-2 Instructions using #Imm1

These instructions are:

```
CFINV                 ; Inverts the value of PSTATE.C
MSR DAIFSet, #Imm4    ; Used to set any or all of DAIF to 1
MSR DAIFClr, #Imm4    ; Used to clear any or all of DAIF to 0
MSR SPSel, #Imm4      ; Used to select the Stack Pointer, between SP_EL0 and SP_ELx
MSR UAO, #Imm4        ; Used to set the value of PSTATE.UAO
MSR PAN, #Imm4        ; Used to set the value of PSTATE.PAN
MSR DIT, #Imm4        ; Used to set the value of PSTATE.DIT
MSR SSBS, #Imm4       ; Used to set the value of PSTATE.SSBS
MSR TCO, #Imm4        ; Used to set the value of PSTATE.TCO
MSR ALLINT, #Imm1     ; Used to set the value of PSTATE.ALLINT
```

The value of `op2` selects the instruction form, which defines the constraints on the values of the `op1` and `Imm4` or `Imm1` arguments, as follows:

`op2` == `0b000` Selects the `CFINV` instruction.

`op2` == `0b011` Selects the `MSR UAO` instruction.

`op2` == `0b100` Selects the `MSR PAN` instruction.

`op2` == `0b101` Selects the `MSR SPSel` instruction.

`op2` == `0b001` Selects the `MSR SSBS` instruction.

`op2` == `0b010` Selects the `MSR DIT` instruction.

`op2` == `0b100` Selects the `MSR TCO` instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`op2 == 0b110` Selects the `MSR DAIFSet` instruction, that sets the specified PSTATE.{D, A, I, F} bits to 1.

`op2 == 0b111` Selects the `MSR DAIFClr` instruction, that clears the specified PSTATE.{D, A, I, F} bits to 0.

`op2 == 0b000` Selects the `MSR ALLINT` instruction.

All other combinations of `op1` and `op2` are reserved, and the corresponding instructions are UNDEFINED.

Note

For PSTATE updates, instruction encodings with bits[4:0] not set to `0b11111` are UNDEFINED.

Writes to PSTATE occur in program order without the need for additional synchronization. Changing PSTATE.SP to use SP_EL0 synchronizes any updates to SP_EL0 that have been written by an `MSR` to SP_EL0, without the need for additional synchronization.

C5.1.4 op0 == `0b01`, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions

The System instructions are encoded with `op0== 0b01`. The different groups of System instructions are identified by the values of `CRn` and `CRm`, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18 16	15 12	11 8	7 5	4 0
1	1	0	1	0	1	0	1	0	0	0	0	1	op1	CRn	CRm	op2	Xt
											op0						

The grouping of these instructions depending on the `CRn` and `CRm` fields is as follows:

`CRn == 0b0111` The instruction group is determined by the value of `CRm`, as follows:

`CRm == 0b0000` Associate a physical address with a memory-mapped location, APAS instruction.

See FEAT_RME_GPC3 instructions.

`CRm == {0b0001, 0b0101}` Instruction cache maintenance instructions.

See Cache maintenance instructions, and data cache zero operations.

`CRm == 0b0010` Branch Record Buffer and Trace Extension instructions.

See Branch Record Buffer instructions and Trace Extension instructions.

`CRm == 0b0011` Prediction restriction instructions.

See Prediction restriction instructions.

`CRm == 0b0100` Data cache zero operations.

See Cache maintenance instructions, and data cache zero operations.

`CRm == {0b0110, 0b1010, 0b1011, 0b1100, 0b1101, 0b1110, 0b1111}` Data cache maintenance instructions.

See Cache maintenance instructions, and data cache zero operations.

`CRm == 0b0111` Guarded Control Stack instructions.

See Guarded Control Stack instructions.

`CRm == {0b1000, 0b1001}` See Address translation instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`CRn == {0b1000, 0b1001}` See TLB maintenance instructions.

`CRn == {0b1011, 0b1111}` See Reserved encoding space for IMPLEMENTATION DEFINED instructions.

C5.1.4.1 Cache maintenance instructions, and data cache zero operations

Table C5-1 lists the Cache maintenance instructions and their encodings. Instructions that take an argument include `Xt` in the instruction syntax. For instructions that do not take an argument, the Rt field is encoded as `0b11111`. For these instructions, if the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

C5.1.4.9 Reserved encoding space for IMPLEMENTATION DEFINED instructions

The A64 instruction set reserves the following encoding space for IMPLEMENTATION DEFINED instructions:

31 30 29 28	27 26 25 24	23 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0 1	0 1 0 1	0 0	L	0 1	op1	1 x 1 1	CRm	op2	Rt
				op0		CRn			

The value of `L` defines the use of `Rt` as follows:

0 `Rt` is an argument supplied to the instruction.

1 `Rt` is a result returned by the instruction.

IMPLEMENTATION DEFINED instructions in this encoding space are accessed using the `SYS`, `SYSL`, and `SYSP` instructions, see SYS, SYSL and SYSP.

Accesses to any of the IMPLEMENTATION DEFINED System instruction encodings that are not trapped are permitted to be UNDEFINED.

See also Reserved encodings for IMPLEMENTATION DEFINED registers.

C5.1.5 op0 == `0b11`, Moves to and from non-debug System registers and Special-purpose registers

The instructions that move data to and from non-debug System registers and Special-purpose registers are encoded with `op0` == `0b11`, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

31 30 29 28	27 26 25 24	23 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0 1	0 1 0 1	0 0	L	1 1	op1	CRn	CRm	op2	Rt
				op0					

The value of `CRn` provides the next level of decode of these instructions, as follows:

`CRn` == {`0b0000`, `0b0001`, `0b0010`, `0b0011`, `0b0101`, `0b0110`, `0b0111`, `0b1001`, `0b1010`, `0b1100`, `0b1101`, `0b1110`}

See Instructions for accessing non-debug System registers.

`CRn` == {`0b0100`}

See Instructions for accessing Special-purpose registers.

`CRn` == {`0b1011`, `0b1111`}

See Reserved encodings for IMPLEMENTATION DEFINED registers.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C5.1.5.1 Instructions for accessing Special-purpose registers

The value of `CRn` provides the next level of decode of these instructions. Accesses to Special-purpose registers are identified by the `CRn` value being `0b0100`, with the exception of RGSR_EL1.

The A64 instructions for accessing Special-purpose registers are:

```
MSR <Special-purpose_register>, Xt    ; Write to Special-purpose register
MRS Xt, <Special-purpose_register>    ; Read from Special-purpose register
```

Where `<Special-purpose_register>` is the register name, for example SP_EL0.

The encoding for Special-purpose register accesses is:

31 30 29 28	27 26 25 24	23 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0 1	0 1 0 1	0 0	L	1 1	op1	0 1 0 0	CRm	op2	Rt
				op0		CRn			

For the encoding of RGSR_EL1, see RGSR_EL1, Random Allocation Tag Seed Register.

The full list of Special-purpose registers is in Table C5-9. The characteristic of a Special-purpose register is that all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization.

Table C5-9 lists the encodings for `op1`, `CRm`, and `op2` fields for accesses to the Special-purpose registers in AArch64.

Table C5-9 Instruction encodings for Special-purpose register accesses

C5.2 Special-purpose registers

This section describes the following Special-purpose registers:

- ALLINT, that holds the PSTATE.ALLINT bit.
- CurrentEL, that holds PSTATE.EL, and that software can read to determine the current Exception level.
- DAIF, that holds the current PSTATE.{D, A, I, F} interrupt mask bits.
- DIT, that holds the PSTATE.DIT bit.
- ELR_EL1, that holds the address to return to for an exception return from EL1.
- ELR_EL2, that holds the address to return to for an exception return from EL2.
- ELR_EL3, that holds the address to return to for an exception return from EL3.
- FPCR, that provides control of floating-point operation.
- FPMR, that controls behaviors of the FP8 instructions.
- FPSR, that provides floating-point status information.
- NZCV, that holds the PSTATE.{N, Z, C, V} condition flags.
- PAN, that holds the PSTATE.PAN state bit.
- PM, that provides access to the Profiling exception mask bit.
- RGSR_EL1, that seeds Random Allocation Tags.
- SP_EL0, that holds the stack pointer for EL0.
- SP_EL1, that holds the stack pointer for EL1.
- SP_EL2, that holds the stack pointer for EL2.
- SP_EL3, that holds the stack pointer for EL3.
- SPSel, that holds PSTATE.SP, that at EL1 or higher selects the current SP.
- SPSR_abt, that holds process state on taking an exception to AArch32 Abort mode.
- SPSR_EL1, that holds process state on taking an exception to AArch64 EL1.
- SPSR_EL2, that holds process state on taking an exception to AArch64 EL2.
- SPSR_EL3, that holds process state on taking an exception to AArch64 EL3.
- SPSR_fiq, that holds process state on taking an exception to AArch32 FIQ mode.
- SPSR_irq, that holds process state on taking an exception to AArch32 IRQ mode.
- SPSR_und, that holds process state on taking an exception to AArch32 Undefined mode.
- SSBS, that holds the PSTATE.SSBS bit.
- SVCR, controls Streaming SVE mode and SME behavior.
- TCO, that holds the PSTATE.TCO bit.
- UAO, that holds the PSTATE.UAO bit.

The following registers are also Special-purpose registers:

- DLR_EL0, that holds the address to return to for a return from Debug state.
- DSPSR_EL0, that holds process state on entry to Debug state.

C5.2.1 ALLINT, All Interrupt Mask Bit

The ALLINT characteristics are:

Purpose

Allows access to the all interrupt mask bit.

Configuration

This register is a Special-purpose register.

This register is present only when FEAT_NMI is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to ALLINT are UNDEFINED.

Attributes

ALLINT is a 64-bit register.

Field descriptions

Bits [63:14]

Reserved, RES0.

ALLINT, bit [13]

All interrupt mask. An interrupt is controlled by PSTATE.ALLINT when all of the following apply:

- SCTLR_ELx.NMI is 1.
- The interrupt is targeted at ELx.
- Execution is at ELx.

ALLINT	Meaning
0b0	This control does not cause any interrupts to be masked.
0b1	If SCTLR_ELx.NMI is 1 and execution is at ELx, an IRQ or FIQ interrupt that is targeted to ELx, with or without Superpriority, is masked.

The value of this bit is set to the inverse value in the SCTLR_ELx.SPINTMASK field on taking an exception to ELx.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [12:0]

Reserved, RES0.

C5.2.2 CurrentEL, Current Exception Level

The CurrentEL characteristics are:

Purpose

Holds the current Exception level.

Configuration

This register is a Special-purpose register.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to CurrentEL are UNDEFINED.

Attributes

CurrentEL is a 64-bit register.

Field descriptions

Bits [63:4]

Reserved, RES0.

EL, bits [3:2]

Current Exception level.

EL	Meaning
`0b00`	EL0.
`0b01`	EL1.
`0b10`	EL2.
`0b11`	EL3.

When the Effective value of HCR_EL2.NV is 1, EL1 read accesses to the CurrentEL register return the value of `0b10` in this field.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL1, this field resets to `'01'`.
  - When the highest implemented Exception level is EL2, this field resets to `'10'`.
  - Otherwise, this field resets to `'11'`.

Bits [1:0]

Reserved, RES0.

C5.2.3 DAIF, Interrupt Mask Bits

The DAIF characteristics are:

Purpose

Allows access to the interrupt mask bits.

Configuration

This register is a Special-purpose register.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to DAIF are UNDEFINED.

Attributes

DAIF is a 64-bit register.

Field descriptions

Bits [63:10]

Reserved, RES0.

D, bit [9]

Process state D mask.

D	Meaning
`0b0`	Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.
`0b1`	Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'1'`.

A, bit [8]

SError exception mask bit.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A	Meaning
0b0	Exception not masked.
0b1	Exception masked.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'1'`.

I, bit [7]

IRQ mask bit.

I	Meaning
0b0	Exception not masked.
0b1	Exception masked.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'1'`.

F, bit [6]

FIQ mask bit.

F	Meaning
0b0	Exception not masked.
0b1	Exception masked.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'1'`.

Bits [5:0]

Reserved, RES0.

C5.2.4 DIT, Data Independent Timing

The DIT characteristics are:

Purpose

Allows access to the Data Independent Timing bit.

Configuration

This register is a Special-purpose register.

This register is present only when FEAT_DIT is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to DIT are UNDEFINED.

Attributes

DIT is a 64-bit register.

Field descriptions

Bits [63:25]

Reserved, RES0.

DIT, bit [24]

Data Independent Timing.

DIT	Meaning
0b0	The architecture makes no statement about the timing properties of any instructions.
0b1	The architecture requires that the execution time of a data-independent-time sequence of code must be independent of all data-independent-time values. For more information, see About PSTATE.DIT.

The list of data-independent-time instructions is:

- Flag Manipulation: CFINV.
- Data Processing – Immediate:
  - Add/subtract (immediate): ADD, ADDS, SUB, and SUBS.
  - Bitfield: BFM, SBFM, and UBFM.
  - Extract: EXTR.
  - Logical (immediate): AND, ANDS, EOR, and ORR.
  - Move wide (immediate): MOVK.
  - Min/max (immediate): SMAX, SMIN, UMAX, and UMIN.
- Data Processing – Register:
  - Add/subtract (extended register): ADD, ADDS, SUB, and SUBS.
  - Add/subtract (shifted register): ADD, ADDS, SUB, and SUBS.
  - Add/subtract (with carry): ADC, ADCS, SBC, and SBCS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - Conditional compare (immediate): CCMN, and CCMP.
  - Conditional compare (register): CCMN, and CCMP.
  - Conditional select: CSEL, CSINC, CSINV, and CSNEG.
  - Data-processing (1 source): ABS, CLS, CLZ, CNT, CTZ, RBIT, REV16, REV32, and REV.
  - Data-processing (2 source): ASRV, CRC32B, CRC32CB, CRC32CH, CRC32CW, CRC32CX, CRC32H, CRC32W, CRC32X, LSLV, LSRV, RORV, SMAX, SMIN, UMAX, and UMIN.
  - Data-processing (3 source): MADD, MSUB, SMADDL, SMSUBL, SMULH, UMADDL, UMSUBL, and UMULH.
  - Evaluate into flags: SETF16, and SETF8.
  - Logical (shifted register): AND, ANDS, BIC, BICS, EON, EOR, ORN, and ORR.
  - Rotate right into flags: RMIF.
- Data Processing – Scalar Floating-Point and Advanced SIMD:
  - Advanced SIMD across lanes: ADDV, SADDLV, SMAXV, SMINV, UADDLV, UMAXV, and UMINV.
  - Advanced SIMD copy: DUP, INS, SMOV, and UMOV.
  - Advanced SIMD extract: EXT.
  - Advanced SIMD modified immediate: BIC, and ORR.
  - Advanced SIMD permute: TRN1, TRN2, UZP1, UZP2, ZIP1, and ZIP2.
  - Advanced SIMD scalar copy: DUP.
  - Advanced SIMD scalar pairwise: ADDP.
  - Advanced SIMD scalar shift by immediate: Advanced SIMD scalar shift by immediate: SHL, SLI, SRSHR, SRI, SRSRA, SSHR, SSRA, URSHR, URSRA, USHR, and USRA.
  - Advanced SIMD scalar three same: ADD, CMEQ, CMGE, CMGT, CMHI, CMHS, CMTST, SQDMULH, SQRDMULH, SSHL, SUB, and USHL.
  - Advanced SIMD scalar three same extra: SQRDMLAH.
  - Advanced SIMD scalar two-register miscellaneous: ABS, CMEQ, CMGE, CMGT, CMLE, CMLT, and NEG.
  - Advanced SIMD scalar x indexed element: SQDMULH, SQRDMLAH, and SQRDMULH.
  - Advanced SIMD shift by immediate: RSHRN2, RSHRN, SHL, SHRN2, SHRN, SLI, SRI, SSHLL2, SSHLL, SSHR, SSRA, USHLL2, USHLL, USHR, and USRA.
  - Advanced SIMD table lookup: LUTI2, LUTI4, TBL, and TBX.
  - Advanced SIMD three different: ADDHN2, ADDHN, PMULL2, PMULL, RADDHN2, RADDHN, RSUBHN2, RSUBHN, SABAL2, SABAL, SABDL2, SABDL, SADDL2, SADDL, SADDW2, SADDW, SMLAL2, SMLAL, SMLSL2, SMLSL, SMULL2, SMULL, SSUBL2, SSUBL, SSUBW2, SSUBW, SUBHN2, SUBHN, UABAL2, UABAL, UABDL2, UABDL, UADDL2, UADDL, UADDW2, UADDW, UMLAL2, UMLAL, UMLSL2, UMLSL, UMULL2, UMULL, USUBL2, USUBL, USUBW2, and USUBW.
  - Advanced SIMD three same: ADD, ADDP, AND, BIC, BIF, BIT, BSL, CMEQ, CMGE, CMGT, CMHI, CMHS, CMTST, EOR, MLA, MLS, MUL, ORN, ORR, PMUL, SABA, SABD, SHADD, SHSUB, SMAX, SMAXP, SMIN, SMINP, SQDMULH, SQRDMULH, SSHL, SUB, UABA, UABD, UHADD, UHSUB, UMAX, UMAXP, UMIN, UMINP, and USHL.
  - Advanced SIMD three-register extension: SDOT, SMMLA, SQRDMLAH, UDOT, UMMLA, USDOT, and USMMLA.
  - Advanced SIMD two-register miscellaneous: ABS, CLS, CLZ, CMEQ, CMGE, CMGT, CMLE, CMLT, CNT, NEG, NOT, RBIT, REV16, REV32, REV64, SADALP, SADDLP, SHLL2, SHLL, UADALP, UADDLP, XTN2, and XTN.
  - Advanced SIMD vector x indexed element: MLA, MLS, MUL, SDOT, SMLAL2, SMLAL, SMLSL2, SMLSL, SMULL2, SMULL, SQDMULH, SQRDMLAH, SQRDMULH, SUDOT, UDOT, UMLAL2, UMLAL, UMLSL2, UMLSL, UMULL2, UMULL, and USDOT.
  - Cryptographic AES: AESD, AESE, AESIMC, and AESMC.
  - Cryptographic four-register: BCAX, EOR3, and SM3SS1.
  - Cryptographic three-register SHA: SHA1C, SHA1M, SHA1P, SHA1SU0, SHA256H2, SHA256H, and SHA256SU1.
  - Cryptographic three-register SHA 512: RAX1, SHA512H2, SHA512H, SHA512SU1, SM3PARTW1, SM3PARTW2, and SM4EKEY.
  - Cryptographic three-register, imm2: SM3TT1A, SM3TT1B, SM3TT2A, and SM3TT2B.
  - Cryptographic three-register, imm6: XAR.
  - Cryptographic two-register SHA: SHA1H, SHA1SU1, and SHA256SU0.
  - Cryptographic two-register SHA 512: SHA512SU0, and SM4E.
  - Floating-point conditional select: FCSEL.
- Loads and Stores:
  - 128-bit atomic memory operations: LDCLRP, LDCLRPA, LDCLRPAL, LDCLRPL, LDSETP, LDSETPA, LDSETPAL, LDSETPL, SWPP, SWPPA, SWPPAL, and SWPPL.
  - Advanced SIMD load/store multiple structures: LD1, LD2, LD3, LD4, ST1, ST2, ST3, and ST4.
  - Advanced SIMD load/store multiple structures (post-indexed): LD1, LD2, LD3, LD4, ST1, ST2, ST3, and ST4.
  - Advanced SIMD load/store single structure: LD1, LD1R, LD2, LD2R, LD3, LD3R, LD4, LD4R, LDAP1, ST1, ST2, ST3, ST4, and STL1.
  - Advanced SIMD load/store single structure (post-indexed): LD1, LD1R, LD2, LD2R, LD3, LD3R, LD4, LD4R, ST1, ST2, ST3, and ST4.

- Atomic memory operations: LDADD, LDADDA, LDADDAB, LDADDAH, LDADDAL, LDADDALB, LDADDALH, LDADDB, LDADDH, LDADDL, LDADDLB, LDADDLH, LDAPR, LDAPRB, LDAPRH, LDCLR, LDCLRA, LDCLRAB, LDCLRAH, LDCLRAL, LDCLRALB, LDCLRALH, LDCLRB, LDCLRH, LDCLRL, LDCLRLB, LDCLRLH, LDEOR, LDEORA, LDEORAB, LDEORAH, LDEORAL, LDEORALB, LDEORALH, LDEORB, LDEORH, LDEORL, LDEORLB, LDEORLH, LDSET, LDSETA, LDSETAB, LDSETAH, LDSETAL, LDSETALB, LDSETALH, LDSETB, LDSETH, LDSETL, LDSETLB, LDSETLH, LDSMAX, LDSMAXA, LDSMAXAB, LDSMAXAH, LDSMAXAL, LDSMAXALB, LDSMAXALH, LDSMAXB, LDSMAXH, LDSMAXL, LDSMAXLB, LDSMAXLH, LDSMIN, LDSMINA, LDSMINAB, LDSMINAH, LDSMINAL, LDSMINALB, LDSMINALH, LDSMINB, LDSMINH, LDSMINL, LDSMINLB, LDSMINLH, LDUMAX, LDUMAXA, LDUMAXAB, LDUMAXAH, LDUMAXAL, LDUMAXALB, LDUMAXALH, LDUMAXB, LDUMAXH, LDUMAXL, LDUMAXLB, LDUMAXLH, LDUMIN, LDUMINA, LDUMINAB, LDUMINAH, LDUMINAL, LDUMINALB, LDUMINALH, LDUMINB, LDUMINH, LDUMINL, LDUMINLB, and LDUMINLH.
- LDAPR/STLR (SIMD&FP): LDAPUR, and STLUR.
- LDAPR/STLR (unscaled immediate): LDAPUR, LDAPURB, LDAPURH, LDAPURSB, LDAPURSH, LDAPURSW, STLUR, STLURB, and STLURH.
- LDAPR/STLR (writeback): LDAPR, and STLR.
- LDIAPP/STILP: LDIAPP, and STILP.
- Load/store exclusive pair: LDAXP, LDXP, STLXP, and STXP.
- Load/store exclusive register: LDAXR, LDAXRB, LDAXRH, LDXR, LDXRB, LDXRH, STLXR, STLXRB, STLXRH, STXR, STXRB and STXRH.
- Load/store no-allocate pair (offset): LDNP, and STNP.
- Load/store ordered: LDAR, LDARB, LDARH, LDLAR, LDLARB, LDLARH, STLLR, STLLRB, STLLRH, STLR, STLRB, and STLRH.
- Load/store register (immediate post-indexed): LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW, STR, STRB, and STRH.
- Load/store register (immediate pre-indexed): LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW, STR, STRB, and STRH.
- Load/store register (pac): LDRAA, and LDRAB.
- Load/store register (register offset): LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW, STR, STRB, and STRH.
- Load/store register (unprivileged): LDTR, LDTRB, LDTRH, LDTRSB, LDTRSH, LDTRSW, STTR, STTRB, and STTRH.
- Load/store register (unscaled immediate): LDUR, LDURB, LDURH, LDURSB, LDURSH, LDURSW, STUR, STURB, and STURH.
- Load/store register (unsigned immediate): LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW, STR, STRB, and STRH.
- Load/store register pair (offset): LDP, LDPSW, and STP.
- Load/store register pair (post-indexed): LDP, LDPSW, and STP.
- Load/store register pair (pre-indexed): LDP, LDPSW, and STP.

- If FEAT_SME is implemented, SME encodings:
  - SME Add Vector to Array: ADDHA, and ADDVA.
  - SME Integer Outer Product - 32 bit: SMOPA, SMOPS, SUMOPA, SUMOPS, UMOPA, UMOPS, USMOPA, and USMOPS.
  - SME Memory: LD1B, LD1D, LD1H, LD1Q, LD1W, LDR, ST1B, ST1D, ST1H, ST1Q, ST1W, and STR.
  - SME Move from Array: MOVA, and MOVAZ.
  - SME Move into Array: MOVA.
  - SME Outer Product - 64 bit:
    - SME Int16 outer product: SMOPA, SMOPS, SUMOPA, SUMOPS, UMOPA, UMOPS, USMOPA, and USMOPS.
  - SME zero array: ZERO.
  - SME2 Expand Lookup Table (Contiguous): LUTI2, and LUTI4.
  - SME2 Expand Lookup Table (Non-contiguous): LUTI2, and LUTI4.
  - SME2 Move Lookup Table: MOVT.
  - SME2 Multi-vector - Indexed (Four registers):
    - SME2 multi-vec indexed long MLA four sources: SMLAL, SMLSL, UMLAL, and UMLSL.
    - SME2 multi-vec indexed long long MLA four sources 32-bit: SMLALL, SMLSLL, SUMLALL, UMLALL, UMLSLL, and USMLALL.
    - SME2 multi-vec indexed long long MLA four sources 64-bit: SMLALL, SMLSLL, UMLALL, and UMLSLL.
    - SME2 multi-vec ternary indexed four registers 32-bit: SDOT, SUDOT, SUVDOT, SVDOT, UDOT, USDOT, USVDOT, and UVDOT.
    - SME2 multi-vec ternary indexed four registers 64-bit: SDOT, SVDOT, UDOT, and UVDOT.
  - SME2 Multi-vector - Indexed (One register):
    - SME2 multi-vec indexed long MLA one source: SMLAL, SMLSL, UMLAL, and UMLSL.
    - SME2 multi-vec indexed long long MLA one source 32-bit: SMLALL, SMLSLL, SUMLALL, UMLALL, UMLSLL, and USMLALL.
    - SME2 multi-vec indexed long long MLA one source 64-bit: SMLALL, SMLSLL, UMLALL, and UMLSLL.

C5.2.5 ELR_EL1, Exception Link Register (EL1)

The ELR_EL1 characteristics are:

Purpose

When taking an exception to EL1, holds the address to return to.

Configuration

This register is a Special-purpose register.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ELR_EL1 are UNDEFINED.

Attributes

ELR_EL1 is a 64-bit register.

Field descriptions

ADDR, bits [63:0]

Return address.

An exception return from EL1 using AArch64 makes ELR_EL1 become UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ELR_EL1

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL3 using the accessor name `ELR_EL1` or `ELR_EL12` are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ELR_EL1
```

C5.2.6 ELR_EL2, Exception Link Register (EL2)

The ELR_EL2 characteristics are:

Purpose

When taking an exception to EL2, holds the address to return to.

Configuration

This register has no effect if EL2 is not enabled in the current Security state.

This register is a Special-purpose register.

AArch64 System register ELR_EL2 bits [31:0] are architecturally mapped to AArch32 System register ELR_hyp[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ELR_EL2 are UNDEFINED.

Attributes

ELR_EL2 is a 64-bit register.

Field descriptions

ADDR, bits [63:0]

Return address.

An exception return from EL2 using AArch64 makes ELR_EL2 become UNKNOWN.

When EL2 is in AArch32 Execution state and an exception is taken from EL0, EL1, or EL2 to EL3 and AArch64 execution, the upper 32-bits of ELR_EL2 are either set to 0 or hold the same value that they did before AArch32 execution. Which option is adopted is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ELR_EL2

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL2 using the accessor name `ELR_EL2` or `ELR_EL1` are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ELR_EL2
```

C5.2.7 ELR_EL3, Exception Link Register (EL3)

The ELR_EL3 characteristics are:

Purpose

When taking an exception to EL3, holds the address to return to.

Configuration

This register is a Special-purpose register.

This register is present only when EL3 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to ELR_EL3 are UNDEFINED.

Attributes

ELR_EL3 is a 64-bit register.

Field descriptions

ADDR, bits [63:0]

Return address.

An exception return from EL3 using AArch64 makes ELR_EL3 become UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ELR_EL3

Accesses to this register use the following encodings in the System register encoding space:

```

C5.2.8 FPCR, Floating-point Control Register

The FPCR characteristics are:

Purpose

Controls behavior of the floating-point instructions.

Configuration

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to nonzero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

This register is a Special-purpose register.

AArch64 System register FPCR bits [26:15] are architecturally mapped to AArch32 System register FPSCR[26:15].

AArch64 System register FPCR bits [12:8] are architecturally mapped to AArch32 System register FPSCR[12:8].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to FPCR are UNDEFINED.

Attributes

FPCR is a 64-bit register.

Field descriptions

Bits [63:27]

Reserved, RES0.

AHP, bit [26]

Alternative half-precision control bit.

AHP	Meaning
0b0	IEEE half-precision format selected.
0b1	Alternative half-precision format selected.

This bit is used only for conversions between half-precision floating-point and other floating-point formats.

The data-processing instructions added as part of the FEAT_FP16 extension always use the IEEE half-precision format, and ignore the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DN, bit [25]

Default NaN use for NaN propagation.

DN	Meaning
`0b0`	NaN operands propagate through to the output of a floating-point operation.
`0b1`	Any operation involving one or more NaNs returns the default NaN. This bit has no effect on the output of the `FABS` and `FNEG` instructions. This bit has no effect on the output of the `FMAX`, `FMAXP`, `FMAXV`, `FMIN`, `FMINP`, and `FMINV` instructions when FPCR.AH is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FZ, bit [24]

Flushing denormalized numbers to zero control bit.

FZ	Meaning
`0b0`	If FPCR.AH is 0, the flushing to zero of single-precision and double-precision denormalized inputs to, and outputs of, floating-point instructions not enabled by this control, but other factors might cause the input denormalized numbers to be flushed to zero. If FPCR.AH is 1, the flushing to zero of single-precision and double-precision denormalized outputs of floating-point instructions not enabled by this control, but other factors might cause the input denormalized numbers to be flushed to zero.
`0b1`	If FPCR.AH is 0, denormalized single-precision and double-precision inputs to, and outputs from, floating-point instructions are flushed to zero. If FPCR.AH is 1, denormalized single-precision and double-precision outputs from floating-point instructions are flushed to zero.

For more information, see ‘Flushing denormalized numbers to zero’ and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

RMode, bits [23:22]

Rounding Mode control field.

RMode	Meaning
`0b00`	Round to Nearest (RN) mode.
`0b01`	Round towards Plus Infinity (RP) mode.
`0b10`	Round towards Minus Infinity (RM) mode.
`0b11`	Round towards Zero (RZ) mode.

The following instructions ignore this field and use Round to Nearest mode:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- All FP8 instructions, as described in 'Summary of FP8 instruction behaviors'.
- When FPCR.AH is 1, then the floating-point reciprocal estimate, step and exponent instructions, floating-point square root estimate and step instructions, and instructions that follow Alternate BFloat16 behaviors, as defined in 'Rounding'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Stride, bits [21:20]

This field has no function in AArch64 state, and nonzero values are ignored during execution in AArch64 state.

This field is included only for context saving and restoration of the AArch32 FPSCR.Stride field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation implements FPSCR.{Stride, Len} as RAZ, access to this field is RAZ/WI.

FZ16, bit [19]

When FEAT_FP16 is implemented:

Flushing denormalized numbers to zero control bit on half-precision data-processing instructions.

FZ16	Meaning
`0b0`	For some instructions, this bit disables flushing to zero of inputs and outputs that are half-precision denormalized numbers.
`0b1`	Flushing denormalized numbers to zero enabled. For some instructions that do not convert a half-precision input to a higher precision output, this bit enables flushing to zero of inputs and outputs that are half-precision denormalized numbers.

For more information, see 'Flushing denormalized numbers to zero' and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Len, bits [18:16]

This field has no function in AArch64 state, and nonzero values are ignored during execution in AArch64 state.

This field is included only for context saving and restoration of the AArch32 FPSCR.Len field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation implements FPSCR.{Stride, Len} as RAZ, access to this field is RAZ/WI.

IDE, bit [15]

Input Denormal floating-point exception trap enable.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IDE	Meaning
`0b0`	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.IDC bit is set to 1.
`0b1`	Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IDC bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled, the value of FPCR.IDE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The Effective value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_TRAPFPE is not implemented and floating-point exception traps are disabled, access to this field is RAZ/WI.

Bit [14]

Reserved, RES0.

EBF, bit [13]

When FEAT_EBF16 is implemented:

The value of this bit controls the numeric behaviors of BFloat16 dot product calculations performed by the BFDOT, BFMMLA, BFMOPA, and BFMOPS instructions. If FEAT_SME2 is implemented, this also controls BFVDOT instruction.

When ID_AA64ISAR1_EL1.BF16 and ID_AA64ZFR0_EL1.BF16 are `0b0010`, the PE supports the FPCR.EBF field. Otherwise, FPCR.EBF is RES0.

EBF	Meaning
`0b0`	These instructions use the standard BFloat16 behaviors: • Ignoring the FPCR.RMode control and using the rounding mode defined for BFloat16. For more information, see 'Round to Odd mode'. • Flushing denormalized inputs and outputs to zero, as if the FPCR.FZ and FPCR.FIZ controls had the value '1'. • Performing unfused multiplies and additions with intermediate rounding of all products and sums.
`0b1`	These instructions use the extended BFloat16 behaviors: • Supporting all four IEEE 754 rounding modes selected by the FPCR.RMode control. • Optionally, flushing denormalized inputs and outputs to zero, as governed by the FPCR.FZ and FPCR.FIZ controls. • Performing a fused two-way sum-of-products for each pair of adjacent BFloat16 elements, without intermediate rounding of the products, but rounding the single-precision sum before addition to the accumulator. • Generating the default NaN as intermediate sum-of-products when any multiplier input is a NaN, or any product is infinity $\times$ 0.0, or there are infinite products with differing signs. • Generating an intermediate sum-of-products of the same infinity when there are infinite products all with the same sign.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IXE, bit [12]

Inexact floating-point exception trap enable.

IXE	Meaning
`0b0`	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.IXC bit is set to 1.
`0b1`	Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IXC bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled, the value of FPCR.IXE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The Effective value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_TRAPFPE is not implemented and floating-point exception traps are disabled, access to this field is RAZ/WI.

UFE, bit [11]

Underflow floating-point exception trap enable.

UFE	Meaning
`0b0`	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.UFC bit is set to 1.
`0b1`	Trapped exception handling selected. If the floating-point exception occurs and Flush-to-zero is not enabled, the PE does not update the FPSR.UFC bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled, the value of FPCR.UFE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The Effective value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_TRAPFPE is not implemented and floating-point exception traps are disabled, access to this field is RAZ/WI.

OFE, bit [10]

Overflow floating-point exception trap enable.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

OFE	Meaning
0b0	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.OFC bit is set to 1.
0b1	Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.OFC bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled, the value of FPCR.OFE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The Effective value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_TRAPFPE is not implemented and floating-point exception traps are disabled, access to this field is RAZ/WI.

DZE, bit [9]

Divide by Zero floating-point exception trap enable.

DZE	Meaning
0b0	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.DZC bit is set to 1.
0b1	Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.DZC bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled, the value of FPCR.DZE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The Effective value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_TRAPFPE is not implemented and floating-point exception traps are disabled, access to this field is RAZ/WI.

IOE, bit [8]

Invalid Operation floating-point exception trap enable.

IOE	Meaning
0b0	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.IOC bit is set to 1.
0b1	Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IOC bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled, the value of FPCR.IOE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The Effective value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_TRAPFPE is not implemented and floating-point exception traps are disabled, access to this field is RAZ/WI.

Bits [7:3]

Reserved, RES0.

NEP, bit [2]

When FEAT_AFP is implemented:

Controls how the output elements other than the lowest element of the vector are determined for Advanced SIMD scalar instructions.

NEP	Meaning
`0b0`	Does not affect how the output elements other than the lowest are determined for Advanced SIMD scalar instructions.

`0b1`	The output elements other than the lowest are taken from the following registers:
	• For 3-input scalar versions of the FMLA (by element) and FMLS (by element) instructions, the <Hd>, <Sd>, or <Dd> register.
	• For 3-input versions of the FMADD, FMSUB, FNMADD, and FNMSUB instructions, the <Ha>, <Sa>, or <Da> register.
	• For 2-input scalar versions of the FACGE, FACGT, FCMEQ (register), FCMGE (register), and FCMGT (register) instructions, the <Hm>, <Sm>, or <Dm> register.
	• For 2-input scalar versions of the FABD, FADD (scalar), FDIV (scalar), FMAX (scalar), FMAXNM (scalar), FMIN (scalar), FMINNM (scalar), FMUL (by element), FMUL (scalar), FMULX (by element), FMULX, FNMUL (scalar), FRECPS, FRSQRTS, and FSUB (scalar) instructions, the <Hn>, <Sn>, or <Dn> register.
	• For 1-input scalar versions of the following instructions, the <Hd>, <Sd>, or <Dd> register:
	  • The (vector) versions of the FCVTAS, FCVTAU, FCVTMS, FCVTMU, FCVTNS, FCVTNU, FCVTPS, and FCVTPU instructions.
	  • The (vector, fixed-point) and (vector, integer) versions of the FCVTZS, FCVTZU, SCVTF, and UCVTF instructions.
	  • The (scalar) versions of the FABS, FNEG, FRINT32X, FRINT32Z, FRINT64X, FRINT64Z, FRINTA, FRINTI, FRINTM, FRINTN, FRINTP, FRINTX, FRINTZ, and FSQRT instructions.
	  • The (scalar, fixed-point) and (scalar, integer) versions of the SCVTF and UCVTF instructions.
	  • The BFCVT, FCVT, FCVTXN, FRECPE, FRECPX, and FRSQRTE instructions.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled, the value of FPCR.NEP is treated as 0 for all purposes other than a direct read or write of the FPCR.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AH, bit [1]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_AFP is implemented:

Alternate Handling. Controls alternate handling of floating-point numbers.

The Arm architecture supports two models for handling some of the corner cases of the floating-point behaviors, such as the nature of flushing of denormalized numbers, the detection of tininess and other exceptions and a range of other behaviors. The value of the FPCR.AH bit selects between these models.

For more information on the FPCR.AH bit, see 'Flushing denormalized numbers to zero', 'Floating-point exceptions and exception traps' and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FIZ, bit [0]

When FEAT_AFP is implemented:

Flush Inputs to Zero. Controls whether single-precision, double-precision, and BFloat16 input operands that are denormalized numbers are flushed to zero.

FIZ	Meaning
0b0	The flushing to zero of single-precision and double-precision denormalized inputs to floating-point instructions not enabled by this control, but other factors might cause the input denormalized numbers to be flushed to zero.
0b1	Denormalized single-precision and double-precision inputs to most floating-point instructions flushed to zero.

For more information, see 'Flushing denormalized numbers to zero' and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing FPCR

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, FPCR
```

C5.2.9 FPMR, Floating-point Mode Register

The FPMR characteristics are:

Purpose

Controls behaviors of the FP8 instructions.

Configuration

On entry to or exit from Streaming SVE mode, FPMR is set to 0.

This register is a Special-purpose register.

This register is present only when FEAT_FPMR is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to FPMR are UNDEFINED.

Attributes

FPMR is a 64-bit register.

Field descriptions

Bits [63:38]

Reserved, RES0.

LSCALE2, bits [37:32]

Downscaling value for instructions that convert the second FP8 input data stream to other floating-point formats.

This value is an unsigned integer that is subtracted from the result exponent.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSCALE, bits [31:24]

Scaling value for instructions that convert other floating-point formats to an FP8 format.

This value is a signed integer that is added to the operand exponent.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [23]

Reserved, RES0.

LSCALE, bits [22:16]

Downscaling value.

This value is an unsigned integer that is subtracted from:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The product or the sum-of-products exponent, for multiplication instructions with FP8 operands.
- The result exponent, for instructions that convert the first FP8 input data stream to other floating-point formats.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OSC, bit [15]

Overflow saturation for FP8 convert instructions. Specifies the result when a floating-point Overflow exception is detected.

OSC	Meaning
`0b0`	Infinity or NaN is generated.
`0b1`	Maximum normal number is generated.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OSM, bit [14]

Overflow saturation for FP8 multiplication instructions. Specifies the result when a floating-point Overflow exception is detected.

OSM	Meaning
`0b0`	Infinity is generated.
`0b1`	Maximum normal number is generated.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [13:9]

Reserved, RES0.

F8D, bits [8:6]

Destination result format for instructions that convert other floating-point values to an FP8 format.

F8D	Meaning
`0b000`	OFP8 E5M2 format.
`0b001`	OFP8 E4M3 format.

All other values are reserved.

Reserved values identify an unsupported format and behave as described in Reserved values in System and memory-mapped registers and translation table entries.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Additionally, FP8 instructions are permitted to set an FP8 result with an unsupported format to `0xFF` and signal an Invalid Operation floating-point exception.

It is software's responsibility to check that a format value is supported in ID_AA64FPFR0_EL1[7:0], before writing it to this field.

For more information about the FP8 formats, see the *OCP 8-bit Floating Point Specification (OFP8)*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F8S2, bits [5:3]

Second FP8 input data stream format for multiplication instructions with FP8 operands, and the corresponding instructions that convert an FP8 format to other floating-point formats.

F8S2	Meaning
`0b000`	OFP8 E5M2 format.
`0b001`	OFP8 E4M3 format.

All other values are reserved.

Reserved values identify an unsupported format and behave as described in Reserved values in System and memory-mapped registers and translation table entries.

Additionally FP8 instructions are permitted to treat FP8 input values with an unsupported format as a signaling NaN.

It is software's responsibility to check that a format value is supported in ID_AA64FPFR0_EL1[7:0], before writing it to this field.

For more information about the FP8 formats, see the *OCP 8-bit Floating Point Specification (OFP8)*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F8S1, bits [2:0]

First FP8 input data stream format for multiplication instructions with FP8 operands, and the corresponding instructions that convert an FP8 format to other floating-point formats.

F8S1	Meaning
`0b000`	OFP8 E5M2 format.
`0b001`	OFP8 E4M3 format.

All other values are reserved.

Reserved values identify an unsupported format and behave as described in Reserved values in System and memory-mapped registers and translation table entries.

Additionally FP8 instructions are permitted to treat FP8 input values with an unsupported format as a signaling NaN.

It is software's responsibility to check that a format value is supported in ID_AA64FPFR0_EL1[7:0], before writing it to this field.

For more information about the FP8 formats, see the *OCP 8-bit Floating Point Specification (OFP8)*.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FPMR

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, FPMR
```

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0100	0b010

C5.2.10 FPSR, Floating-point Status Register

The FPSR characteristics are:

Purpose

Provides floating-point system status information.

Configuration

On entry to or exit from Streaming SVE mode, FPSR.{IOC, DZC, OFC, UFC, IXC, IDC, QC} are set to 1 and the remaining bits are set to 0.

This register is a Special-purpose register.

AArch64 System register FPSR bits [31:27] are architecturally mapped to AArch32 System register FPSCR[31:27].

AArch64 System register FPSR bit [7] is architecturally mapped to AArch32 System register FPSCR[7].

AArch64 System register FPSR bits [4:0] are architecturally mapped to AArch32 System register FPSCR[4:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to FPSR are UNDEFINED.

Attributes

FPSR is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

N, bit [31]

When FEAT_AA32 is implemented and FEAT_FP is implemented:

Negative condition flag for AArch32 floating-point comparison operations.

Note

AArch64 floating-point comparisons set the PSTATE.N flag instead.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Z, bit [30]

When FEAT_AA32 is implemented and FEAT_FP is implemented:

Zero condition flag for AArch32 floating-point comparison operations.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

AArch64 floating-point comparisons set the PSTATE.Z flag instead.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

C, bit [29]

When FEAT_AA32 is implemented and FEAT_FP is implemented:

Carry condition flag for AArch32 floating-point comparison operations.

Note

AArch64 floating-point comparisons set the PSTATE.C flag instead.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

V, bit [28]

When FEAT_AA32 is implemented and FEAT_FP is implemented:

Overflow condition flag for AArch32 floating-point comparison operations.

Note

AArch64 floating-point comparisons set the PSTATE.V flag instead.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

QC, bit [27]

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [26:8]

Reserved, RES0.

IDC, bit [7]

Input Denormal cumulative floating-point exception bit. This bit is set to 1 to indicate that the Input Denormal floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IDE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.IDE is 0.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXC, bit [4]

Inexact cumulative floating-point exception bit. This bit is set to 1 to indicate that the Inexact floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IXE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.IXE is 0.

The criteria for the Inexact floating-point exception to occur are affected by whether denormalized numbers are flushed to zero and by the value of the FPCR.AH bit. For more information, see 'Floating-point exceptions and exception traps'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFC, bit [3]

Underflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Underflow floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.UFE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.UFE is 0 or if flushing denormalized numbers to zero is enabled.

The criteria for the Underflow floating-point exception to occur are affected by whether denormalized numbers are flushed to zero and by the value of the FPCR.AH bit. For more information, see 'Floating-point exceptions and exception traps'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFC, bit [2]

Overflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Overflow floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.OFE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.OFE is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZC, bit [1]

Divide by Zero cumulative floating-point exception bit. This bit is set to 1 to indicate that the Divide by Zero floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.DZE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.DZE is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOC, bit [0]

Invalid Operation cumulative floating-point exception bit. This bit is set to 1 to indicate that the Invalid Operation floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IOE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.IOE is 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The criteria for the Invalid Operation floating-point exception to occur are affected by the value of the FPCR.AH bit. For more information, see ‘Floating-point exceptions and exception traps’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C5.2.11 NZCV, Condition Flags

The NZCV characteristics are:

Purpose

Allows access to the condition flags.

Configuration

This register is a Special-purpose register.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to NZCV are UNDEFINED.

Attributes

NZCV is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative condition flag. Set to 1 if the result of the last flag-setting instruction was negative.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Bits [27:0]

Reserved, RES0.

Accessing NZCV

The MSR (register) and MRS instructions used to access NZCV are data-independent-time instructions as described in About PSTATE.DIT.

Accesses to this register use the following encodings in the System register encoding space:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.12 PAN, Privileged Access Never

The PAN characteristics are:

Purpose

Allows access to the Privileged Access Never bit.

Configuration

This register is a Special-purpose register.

This register is present only when FEAT_PAN is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to PAN are UNDEFINED.

Attributes

PAN is a 64-bit register.

Field descriptions

Bits [63:23]

Reserved, RES0.

PAN, bit [22]

Privileged Access Never.

PAN	Meaning
0b0	Privileged reads and write are not disabled by this mechanism.
0b1	Disables privileged read and write accesses to addresses accessible at EL0 for an enabled stage 1 translation regime that defines the EL0 permissions.

The value of this bit is usually preserved on taking an exception, except in the following situations:

- When the target of the exception is EL1, and the value of the SCTLR_EL1.SPAN bit is 0, this bit is set to 1.
- When the target of the exception is EL2, the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, and the value of the SCTLR_EL2.SPAN bit is 0, this bit is set to 1.
- When the target of the exception is EL2, the Effective value of HCR_EL2.{E2H, TGE} is {1, 0}, and the value of the SCTLR_EL2.SPAN bit is 0, the following applies:
  - It is IMPLEMENTATION SPECIFIC whether this bit is set to 1. Arm recommends that it is set to 1 in this case.

Bits [21:0]

Reserved, RES0.

Accessing PAN

C5.2.13 PM, Profiling Exception Mask

The PM characteristics are:

Purpose

Allows access to the Profiling exception Mask bit.

Configuration

This register is a Special-purpose register.

This register is present only when ((IsFeatureImplemented(FEAT_EBEP) || IsFeatureImplemented(FEAT_SPE_EXC)) || IsFeatureImplemented(FEAT_TRBE_EXC)) && IsFeatureImplemented(FEAT_AA64). Otherwise, direct accesses to PM are UNDEFINED.

Attributes

PM is a 64-bit register.

Field descriptions

Bits [63:33]

Reserved, RES0.

PM, bit [32]

PMU Exception Mask.

PM	Meaning
0b0	Does not cause the Profiling exception to be masked.
0b1	Causes the Profiling exception to be masked.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

C5.2.14 RGSR_EL1, Random Allocation Tag Seed Register.

The RGSR_EL1 characteristics are:

Purpose

Random Allocation Tag Seed Register.

Configuration

When GCR_EL1.RRND is 1, updates to RGSR_EL1 are implementation-specific.

RGSR_EL1 is a Special-purpose register.

This register is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to RGSR_EL1 are UNDEFINED.

Attributes

RGSR_EL1 is a 64-bit register.

Field descriptions

RRND0 variant when GCR_EL1.RRND == '0':

Bits [63:24]

Reserved, RES0.

SEED, bits [23:8] (RRND0 variant)

Seed register used for generating values returned by `RandomTag()`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [7:4]

Reserved, RES0.

TAG, bits [3:0]

Tag generated by the most recent IRG instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

RRND1 variant otherwise:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [63:56]

Reserved, RES0.

IMPLEMENTATION DEFINED, bits [55:8] (RRND1 variant)

IMPLEMENTATION DEFINED.

Note

Software is recommended to avoid writing SEED[15:0] with a value of zero, unless this has been generated by the PE in response to an earlier value with SEED being nonzero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [7:4]

Reserved, RES0.

TAG, bits [3:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing RGSR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```

C5.2.15 SP_EL0, Stack Pointer (EL0)

The SP_EL0 characteristics are:

Purpose

Holds the stack pointer associated with EL0. At higher Exception levels, this is used as the current stack pointer when the value of SPSel.SP is 0.

Configuration

This register is a Special-purpose register.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to SP_EL0 are UNDEFINED.

Attributes

SP_EL0 is a 64-bit register.

Field descriptions

StackPointer, bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SP_EL0

When the value of PSTATE.SP is 0, this register is accessible at all Exception levels as the current stack pointer.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, SP_EL0
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0001	0b000

C5.2.16 SP_EL1, Stack Pointer (EL1)

The SP_EL1 characteristics are:

Purpose

Holds the stack pointer associated with EL1. The value of SPSel.SP determines the current stack pointer.

Configuration

This register is a Special-purpose register.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to SP_EL1 are UNDEFINED.

Attributes

SP_EL1 is a 64-bit register.

Field descriptions

StackPointer, bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SP_EL1

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of SPSel.SP is 1, this register is also accessible at EL1 as the current stack pointer.

Note

When the value of SPSel.SP is 0, SP_EL0 is used as the current stack pointer at all Exception levels.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, SP_EL1
```

C5.2.17 SP_EL2, Stack Pointer (EL2)

The SP_EL2 characteristics are:

Purpose

Holds the stack pointer associated with EL2. The value of SPSel.SP determines the current stack pointer.

Configuration

This register has no effect if EL2 is not enabled in the current Security state.

This register is a Special-purpose register.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to SP_EL2 are UNDEFINED.

Attributes

SP_EL2 is a 64-bit register.

Field descriptions

StackPointer, bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SP_EL2

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of SPSel.SP is 1, this register is also accessible at EL2 as the current stack pointer.

Note

When the value of SPSel.SP is 0, SP_EL0 is used as the current stack pointer at all Exception levels.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, SP_EL2
```

C5.2.18 SP_EL3, Stack Pointer (EL3)

The SP_EL3 characteristics are:

Purpose

Holds the stack pointer associated with EL3. The value of SPSel.SP determines the current stack pointer.

Configuration

This register is a Special-purpose register.

This register is present only when EL3 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to SP_EL3 are UNDEFINED.

Attributes

SP_EL3 is a 64-bit register.

Field descriptions

StackPointer, bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SP_EL3

This register is not accessible using MRS and MSR instructions.

When the value of SPSel.SP is 1, this register is accessible at EL3 as the current stack pointer.

Note

When the value of SPSel.SP is 0, SP_EL0 is used as the current stack pointer at all Exception levels.

Non-Confidential

C5.2.19 SPSel, Stack Pointer Select

The SPSel characteristics are:

Purpose

Allows the Stack Pointer to be selected between SP_EL0 and SP_ELx.

Configuration

This register is a Special-purpose register.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to SPSel are UNDEFINED.

Attributes

SPSel is a 64-bit register.

Field descriptions

Bits [63:1]

Reserved, RES0.

SP, bit [0]

Stack pointer to use. Possible values of this bit are:

SP	Meaning
`0b0`	Use SP_EL0 at all Exception levels.
`0b1`	Use SP_ELx for Exception level ELx. When FEAT_NMI is implemented and SCTLR_ELx.SPINTMASK is 1, if execution is at ELx, an IRQ or FIQ interrupt that is targeted to ELx is masked regardless of any indication of Superpriority.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'1'`.

Accessing SPSel

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, SPSel
```

C5.2.20 SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

Purpose

Holds the saved process state when an exception is taken to Abort mode.

Configuration

If EL1 only supports execution in AArch64 state, this register is RES0 from EL2 and EL3.

This register is a Special-purpose register.

AArch64 System register SPSR_abt bits [31:0] are architecturally mapped to AArch32 System register SPSR_abt[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to SPSR_abt are UNDEFINED.

Attributes

SPSR_abt is a 64-bit register.

Field descriptions

When FEAT_AA32EL1 is not implemented:

Bits [63:0]

Reserved, RES0.

Otherwise:

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Abort mode, and copied to PSTATE.N on executing an exception return operation in Abort mode.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Abort mode, and copied to PSTATE.Z on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Abort mode, and copied to PSTATE.C on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Abort mode, and copied to PSTATE.V on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Abort mode, and copied to PSTATE.Q on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to Abort mode, and copied to PSTATE.IT on executing an exception return operation in Abort mode.

On executing an exception return operation in Abort mode, SPSR_abt.IT must contain a value that is valid for the instruction being returned to.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [24]

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state.

Armv8 does not support the Jazelle state.

Reserved, RES0.

SSBS, bit [23]

When FEAT_SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Abort mode, and copied to PSTATE.SSBS on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Abort mode, and copied to PSTATE.PAN on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Abort mode, and copied to PSTATE.DIT on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Abort mode, and copied to PSTATE.IL on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Abort mode, and copied to PSTATE.GE on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to Abort mode, and copied to PSTATE.E on executing an exception return operation in Abort mode.

If the implementation does not support big-endian operation, SPSR_abt.E is RES0. If the implementation does not support little-endian operation, SPSR_abt.E is RES1. On executing an exception return operation in Abort mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_abt.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_abt.E is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SError exception mask. Set to the value of PSTATE.A on taking an exception to Abort mode, and copied to PSTATE.A on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Abort mode, and copied to PSTATE.I on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Abort mode, and copied to PSTATE.F on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Abort mode, and copied to PSTATE.T on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Abort mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Abort mode.

M[4:0]	Meaning
`0b10000`	User.
`0b10001`	FIQ.
`0b10010`	IRQ.
`0b10011`	Supervisor.
`0b10111`	Abort.
`0b11011`	Undefined.
`0b11111`	System.

Other values are reserved. If SPSR_abt.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Abort mode is an illegal return event, as described in ‘Illegal return events from AArch32 state’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_abt

The MSR (register) and MRS instructions used to access SPSR_abt are data-independent-time instructions as described in About PSTATE.DIT.

C5.2.21 SPSR_EL1, Saved Program Status Register (EL1)

The SPSR_EL1 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL1.

Configuration

This register is a Special-purpose register.

AArch64 System register SPSR_EL1 bits [31:0] are architecturally mapped to AArch32 System register SPSR_svc[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to SPSR_EL1 are UNDEFINED.

Attributes

SPSR_EL1 is a 64-bit register.

Field descriptions

When FEAT_AA32 is implemented and GetSPSR_EL1_M4() == '1':

An exception return from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

Bits [63:37]

Reserved, RES0.

UINJ, bit [36]

When FEAT_UINJ is implemented:

Inject Undefined Instruction exception. Set to 0 on taking an exception to EL1, and copied to PSTATE.UINJ on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [35:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL1, and copied to PSTATE.N on executing an exception return operation in EL1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL1, and copied to PSTATE.Z on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL1, and copied to PSTATE.C on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL1, and copied to PSTATE.V on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to EL1, and copied to PSTATE.Q on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to EL1, and copied to PSTATE.IT on executing an exception return operation in EL1.

On executing an exception return operation in EL1, SPSR_EL1.IT must contain a value that is valid for the instruction being returned to.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DIT, bit [24]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL1, and copied to PSTATE.DIT on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSBS, bit [23]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL1, and copied to PSTATE.SSBS on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL1, and copied to PSTATE.PAN on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL1, and conditionally copied to PSTATE.SS on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL1, and copied to PSTATE.IL on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]
