  - The lowest address that has been copied to.
  - The highest address that has not been copied to + 1.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

C6.2.127 CPYPTN, CPYMTN, CPYETN

Memory copy, reads and writes unprivileged and non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTN, then CPYMTN, and then CPYETN.

CPYPTN performs some preconditioning of the arguments suitable for using the CPYMTN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMTN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYETN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPTN:

- If Xn[63:55] != ‘000000000’, the copy size Xn is saturated to `0x007FFFFFFFFFFFFF`.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPTN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPTN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMTN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
    - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
  - If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
    - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMTN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYETN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYETN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - The lowest address that has been copied from.
  - The highest address that has been copied from + 1.
- Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
  - The lowest address that has been copied to.
  - The highest address that has not been copied to + 1.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

C6.2.128 CPYPTRN, CPYMTRN, CPYETRN

Memory copy, reads and writes unprivileged, reads non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTRN, then CPYMTRN, and then CPYETRN.

CPYPTRN performs some preconditioning of the arguments suitable for using the CPYMTRN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMTRN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYETRN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPTRN:

- If Xn[63:55] != ‘000000000’, the copy size Xn is saturated to `0x007FFFFFFFFFFFFF`.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPTRN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPTRN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMTRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
    - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
  - If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
    - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMTRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYETRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYETRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - The lowest address that has been copied from.
  - The highest address that has been copied from + 1.
- Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
  - The lowest address that has been copied to.
  - The highest address that has not been copied to + 1.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)

31 30	29 27	26	25 24	23 22	21	20 16	15 12	11 10	9 5	4 0
sz	0 1 1	1	0 1	op1	0	Rs	1 0 1 1	0 1	Rn	Rd
		o0					op2			

Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPTRN  [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMTRN  [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYETRN  [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly Memory Copy and Memory Set CPY* and Crossing a page boundary with different memory types or Shareability attributes.

Assembler Symbols

<Xd>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the “Rd” field.

For the “Epilogue” and “Main” variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the “Rd” field.

<Xs>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the “Rs” field.

For the “Epilogue” and “Main” variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the “Rs” field.

<Xn>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the “Rn” field.

For the “Main” variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the “Rn” field.

For the “Epilogue” variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the “Rn” field.

C6.2.129 CPYPTWN, CPYMTWN, CPYETWN

Memory copy, reads and writes unprivileged, writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTWN, then CPYMTWN, and then CPYETWN.

CPYPTWN performs some preconditioning of the arguments suitable for using the CPYMTWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMTWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYETWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPTWN:

- If Xn[63:55] != ‘000000000’, the copy size Xn is saturated to `0x007FFFFFFFFFFFFF`.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPTWN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPTWN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMTWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
    - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
  - If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
    - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMTWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYETWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYETWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - The lowest address that has been copied from.
  - The highest address that has been copied from + 1.
- Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
  - The lowest address that has been copied to.
  - The highest address that has not been copied to + 1.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)

31 30	29 27	26	25 24	23 22	21	20 16	15 12	11 10	9 5	4 0

Assembler Symbols

<Xd>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the “Rd” field.

For the “Epilogue” and “Main” variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the “Rd” field.

<Xs>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the “Rs” field.

For the “Epilogue” and “Main” variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the “Rs” field.

<Xn>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the “Rn” field.

For the “Main” variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the “Rn” field.

For the “Epilogue” variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the “Rn” field.

C6.2.130 CPYPWN, CPYMWN, CPYEWN

Memory copy, writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWN, then CPYMWN, and then CPYEWN.

CPYPWN performs some preconditioning of the arguments suitable for using the CPYMWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPWN:

- If Xn[63:55] != ‘000000000’, the copy size Xn is saturated to `0x007FFFFFFFFFFFFF`.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPWN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPWN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:

Non-Confidential

    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
    - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
  - If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
    - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYEWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYEWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:

Assembler Symbols

<Xd>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the “Rd” field.

For the “Epilogue” and “Main” variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the “Rd” field.

<Xs>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the “Rs” field.

For the “Epilogue” and “Main” variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the “Rs” field.

<Xn>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the “Rn” field.

For the “Main” variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the “Rn” field.

For the “Epilogue” variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the “Rn” field.

C6.2.131 CPYPWT, CPYMWT, CPYEWT

Memory copy, writes unprivileged

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWT, then CPYMWT, and then CPYEWT.

CPYPWT performs some preconditioning of the arguments suitable for using the CPYMWT instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMWT copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEWT copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPWT:

- If Xn[63:55] != ‘000000000’, the copy size Xn is saturated to `0x007FFFFFFFFFFFFF`.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPWT, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPWT, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMWT, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
    - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
  - If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
    - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMWT, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYEWT, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYEWT, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - The lowest address that has been copied from.
  - The highest address that has been copied from + 1.
- Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
  - The lowest address that has been copied to.
  - The highest address that has not been copied to + 1.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

C6.2.132 CPYPWTN, CPYMWTN, CPYEWTN

Memory copy, writes unprivileged, reads and writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTN, then CPYMWTN, and then CPYEWTN.

CPYPWTN performs some preconditioning of the arguments suitable for using the CPYMWTN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMWTN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEWTN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPWTN:

- If Xn[63:55] != ‘000000000’, the copy size Xn is saturated to `0x007FFFFFFFFFFFFF`.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPWTN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPWTN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMWTN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
    - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
  - If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
    - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMWTN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYEWTN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYEWTN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - The lowest address that has been copied from.
  - The highest address that has been copied from + 1.
- Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
  - The lowest address that has been copied to.
  - The highest address that has not been copied to + 1.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

C6.2.133 CPYPWTRN, CPYMWTRN, CPYEWTRN

Memory copy, writes unprivileged, reads non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTRN, then CPYMWTRN, and then CPYEWTRN.

CPYPWTRN performs some preconditioning of the arguments suitable for using the CPYMWTRN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMWTRN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEWTRN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPWTRN:

- If Xn[63:55] != ‘000000000’, the copy size Xn is saturated to `0x007FFFFFFFFFFFFF`.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPWTRN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPWTRN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMWTRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
    - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
  - If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
    - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMWTRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYEWTRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYEWTRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - The lowest address that has been copied from.
  - The highest address that has been copied from + 1.
- Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
  - The lowest address that has been copied to.
  - The highest address that has not been copied to + 1.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)

31 30	29 27	26	25 24	23 22	21	20 16	15 12	11 10	9 5	4 0
sz	0 1 1	1	0 1	op1	0	Rs	1 0 0 1	0 1	Rn	Rd
		o0					op2			

Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPWTRN  [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMWTRN  [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYEWTRN  [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly Memory Copy and Memory Set CPY* and Crossing a page boundary with different memory types or Shareability attributes.

Assembler Symbols

<Xd>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the “Rd” field.

For the “Epilogue” and “Main” variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the “Rd” field.

<Xs>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the “Rs” field.

For the “Epilogue” and “Main” variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the “Rs” field.

<Xn>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the “Rn” field.

For the “Main” variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the “Rn” field.

For the “Epilogue” variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the “Rn” field.

C6.2.134 CPYPWTWN, CPYMWTWN, CPYEWTWN

Memory copy, writes unprivileged and non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTWN, then CPYMWTWN, and then CPYEWTWN.

CPYPWTWN performs some preconditioning of the arguments suitable for using the CPYMWTWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMWTWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEWTWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPWTWN:

- If Xn[63:55] != ‘000000000’, the copy size Xn is saturated to `0x007FFFFFFFFFFFFF`.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPWTWN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPWTWN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMWTWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
    - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
  - If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
    - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMWTWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYEWTWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYEWTWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - The lowest address that has been copied from.
  - The highest address that has been copied from + 1.
- Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
  - The lowest address that has been copied to.
  - The highest address that has not been copied to + 1.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is ‘11’.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)

31 30	29 27	26	25 24	23 22	21	20 16	15 12	11 10	9 5	4 0
sz	0 1 1	1	0 1	op1	0	Rs	0 1 0 1	0 1	Rn	Rd
		o0					op2			

Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPWTWN  [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMWTWN  [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYEWTWN  [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);

Assembler Symbols

<Xd>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the “Rd” field.

For the “Epilogue” and “Main” variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the “Rd” field.

<Xs>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the “Rs” field.

For the “Epilogue” and “Main” variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the “Rs” field.

<Xn>

For the “Prologue” variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the “Rn” field.

For the “Main” variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the “Rn” field.

For the “Epilogue” variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the “Rn” field.

C6.2.135 CRC32B, CRC32H, CRC32W, CRC32X

CRC32 checksum

This instruction performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial `0x04C11DB7` is used for the CRC calculation.

In an Armv8.0 implementation, this is an OPTIONAL instruction. From Armv8.1, it is mandatory for all implementations to implement this instruction.

Note

ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.

CRC

(FEAT_CRC32)

31	30	29	28	21	20	16	15	13	12	11 10	9	5	4	0
sf	0	0	1 1 0 1 0 1 1 0		Rm		0 1 0		0	sz	Rn		Rd	
		S							C					

Encoding for the CRC32B variant

Applies when `(sf == 0 && sz == 00)`

```
CRC32B  <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32H variant

Applies when `(sf == 0 && sz == 01)`

```
CRC32H  <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32W variant

Applies when `(sf == 0 && sz == 10)`

```
CRC32W  <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32X variant

Applies when `(sf == 1 && sz == 11)`

```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose accumulator output register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose accumulator input register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the general-purpose data source register, encoded in the “Rm” field.

<Xm>

Is the 64-bit name of the general-purpose data source register, encoded in the “Rm” field.

Operation

```
let acc : bits(32) = X{32}(n);       // accumulator
let val : bits(size) = X{size}(m);   // input value
let poly : bits(32) = 0x4C11DB7[:32];

let tempacc : bits(32+size) = BitReverse{32}(acc)::Zeros{size};
let tempval : bits(size+32) = BitReverse{size}(val)::Zeros{32};

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X{32}(d) = BitReverse{32}(Poly32Mod2{32+size}(tempacc XOR tempval, poly));
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.136 CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC32C checksum

This instruction performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial `0x1EDC6F41` is used for the CRC calculation.

In an Armv8.0 implementation, this is an OPTIONAL instruction. From Armv8.1, it is mandatory for all implementations to implement this instruction.

Note

ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.

CRC

(FEAT_CRC32)

31	30	29	28							21	20				16	15			13	12	11	10	9				5	4				0
sf	0	0	1	1	0	1	0	1	1	0	Rm					0	1	0		1	sz		Rn					Rd				
		S																		C												

Encoding for the CRC32CB variant

Applies when `(sf == 0 && sz == 00)`

```
CRC32CB  <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32CH variant

Applies when `(sf == 0 && sz == 01)`

```
CRC32CH  <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32CW variant

Applies when `(sf == 0 && sz == 10)`

```
CRC32CW  <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32CX variant

Applies when `(sf == 1 && sz == 11)`

```
CRC32CX  <Wd>, <Wn>, <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CRC32) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
if sf == '1' && sz != '11' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && sz == '11' then EndOfDecode(Decode_UNDEF); end;
let size : integer{} = 8 << UInt(sz);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose accumulator output register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose accumulator input register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the general-purpose data source register, encoded in the “Rm” field.

<Xm>

Is the 64-bit name of the general-purpose data source register, encoded in the “Rm” field.

Operation

```
let acc : bits(32) = X{32}(n);       // accumulator
let val : bits(size) = X{size}(m);   // input value
let poly : bits(32) = 0x1EDC6F41[:32];

let tempacc : bits(32+size) = BitReverse{32}(acc)::Zeros{size};
let tempval : bits(size+32) = BitReverse{size}(val)::Zeros{32};

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X{32}(d) = BitReverse{32}(Poly32Mod2{32+size}(tempacc XOR tempval, poly));
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.137 CSDB

Consumption of speculative data barrier

This instruction is a memory barrier that controls speculative execution arising from data value prediction. For more information and details of the semantics, see Consumption of Speculative Data Barrier (CSDB).

31–29	28–26	25–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 0	0 0 1 0 (CRm)	1 0 0 (op2)	1 1 1 1 1

Encoding

```
CSDB
```

Decode for this encoding

```
// Empty.
```

Operation

```
ConsumptionOfSpeculativeDataBarrier();
```

C6.2.138 CSEL

Conditional select

This instruction writes the value of the first source register to the destination register if the condition is TRUE. If the condition is FALSE, it writes the value of the second source register to the destination register.

31	30	29	28	21	20	16	15	12	11	10	9	5	4	0
sf	0	0	1 1 0 1 0 1 0 0		Rm		cond		0	0	Rn		Rd	
	op	S								o2				

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSEL  <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSEL  <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<cond>

Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO

C6.2.139 CSET

Conditional set

This instruction sets the destination register to 1 if the condition is TRUE, and otherwise sets it to 0.

This is an alias of CSINC. This means:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSET  <Wd>, <invcond>
```

is equivalent to

```
CSINC  <Wd>, WZR, WZR, <cond>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSET  <Xd>, <invcond>
```

is equivalent to

```
CSINC  <Xd>, XZR, XZR, <cond>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<invcond>

Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in “cond”:

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

cond	<invcond>	Description
0010	CC|LO	Maps to <cond> CS.
0011	CS|HS	Maps to <cond> CC.
0100	PL	Maps to <cond> MI.
0101	MI	Maps to <cond> PL.

1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

Operational Information

The description of CSINC gives the operational information for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.140 CSETM

Conditional set mask

This instruction sets all bits of the destination register to 1 if the condition is TRUE, and otherwise sets all bits to 0.

This is an alias of CSINV. This means:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSETM  <Wd>, <invcond>
```

is equivalent to

```
CSINV  <Wd>, WZR, WZR, <cond>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSETM  <Xd>, <invcond>
```

is equivalent to

```
CSINV  <Xd>, XZR, XZR, <cond>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<invcond>

Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in “cond”:

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.

1001	HI	Maps to <cond> LS.
1010	LT	Maps to <cond> GE.
1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

The description of CSINV gives the operational pseudocode for this instruction.

Operational Information

The description of CSINV gives the operational information for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.141 CSINC

Conditional select increment

This instruction returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register incremented by 1.

This instruction is used by the aliases CINC and CSET.

31	30	29	28							21	20	16	15	12	11	10	9	5	4	0
sf	0	0	1	1	0	1	0	1	0	0	Rm		cond		0	1	Rn		Rd	
	op	S														o2				

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSINC  <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSINC  <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<cond>

Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
CINC	Rm != '11111' && Rn != '11111' && !(cond IN {'111x'}) && Rn == Rm
CSET	Rm == '11111' && Rn == '11111' && !(cond IN {'111x'})

Operation

```
var result : bits(datasize);
if ConditionHolds(condition) then
    result = X{datasize}(n);
else
    result = X{datasize}(m) + 1;
end;

X{datasize}(d) = result;
```

Operational Information

C6.2.142 CSINV

Conditional select invert

This instruction returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the bitwise inversion value of the second source register.

This instruction is used by the aliases CINV and CSETM.

31	30	29	28							21	20	16	15	12	11	10	9	5	4	0
sf	1	0	1	1	0	1	0	1	0	0	Rm		cond		0	0	Rn		Rd	
	op	S														o2				

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSINV  <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSINV  <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<cond>

Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS

C6.2.143 CSNEG

Conditional select negation

This instruction returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the negated value of the second source register.

This instruction is used by the alias CNEG.

31	30	29	28							21	20	16	15	12	11	10	9	5	4	0
sf	1	0	1	1	0	1	0	1	0	0	Rm		cond		0	1	Rn		Rd	
	op	S														o2				

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSNEG  <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSNEG  <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<cond>

Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS

1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
CNEG	!(cond IN {'111x'}) && Rn == Rm

Operation

```
var result : bits(datasize);
if ConditionHolds(condition) then
    result = X{datasize}(n);
else
    result = NOT X{datasize}(m) + 1;
end;

X{datasize}(d) = result;
```

Operational Information

C6.2.144 CTZ

Count trailing zeros

This instruction determines the number of consecutive binary zero bits, starting from the least significant bit in the source register, and places the result in the destination register.

Integer

(FEAT_CSSC)

31	30	29	28	21	20	16	15	10	9	5	4	0
sf	1	0	1 1 0 1 0 1 1 0		0 0 0 0 0		0 0 0 1 1 0		Rn		Rd	
		S			opcode2		opcode					

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CTZ  <Wd>, <Wn>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CTZ  <Xd>, <Xn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let datasize : integer{} = 32 << UInt(sf);
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = CountLeadingZeroBits(BitReverse{datasize}(operand1));

X{datasize}(d) = result[datasize-1:0];
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.145 DC

Data cache operation

For more information, see op0 == `0b01`, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31–29	28–26	25–22	21	20–19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0	0 (L)	0 1	op1	0 1 1 1 (CRn)	CRm	op2	Rt

Encoding

```
DC  <dc_op>, <Xt>
```

is equivalent to

```
SYS  #<op1>, C7, <Cm>, #<op2>, <Xt>
```

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_DC`.

Assembler Symbols

<dc_op>

Is a DC operation name, as listed for the DC system instruction group, encoded in “op1:CRm:op2”:

op1	CRm	op2	<dc_op>	Architectural Feature	Description
000	0110	001	IVAC	-	For more information, see DC IVAC.

C6.2.146 DCPS1

Debug change PE state to EL1

This instruction, when executed in Debug state:

- If executed at EL0, changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at ELx, selects SP_ELx.

The target Exception level of a DCPS1 instruction is:

- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

When the target Exception level of a DCPS1 instruction is ELx, on executing this instruction:

- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR_ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_ELx.EE.

This instruction is always UNDEFINED in Non-debug state.

This instruction is UNDEFINED at EL0 if EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE == 1.

For more information on the operation of the DCPS<n> instructions, see DCPS.

31 29	28 26	25 24	23 21	20 5	4 2	1 0
1 1 0	1 0 1	0 0	1 0 1	imm16	0 0 0	0 1
			opc		op2	LL

Encoding

```
DCPS1  {#<imm>}
```

Decode for this encoding

```
// Empty.
```

Assembler Symbols

<imm>

Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the “imm16” field.

Operation

```
if !Halted() then Undefined(); end;
DCPSInstruction(EL1);
```

C6.2.147 DCPS2

Debug change PE state to EL2

This instruction, when executed in Debug state:

- If executed at EL0 or EL1, changes the current Exception level and SP to EL2 using SP_EL2.
- Otherwise, if executed at ELx, selects SP_ELx.

The target Exception level of a DCPS2 instruction is:

- EL2 if the instruction is executed at an Exception level that is not EL3.
- EL3 if the instruction is executed at EL3.

When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:

- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR_ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_ELx.EE.

This instruction is always UNDEFINED in Non-debug state.

This instruction is UNDEFINED at the following Exception levels:

- All Exception levels if EL2 is not implemented.
- At EL0 and EL1 if EL2 is disabled in the current Security state.

For more information on the operation of the DCPS<n> instructions, see DCPS.

31 29	28 26	25 24	23 21	20 5	4 2	1 0
1 1 0	1 0 1	0 0	1 0 1	imm16	0 0 0	1 0

C6.2.148 DCPS3

Debug change PE state to EL3

This instruction, when executed in Debug state:

- If executed at EL3, selects SP_EL3.
- Otherwise, changes the current Exception level and SP to EL3 using SP_EL3.

The target Exception level of a DCPS3 instruction is EL3.

On executing a DCPS3 instruction:

- ELR_EL3 becomes UNKNOWN.
- SPSR_EL3 becomes UNKNOWN.
- ESR_EL3 becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_EL3.EE.

This instruction is always UNDEFINED in Non-debug state.

This instruction is UNDEFINED at all Exception levels if either:

- EDSCR.SDD == 1.
- EL3 is not implemented.

For more information on the operation of the DCPS<n> instructions, see DCPS.

if !IsFeatureImplemented(FEAT_XS) then EndOfDecode(Decode_UNDEF); end;
let types : MBReqTypes = MBReqTypes_All;
var nXS : boolean = TRUE;
let alias : DSBAlias = DSBAlias_DSB;
var scope : MBMaintenanceScope;
case imm2 of
    when '00' => scope = MBMaintenanceScope_OuterShareable;
    when '01' => scope = MBMaintenanceScope_Nonshareable;
    when '10' => scope = MBMaintenanceScope_InnerShareable;
    when '11' => scope = MBMaintenanceScope_OuterShareable;
end;
```

Assembler Symbols

<option>

For the “Memory barrier” variant: specifies the limitation on the Memory Effects and maintenance operations ordered by the barrier operation, and is encoded in “CRm”.

Note

The value `0b0000` is used to encode `SSBB` and the value `0b0100` is used to encode `PSSBB`.

For more information on whether an access is before or after a barrier instruction, see Data Synchronization Barrier (DSB).

CRm	<option>	Description
0001	OSHLD	This option has the same behavior as LD and is deprecated.
0010	OSHST	This option has the same behavior as ST and is deprecated.
0011	OSH	This option has the same behavior as SY.
0101	NSHLD	This option has the same behavior as LD and is deprecated.
0110	NSHST	This option has the same behavior as ST and is deprecated.
0111	NSH	Non-shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.
1001	ISHLD	This option has the same behavior as LD and is deprecated.
1010	ISHST	This option has the same behavior as ST and is deprecated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CRm	<option>	Description
1011	ISH	Inner Shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.
1x00	RESERVED	•
1101	LD	Reads are the required access type before the barrier instruction. Reads and writes are the required access types after the barrier instruction.
1110	ST	Writes are the required access type, both before and after the barrier instruction.
1111	SY	Outer Shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.

All encodings of “CRm” that are listed as reserved can be encoded using the #<imm> syntax. All reserved options have the same behavior as SY, but software must not rely on this behavior.

For the “Memory nXS barrier” variant: specifies the limitation on the barrier operation, and is encoded in “imm2”:

imm2	<option>	Description
00	OSH	This option has the same behavior as SY.
01	NSH	Non-shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.
10	ISH	Inner Shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.
11	SY	Outer Shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.

<imm>

Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the “CRm” field.

Alias Conditions

Alias	Is preferred when
PSSBB	CRm == '0100'
SSBB	CRm == '0000'

Operation

```
case alias of
    when DSBAlias_SSBB =>
        SpeculativeStoreBypassBarrierToVA();
    when DSBAlias_PSSBB =>
        SpeculativeStoreBypassBarrierToPA();
    when DSBAlias_DSB =>
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
        if !nXS && IsFeatureImplemented(FEAT_XS) then
            nXS = PSTATE.EL IN {EL0, EL1} && IsHCRXEL2Enabled() && HCRX_EL2().FnXS == '1';
        end;
        DataSynchronizationBarrier(scope, types, nXS);
    otherwise =>
        unreachable;
end;
```

C6.2.153 DVP

Data value prediction restriction by context

This instruction prevents data value predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.

For more information, see DVP RCTX, Data Value Prediction Restriction by Context.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_SPECRES)

31–29	28–26	25–22	21	20–19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0	0	0 1	0 1 1	0 1 1 1	0 0 1 1	1 0 1	Rt
			L	op1		CRn	CRm	op2	

Encoding

```
DVP  RCTX, <Xt>
```

is equivalent to

```
SYS  #3, C7, C3, #5, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose source register, encoded in the “Rt” field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.154 EON (shifted register)

Bitwise exclusive-OR NOT (shifted register)

This instruction performs a bitwise exclusive-OR NOT between a register value and an optionally-shifted register value, and writes the result to the destination register.

31	30 29	28 24	23 22	21	20 16	15 10	9 5	4 0
sf	1 0	0 1 0 1 0	shift	1	Rm	imm6	Rn	Rd
	opc			N				

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
EON  <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
EON  <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

shift	<shift>
10	ASR
11	ROR

<amount>

For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 XOR NOT operand2;

X{datasize}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.155 EOR (immediate)

Bitwise exclusive-OR (immediate)

This instruction performs a bitwise exclusive-OR between a register value and an immediate value, and writes the result to the destination register.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	1 0 (opc)	1 0 0 1 0 0	N	immr	imms	Rn	Rd

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
EOR  <Wd|WSP>, <Wn>, #<imm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
EOR  <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
if sf == '0' && N != '0' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
var imm : bits(datasize);
(imm, -) = DecodeBitMasks{datasize}(N, imms, immr, TRUE);
```

Assembler Symbols

<Wd|WSP>

Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<imm>

Is the bitmask immediate. For encoding information, see Logical (immediate).

<Xd|SP>

Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = imm;
let result : bits(datasize) = operand1 XOR operand2;

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.156 EOR (shifted register)

Bitwise exclusive-OR (shifted register)

This instruction performs a bitwise exclusive-OR between a register value and an optionally-shifted register value, and writes the result to the destination register.

31	30 29	28 24	23 22	21	20 16	15 10	9 5	4 0
sf	1 0 (opc)	0 1 0 1 0	shift	0 (N)	Rm	imm6	Rn	Rd

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
EOR  <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
EOR  <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

shift	<shift>
10	ASR
11	ROR

<amount>

For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 XOR operand2;

X{datasize}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

C6.2.157 ERET

Exception return

This instruction restores PSTATE from the SPSR, and branches to the address held in the ELR.

The SPSR is checked for the current Exception level for an illegal return event. See Illegal exception returns from AArch64 state.

ERET is UNDEFINED at EL0.

31–29	28–26	25	24–21	20–16	15–12	11	10	9–5	4–0
1 1 0	1 0 1	1	0 1 0 0	1 1 1 1 1	0 0 0 0	0	0	1 1 1 1 1	0 0 0 0 0
			opc	op2		A	M	Rn	op4

Encoding

```
ERET
```

Decode for this encoding

```
let pac : boolean = FALSE;
let use_key_a : boolean = TRUE;
```

Operation

```
if PSTATE.EL == EL0 then Undefined(); end;
AArch64_CheckForERetTrap(pac, use_key_a);
let target : bits(64) = ELR_ELx();

AArch64_ExceptionReturn(target, SPSR_ELx());
```

Non-Confidential

C6.2.158 ERETAA, ERETAB

Exception return, with pointer authentication

This instruction authenticates the address in ELR, using SP as the modifier and the specified key, restores PSTATE from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for `ERETAA`. Key B is used for `ERETAB`.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The authenticated address is not written back to ELR.

The SPSR is checked for the current Exception level for an illegal return event. See Illegal exception returns from AArch64 state.

`ERETAA` and `ERETAB` are UNDEFINED at EL0.

Integer

(FEAT_PAuth)

31–25	24–21	20–16	15–12	11	10	9–5	4–0
1 1 0 1 0 1 1	0 1 0 0	1 1 1 1 1	0 0 0 0	1	M	1 1 1 1 1	1 1 1 1 1
	opc	op2		A		Rn	op4

Encoding for the ERETAA variant

Applies when `(M == 0)`

```
ERETAA
```

Encoding for the ERETAB variant

Applies when `(M == 1)`

```
ERETAB
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let use_key_a : boolean = (M == '0');
let pac : boolean = TRUE;
let auth_then_branch : boolean = TRUE;
```

Operation

```
if PSTATE.EL == EL0 then Undefined(); end;
AArch64_CheckForERetTrap(pac, use_key_a);

var target : bits(64) = ELR_ELx();
let modifier : bits(64) = SP{64}();
if use_key_a then
    target = AuthIA(target, modifier, auth_then_branch);
else
    target = AuthIB(target, modifier, auth_then_branch);
end;

AArch64_ExceptionReturn(target, SPSR_ELx());
```

C6.2.159 ESB

Error synchronization barrier

This instruction is an error synchronization event that might also update DISR_EL1 and VDISR_EL2.

This instruction can be used at all Exception levels and in Debug state.

In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. For more information, see RAS PE architecture and Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture (ARM IHI 0100).

If FEAT_RAS is not implemented, this instruction executes as a `NOP`.

System

(FEAT_RAS)

31–29	28–26	25–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 0	0 0 1 0 (CRm)	0 0 0 (op2)	1 1 1 1 1

Encoding

```
ESB
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_RAS) then EndOfDecode(Decode_NOP); end;
```

Operation

```
SynchronizeErrors();
AArch64_ESBOperation();
if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then
    AArch64_vESBOperation();
elsif IsFeatureImplemented(FEAT_E3DSE) && PSTATE.EL != EL3 then
    AArch64_dESBOperation();
end;
TakeUnmaskedSErrorInterrupts();
```

C6.2.160 EXTR

Extract register

This instruction extracts a register from a pair of registers.

This instruction is used by the alias ROR (immediate).

31	30 29	28 23	22	21	20 16	15 10	9 5	4 0
sf	0 0	1 0 0 1 1 1	N	0	Rm	imms	Rn	Rd
	op21			o0				

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0 && imms == 0xxxxx)`

```
EXTR  <Wd>, <Wn>, <Wm>, #<lsb>
```

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
EXTR  <Xd>, <Xn>, <Xm>, #<lsb>
```

Decode for all variants of this encoding

```
if N != sf then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && imms[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let lsb : integer{} = UInt(imms);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<lsb>

For the “32-bit” variant: is the least significant bit position from which to extract, in the range 0 to 31, encoded in the “imms” field.

For the “64-bit” variant: is the least significant bit position from which to extract, in the range 0 to 63, encoded in the “imms” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
`ROR (immediate)`	`Rn == Rm`

Operation

```
var result : bits(datasize);
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let concat : bits(2*datasize) = operand1::operand2;

result = concat[(lsb+datasize)-1:lsb];

X{datasize}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.161 GCSB

Guarded Control Stack barrier

This instruction generates a GCSB effect.

If FEAT_GCS is not implemented, this instruction executes as a `NOP`.

System

(FEAT_GCS)

31–29	28–26	25–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 0	0 0 1 0 (CRm)	0 1 1 (op2)	1 1 1 1 1

Encoding

```
GCSB  DSYNC
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_GCS) then EndOfDecode(Decode_NOP); end;
```

Operation

```
GCSSynchronizationBarrier();
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.162 GCSPOPCX

Guarded Control Stack pop and compare exception return record

This instruction loads an exception return record from the location indicated by the current GCS pointer register, compares the loaded values with the current ELR_ELx, SPSR_ELx, and LR, and increments the pointer by the size of a GCS exception return record.

For more information, see GCSPOPCX, Guarded Control Stack Pop and Compare exception return record.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)

Encoding

```
GCSPOPCX
```

is equivalent to

```
SYS  #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}
```

and is always the preferred disassembly.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.163 GCSPOPM

Guarded Control Stack pop

This instruction loads the 64-bit doubleword that is pointed to by the current GCS pointer register, writes it to the destination register, and increments the current GCS pointer register by the size of a GCS procedure return record.

For more information, see GCSPOPM, Guarded Control Stack Pop.

This is an alias of SYSL. This means:

- The encodings in this description are named to match the encodings of SYSL.
- The description of SYSL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)

31 29	28 26	25 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0	1 0 1	0 1 0 0	1	0 1	0 1 1	0 1 1 1	0 1 1 1	0 0 1	Rt
			L	op1		CRn	CRm	op2	

Encoding

```
GCSPOPM    {<Xt>}
```

is equivalent to

```
SYSL  <Xt>, #<op1>, <Cn>, <Cm>, #<op2>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>

Is the 64-bit name of the optional general-purpose destination register, encoded in the “Rt” field. Defaults to XZR if absent.

Operation

The description of SYSL gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.164 GCSPOPX

Guarded Control Stack pop exception return record

This instruction loads an exception return record from the location indicated by the current GCS pointer register, checks that the record is an exception return record, and increments the pointer by the size of a Guarded Control Stack exception return record.

For more information, see GCSPOPX, Guarded Control Stack Pop exception return record.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)

31–29	28–26	25–22	21	20–19	18–16	15–12	11–8	7–5	4–0

Non-Confidential

C6.2.165 GCSPUSHM

Guarded Control Stack push

This instruction decrements the current GCS pointer register by the size of a GCS procedure return record and stores an entry to the Guarded Control Stack.

For more information, see GCSPUSHM, Guarded Control Stack Push.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)

31 29	28 26	25 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0	1 0 1	0 1 0 0	0	0 1	0 1 1	0 1 1 1	0 1 1 1	0 0 0	Rt
			L		op1	CRn	CRm	op2	

Encoding

```
GCSPUSHM  <Xt>
```

is equivalent to

```
SYS  #3, C7, C7, #0, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose source register, encoded in the “Rt” field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.166 GCSPUSHX

Guarded Control Stack push exception return record

This instruction decrements the current GCS pointer register by the size of a Guarded Control Stack exception return record and stores an exception return record to the Guarded Control Stack.

For more information, see GCSPUSHX, Guarded Control Stack Push exception return record.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)

31–29	28–26	25–22	21	20–19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0	0	0 1	0 0 0	0 1 1 1	0 1 1 1	1 0 0	Rt
			L	op1		CRn	CRm	op2	

Encoding

```
GCSPUSHX
```

is equivalent to

```
SYS  #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}
```

and is always the preferred disassembly.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Non-Confidential

C6.2.167 GCSSS1

Guarded Control Stack switch stack 1

This instruction validates that the stack being switched to contains a Valid GCS cap record, stores an In-progress GCS cap record to the stack that is being switched to, and sets the current GCS pointer register to the stack that is being switched to.

If the instruction generates a synchronous Data Abort exception, Watchpoint exception, GPC exception, or GCS Data Check exception, the value of GCSPR_ELx for the current Exception level is restored to the value held in the register before the instruction was executed.

For more information, see GCSSS1, Guarded Control Stack Switch Stack 1.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)

Encoding

```
GCSSS1  <Xt>
```

is equivalent to

```
SYS  #3, C7, C7, #2, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose source register, encoded in the “Rt” field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.168 GCSSS2

Guarded Control Stack switch stack 2

This instruction validates that the most recent entry of the Guarded Control Stack being switched to contains an In-progress GCS cap record, stores a Valid GCS cap record to the Guarded Control Stack that is being switched from, and sets Xt to the Guarded Control Stack pointer that is being switched from.

For more information, see GCSSS2, Guarded Control Stack Switch Stack 2.

This is an alias of SYSL. This means:

- The encodings in this description are named to match the encodings of SYSL.
- The description of SYSL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)

Encoding

```
GCSSS2  <Xt>
```

is equivalent to

```
SYSL  <Xt>, #<op1>, <Cn>, <Cm>, #<op2>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rt” field.

Operation

The description of SYSL gives the operational pseudocode for this instruction.

Non-Confidential

C6.2.169 GCSSTR

Guarded Control Stack store register

This instruction stores a doubleword from a register to memory. The address that is used for the store is calculated from a base register.

Integer

(FEAT_GCS)

31–28	27	26	25	24–15	14–12	11–10	9–5	4–0
1 1 0 1	1	0	0	1 0 0 0 1 1 1 1 1 0	0 0 0 (opc)	1 1	Rn	Rt

Encoding

```
GCSSTR  <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_GCS) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Operation

```
var address : bits(64);

let effective_el : bits(2) = PSTATE.EL;

if effective_el == PSTATE.EL then
    CheckGCSSTREnabled();
end;

let privileged : boolean = effective_el != EL0;
let accdesc : AccessDescriptor = CreateAccDescGCS(MemOp_STORE, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

Mem{64}(address, accdesc) = X{64}(t);
```

Non-Confidential

C6.2.170 GCSSTTR

Guarded Control Stack store register (unprivileged)

This instruction stores a doubleword from a register to memory. The address that is used for the store is calculated from a base register.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1 and the Effective value of HCR_EL2.{NV1, NV} is not {1, 1}.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_GCS)

31–28	27	26	25	24–15	14–12	11–10	9–5	4–0
1 1 0 1	1	0	0	1 0 0 0 1 1 1 1 1 0	0 0 1	1 1	Rn	Rt
					opc			

Encoding

```
GCSSTTR  <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_GCS) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);

let effective_el : bits(2) = if AArch64_IsUnprivAccessPriv() then PSTATE.EL else EL0;

if effective_el == PSTATE.EL then
    CheckGCSSTREnabled();
end;

let privileged : boolean = effective_el != EL0;
let accdesc : AccessDescriptor = CreateAccDescGCS(MemOp_STORE, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    address = X{64}(n);
end;

Mem{64}(address, accdesc) = X{64}(t);
```

C6.2.171 GMI

Tag mask insert

This instruction inserts the tag in the first source register into the excluded set specified in the second source register, writing the new excluded set to the destination register.

Integer

(FEAT_MTE)

31	30	29	28	27 25	24 21	20 16	15 10	9 5	4 0
1	0	0	1	1 0 1	0 1 1 0	Rm	0 0 0 1 0 1	Rn	Rd
sf		S					opcode		

Encoding

```
GMI  <Xd>, <Xn|SP>, <Xm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Operation

```
let address : bits(64) = if n == 31 then SP{64}() else X{64}(n);
var mask : bits(64) = X{64}(m);
let tag : bits(4) = AArch64_AllocationTagFromAddress(address);

mask[UInt(tag)] = '1';
X{64}(d) = mask;
```

C6.2.172 HINT

Hint instruction

This instruction is for the instruction set space that is reserved for architectural hint instructions.

Some encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.

31 29	28 26	25 12	11 8	7 5	4 0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 0	CRm	op2	1 1 1 1 1

Encoding

```
HINT  #<imm>
```

Decode for this encoding

```
var op : SystemHintOp;

Assembler Symbols

<imm>

Is a 7-bit unsigned immediate, in the range 0 to 127, encoded in the “CRm:op2” field.

The encodings that are allocated to architectural hint functionality are described in the ‘Hints’ table in the ‘Index by Encoding’.

Note

For allocated encodings of “CRm:op2”:

- A disassembler will disassemble the allocated instruction, rather than the `HINT` instruction.
- An assembler may support assembly of allocated encodings using `HINT` with the corresponding `<imm>` value, but it is not required to do so.

Operation

```
case op of
    when SystemHintOp_YIELD =>
        Hint_Yield();

    when SystemHintOp_DGH =>
        Hint_DGH();

    when SystemHintOp_WFE =>
        Hint_WFE();

    when SystemHintOp_WFI =>
        Hint_WFI();

    when SystemHintOp_SEV =>

C6.2.173 HINTE

Hint instruction (extended)

This instruction is the extended instruction set space that is reserved for future architectural hint instructions. The encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.

System

(FEAT_HINTE)

31 29	28 26	25 22	21	20 19	18 16	15 12	11 5	4 0
1 1 0	1 0 1	0 1 0 0	L	0 0	imm3	0 0 1 0	imm7	Rt

Encoding

Applies when `(!(L == 0 && imm3 == 011 && Rt == 11111))`

```
HINTE  #<imm16>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_HINTE) then EndOfDecode(Decode_UNDEF); end;
```

Assembler Symbols

<imm16>

Is a 16-bit unsigned immediate, in the range 0 to 65535, excluding the values 12319 to 16383 in increments of 32, encoded in the “L:imm3:imm7:Rt” fields.

Operation

```
return; // Do nothing
```

Non-Confidential

C6.2.174 HLT

Halt instruction

This instruction can generate a Halt Instruction debug event, which causes entry into Debug state.

Within a guarded memory region, while PSTATE.BTYPE != `0b00`, an `HLT` instruction that would cause entry into Debug state will not generate a Branch Target exception and will cause entry into Debug state as normal. For more information, see PSTATE.BTYPE.

31–29	28–26	25–24	23–21	20–5	4–2	1–0
1 1 0	1 0 1	0 0	0 1 0	imm16	0 0 0	0 0
			opc		op2	LL

Encoding

```
HLT  #<imm>
```

Decode for this encoding

```
if EDSCR().HDE == '0' || !HaltingAllowed() then
    EndOfDecode(Decode_UNDEF);
elsif IsFeatureImplemented(FEAT_BTI) then
    SetBTypeCompatible(TRUE);
end;
```

Assembler Symbols

<imm>

Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

Operation

```
let is_async : boolean = FALSE;
let fault : FaultRecord = NoFault();
Halt(DebugHalt_HaltInstruction, is_async, fault);
```

C6.2.175 HVC

Hypervisor call

This instruction causes an exception to EL2. Software executing at EL1 can use this instruction to call the hypervisor to request a service.

The `HVC` instruction is UNDEFINED:

- When EL3 is implemented and SCR_EL3.HCE is set to 0.
- When EL3 is not implemented and HCR_EL2.HCD is set to 1.
- When EL2 is not implemented.
- At EL1 if EL2 is not enabled in the current Security state.
- At EL0.

On executing an `HVC` instruction, the PE records the exception as a Hypervisor Call exception in ESR_ELx, using the EC syndrome value `0x16`, and the value of the immediate argument.

31 29	28 26	25 24	23 21	20 5	4 2	1 0
1 1 0	1 0 1	0 0	0 0 0	imm16	0 0 0	1 0
			opc		op2	LL

Encoding

```
HVC  #<imm>
```

Decode for this encoding

```
if !HaveEL(EL2) then EndOfDecode(Decode_UNDEF); end;
let imm : bits(16) = imm16;
```

Assembler Symbols

<imm>

Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

Operation

```
if PSTATE.EL == EL0 then Undefined(); end;
if PSTATE.EL == EL1 && !EL2Enabled() then Undefined(); end;
if !HaveEL(EL3) && HCR_EL2().HCD == '1' then Undefined(); end;
if HaveEL(EL3) && SCR_EL3().HCE == '0' then Undefined(); end;

AArch64_CallHypervisor(imm);
```

C6.2.176 IC

Instruction cache operation

For more information, see op0 == `0b01`, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31–29	28–26	25–22	21	20–19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0	0 (L)	0 1	op1	0 1 1 1 (CRn)	CRm	op2	Rt

Encoding

```
IC  <ic_op>{, <Xt>}
```

is equivalent to

```
SYS  #<op1>, C7, <Cm>, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_IC`.

Assembler Symbols

<ic_op>

Is an IC operation name, as listed for the IC system instruction pages, encoded in “op1:CRm:op2”:

op1	CRm	op2	<ic_op>	Description
000	0001	000	IALLUIS	For more information, see IC IALLUIS.
000	0101	000	IALLU	For more information, see IC IALLU.
011	0101	001	IVAU	For more information, see IC IVAU.

<Xt>

Is the 64-bit name of the optional general-purpose source register, defaulting to ‘11111’, encoded in the “Rt” field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.177 IRG

Insert random tag

This instruction inserts a random Logical Address Tag into the address in the first source register, and writes the result to the destination register. Any tags specified in the optional second source register or in GCR_EL1.Exclude are excluded from the selection of the random Logical Address Tag.

Integer

(FEAT_MTE)

31	30	29	28	27 25	24 21	20 16	15 10	9 5	4 0
1	0	0	1	1 0 1	0 1 1 0	Rm	0 0 0 1 0 0	Rn	Rd
sf		S					opcode		

Encoding

```
IRG  <Xd|SP>, <Xn|SP>{, <Xm>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Xd|SP>

Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field. Defaults to XZR if absent.

Operation

```
let operand : bits(64) = if n == 31 then SP{64}() else X{64}(n);
let exclude_reg : bits(64) = X{64}(m);
let exclude : bits(16) = exclude_reg[15:0] OR GCR_EL1().Exclude;

let rtag : bits(4) = AArch64_ChooseTagOrZero(exclude);
let result : bits(64) = AArch64_AddressWithAllocationTag(operand, rtag);

if d == 31 then
    SP{64}() = result;
else
    X{64}(d) = result;
end;
```

C6.2.178 ISB

Instruction synchronization barrier

This instruction flushes the pipeline in the PE and is a context synchronization event. For more information, see Instruction Synchronization Barrier (ISB).

31 29	28 26	25 12	11 8	7	6 5	4 0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 1	CRm	1	1 0	1 1 1 1 1
					opc	Rt

Encoding

```
ISB  {<option>|#<imm>}
```

Decode for this encoding

```
// no additional decoding required
```

Assembler Symbols

<option>

Specifies an optional limitation on the barrier operation. Values are:

SY Full system barrier operation, encoded as CRm = `0b1111`. Can be omitted.

All other encodings of “CRm” are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

<imm>

Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the “CRm” field.

Operation

```
InstructionSynchronizationBarrier();

if IsFeatureImplemented(FEAT_BRBE) && BRBEBranchOnISB() then
    BRBEISB();
end;
```

C6.2.179 LD64B

Single-copy atomic 64-byte load

This instruction derives an address from a base register value, loads eight 64-bit doublewords from a memory location, and writes them to consecutive registers. The load starts at register `Xt`, with the data being read as `X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt = Data[511:0]`. The data is loaded atomically and is required to be 64-byte aligned.

It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports `LD64B` also supports `ST64B`.

For more information, including about the memory types accessible and how the accesses are performed, see Single-copy atomic 64-byte load/store.

Integer

(FEAT_LS64)

Encoding

```
LD64B  <Xt>, [<Xn|SP> {, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LS64) then EndOfDecode(Decode_UNDEF); end;
if Rt[4:3] == '11' || Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;
let withstatus : boolean = FALSE;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let tagchecked : boolean = n != 31;
let acqrel : boolean = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LD64B.

Assembler Symbols

<Xt>

Is the 64-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Operation

```
CheckLDST64BEnabled(acqrel);

var data : bits(512);
var address : bits(64);
var value : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLS64(MemOp_LOAD, withstatus, acqrel, tagchecked);

if n == 31 then
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

data = MemLoad64B(address, accdesc);

for i = 0 to 7 do
    value = data[63+64*i : 64*i];
    if BigEndian(accdesc.acctype) then value = BigEndianReverse{64}(value); end;
    X{64}(t+i) = value;
end;
```

C6.2.180 LDADD, LDADDA, LDADDAL, LDADDL

Atomic add on word or doubleword

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR` or `XZR`, `LDADDA` and `LDADDAL` load from memory with acquire semantics.
  - `LDADDL` and `LDADDAL` store to memory with release semantics.
  - `LDADD` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STADD, STADDL.

Integer

(FEAT_LSE)

C6.2.181 LDADDB, LDADDAB, LDADDALB, LDADDLB

Atomic add on byte

This instruction atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not `WZR`, `LDADDAB` and `LDADDALB` load from memory with acquire semantics.
  - `LDADDLB` and `LDADDALB` store to memory with release semantics.
  - `LDADDB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STADDB, STADDLB.

Is the 32-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Alias Conditions

Alias	Is preferred when
STADDB, STADDLB	A == '0' && Rt == '11111'

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_ADD, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(8) = ARBITRARY : bits(8); // Irrelevant when not executing CAS
let value : bits(8) = X{8}(s);
let data : bits(8) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{32}(t) = ZeroExtend{32}(data);
end;
```

Operational Information

C6.2.182 LDADDH, LDADDAH, LDADDALH, LDADDLH

Atomic add on halfword

This instruction atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not `WZR`, `LDADDAH` and `LDADDALH` load from memory with acquire semantics.
  - `LDADDLH` and `LDADDALH` store to memory with release semantics.
  - `LDADDH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STADDH, STADDLH.

Integer

C6.2.183 LDAPR

Load-acquire RCpc register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

`LDAPR` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

It has encodings from 2 classes: Post-index and No offset

Post-index

(FEAT_LRCPC3)

31	30	29						23	22	21										10	9			5	4			0
1	x	0	1	1	0	0	1	1	1	0	0	0	0	0	0	0	0	0	0	1	0	Rn			Rt

C6.2.191 LDAPURSW

Load-acquire RCpc register signed word (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a signed word from memory, sign-extends it, and writes it to a register.

`LDAPURSW` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Unscaled offset

(FEAT_LRCPC2)

31	30	29	28	27	26	25	24	23	22	21	20 … 12	11	10	9 … 5	4 … 0
1	0	0	1	1	0	0	1	1	0	0	imm9	0	0	Rn	Rt
size								opc							

Encoding

```
LDAPURSW  <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF); end;
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32;
let acquirepc : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

C6.2.192 LDAR

Load-acquire register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register.

`LDAR` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

31	30	29						23	22	21	20				16	15	14				10	9			5	4			0
1	x	0	0	1	0	0	0	1	1	0	(1)	(1)	(1)	(1)	(1)	1	(1)	(1)	(1)	(1)	(1)	Rn				Rt			
size									L		Rs					o0	Rt2												

Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDAR  <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDAR  <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 8 << UInt(size);
let regsize : integer{} = if datasize == 64 then 64 else 32;
let acquire : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

C6.2.193 LDARB

Load-acquire register byte

This instruction derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register.

`LDARB` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

31 30	29 28	27	26	25	24 23	22	21	20 16	15	14 10	9 5	4 0
0 0	0 0	1	0	0	0 1	1	0	(1)(1)(1)(1)(1)	1	(1)(1)(1)(1)(1)	Rn	Rt
size						L		Rs	o0	Rt2		

Encoding

```
LDARB  <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescAcqRel(MemOp_LOAD, tagchecked, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let data : bits(8) = Mem{8}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

C6.2.194 LDARH

Load-acquire register halfword

This instruction derives an address from a base register value, loads a halfword from memory, zero-extends it, and writes it to a register.

`LDARH` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

31 30	29 28	27	26	25	24 23	22	21	20 16	15	14 10	9 5	4 0
0 1	0 0	1	0	0	0 1	1	0	(1)(1)(1)(1)(1)	1	(1)(1)(1)(1)(1)	Rn	Rt
size						L		Rs	o0	Rt2		

Encoding

```
LDARH  <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescAcqRel(MemOp_LOAD, tagchecked, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let data : bits(16) = Mem{16}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

C6.2.195 LDATXR

Load-acquire unprivileged exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `LDATXR` is equivalent to `LDXR`.

For information about addressing modes, see Load/Store addressing modes.

No offset

(FEAT_LSUI)

Encoding for the 32-bit variant

Applies when `(sz == 0)`

```
LDATXR  <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

C6.2.196 LDAXP

Load-acquire exclusive pair of registers

This instruction derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores.

`LDAXP` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

31	30	29						23	22	21	20				16	15	14				10	9				5	4				0
1	sz	0	0	1	0	0	0	0	1	1	(1)(1)(1)(1)(1)					1	Rt2					Rn					Rt				
									L		Rs					o0															

Encoding for the 32-bit variant

Applies when `(sz == 0)`

```
LDAXP  <Wt1>, <Wt2>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(sz == 1)`

```
LDAXP  <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 32 << UInt(sz);
let datasize : integer{} = elsize * 2;
let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rt_unknown = TRUE;    // result is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs and LDAXP.

C6.2.200 LDCLR, LDCLRA, LDCLRAL, LDCLRL

Atomic bit clear on word or doubleword

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR` or `XZR`, `LDCLRA` and `LDCLRAL` load from memory with acquire semantics.
  - `LDCLRL` and `LDCLRAL` store to memory with release semantics.
  - `LDCLR` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STCLR, STCLRL.

Integer

Assembler Symbols

<Ws>

Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the “Rs” field.

<Wt>

Is the 32-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Alias Conditions

Alias	Is preferred when
STEORH, STEORLH	A == '0' && Rt == '11111'

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_EOR, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(16) = ARBITRARY : bits(16); // Irrelevant when not executing CAS
let value : bits(16) = X{16}(s);
let data : bits(16) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{32}(t) = ZeroExtend{32}(data);
end;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.207 LDG

Load Allocation Tag

This instruction loads an Allocation Tag from a memory address, generates a Logical Address Tag from the Allocation Tag and merges it into the destination register. The address used for the load is calculated from the base register and an immediate signed offset scaled by the Tag Granule.

Integer

(FEAT_MTE)

31	28	27	26	25	24	23	22	21	20	12	11	10	9	5	4	0
1 1 0 1		1	0	0	1	0	1	1	imm9		0	0	Rn		Rt	
						opc					op2					

Encoding

```
LDG  <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the optional signed immediate offset, a multiple of 16 in the range -4096 to 4080, defaulting to 0 and encoded in the “imm9” field.

Operation

```
var address : bits(64);
var tag : bits(4);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let stzgm : boolean = FALSE;
let accdesc : AccessDescriptor = CreateAccDescLDGSTG(MemOp_LOAD, stzgm, t);

address = AddressAdd(address, offset, accdesc);
address = AlignDownSize(address, TAG_GRANULE);

tag = AArch64_MemTag(address, accdesc);
X{64}(t) = AArch64_AddressWithAllocationTag(X{64}(t), tag);
```

C6.2.208 LDGM

Load tag multiple

This instruction reads a naturally aligned block of N Allocation Tags, where the size of N is identified in GMID_EL1.BS, and writes the Allocation Tag read from address A to the destination register at 4*A<7:4>+3:4*A<7:4>. Bits of the destination register not written with an Allocation Tag are set to 0.

This instruction is UNDEFINED at EL0.

This instruction generates an Unchecked access.

Integer

C6.2.209 LDIAPP

Load-Acquire RCpc ordered pair of registers

This instruction calculates an address from a base register value and an optional offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. The instruction also has memory ordering semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release, with the additional requirement that:

- The Memory effects associated with Xt1/Wt1 are Ordered-before the Memory effects associated with Xt2/Wt2.
- `LDIAPP` loads from memory with Acquire semantics.

For information about addressing modes, see Load/Store addressing modes.

Integer

(FEAT_LRCPC3)

31	30	29						23	22	21	20			16	15			12	11	10	9			5	4			0

Assembler Symbols

<Wt1>

Is the 32-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.

<Wt2>

Is the 32-bit name of the second general-purpose register to be transferred, encoded in the “Rt2” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Post-index 32-bit” and “Pre-index 32-bit” variants: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the “imm7” field as <imm>/4.

For the “Post-index 64-bit” and “Pre-index 64-bit” variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the “imm7” field as <imm>/8.

For the “Signed offset 32-bit” variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the “imm7” field as <imm>/4.

For the “Signed offset 64-bit” variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the “imm7” field as <imm>/8.

<Xt1>

Is the 64-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.

<Xt2>

Is the 64-bit name of the second general-purpose register to be transferred, encoded in the “Rt2” field.

C6.2.216 LDR (immediate)

Load register (immediate)

This instruction loads a word or doubleword from memory and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes. The Unsigned offset variant scales the immediate offset value by the size of the value accessed before adding it to the base register value.

It has encodings from 3 classes: Post-index, Pre-index, and Unsigned offset

Post-index

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the signed immediate byte offset, in the range -256 to 255, encoded in the “imm9” field.

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<pimm>

For the “32-bit” variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the “imm12” field as <pimm>/4.

For the “64-bit” variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the “imm12” field as <pimm>/8.

```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;         // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let scale : integer{} = UInt(size);
let shift : integer{} = if S == '1' then scale else 0;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm>

When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm>

When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend>

Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount>

For the “32-bit” variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#2

For the “64-bit” variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#3

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 8 << scale;
let regsize : integer{} = if datasize == 64 then 64 else 32;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

C6.2.219 LDRAA, LDRAB

Load register, with pointer authentication

This instruction authenticates an address from a base register using a modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit doubleword from memory at this resulting address into a register.

Key A is used for `LDRAA`. Key B is used for `LDRAB`.

If the authentication passes, the PE behaves the same as for an `LDR` instruction. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction is used. In this case, the address that is written back to the base register does not include the pointer authentication code.

For information about addressing modes, see Load/Store addressing modes.

```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the optional signed immediate byte offset, a multiple of 8 in the range -4096 to 4088, defaulting to 0 and encoded in the “S:imm9” field as <simm>/8.

Operation

```
var address : bits(64);
let privileged : boolean = PSTATE.EL != EL0;
let auth_then_branch : boolean = TRUE;

let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);
if n == 31 then
    address = SP{64}();
else
    address = X{64}(n);
end;

if use_key_a then
    address = AuthDA(address, X{64}(31), auth_then_branch);
else
    address = AuthDB(address, X{64}(31), auth_then_branch);
end;

if n == 31 then
    CheckSPAlignment();
end;

address = AddressAdd(address, offset, accdesc);
X{64}(t) = Mem{64}(address, accdesc);

if wback then
    if wb_unknown then
        address = ARBITRARY : bits(64);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;

C6.2.220 LDRB (immediate)

Load register byte (immediate)

This instruction loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index, Pre-index, and Unsigned offset

Post-index

31	30	29	28	27	26	25	24	23	22	21	20 … 12	11	10	9 … 5	4 … 0
0	0	1	1	1	0	0	0	0	1	0	imm9	0	1	Rn	Rt
size					VR			opc							

Encoding

```
LDRB  <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = TRUE;
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index

31	30	29	28	27	26	25	24	23	22	21	20 … 12	11	10	9 … 5	4 … 0
0	0	1	1	1	0	0	0	0	1	0	imm9	1	1	Rn	Rt
size					VR			opc							

Encoding

```
LDRB  <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = FALSE;
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset

31	30	29	28	27	26	25	24	23	22	21 … 10	9 … 5	4 … 0
0	0	1	1	1	0	0	1	0	1	imm12	Rn	Rt
size					VR			opc				

Encoding

```
LDRB  <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
var wback : boolean = FALSE;
let postindex : boolean = FALSE;
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 0);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRB (immediate).

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the signed immediate byte offset, in the range -256 to 255, encoded in the “imm9” field.

<pimm>

Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var wb_unknown : boolean = FALSE;

C6.2.221 LDRB (register)

Load register byte (register)

This instruction calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.

31 30	29 27	26	25 24	23 22	21	20 16	15 13	12	11 10	9 5	4 0
0 0	1 1 1	0	0 0	0 1	1	Rm	option	S	1 0	Rn	Rt
size		VR		opc							

Encoding for the Extended register variant

Applies when `(option != 011)`

```
LDRB  <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the Shifted register variant

Applies when `(option == 011)`

```
LDRB  <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;         // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = 0;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm>

When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm>

When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend>

Is the index extend specifier, encoded in “option”:

option	<extend>
010	UXTW
110	SXTW
111	SXTX

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

C6.2.223 LDRH (register)

Load register halfword (register)

This instruction calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.

31 30	29 28	27	26	25	24	23 22	21	20 16	15 13	12	11 10	9 5	4 0
0 1	1 1	1	0	0	0	0 1	1	Rm	option	S	1 0	Rn	Rt
size			VR			opc							

Encoding

```
LDRH  <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;         // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm>

When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm>

When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend>

Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount>

Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

S	<amount>
0	#0
1	#1

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(16) = Mem{16}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

C6.2.225 LDRSB (register)

Load register signed byte (register)

This instruction calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.

31 30	29 27	26	25 24	23 22	21	20 16	15 13	12	11 10	9 5	4 0
0 0	1 1 1	0	0 0	1 x	1	Rm	option	S	1 0	Rn	Rt
size		VR		opc							

Encoding for the 32-bit with extended register offset variant

Applies when `(opc == 11 && option != 011)`

```
LDRSB  <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the 32-bit with shifted register offset variant

Applies when `(opc == 11 && option == 011)`

```
LDRSB  <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Encoding for the 64-bit with extended register offset variant

Applies when `(opc == 10 && option != 011)`

```
LDRSB  <Xt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the 64-bit with shifted register offset variant

Applies when `(opc == 10 && option == 011)`

```
LDRSB  <Xt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;         // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = 0;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm>

When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm>

When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<extend>

Is the index extend specifier, encoded in “option”:

option	<extend>
010	UXTW
110	SXTW
111	SXTX

<amount>

Is the index shift amount, it must be #0, encoded in “S” as 0 if omitted, or as 1 if present.

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let regsize : integer{} = 64 >> UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(8) = Mem{8}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);
```

C6.2.226 LDRSH (immediate)

Load register signed halfword (immediate)

This instruction loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index, Pre-index, and Unsigned offset

Post-index

31 30	29 27	26	25 24	23 22	21	20 12	11 10	9 5	4 0
0 1	1 1 1	0	0 0	1 x	0	imm9	0 1	Rn	Rt
size		VR		opc					

Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSH  <Wt>, [<Xn|SP>], #<simm>
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDRSH  <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = TRUE;
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index

31 30	29 27	26	25 24	23 22	21	20 12	11 10	9 5	4 0
0 1	1 1 1	0	0 0	1 x	0	imm9	1 1	Rn	Rt
size		VR		opc					

Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSH  <Wt>, [<Xn|SP>, #<simm>]!
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDRSH  <Xt>, [<Xn|SP>, #<simm>]!
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for all variants of this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = FALSE;
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset

31 30	29 27	26	25 24	23 22	21 10	9 5	4 0
0 1	1 1 1	0	0 1	1 x	imm12	Rn	Rt
size		VR		opc			

Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSH  <Wt>, [<Xn|SP>{, #<pimm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDRSH  <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
var wback : boolean = FALSE;
let postindex : boolean = FALSE;
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 1);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRSH (immediate).

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the signed immediate byte offset, in the range -256 to 255, encoded in the “imm9” field.

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<pimm>

Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the “imm12” field as <pimm>/2.

C6.2.227 LDRSH (register)

Load register signed halfword (register)

This instruction calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.

31 30	29 27	26	25 24	23 22	21	20 16	15 13	12	11 10	9 5	4 0
0 1	1 1 1	0	0 0	1 x	1	Rm	option	S	1 0	Rn	Rt
size		VR		opc							

Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSH  <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDRSH  <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;         // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm>

When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm>

When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend>

Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<extend>
110	SXTW
111	SXTX

<amount>

Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#1

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let regsize : integer{} = 64 >> UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;

C6.2.229 LDRSW (literal)

Load register signed word (literal)

This instruction calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.

31	30	29	28	27	26	25	24	23 … 5	4 … 0
1	0	0	1	1	0	0	0	imm19	Rt
opc					VR				

Encoding

```
LDRSW  <Xt>, <label>
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = FALSE;

let offset : bits(64) = SignExtend{}(imm19::'00');
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.

<label>

Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as “imm19” times 4.

Operation

```
let address : bits(64) = PC64() + offset;
let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

let data : bits(32) = Mem{32}(address, accdesc);
X{64}(t) = SignExtend{64}(data);
```

C6.2.230 LDRSW (register)

Load register signed word (register)

This instruction calculates an address from a base register value and an offset register value, loads a word from memory, sign-extends it to form a 64-bit value, and writes it to a register. The offset register value can be shifted left by 0 or 2 bits. For information about addressing modes, see Load/Store addressing modes.

31 30	29 28	27	26	25	24	23 22	21	20 16	15 13	12	11 10	9 5	4 0
1 0	1 1	1	0	0	0	1 0	1	Rm	option	S	1 0	Rn	Rt
size			VR			opc							

Encoding

```
LDRSW  <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;         // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = if S == '1' then 2 else 0;
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm>

When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm>

When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend>

Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<amount>

Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#2

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(32) = Mem{32}(address, accdesc);
X{64}(t) = SignExtend{64}(data);

C6.2.231 LDSET, LDSETA, LDSETAL, LDSETL

Atomic bit set on word or doubleword

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR` or `XZR`, `LDSETA` and `LDSETAL` load from memory with acquire semantics.
  - `LDSETL` and `LDSETAL` store to memory with release semantics.
  - `LDSET` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STSET, STSETL.

Integer

C6.2.238 LDSMIN, LDSMINA, LDSMINAL, LDSMINL

Atomic signed minimum on word or doubleword

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR` or `XZR`, `LDSMINA` and `LDSMINAL` load from memory with acquire semantics.
  - `LDSMINL` and `LDSMINAL` store to memory with release semantics.
  - `LDSMIN` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STSMIN, STSMINL.

C6.2.241 LDTADD, LDTADDA, LDTADDAL, LDTADDL

Atomic add unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR`, or `XZR`, `LDTADDA` and `LDTADDAL` load from memory with acquire semantics.
  - `LDTADDL` and `LDTADDAL` store to memory with release semantics.
  - `LDTADD` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

This instruction is used by the alias STTADD, STTADDL.

C6.2.242 LDTCLR, LDTCLRA, LDTCLRAL, LDTCLRL

Atomic bit clear unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR`, or `XZR`, `LDTCLRA` and `LDTCLRAL` load from memory with acquire semantics.
  - `LDTCLRL` and `LDTCLRAL` store to memory with release semantics.
  - `LDTCLR` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

This instruction is used by the alias STTCLR, STTCLRL.

C6.2.243 LDTNP

Load unprivileged pair of registers, with non-temporal hint

This instruction calculates an address from a base register value and an immediate offset, loads two 64-bit doublewords from memory, and writes them to two registers. For information about addressing modes, see Load/Store addressing modes. For information about non-temporal pair instructions, see Load/Store non-temporal pair.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Signed offset

C6.2.250 LDTRSW

Load register signed word (unprivileged)

This instruction loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see Load/Store addressing modes.

31 30	29 28	27	26	25	24	23 22	21	20 … 12	11 10	9 … 5	4 … 0
1 0	1 1	1	0	0	0	1 0	0	imm9	1 0	Rn	Rt
size			VR			opc					

Encoding

```
LDTRSW  <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm>

Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let datasize : integer{} = 32;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{64}(t) = SignExtend{64}(data);
```

C6.2.251 LDTSET, LDTSETA, LDTSETAL, LDTSETL

Atomic bit set unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR`, or `XZR`, `LDTSETA` and `LDTSETAL` load from memory with acquire semantics.
  - `LDTSETL` and `LDTSETAL` store to memory with release semantics.
  - `LDTSET` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

This instruction is used by the alias STTSET, STTSETL.

C6.2.252 LDTXR

Load unprivileged exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or a 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `LDTXR` is equivalent to `LDXR`.

For information about addressing modes, see Load/Store addressing modes.

C6.2.257 LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB

Atomic unsigned minimum on byte

This instruction atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not `WZR`, `LDUMINAB` and `LDUMINALB` load from memory with acquire semantics.
  - `LDUMINLB` and `LDUMINALB` store to memory with release semantics.
  - `LDUMINB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STUMINB, STUMINLB.

C6.2.265 LDXP

Load exclusive pair of registers

This instruction derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores. For information about addressing modes, see Load/Store addressing modes.

31	30	29						23	22	21	20				16	15	14				10	9				5	4				0
1	sz	0	0	1	0	0	0	0	1	1	(1)(1)(1)(1)(1)					0	Rt2					Rn					Rt				
									L		Rs					o0															

Encoding for the 32-bit variant

Applies when `(sz == 0)`

```
LDXP  <Wt1>, <Wt2>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(sz == 1)`

```
LDXP  <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 32 << UInt(sz);
let datasize : integer{} = elsize * 2;
let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rt_unknown = TRUE;    // result is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs and LDXP.

Assembler Symbols

<Wt1>

Is the 32-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.

<Wt2>

Is the 32-bit name of the second general-purpose register to be transferred, encoded in the “Rt2” field.

C6.2.266 LDXR

Load exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or a 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores.

For information about addressing modes, see Load/Store addressing modes.

Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDXR  <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDXR  <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 8 << UInt(size);
let regsize : integer{} = if elsize == 64 then 64 else 32;
let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>

C6.2.269 LSL (register)

Logical shift left (register)

This instruction shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is left-shifted.

This is an alias of LSLV. This means:

- The encodings in this description are named to match the encodings of LSLV.
- The description of LSLV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	21	20	16	15	12	11	10	9	5	4	0
sf	0	0	1 1 0 1 0 1 1 0		Rm		0 0 1 0		0	0	Rn		Rd	
		S								op2				

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
LSL  <Wd>, <Wn>, <Wm>
```

is equivalent to

```
LSLV  <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
LSL  <Xd>, <Xn>, <Xm>
```

is equivalent to

```
LSLV  <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

C6.2.270 LSL (immediate)

Logical shift left (immediate)

This instruction shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	1 0	1 0 0 1 1 0	N	immr	!IN{x11111}	Rn	Rd
	opc				imms		

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0 && imms != 011111)`

```
LSL  <Wd>, <Wn>, #<shift>
```

is equivalent to

```
UBFM  <Wd>, <Wn>, #(-<shift>  MOD  32), #(31-<shift>)
```

and is the preferred disassembly when `UInt(imms) + 1 == UInt(immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1 && imms != 111111)`

```
LSL  <Xd>, <Xn>, #<shift>
```

is equivalent to

```
UBFM  <Xd>, <Xn>, #(-<shift>  MOD  64), #(63-<shift>)
```

and is the preferred disassembly when `UInt(imms) + 1 == UInt(immr)`.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<shift>

For the “32-bit” variant: is the shift amount, in the range 0 to 31.

For the “64-bit” variant: is the shift amount, in the range 0 to 63.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

C6.2.271 LSLV

Logical shift left variable

This instruction shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is left-shifted.

This instruction is used by the alias LSL (register).

31	30	29	28	21	20	16	15	12	11	10	9	5	4	0
sf	0	0	1 1 0 1 0 1 1 0		Rm		0 0 1 0		0	0	Rn		Rd	
		S								op2				

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
LSLV  <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
LSLV  <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(op2);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

C6.2.272 LSR (register)

Logical shift right (register)

This instruction shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This is an alias of LSRV. This means:

- The encodings in this description are named to match the encodings of LSRV.
- The description of LSRV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28							21	20				16	15				12	11	10	9				5	4				0
sf	0	0	1	1	0	1	0	1	1	0	Rm					0	0	1	0		0	1	Rn					Rd			
		S																			op2										

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
LSR  <Wd>, <Wn>, <Wm>
```

is equivalent to

```
LSRV  <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
LSR  <Xd>, <Xn>, <Xm>
```

is equivalent to

```
LSRV  <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

Operation

The description of LSRV gives the operational pseudocode for this instruction.

Operational Information

The description of LSRV gives the operational information for this instruction.

Non-Confidential

C6.2.273 LSR (immediate)

Logical shift right (immediate)

This instruction shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	1 0	1 0 0 1 1 0	N	immr	x 1 1 1 1 1	Rn	Rd
	opc				imms		

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0 && imms == 011111)`

```
LSR  <Wd>, <Wn>, #<shift>
```

is equivalent to

```
UBFM  <Wd>, <Wn>, #<shift>, #31
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1 && imms == 111111)`

```
LSR  <Xd>, <Xn>, #<shift>
```

is equivalent to

```
UBFM  <Xd>, <Xn>, #<shift>, #63
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<shift>

For the “32-bit” variant: is the shift amount, in the range 0 to 31, encoded in the “immr” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, encoded in the “immr” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

C6.2.274 LSRV

Logical shift right variable

This instruction shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This instruction is used by the alias LSR (register).

31	30	29	28							21	20				16	15				12	11	10	9				5	4				0
sf	0	0	1	1	0	1	0	1	1	0	Rm					0	0	1	0		0	1	Rn					Rd			
		S																				op2									

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
LSRV  <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
LSRV  <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(op2);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

C6.2.275 MADD

Multiply-add

This instruction multiplies two register values, adds a third register value, and writes the result to the destination register.

This instruction is used by the alias MUL.

31	30 29	28 24	23 21	20 16	15	14 10	9 5	4 0
sf	0 0	1 1 0 1 1	0 0 0	Rm	0	Ra	Rn	Rd
	op54		op31		o0			

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MADD  <Wd>, <Wn>, <Wm>, <Wa>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MADD  <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Wa>

Is the 32-bit name of the third general-purpose source register holding the addend, encoded in the “Ra” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xa>

Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the “Ra” field.

Alias Conditions

Alias	Is preferred when
MUL	Ra == '11111'

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let operand3 : bits(datasize) = X{datasize}(a);

let result : integer = UInt(operand3) + UInt(operand1) * UInt(operand2);

X{datasize}(d) = result[datasize-1:0];
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.276 MADDPT

Multiply-add checked pointer

This instruction multiplies two register values, adds a third register value, and writes the result to the destination register. The intermediate product is treated as the offset.

If the operation would have generated a result where the most significant 8 bits of the result register differ from the most significant 8 bits of the base register, then the result is modified such that it is likely to be non-canonical when used as an address.

If the intermediate product cannot be correctly represented as a 64-bit two's complement value, then the result is modified such that it is likely to be non-canonical when used as an address.

Integer

(FEAT_CPA)

31	30 29	28	27 25	24	23 21	20 16	15	14 10	9 5	4 0
1	0 0	1	1 0 1	1	0 1 1	Rm	0	Ra	Rn	Rd
sf	op54				op31		o0			

Encoding

```
MADDPT  <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CPA) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn>

Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Xm>

Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa>

Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

```
let operand1 : bits(64) = X{64}(n);
let operand2 : bits(64) = X{64}(m);
let operand3 : bits(64) = X{64}(a);

var result : bits(64);

let product : integer = SInt(operand1) * SInt(operand2);
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
// Signed and unsigned twos complement arithmetic are equivalent if only a
// fixed number of bits are considered.
result = operand3 + product[63:0];

let overflow : boolean = (product != SInt(product[63:0]));
result = PointerMultiplyAddCheck(result, operand3, overflow);

X{64}(d) = result;
```

C6.2.277 MNEG

Multiply-negate

This instruction multiplies two register values, negates the product, and writes the result to the destination register.

This is an alias of MSUB. This means:

- The encodings in this description are named to match the encodings of MSUB.
- The description of MSUB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 24	23 21	20 16	15	14 10	9 5	4 0
sf	0 0	1 1 0 1 1	0 0 0	Rm	1	1 1 1 1 1	Rn	Rd
	op54		op31		o0	Ra		

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MNEG  <Wd>, <Wn>, <Wm>
```

is equivalent to

```
MSUB  <Wd>, <Wn>, <Wm>, WZR
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MNEG  <Xd>, <Xn>, <Xm>
```

is equivalent to

```
MSUB  <Xd>, <Xn>, <Xm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xm>

Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

The description of MSUB gives the operational pseudocode for this instruction.

Operational Information

The description of MSUB gives the operational information for this instruction.

Non-Confidential

C6.2.278 MOV (to/from SP)

Move register value to or from SP

This instruction copies the value of a register to or from the stack pointer.

This is an alias of ADD (immediate). This means:

- The encodings in this description are named to match the encodings of ADD (immediate).
- The description of ADD (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MOV  <Wd|WSP>, <Wn|WSP>
```

is equivalent to

```
ADD  <Wd|WSP>, <Wn|WSP>, #0
```

and is the preferred disassembly when `Rd == '11111' || Rn == '11111'`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOV  <Xd|SP>, <Xn|SP>
```

is equivalent to

```
ADD  <Xd|SP>, <Xn|SP>, #0
```

and is the preferred disassembly when `Rd == '11111' || Rn == '11111'`.

Assembler Symbols

<Wd|WSP>

Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Wn|WSP>

Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

<Xd|SP>

Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

Operation

The description of ADD (immediate) gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operational Information

The description of ADD (immediate) gives the operational information for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.279 MOV (inverted wide immediate)

Move inverted wide immediate value

This instruction moves an inverted 16-bit immediate value to a register.

This is an alias of MOVN. This means:

- The encodings in this description are named to match the encodings of MOVN.
- The description of MOVN gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 23	22 21	20 5	4 0
sf	0 0	1 0 0 1 0 1	hw	imm16	Rd
	opc				

Encoding for the 32-bit variant

Applies when `(sf == 0 && hw == 0x)`

```
MOV  <Wd>, #<imm>
```

is equivalent to

```
MOVN  <Wd>, #<imm16>, LSL  #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00') && !IsOnes(imm16)`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOV  <Xd>, #<imm>
```

is equivalent to

```
MOVN  <Xd>, #<imm16>, LSL  #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<imm>

For the “32-bit” variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in “imm16:hw”, but excluding `0xFFFF0000` and `0x0000FFFF`.

For the “64-bit” variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in “imm16:hw”.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

The description of MOVN gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.280 MOV (wide immediate)

Move wide immediate value

This instruction moves a 16-bit immediate value to a register.

This is an alias of MOVZ. This means:

- The encodings in this description are named to match the encodings of MOVZ.
- The description of MOVZ gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 … 23	22 21	20 … 5	4 … 0
sf	1 0 (opc)	1 0 0 1 0 1	hw	imm16	Rd

Encoding for the 32-bit variant

Applies when `(sf == 0 && hw == 0x)`

```
MOV  <Wd>, #<imm>
```

is equivalent to

```
MOVZ  <Wd>, #<imm16>, LSL  #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOV  <Xd>, #<imm>
```

is equivalent to

```
MOVZ  <Xd>, #<imm16>, LSL  #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<imm>

For the “32-bit” variant: is a 32-bit immediate which can be encoded in “imm16:hw”.

For the “64-bit” variant: is a 64-bit immediate which can be encoded in “imm16:hw”.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

The description of MOVZ gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.281 MOV (bitmask immediate)

Move bitmask immediate value

This instruction writes a bitmask immediate value to a register.

This is an alias of ORR (immediate). This means:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The description of ORR (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	0 1	1 0 0 1 0 0	N	immr	imms	1 1 1 1 1	Rd
	opc					Rn	

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
MOV  <Wd|WSP>, #<imm>
```

is equivalent to

```
ORR  <Wd|WSP>, WZR, #<imm>
```

and is the preferred disassembly when `!MoveWidePreferred(sf, N, imms, immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOV  <Xd|SP>, #<imm>
```

is equivalent to

```
ORR  <Xd|SP>, XZR, #<imm>
```

and is the preferred disassembly when `!MoveWidePreferred(sf, N, imms, immr)`.

Assembler Symbols

<Wd|WSP>

Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<imm>

For the “32-bit” variant: is the bitmask immediate, encoded in “imms:immr”, but excluding values which could be encoded by MOVZ or MOVN.

For the “64-bit” variant: is the bitmask immediate, encoded in “N:imms:immr”, but excluding values which could be encoded by MOVZ or MOVN.

<Xd|SP>

Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

Operation

The description of ORR (immediate) gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operational Information

The description of ORR (immediate) gives the operational information for this instruction.

Non-Confidential

C6.2.282 MOV (register)

Move register value

This instruction copies the value in a source register to the destination register.

This is an alias of ORR (shifted register). This means:

- The encodings in this description are named to match the encodings of ORR (shifted register).
- The description of ORR (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 24	23 22	21	20 16	15 10	9 5	4 0
sf	0 1	0 1 0 1 0	0 0	0	Rm	0 0 0 0 0 0	1 1 1 1 1	Rd
	opc		shift	N		imm6	Rn	

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MOV  <Wd>, <Wm>
```

is equivalent to

```
ORR  <Wd>, WZR, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOV  <Xd>, <Xm>
```

is equivalent to

```
ORR  <Xd>, XZR, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wm>

Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xm>

Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.

Operation

The description of ORR (shifted register) gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operational Information

The description of ORR (shifted register) gives the operational information for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.283 MOVK

Move wide with keep

This instruction moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.

31	30 29	28 23	22 21	20 5	4 0
sf	1 1	1 0 0 1 0 1	hw	imm16	Rd
	opc				

Encoding for the 32-bit variant

Applies when `(sf == 0 && hw == 0x)`

```
MOVK  <Wd>, #<imm>{, LSL #<shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOVK  <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
if sf == '0' && hw[1] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let datasize : integer{} = 32 << UInt(sf);
let imm : bits(16) = imm16;
let pos : integer{} = UInt(hw) << 4;
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<imm>

Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

<shift>

For the “32-bit” variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the “hw” field as <shift>/16.

For the “64-bit” variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32, or 48, encoded in the “hw” field as <shift>/16.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

```
var result : bits(datasize) = X{datasize}(d);

result[pos+15:pos] = imm;

X{datasize}(d) = result;
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.284 MOVN

Move wide with NOT

This instruction moves the inverse of an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (inverted wide immediate).

31	30 29	28 23	22 21	20 5	4 0
sf	0 0	1 0 0 1 0 1	hw	imm16	Rd

opc

Encoding for the 32-bit variant

Applies when `(sf == 0 && hw == 0x)`

```
MOVN  <Wd>, #<imm>{, LSL #<shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOVN  <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
if sf == '0' && hw[1] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let datasize : integer{} = 32 << UInt(sf);
let imm : bits(16) = imm16;
let pos : integer{} = UInt(hw) << 4;
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<imm>

Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

<shift>

For the “32-bit” variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the “hw” field as <shift>/16.

For the “64-bit” variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32, or 48, encoded in the “hw” field as <shift>/16.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Alias Conditions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alias	Of variant	Is preferred when
MOV (inverted wide immediate)	32-bit	!(IsZero(imm16) && hw != '00') && !IsOnes(imm16)
MOV (inverted wide immediate)	64-bit	!(IsZero(imm16) && hw != '00')

Operation

```
var result : bits(datasize) = Zeros{};

result[pos+15:pos] = imm;

X{datasize}(d) = NOT result;
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.285 MOVZ

Move wide with zero

This instruction moves an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (wide immediate).

31	30 29	28 23	22 21	20 5	4 0
sf	1 0	1 0 0 1 0 1	hw	imm16	Rd
	opc				

Encoding for the 32-bit variant

Applies when `(sf == 0 && hw == 0x)`

```
MOVZ  <Wd>, #<imm>{, LSL #<shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOVZ  <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
if sf == '0' && hw[1] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let datasize : integer{} = 32 << UInt(sf);
let imm : bits(16) = imm16;
let pos : integer{} = UInt(hw) << 4;
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<imm>

Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

<shift>

For the “32-bit” variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the “hw” field as <shift>/16.

For the “64-bit” variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32, or 48, encoded in the “hw” field as <shift>/16.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Alias Conditions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alias	Is preferred when
MOV (wide immediate)	!(IsZero(imm16) && hw != '00')

Operation

```
var result : bits(datasize) = Zeros{};

result[pos+15:pos] = imm;

X{datasize}(d) = result;
```

C6.2.286 MRRS

Move System register to two adjacent general-purpose registers

This instruction allows the PE to read an AArch64 128-bit System register into two adjacent 64-bit general-purpose registers.

System

(FEAT_SYSREG128)

31–29	28–26	25–22	21	20	19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 1	1	1	o0	op1	CRn	CRm	op2	Rt
			L							

Encoding

```
MRRS  <Xt>, <Xt+1>, (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>)
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SYSREG128) then EndOfDecode(Decode_UNDEF); end;
if Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;

let t : integer       = UInt(Rt);
let t2 : integer      = UInt(Rt+1);
let sys_op0 : bits(2) = '1' :: o0;
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<Xt>

Is the 64-bit name of the first general-purpose destination register, encoded in the “Rt” field.

<Xt+1>

Is the 64-bit name of the second general-purpose destination register, encoded as “Rt” +1.

<systemreg>

Is a System register name, encoded in “o0:op1:CRn:CRm:op2”.

<op0>

Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<op1>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Cn>

Is a name ‘Cn’, with ‘n’ in the range 0 to 15, encoded in the “CRn” field.

<Cm>

Is a name ‘Cm’, with ‘m’ in the range 0 to 15, encoded in the “CRm” field.

<op2>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

Operation

```
AArch64_SysRegRead128(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t, t2);
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.287 MRS

Move System register to general-purpose register

This instruction allows the PE to read an AArch64 System register into a general-purpose register.

31–29	28–26	25–22	21	20	19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0	1	1	o0	op1	CRn	CRm	op2	Rt
			L							

Encoding

```
MRS  <Xt>, (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>)
```

Decode for this encoding

```
let t : integer       = UInt(Rt);
let sys_op0 : bits(2) = '1' :: o0;
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rt” field.

<systemreg>

Is a System register name, encoded in “o0:op1:CRn:CRm:op2”.

The System register names are defined in AArch64 System Register Descriptions.

<op0>

Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<op1>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

<Cn>

Is a name ‘Cn’, with ‘n’ in the range 0 to 15, encoded in the “CRn” field.

<Cm>

Is a name ‘Cm’, with ‘m’ in the range 0 to 15, encoded in the “CRm” field.

<op2>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

C6.2.288 MSR (immediate)

Move immediate value to special register

This instruction moves an immediate value to selected bits of the PSTATE. For more information, see Process state, PSTATE.

The bits that can be written by this instruction are:

- PSTATE.D, PSTATE.A, PSTATE.I, PSTATE.F, and PSTATE.SP.
- If FEAT_SSBS is implemented, PSTATE.SSBS.
- If FEAT_PAN is implemented, PSTATE.PAN.
- If FEAT_UAO is implemented, PSTATE.UAO.
- If FEAT_DIT is implemented, PSTATE.DIT.
- If FEAT_MTE is implemented, PSTATE.TCO.
- If FEAT_NMI is implemented, PSTATE.ALLINT.
- If FEAT_SME is implemented, PSTATE.SM and PSTATE.ZA.
- If FEAT_EBEP, FEAT_SPE_EXC, or FEAT_TRBE_EXC is implemented, PSTATE.PM.

If FEAT_MTE is implemented and FEAT_MTE2 is not implemented, it is IMPLEMENTATION DEFINED whether writes to PSTATE.TCO by this instruction are ignored.

This instruction is used by the aliases SMSTART and SMSTOP.

31–29	28–26	25–19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0	op1	0 1 0 0	CRm	op2	1 1 1 1 1 (Rt)

Encoding

Applies when `(!(op1 == 000 && op2 IN {00x, 010}))`

```
MSR  <pstatefield>, #<imm>
```

Decode for this encoding

```
if op1 == '000' && op2 == '000' then See("CFINV"); end;
if op1 == '000' && op2 == '001' then See("XAFLAG"); end;
if op1 == '000' && op2 == '010' then See("AXFLAG"); end;

var min_EL : bits(2);

C6.2.289 MSR (register)

Move general-purpose register to System register

This instruction allows the PE to write an AArch64 System register from a general-purpose register.

31–29	28–26	25–22	21	20	19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0	0	1	o0	op1	CRn	CRm	op2	Rt
			L							

Encoding

```
MSR  (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>), <Xt>
```

Decode for this encoding

```
let t : integer       = UInt(Rt);
let sys_op0 : bits(2) = '1' :: o0;
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<systemreg>

Is a System register name, encoded in “o0:op1:CRn:CRm:op2”.

The System register names are defined in AArch64 System Register Descriptions.

<op0>

Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<op1>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

<Cn>

Is a name ‘Cn’, with ‘n’ in the range 0 to 15, encoded in the “CRn” field.

<Cm>

Is a name ‘Cm’, with ‘m’ in the range 0 to 15, encoded in the “CRm” field.

<op2>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

<Xt>

Is the 64-bit name of the general-purpose source register, encoded in the “Rt” field.

C6.2.290 MSRR

Move two adjacent general-purpose registers to System register

This instruction allows the PE to write an AArch64 128-bit System register from two adjacent 64-bit general-purpose registers.

System

(FEAT_SYSREG128)

31 29	28 26	25 22	21	20	19	18 16	15 12	11 8	7 5	4 0
1 1 0	1 0 1	0 1 0 1	0	1	o0	op1	CRn	CRm	op2	Rt
			L							

Encoding

```
MSRR  (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>), <Xt>, <Xt+1>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SYSREG128) then EndOfDecode(Decode_UNDEF); end;
if Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;

let t : integer       = UInt(Rt);
let t2 : integer      = UInt(Rt+1);
let sys_op0 : bits(2) = '1' :: o0;
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<systemreg>

Is a System register name, encoded in “o0:op1:CRn:CRm:op2”.

<op0>

Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<op1>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

<Cn>

Is a name ‘Cn’, with ‘n’ in the range 0 to 15, encoded in the “CRn” field.

<Cm>

Is a name ‘Cm’, with ‘m’ in the range 0 to 15, encoded in the “CRm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<op2>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

<Xt>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rt” field.

<Xt+1>

Is the 64-bit name of the second general-purpose source register, encoded as “Rt” +1.

Operation

```
AArch64_SysRegWrite128(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t, t2);
```

C6.2.291 MSUB

Multiply-subtract

This instruction multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register.

This instruction is used by the alias MNEG.

31	30 29	28 24	23 21	20 16	15	14 10	9 5	4 0
sf	0 0	1 1 0 1 1	0 0 0	Rm	1	Ra	Rn	Rd
	op54		op31		o0			

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MSUB  <Wd>, <Wn>, <Wm>, <Wa>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MSUB  <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Wa>

Is the 32-bit name of the third general-purpose source register holding the minuend, encoded in the “Ra” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xa>

Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the “Ra” field.

Alias Conditions

Alias	Is preferred when
MNEG	Ra == '11111'

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let operand3 : bits(datasize) = X{datasize}(a);

let result : integer = UInt(operand3) - UInt(operand1) * UInt(operand2);

X{datasize}(d) = result[datasize-1:0];
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.292 MSUBPT

Multiply-subtract checked pointer

This instruction multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register. The intermediate product is treated as the offset.

If the operation would have generated a result where the most significant 8 bits of the result register differ from the most significant 8 bits of the base register, then the result is modified such that it is likely to be non-canonical when used as an address.

If the intermediate product cannot be correctly represented as a 64-bit two's complement value, then the result is modified such that it is likely to be non-canonical when used as an address.

Integer

(FEAT_CPA)

Encoding

```
MSUBPT  <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CPA) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn>

Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Xm>

Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa>

Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

```
let operand1 : bits(64) = X{64}(n);
let operand2 : bits(64) = X{64}(m);
let operand3 : bits(64) = X{64}(a);

var result : bits(64);

let product : integer = SInt(operand1) * SInt(operand2);
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
// Signed and unsigned twos complement arithmetic are equivalent if only a
// fixed number of bits are considered.
result = operand3 - product[63:0];

let overflow : boolean = (product != SInt(product[63:0]));
result = PointerMultiplyAddCheck(result, operand3, overflow);

X{64}(d) = result;
```

C6.2.293 MUL

Multiply

This instruction multiplies two register values and writes the result to the destination register.

This is an alias of MADD. This means:

- The encodings in this description are named to match the encodings of MADD.
- The description of MADD gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 24	23 21	20 16	15	14 10	9 5	4 0
sf	0 0	1 1 0 1 1	0 0 0	Rm	0	1 1 1 1 1	Rn	Rd
	op54		op31		o0	Ra		

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MUL  <Wd>, <Wn>, <Wm>
```

is equivalent to

```
MADD  <Wd>, <Wn>, <Wm>, WZR
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MUL  <Xd>, <Xn>, <Xm>
```

is equivalent to

```
MADD  <Xd>, <Xn>, <Xm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xm>

Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

The description of MADD gives the operational pseudocode for this instruction.

Operational Information

The description of MADD gives the operational information for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.294 MVN

Bitwise NOT

This instruction writes the bitwise inverse of a register value to the destination register.

This is an alias of ORN (shifted register). This means:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 24	23 22	21	20 16	15 10	9 5	4 0
sf	0 1	0 1 0 1 0	shift	1	Rm	imm6	1 1 1 1 1	Rd
	opc			N			Rn	

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MVN  <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ORN  <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MVN  <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ORN  <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wm>

Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.

<shift>

Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

shift	<shift>
01	LSR
10	ASR
11	ROR

<amount>

For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xm>

Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.

Operation

The description of ORN (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of ORN (shifted register) gives the operational information for this instruction.

Non-Confidential

C6.2.295 NEG (shifted register)

Negate (shifted register)

This instruction negates an optionally-shifted register value, and writes the result to the destination register.

This is an alias of SUB (shifted register). This means:

- The encodings in this description are named to match the encodings of SUB (shifted register).
- The description of SUB (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
NEG  <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUB  <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
NEG  <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUB  <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wm>

Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.

<shift>

Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

shift	<shift>
01	LSR
10	ASR
11	RESERVED

<amount>

For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xm>

Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.

Operation

The description of SUB (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of SUB (shifted register) gives the operational information for this instruction.

C6.2.296 NEGS

Negate, setting flags

This instruction negates an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	24	23 22	21	20	16	15	10	9	5	4	0
sf	1	1	0 1 0 1 1		shift	0	Rm		imm6		1 1 1 1 1		!=11111	
	op	S										Rn		Rd

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
NEGS  <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS  <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
NEGS  <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS  <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wm>

Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.

<shift>

Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

C6.2.297 NGC

Negate with carry

This instruction negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register.

This is an alias of SBC. This means:

- The encodings in this description are named to match the encodings of SBC.
- The description of SBC gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28							21	20				16	15						10	9				5	4				0
sf	1	0	1	1	0	1	0	0	0	0	Rm					0	0	0	0	0	0		1	1	1	1	1	Rd				
	op	S																							Rn							

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
NGC  <Wd>, <Wm>
```

is equivalent to

```
SBC  <Wd>, WZR, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
NGC  <Xd>, <Xm>
```

is equivalent to

```
SBC  <Xd>, XZR, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wm>

Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xm>

Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.

Operation

The description of SBC gives the operational pseudocode for this instruction.

C6.2.299 NOP

No operation

This instruction does nothing, other than advance the value of the program counter by 4. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a `NOP` instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, `NOP` instructions are not suitable for timing loops.

31–29	28–26	25–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 0	0 0 0 0 (CRm)	0 0 0 (op2)	1 1 1 1 1

Encoding

```
NOP
```

Decode for this encoding

```
// Empty.
```

Operation

```
return; // Do nothing
```

C6.2.300 ORN (shifted register)

Bitwise OR NOT (shifted register)

This instruction performs a bitwise (inclusive) OR between a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MVN.

31	30 29	28 24	23 22	21	20 16	15 10	9 5	4 0
sf	0 1 (opc)	0 1 0 1 0	shift	1 (N)	Rm	imm6	Rn	Rd

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ORN  <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ORN  <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

shift	<shift>
01	LSR
10	ASR
11	ROR

<amount>

For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
MVN	Rn == '11111'

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 OR NOT operand2;

X{datasize}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

C6.2.301 ORR (immediate)

Bitwise OR (immediate)

This instruction performs a bitwise (inclusive) OR between a register value and an immediate value, and writes the result to the destination register.

This instruction is used by the alias MOV (bitmask immediate).

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	0 1 (opc)	1 0 0 1 0 0	N	immr	imms	Rn	Rd

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
ORR  <Wd|WSP>, <Wn>, #<imm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ORR  <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
if sf == '0' && N != '0' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
var imm : bits(datasize);
(imm, -) = DecodeBitMasks{datasize}(N, imms, immr, TRUE);
```

Assembler Symbols

<Wd|WSP>

Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<imm>

Is the bitmask immediate. For encoding information, see Logical (immediate).

<Xd|SP>

Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alias Conditions

Alias	Is preferred when
MOV (bitmask immediate)	Rn == '11111' && !MoveWidePreferred(sf, N, imms, immr)

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = imm;
let result : bits(datasize) = operand1 OR operand2;

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.302 ORR (shifted register)

Bitwise OR (shifted register)

This instruction performs a bitwise (inclusive) OR between a register value and an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MOV (register).

31	30 29	28 24	23 22	21	20 16	15 10	9 5	4 0
sf	0 1 (opc)	0 1 0 1 0	shift	0 (N)	Rm	imm6	Rn	Rd

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ORR  <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ORR  <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

shift	<shift>
01	LSR
10	ASR
11	ROR

<amount>

For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
MOV (register)	shift == '00' && imm6 == '000000' && Rn == '11111'

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 OR operand2;

X{datasize}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.303 PACDA, PACDZA

Pointer Authentication Code for data address, using key A

This instruction calculates and inserts a Pointer Authentication Code for a data address, using a modifier and key A.

The address is in the general-purpose register that is specified by `<Xd>`.

The modifier is:

- In the general-purpose register or stack pointer that is specified by `<Xn|SP>` for `PACDA`.
- The value zero, for `PACDZA`.

Integer

(FEAT_PAuth)

31	30	29	28							21	20				16	15	14	13	12		10	9	5	4	0
1	1	0	1	1	0	1	0	1	1	0	0	0	0	0	1	0	0	Z	0	1	0	Rn		Rd	
sf		S									opcode2														

Encoding for the PACDA variant

Applies when `(Z == 0)`

```
PACDA  <Xd>, <Xn|SP>
```

Encoding for the PACDZA variant

Applies when `(Z == 1 && Rn == 11111)`

```
PACDZA  <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

var source_is_sp : boolean = FALSE;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);

if Z == '0' then // PACDA
    if n == 31 then source_is_sp = TRUE; end;
else // PACDZA
    if n != 31 then EndOfDecode(Decode_UNDEF); end;
end;
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the “Rn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
if source_is_sp then
    X{64}(d) = AddPACDA(X{64}(d), SP{64}());
else
    X{64}(d) = AddPACDA(X{64}(d), X{64}(n));
end;
```

C6.2.304 PACDB, PACDZB

Pointer Authentication Code for data address, using key B

This instruction calculates and inserts a Pointer Authentication Code for a data address, using a modifier and key B.

The address is in the general-purpose register that is specified by `<Xd>`.

The modifier is:

- In the general-purpose register or stack pointer that is specified by `<Xn|SP>` for `PACDB`.
- The value zero, for `PACDZB`.

Integer

(FEAT_PAuth)

31	30	29	28							21	20				16	15	14	13	12		10	9	5	4	0
1	1	0	1	1	0	1	0	1	1	0	0	0	0	0	1	0	0	Z	0	1	1	Rn		Rd	
sf		S									opcode2														

Encoding for the PACDB variant

Applies when `(Z == 0)`

```
PACDB  <Xd>, <Xn|SP>
```

Encoding for the PACDZB variant

Applies when `(Z == 1 && Rn == 11111)`

```
PACDZB  <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

var source_is_sp : boolean = FALSE;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);

if Z == '0' then // PACDB
    if n == 31 then source_is_sp = TRUE; end;
else // PACDZB
    if n != 31 then EndOfDecode(Decode_UNDEF); end;
end;
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the “Rn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

C6.2.305 PACGA

Pointer Authentication Code, using generic key

This instruction calculates the Pointer Authentication Code for a 64-bit value in the first source register, using a modifier in the second source register, and the generic key. The calculated Pointer Authentication Code is written to the most significant 32 bits of the destination register, and the least significant 32 bits of the destination register are set to zero.

Integer

(FEAT_PAuth)

31	30	29	28	27 25	24 21	20 16	15 10	9 5	4 0
1	0	0	1	1 0 1	0 1 1 0	Rm	0 0 1 1 0 0	Rn	Rd
sf		S					opcode		

Encoding

```
PACGA  <Xd>, <Xn>, <Xm|SP>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let source_is_sp : boolean = m == 31;
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm|SP>

Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the “Rm” field.

Operation

```
if source_is_sp then
    X{64}(d) = AddPACGA(X{64}(n), SP{64}());
else
    X{64}(d) = AddPACGA(X{64}(n), X{64}(m));
end;
```

C6.2.306 PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA

Pointer Authentication Code for instruction address, using key A

This instruction calculates and inserts a Pointer Authentication Code for an instruction address, using a modifier and key A.

The address is:

- In the general-purpose register that is specified by `<Xd>` for `PACIA` and `PACIZA`.
- In X17, for `PACIA1716`.
- In X30, for `PACIASP` and `PACIAZ`.

The modifier is:

- In the general-purpose register or stack pointer that is specified by `<Xn|SP>` for `PACIA`.
- The value zero, for `PACIZA` and `PACIAZ`.
- In X16, for `PACIA1716`.
- In SP, for `PACIASP`.

If FEAT_PAuth_LR is implemented and PSTATE.PACM is 1, then `PACIA1716` and `PACIASP` include a second modifier that is:

- In X15, for `PACIA1716`.
- The value of PC, for `PACIASP`.

A `PACIASP` instruction has an implicit `BTI` instruction. The implicit `BTI` instruction of a `PACIASP` instruction is always compatible with PSTATE.BTYPE == `0b01` and PSTATE.BTYPE == `0b10`. Controls in SCTLR_ELx configure whether the implicit `BTI` instruction of a `PACIASP` instruction is compatible with PSTATE.BTYPE == `0b11`. For more information, see PSTATE.BTYPE.

It has encodings from 2 classes: Integer and System

C6.2.315 PRFM (immediate)

Prefetch memory (immediate)

This instruction provides a hint to the memory system.

The `PRFM IR` variant of this instruction signals to the memory system that the thread of execution on the current PE will read a location that might not yet have been updated with the value the thread needs, and that the memory system should optimize for low-latency delivery of that value when the write by the other observer does occur.

The other variants of this instruction signal to the memory system that memory accesses to a location are likely to occur soon. The memory system can respond by taking actions that are expected to speed up the memory access when it does occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

For all variants of this instruction, the address for memory accesses is calculated from a base register value and an immediate offset.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - When FEAT_PCDPHINT is implemented, IR for intent to read on update.
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
  - When FEAT_PRFMSLC is implemented, SLC for system level cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a `PRFM` instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

For information about addressing modes, see Load/Store addressing modes.

31 30	29 28	27	26	25	24	23 22	21 … 10	9 … 5	4 … 0
1 1	1 1	1	0	0	1	1 0	imm12	Rn	Rt
size			VR			opc			

Encoding

```
PRFM  (<prfop>|#<imm5>), [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 3);
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = FALSE;
```

Assembler Symbols

C6.2.316 PRFM (literal)

Prefetch memory (literal)

This instruction signals to the memory system that memory accesses to a location are likely to occur soon. The memory system can respond by taking actions that are expected to speed up the memory access when it does occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

The address for memory accesses is calculated from the PC value and an immediate offset.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
  - When FEAT_PRFMSLC is implemented, SLC for system level cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a `PRFM` instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

For information about addressing modes, see Load/Store addressing modes.

C6.2.317 PRFM (register)

Prefetch memory (register)

This instruction signals to the memory system that memory accesses to a location are likely to occur soon. The memory system can respond by taking actions that are expected to speed up the memory access when it does occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

The address for memory accesses is calculated from a base register value and an offset register value. The offset register value can optionally be shifted and extended.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
  - When FEAT_PRFMSLC is implemented, SLC for system level cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a `PRFM` instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

For information about addressing modes, see Load/Store addressing modes.

C6.2.318 PRFUM

Prefetch memory (unscaled offset)

This instruction signals to the memory system that memory accesses to a location are likely to occur soon. The memory system can respond by taking actions that are expected to speed up the memory access when it does occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

The address for memory accesses is calculated from a base register value and a signed, unscaled immediate offset.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
  - When FEAT_PRFMSLC is implemented, SLC for system level cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a `PRFUM` instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

For information about addressing modes, see Load/Store addressing modes.

C6.2.319 PSB

Profiling synchronization barrier

This instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. For information about the synchronization behavior when a `DSB` instruction follows a `PSB` instruction in program order, see Synchronization and Statistical Profiling.

If FEAT_SPE is not implemented, this instruction executes as a `NOP`.

System

(FEAT_SPE)

31–29	28–26	25–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 0	0 0 1 0 (CRm)	0 0 1 (op2)	1 1 1 1 1

Encoding

```
PSB  CSYNC
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SPE) then EndOfDecode(Decode_NOP); end;
```

Operation

```
CheckPSBTrap();

ProfilingSynchronizationBarrier();
```

C6.2.320 PSSBB

Physical speculative store bypass barrier

This instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions. For more information and details of the semantics, see Physical Speculative Store Bypass Barrier (PSSBB).

This is an alias of DSB. This means:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31–29	28–26	25–12	11–8	7	6–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 1	0 1 0 0	1	0 0	1 1 1 1 1
			CRm		opc	Rt

Encoding

```
PSSBB
```

is equivalent to

```
DSB   #4
```

and is always the preferred disassembly.

Operation

The description of DSB gives the operational pseudocode for this instruction.

C6.2.321 RBIT

Reverse bits

This instruction reverses the bit order in a register.

31	30	29	28							21	20					16	15						10	9				5	4				0
sf	1	0	1	1	0	1	0	1	1	0	0	0	0	0	0		0	0	0	0	0	0		Rn					Rd				
		S									opcode2										opcode												

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
RBIT  <Wd>, <Wn>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
RBIT  <Xd>, <Xn>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

```
let operand : bits(datasize) = X{datasize}(n);
var result : bits(datasize);

for i = 0 to datasize-1 do
    result[(datasize-1)-i] = operand[i];
end;

X{datasize}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.322 RCWCAS, RCWCASA, RCWCASAL, RCWCASL

Read check write compare and swap doubleword in memory

This instruction reads a 64-bit doubleword from memory, and compares it against the value held in a register. If the comparison is equal, the value in a second register is conditionally written to memory. Storing back to memory is conditional on RCW Checks. If the compare fails or the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the update of memory.

- If the destination register is not `XZR`, `RCWCASA` and `RCWCASAL` load from memory with acquire semantics.
  - `RCWCASL` and `RCWCASAL` store to memory with release semantics.
  - `RCWCAS` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

Integer

C6.2.323 RCWCASP, RCWCASPA, RCWCASPAL, RCWCASPL

Read check write compare and swap quadword in memory

This instruction reads a 128-bit quadword from memory, and compares it against the value held in a pair of registers. If the comparison is equal, the value in a second pair of registers is conditionally written to memory. Storing back to memory is conditional on RCW Checks. If the compare fails or the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the update of memory.

- `RCWCASPA` and `RCWCASPAL` load from memory with acquire semantics.
  - `RCWCASPL` and `RCWCASPAL` store to memory with release semantics.
  - `RCWCASP` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

Integer

C6.2.324 RCWCLR, RCWCLRA, RCWCLRAL, RCWCLRL

Read check write atomic bit clear on doubleword in memory

This instruction atomically loads a 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and conditionally stores the result back to memory. Storing of the result back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the destination register. If the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the RCW Checks.

- If the destination register is not `XZR`, `RCWCLRA` and `RCWCLRAL` load from memory with acquire semantics.
  - `RCWCLRL` and `RCWCLRAL` store to memory with release semantics.
  - `RCWCLR` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

C6.2.325 RCWCLRP, RCWCLRPA, RCWCLRPAL, RCWCLRPL

Read check write atomic bit clear on quadword in memory

This instruction atomically loads a 128-bit quadword from memory, performs a bitwise AND with the complement of the value held in a pair of registers on it, and conditionally stores the result back to memory.
Storing of the result back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the same pair of registers. If the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the RCW Checks.

- `RCWCLRPA` and `RCWCLRPAL` load from memory with acquire semantics.
  - `RCWCLRPL` and `RCWCLRPAL` store to memory with release semantics.
  - `RCWCLRP` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

C6.2.330 RCWSET, RCWSETA, RCWSETAL, RCWSETL

Read check write atomic bit set on doubleword in memory

This instruction atomically loads a 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and conditionally stores the result back to memory. Storing of the result back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the destination register. If the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the RCW Checks.

- If the destination register is not `XZR`, `RCWSETA` and `RCWSETAL` load from memory with acquire semantics.
  - `RCWSETL` and `RCWSETAL` store to memory with release semantics.
  - `RCWSET` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

C6.2.336 RCWSWP, RCWSWPA, RCWSWPAL, RCWSWPL

Read check write swap doubleword in memory

This instruction atomically loads a 64-bit doubleword from a memory location, and conditionally stores the value held in a register back to the same memory location. Storing back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the destination register. If the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the RCW Checks.

- If the destination register is not `XZR`, `RCWSWPA` and `RCWSWPAL` load from memory with acquire semantics.
  - `RCWSWPL` and `RCWSWPAL` store to memory with release semantics.
  - `RCWSWP` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

C6.2.338 RET

Return from subroutine

This instruction branches unconditionally to an address in a register. This instruction provides a hint that this is a subroutine return.

31	29	28	26	25	24	23	22	21	20	16	15	12	11	10	9	5	4	0
1 1 0		1 0 1		1	0	0	1	0	1 1 1 1 1		0 0 0 0		0	0	Rn		0 0 0 0 0	
					Z			op	op2				A	M				Rm

Encoding

```
RET  {<Xn>}
```

Decode for this encoding

```
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xn>

Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the “Rn” field. Defaults to X30 if absent.

Operation

```
var target : bits(64) = X{}(n);
if IsFeatureImplemented(FEAT_GCS) && GCSPCREnabled(PSTATE.EL) then
    target = LoadCheckGCSRecord(target, GCSInstType_PRET);
    SetCurrentGCSPointer(GetCurrentGCSPointer() + 8);
end;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '00';

C6.2.339 RETAA, RETAB

Return from subroutine, with pointer authentication

This instruction authenticates the address that is held in LR, using SP as the modifier and the specified key, and branches to the authenticated address.

Key A is used for `RETAA`. Key B is used for `RETAB`.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The authenticated address is not written back to LR.

This instruction provides a hint that this is a subroutine return.

If FEAT_PAuth_LR is implemented and PSTATE.PACM is 1, then `RETAA` and `RETAB` include a second modifier that is in X16.

Integer

(FEAT_PAuth)

C6.2.340 RETAASPPC, RETABSPPC

Return from subroutine, with enhanced pointer authentication using an immediate offset

This instruction authenticates the address that is held in LR, using SP as the first modifier, the specified immediate subtracted from PC as the second modifier, and the specified key, and branches to the authenticated address.

Key A is used for `RETAASPPC`. Key B is used for `RETABSPPC`.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The authenticated address is not written back to LR.

This instruction provides a hint that this is a subroutine return.

C6.2.345 REV64

Reverse bytes

This instruction reverses the byte order in a 64-bit general-purpose register.

When assembling for Armv8.2, an assembler must support this pseudo-instruction. It is OPTIONAL whether an assembler supports this pseudo-instruction when assembling for an architecture earlier than Armv8.2.

This is a pseudo-instruction of REV. This means:

- The encodings in this description are named to match the encodings of REV.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of REV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27 25	24 21	20 16	15 12	11 10	9 5	4 0
1	1	0	1	1 0 1	0 1 1 0	0 0 0 0 0	0 0 0 0	1 1	Rn	Rd
sf		S				opcode2		opc		

Encoding

```
REV64  <Xd>, <Xn>
```

is equivalent to

```
REV  <Xd>, <Xn>
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of REV gives the operational pseudocode for this instruction.

Operational Information

The description of REV gives the operational information for this instruction.

C6.2.346 RMIF

Rotate, mask insert flags

This instruction performs a rotation right of a value held in a general-purpose register by an immediate value, and then inserts a selection of the bottom four bits of the result of the rotation into the PSTATE flags, under the control of a second immediate mask.

Integer

(FEAT_FlagM)

Encoding

```
RMIF  <Xn>, #<shift>, #<mask>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_FlagM) then EndOfDecode(Decode_UNDEF); end;
let imm : integer{} = UInt(imm6);
let flagmask : bits(4) = mask;
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

<shift>

Is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<mask>

Is the flag bit mask, an immediate in the range 0 to 15, which selects the bits that are inserted into the NZCV condition flags, encoded in the “mask” field.

Operation

```
let reg : bits(64) = X{64}(n);
let flags : bits(4) = (reg::reg)[imm+3:imm];
if flagmask[3] == '1' then PSTATE.N = flags[3]; end;
if flagmask[2] == '1' then PSTATE.Z = flags[2]; end;
if flagmask[1] == '1' then PSTATE.C = flags[1]; end;
if flagmask[0] == '1' then PSTATE.V = flags[0]; end;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.347 ROR (immediate)

Rotate right (immediate)

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This is an alias of EXTR. This means:

- The encodings in this description are named to match the encodings of EXTR.
- The description of EXTR gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28					23	22	21	20					16	15					10	9				5	4				0
sf	0	0	1	0	0	1	1	1	N	0	Rm						imms						Rn					Rd				
	op21									o0																						

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0 && imms == 0xxxxx)`

```
ROR  <Wd>, <Ws>, #<shift>
```

is equivalent to

```
EXTR  <Wd>, <Ws>, <Ws>, #<shift>
```

and is the preferred disassembly when `Rn == Rm`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
ROR  <Xd>, <Xs>, #<shift>
```

is equivalent to

```
EXTR  <Xd>, <Xs>, <Xs>, #<shift>
```

and is the preferred disassembly when `Rn == Rm`.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Ws>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” and “Rm” fields.

<shift>

For the “32-bit” variant: is the amount by which to rotate, in the range 0 to 31, encoded in the “imms” field.

For the “64-bit” variant: is the amount by which to rotate, in the range 0 to 63, encoded in the “imms” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xs>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” and “Rm” fields.

C6.2.348 ROR (register)

Rotate right (register)

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This is an alias of RORV. This means:

- The encodings in this description are named to match the encodings of RORV.
- The description of RORV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28							21	20				16	15				12	11	10	9				5	4				0
sf	0	0	1	1	0	1	0	1	1	0	Rm					0	0	1	0		1	1	Rn					Rd			
		S																				op2									

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ROR  <Wd>, <Wn>, <Wm>
```

is equivalent to

```
RORV  <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ROR  <Xd>, <Xn>, <Xm>
```

is equivalent to

```
RORV  <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

C6.2.349 RORV

Rotate right variable

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ROR (register).

31	30	29	28							21	20				16	15				12	11	10	9				5	4				0
sf	0	0	1	1	0	1	0	1	1	0	Rm					0	0	1	0		1	1	Rn					Rd			
		S																			op2										

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
RORV  <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
RORV  <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(op2);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

Non-Confidential

C6.2.350 RPRFM

Range prefetch memory

This instruction signals the memory system that data memory accesses from a specified range of addresses are likely to occur in the near future. The instruction may also signal the memory system about the likelihood of data reuse of the specified range of addresses. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as prefetching locations within the specified address ranges into one or more caches. The memory system may also exploit the data reuse hints to decide whether to retain the data in other caches upon eviction from the innermost caches or to discard it.

The effect of an `RPRFM` instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

An `RPRFM` instruction specifies the type of accesses and range of addresses using the following parameters:

- ‘Access type’, encoded in `Rt<0>`, specifies:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- ‘Policy’, encoded in `Rt<2:1>`, specifies:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once. If a streaming prefetch is specified, then the ‘ReuseDistance’ parameter is ignored.
- ‘BaseAddress’, in the 64-bit base register, holds the initial block address for the accesses.
- ‘ReuseDistance’, in the metadata register bits[63:60], indicates the maximum number of bytes to be accessed by this PE before executing the next `RPRFM` instruction that specifies the same range. This includes the total number of bytes inside and outside of the range that will be accessed by the same PE. This parameter can be used to influence cache eviction and replacement policies, in order to retain the data in the most optimal levels of the memory hierarchy after each access. If software cannot easily determine the amount of other memory that will be accessed, these bits can be set to zero to indicate that ‘ReuseDistance’ is not known. Otherwise, these four bits encode decreasing powers of two in the range 512MiB (`0b0001`) to 32KiB (`0b1111`).
- ‘Stride’, in the metadata register bits[59:38], is a signed, two’s complement integer encoding of the number of bytes to advance the block address after ‘Length’ bytes have been accessed, in the range -2MiB to +2MiB-1B. A negative value indicates that the block address is advanced in a descending direction.
- ‘Count’, in the metadata register bits[37:22], is an unsigned integer encoding of the number of blocks of data to be accessed minus 1, representing the range 1 to 65536 blocks. If ‘Count’ is 0, then the ‘Stride’ parameter is ignored and only a single block of contiguous bytes from ‘BaseAddress’ to (‘BaseAddress’ + ‘Length’ - 1) is described.
- ‘Length’, in the metadata register bits[21:0], is a signed, two’s complement integer encoding of the number of contiguous bytes to be accessed starting from the current block address, without changing the block address, in the range -2MiB to +2MiB-1B. A negative value indicates that the bytes are accessed in a descending direction.

Note

Software is expected to honor the parameters it provides to the `RPRFM` instruction, and the same PE should access all locations in the range, in the direction specified by the sign of the ‘Length’ and ‘Stride’ parameters. A range prefetch is considered active on a PE until all locations in the range have been accessed by the PE. A range prefetch might also be inactivated by the PE prior to completion, for example due to a software context switch or lack of hardware resources.
Software should not specify overlapping addresses in multiple active ranges. If a range is expected to be accessed by both load and store instructions (read-modify-write), then a single range with an ‘Access type’ parameter of `PST` (prefetch for store) should be specified.

Integer

(FEAT_RPRFM)

31	30	29	28	27	26	25	24	23	22	21	20 … 16	15	14	13	12	11	10	9 … 5	4	3	2	1	0
1	1	1	1	1	0	0	0	1	0	1	Rm	x	1	x	S	1	0	Rn	1	1	x	x	x
size					VR			opc				option							Rt				

Encoding

Non-Confidential

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_RPRFM) then EndOfDecode(Decode_NOP); end;
let operation : bits(6) = option[2]::option[0]::S::Rt[2:0];
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
```

Assembler Symbols

<rprfop>

Is the range prefetch operation, encoded in “option:S:Rt”:

option	S	Rt	<rprfop>
010	0	11000	PLDKEEP
010	0	11001	PSTKEEP
010	0	11100	PLDSTRM
010	0	11101	PSTSTRM

For other encodings, use <imm6>.

<imm6>

Is the range prefetch operation encoding as an immediate, in the range 0 to 63, encoded in “option<2>:option<0>:S:Rt<2:0>”. This syntax is only for encodings that are not representable using `<rprfop>`.

<Xm>

Is the 64-bit name of the general-purpose register that holds an encoding of the metadata, encoded in the “Rm” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Operation

```
let address : bits(64)  = if n == 31 then SP{64}() else X{64}(n);
let metadata : bits(64) = X{}(m);
let stride : integer = SInt(metadata[59:38]);
let count : integer  = UInt(metadata[37:22]) + 1;
let length : integer = SInt(metadata[21:0]);
var reuse : integer;

if metadata[63:60] == '0000' then
    reuse = -1; // Not known
else
    reuse = 32768 << (15 - UInt(metadata[63:60]));
end;

Hint_RangePrefetch(address, length, stride, count, reuse, operation);
```

C6.2.354 SBFIZ

Signed bitfield insert in zeros

This instruction copies a bitfield of `<width>` bits from the least significant bits of the source register to bit position `<lsb>` of the destination register, setting the destination bits below the bitfield to zero, and the bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	0 0	1 0 0 1 1 0	N	immr	imms	Rn	Rd
	opc						

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
SBFIZ  <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM  <Wd>, <Wn>, #(-<lsb>  MOD  32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
SBFIZ  <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM  <Xd>, <Xn>, #(-<lsb>  MOD  64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<lsb>

For the “32-bit” variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.

For the “64-bit” variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<width>

For the “32-bit” variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the “64-bit” variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

C6.2.355 SBFM

Signed bitfield move

This instruction is usually accessed using one of its aliases, which are always preferred for disassembly.

If `<imms>` is greater than or equal to `<immr>`, this copies a bitfield of (`<imms>`-`<immr>`+1) bits starting from bit position `<immr>` in the source register to the least significant bits of the destination register.

If `<imms>` is less than `<immr>`, this copies a bitfield of (`<imms>`+1) bits from the least significant bits of the source register to bit position (regsize-`<immr>`) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases, the destination bits below the bitfield are set to zero, and the bits above the bitfield are set to a copy of the most significant bit of the bitfield.

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	0 0	1 0 0 1 1 0	N	immr	imms	Rn	Rd
	opc						

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
SBFM  <Wd>, <Wn>, #<immr>, #<imms>
```

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
SBFM  <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
if sf == '1' && N != '1' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && (N != '0' || immr[5] != '0' || imms[5] != '0') then
    EndOfDecode(Decode_UNDEF);
end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let s : integer = UInt(imms);
let r : integer = UInt(immr);

var wmask : bits(datasize);
var tmask : bits(datasize);
(wmask, tmask) = DecodeBitMasks{datasize}(N, imms, immr, FALSE);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<immr>

For the “32-bit” variant: is the right rotate amount, in the range 0 to 31, encoded in the “immr” field.

For the “64-bit” variant: is the right rotate amount, in the range 0 to 63, encoded in the “immr” field.

<imms>

For the “32-bit” variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the “imms” field.

For the “64-bit” variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the “imms” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Alias Conditions

Alias	Of variant	Is preferred when
ASR (immediate)	32-bit	imms == '011111'
ASR (immediate)	64-bit	imms == '111111'
SBFIZ		UInt(imms) < UInt(immr)
SBFX		BFXPreferred(sf, opc<1>, imms, immr)
SXTB		immr == '000000' && imms == '000111'
SXTH		immr == '000000' && imms == '001111'
SXTW		immr == '000000' && imms == '011111'

Operation

```
let src : bits(datasize) = X{}(n);

// Perform bitfield move on low bits
let bot : bits(datasize) = ROR(src, r) AND wmask;
let top : bits(datasize) = Replicate{}(src[s]);

// Combine extension bits and result bits
X{datasize}(d) = (top AND NOT tmask) OR (bot AND tmask);
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.356 SBFX

Signed bitfield extract

This instruction copies a bitfield of `<width>` bits starting from bit position `<lsb>` in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	0 0 (opc)	1 0 0 1 1 0	N	immr	imms	Rn	Rd

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
SBFX  <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM  <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc[1], imms, immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
SBFX  <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM  <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc[1], imms, immr)`.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<lsb>

For the “32-bit” variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.

For the “64-bit” variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.

<width>

For the “32-bit” variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the “64-bit” variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

C6.2.357 SDIV (quotient)

Signed divide

This instruction divides the first signed source register value by the second signed source register value, and writes the result to the destination register. Dividing by zero writes the value zero to the destination register. The condition flags are not affected.

31	30	29	28	21	20	16	15	11	10	9	5	4	0
sf	0	0	1 1 0 1 0 1 1 0		Rm		0 0 0 0 1		1	Rn		Rd	
		S							o1				

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SDIV  <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SDIV  <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

C6.2.358 SETF8, SETF16

Evaluation of 8-bit or 16-bit flag values

This instruction sets the PSTATE.NZV flags based on the value in the specified general-purpose register. `SETF8` treats the value as an 8-bit value. `SETF16` treats the value as a 16-bit value.

The PSTATE.C flag is not affected by these instructions.

Integer

(FEAT_FlagM)

Encoding for the SETF8 variant

Applies when `(sz == 0)`

```
SETF8  <Wn>
```

Encoding for the SETF16 variant

Applies when `(sz == 1)`

```
SETF16  <Wn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FlagM) then EndOfDecode(Decode_UNDEF); end;
let size : integer{} = 8 << UInt(sz);
let n : integer = UInt(Rn);
```

Assembler Symbols

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

```
let reg : bits(32) = X{32}(n);
PSTATE.N = reg[size-1];
PSTATE.Z = if reg[size-1:0] == Zeros{size} then '1' else '0';
PSTATE.V = reg[size] XOR reg[size-1];
//PSTATE.C unchanged;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

C6.2.359 SETGP, SETGM, SETGE

Memory set with tag setting

These instructions set a requested number of bytes in memory to the value in the least significant byte of the source data register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register that holds the first address to be set. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGP, then SETGM, and then SETGE.

SETGP performs some preconditioning of the arguments suitable for using the SETGM instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETGM sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETGE sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETGP:

- If Xn[63] == ‘1’, the set size is saturated to `0x7FFFFFFFFFFFFFF0`.

On completion of SETGP, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETGP, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETGM, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETGM, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETGE, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On completion of the instruction, Xn holds 0.

For SETGE, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

Integer

(FEAT_MOPS && FEAT_MTE)

31 30	29 27	26	25 24	23 22	21	20 16	15 12	11 10	9 5	4 0

C6.2.360 SETGPN, SETGMN, SETGEN

Memory set with tag setting, non-temporal

These instructions set a requested number of bytes in memory to the value in the least significant byte of the source data register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register that holds the first address to be set. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPN, then SETGMN, and then SETGEN.

SETGPN performs some preconditioning of the arguments suitable for using the SETGMN instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETGMN sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETGEN sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETGPN:

- If Xn[63] == ‘1’, the set size is saturated to `0x7FFFFFFFFFFFFFF0`.

On completion of SETGPN, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETGPN, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETGMN, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETGMN, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETGEN, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On completion of the instruction, Xn holds 0.

For SETGEN, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

C6.2.361 SETGPT, SETGMT, SETGET

Memory set with tag setting, unprivileged

These instructions set a requested number of bytes in memory to the value in the least significant byte of the source data register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register that holds the first address to be set. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPT, then SETGMT, and then SETGET.

SETGPT performs some preconditioning of the arguments suitable for using the SETGMT instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETGMT sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETGET sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETGPT:

- If Xn[63] == ‘1’, the set size is saturated to `0x7FFFFFFFFFFFFFF0`.

On completion of SETGPT, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETGPT, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETGMT, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETGMT, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETGET, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On completion of the instruction, Xn holds 0.

For SETGET, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is ‘11’.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

C6.2.362 SETGPTN, SETGMTN, SETGETN

Memory set with tag setting, unprivileged and non-temporal

These instructions set a requested number of bytes in memory to the value in the least significant byte of the source data register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register that holds the first address to be set. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPTN, then SETGMTN, and then SETGETN.

SETGPTN performs some preconditioning of the arguments suitable for using the SETGMTN instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETGMTN sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETGETN sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETGPTN:

- If Xn[63] == ‘1’, the set size is saturated to `0x7FFFFFFFFFFFFFF0`.

On completion of SETGPTN, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETGPTN, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETGMTN, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETGMTN, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETGETN, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

For SETGETN, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is ‘11’.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

C6.2.363 SETP, SETM, SETE

Memory set

These instructions set a required number of bytes in memory to the value in the least significant byte of the source data register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETP, then SETM, and then SETE.

SETP performs some preconditioning of the arguments suitable for using the SETM instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETM sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETE sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETP:

- If Xn[63] == ‘1’, the set size is saturated to `0x7FFFFFFFFFFFFFFF`.

On completion of SETP, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETP, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETM, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETM, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETE, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For SETE, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

C6.2.364 SETPN, SETMN, SETEN

Memory set, non-temporal

These instructions set a required number of bytes in memory to the value in the least significant byte of the source data register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPN, then SETMN, and then SETEN.

SETPN performs some preconditioning of the arguments suitable for using the SETMN instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETMN sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETEN sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETPN:

- If Xn[63] == ‘1’, the set size is saturated to `0x7FFFFFFFFFFFFFFF`.

On completion of SETPN, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETPN, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETMN, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETMN, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETEN, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For SETEN, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

C6.2.365 SETPT, SETMT, SETET

Memory set, unprivileged

These instructions set a required number of bytes in memory to the value in the least significant byte of the source data register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPT, then SETMT, and then SETET.

SETPT performs some preconditioning of the arguments suitable for using the SETMT instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETMT sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETET sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETPT:

- If Xn[63] == ‘1’, the set size is saturated to `0x7FFFFFFFFFFFFFFF`.

On completion of SETPT, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETPT, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETMT, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETMT, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETET, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For SETET, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is ‘11’.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

C6.2.366 SETPTN, SETMTN, SETETN

Memory set, unprivileged and non-temporal

These instructions set a required number of bytes in memory to the value in the least significant byte of the source data register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPTN, then SETMTN, and then SETETN.

SETPTN performs some preconditioning of the arguments suitable for using the SETMTN instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETMTN sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETETN sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see Memory Copy and Memory Set exceptions.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETPTN:

- If Xn[63] == ‘1’, the set size is saturated to `0x7FFFFFFFFFFFFFFF`.

On completion of SETPTN, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETPTN, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETMTN, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETMTN, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETETN, option A, when PSTATE.C = ‘0’:

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For SETETN, option B, when PSTATE.C = ‘1’:

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is ‘11’.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

C6.2.369 SMADDL

Signed multiply-add long

This instruction multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMULL (32-bit).

31	30 29	28	27 25	24	23	22 21	20 16	15	14 10	9 5	4 0
1	0 0	1	1 0 1	1	0	0 1	Rm	0	Ra	Rn	Rd
sf	op54				U			o0			

Encoding

```
SMADDL  <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Xa>

Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the “Ra” field.

Alias Conditions

Alias	Is preferred when
SMULL (32-bit)	Ra == '11111'

Operation

```
let operand1 : bits(32) = X{32}(n);
let operand2 : bits(32) = X{32}(m);
let operand3 : bits(64) = X{64}(a);

let result : integer = SInt(operand3) + SInt(operand1) * SInt(operand2);

X{64}(d) = result[63:0];
```

C6.2.372 SMC

Secure monitor call

This instruction causes an exception to EL3.

`SMC` is available only for software executing at EL1 or higher. It is UNDEFINED at EL0.

If the values of HCR_EL2.TSC and SCR_EL3.SMD are both 0, execution of an `SMC` instruction at EL1 or higher generates a Secure Monitor Call exception, recording it in ESR_ELx, using the EC syndrome value `0x17`, that is taken to EL3.

If the value of HCR_EL2.TSC is 1 and EL2 is enabled in the current Security state, execution of an `SMC` instruction at EL1 generates an exception that is taken to EL2, regardless of the value of SCR_EL3.SMD.

If the value of HCR_EL2.TSC is 0 and the value of SCR_EL3.SMD is 1, the SMC instruction is UNDEFINED.

31–29	28–26	25–24	23–21	20–5	4–2	1–0
1 1 0	1 0 1	0 0	0 0 0 (opc)	imm16	0 0 0 (op2)	1 1 (LL)

Encoding

```
SMC  #<imm>
```

Decode for this encoding

```
let imm : bits(16) = imm16;
```

Assembler Symbols

<imm>

Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

Operation

```
if PSTATE.EL == EL0 then Undefined(); end;
AArch64_CheckForSMCUndefOrTrap(imm);
AArch64_CallSecureMonitor(imm);
```

C6.2.375 SMNEGL

Signed multiply-negate long

This instruction multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This is an alias of SMSUBL. This means:

- The encodings in this description are named to match the encodings of SMSUBL.
- The description of SMSUBL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28	27 25	24	23	22 21	20 16	15	14 10	9 5	4 0
1	0 0	1	1 0 1	1	0	0 1	Rm	1	1 1 1 1 1	Rn	Rd
sf	op54				U			o0	Ra		

Encoding

```
SMNEGL  <Xd>, <Wn>, <Wm>
```

is equivalent to

```
SMSUBL  <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

The description of SMSUBL gives the operational pseudocode for this instruction.

Operational Information

The description of SMSUBL gives the operational information for this instruction.

C6.2.376 SMSTART

Enable access to Streaming SVE mode and SME architectural state

This instruction enables access to Streaming SVE mode and SME architectural state.

SMSTART enters Streaming SVE mode, and enables the SME ZA storage.

SMSTART SM enters Streaming SVE mode, but does not enable the SME ZA storage.

SMSTART ZA enables the SME ZA storage, but does not cause an entry to Streaming SVE mode.

This is an alias of MSR (immediate). This means:

- The encodings in this description are named to match the encodings of MSR (immediate).
- The description of MSR (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_SME)

31–29	28–26	25–19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0	0 1 1	0 1 0 0	0 x x 1	0 1 1	1 1 1 1 1
			op1		CRm	op2	Rt

Encoding

```
SMSTART  {<option>}
```

is equivalent to

```
MSR  <pstatefield>, #1
```

and is always the preferred disassembly.

Assembler Symbols

<option>

Is an optional mode, encoded in “CRm<2:1>”:

CRm<2:1>	<option>	Description
00	RESERVED	•
01	SM	Maps to <pstatefield> SVCRSM.
10	ZA	Maps to <pstatefield> SVCRZA.
11	[absent]	Maps to <pstatefield> SVCRSMZA.

Operation

The description of MSR (immediate) gives the operational pseudocode for this instruction.

C6.2.377 SMSTOP

Disable access to Streaming SVE mode and SME architectural state

This instruction disables access to Streaming SVE mode and SME architectural state.

SMSTOP exits Streaming SVE mode, and disables the SME ZA storage.

SMSTOP SM exits Streaming SVE mode, but does not disable the SME ZA storage.

SMSTOP ZA disables the SME ZA storage, but does not cause an exit from Streaming SVE mode.

This is an alias of MSR (immediate). This means:

- The encodings in this description are named to match the encodings of MSR (immediate).
- The description of MSR (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_SME)

C6.2.378 SMSUBL

Signed multiply-subtract long

This instruction multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMNEGL.

31	30 29	28	27 25	24	23	22 21	20 16	15	14 10	9 5	4 0
1	0 0	1	1 0 1	1	0	0 1	Rm	1	Ra	Rn	Rd
sf	op54				U			o0			

Encoding

```
SMSUBL  <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Xa>

Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the “Ra” field.

Alias Conditions

Alias	Is preferred when
SMNEGL	Ra == '11111'

Operation

```
let operand1 : bits(32) = X{32}(n);
let operand2 : bits(32) = X{32}(m);
let operand3 : bits(64) = X{64}(a);

let result : integer = SInt(operand3) - SInt(operand1) * SInt(operand2);

X{64}(d) = result[63:0];

sf	op54				U			o0	Ra		

Encoding

```
SMULH  <Xd>, <Xn>, <Xm>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

```
let operand1 : bits(64) = X{64}(n);
let operand2 : bits(64) = X{64}(m);

let result : integer = SInt(operand1) * SInt(operand2);

X{64}(d) = result[127:64];
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.380 SMULL (32-bit)

Signed multiply long

This instruction multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This is an alias of SMADDL. This means:

- The encodings in this description are named to match the encodings of SMADDL.
- The description of SMADDL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28	27 25	24	23	22 21	20 16	15	14 10	9 5	4 0
1	0 0	1	1 0 1	1	0	0 1	Rm	0	1 1 1 1 1	Rn	Rd
sf	op54				U			o0	Ra		

Encoding

```
SMULL  <Xd>, <Wn>, <Wm>
```

is equivalent to

```
SMADDL  <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

The description of SMADDL gives the operational pseudocode for this instruction.

Operational Information

The description of SMADDL gives the operational information for this instruction.

C6.2.382 ST2G

Store Allocation Tags

This instruction stores an Allocation Tag to two Tag Granules of memory. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag Granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index, Pre-index, and Signed offset

Post-index

C6.2.383 ST64B

Single-copy atomic 64-byte store without status result

This instruction stores eight 64-bit doublewords from consecutive registers to a memory location. The store starts at register `Xt`, with the data being formed as `Data[511:0] = X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt`. The data is stored atomically and is required to be 64-byte aligned.

It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports `ST64B` also supports `LD64B`.

For more information, including about the memory types accessible and how the accesses are performed, see Single-copy atomic 64-byte load/store.

Integer

(FEAT_LS64)

Encoding

```
ST64B  <Xt>, [<Xn|SP> {, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LS64) then EndOfDecode(Decode_UNDEF); end;
if Rt[4:3] == '11' || Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;
let withstatus : boolean = FALSE;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let tagchecked : boolean = n != 31;
let acqrel : boolean = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly ST64B.

Assembler Symbols

<Xt>

Is the 64-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Operation

```
CheckLDST64BEnabled(acqrel);

var data : bits(512);
var address : bits(64);
var value : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLS64(MemOp_STORE, withstatus, acqrel, tagchecked);

for i = 0 to 7 do

C6.2.384 ST64BV

Single-copy atomic 64-byte store with status result

This instruction stores eight 64-bit doublewords from consecutive registers to a memory location, and writes the status result of the store to a register. The store starts at register `Xt`, with the data being formed as `Data[511:0] = X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt`. The data is stored atomically and is required to be 64-byte aligned.

It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports `ST64BV` also supports `ST64BV0`.

For more information, including about the memory types accessible and how the accesses are performed, see Single-copy atomic 64-byte load/store.

Integer

C6.2.389 STCLR, STCLRL

Atomic bit clear on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

- `STCLR` does not have release semantics.
- `STCLRL` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDCLR, LDCLRA, LDCLRAL, LDCLRL. This means:

- The encodings in this description are named to match the encodings of LDCLR, LDCLRA, LDCLRAL, LDCLRL.
- The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C6.2.398 STILP

Store-release ordered pair of registers

This instruction calculates an address from a base register value and an optional offset, and stores two 32-bit words or two 64-bit doublewords to the calculated address, from two registers. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. The instruction also has memory ordering semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release, with the additional requirement that:

- When using the pre-index addressing mode, the Memory effects associated with Xt2/Wt2 are Ordered-before the Memory effects associated with Xt1/Wt1.
- For all other addressing modes, the Memory effects associated with Xt1/Wt1 are Ordered-before the Memory effects associated with Xt2/Wt2.

For information about addressing modes, see Load/Store addressing modes.

Integer

(FEAT_LRCPC3)

31	30	29						23	22	21	20			16	15			12	11	10	9			5	4			0
1	x	0	1	1	0	0	1	0	0	0	Rt2				0	0	0	x	1	0	Rn				Rt			
size									L						opc2													

Encoding for the 32-bit pre-index variant

Applies when `(size == 10 && opc2 == 0000)`

```
STILP  <Wt1>, <Wt2>, [<Xn|SP>, #-8]!
```

Encoding for the 32-bit variant

Applies when `(size == 10 && opc2 == 0001)`

```
STILP  <Wt1>, <Wt2>, [<Xn|SP>]
```

Encoding for the 64-bit pre-index variant

Applies when `(size == 11 && opc2 == 0000)`

```
STILP  <Xt1>, <Xt2>, [<Xn|SP>, #-16]!
```

Encoding for the 64-bit variant

Applies when `(size == 11 && opc2 == 0001)`

```
STILP  <Xt1>, <Xt2>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC3) then EndOfDecode(Decode_UNDEF); end;
let ispair : boolean = TRUE;
let wback : boolean = opc2[0] == '0';
```

`STILP` has the same CONSTRAINED UNPREDICTABLE behavior as `STP`. For information about this CONSTRAINED UNPREDICTABLE behavior, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STP and STILP.

C6.2.405 STLTXR

Store-release unprivileged exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `STLTXR` is equivalent to `STXR`.

For information about addressing modes, see Load/Store addressing modes.

No offset

end;
```

STLTXR has the same CONSTRAINED UNPREDICTABLE behavior as STLXR. For information about this CONSTRAINED UNPREDICTABLE behavior, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXR.

Assembler Symbols

<Ws>

Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the “Rs” field. The value returned is:

0 If the operation updates memory.
1 If the operation fails to update memory.

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64_ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64_ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(elsize);

let dbytes : integer{} = elsize DIV 8;
let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(elsize);
else
    data = X{elsize}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, dbytes, accdesc) then

C6.2.409 STLXP

Store-release exclusive pair of registers

This instruction stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. The instruction also has memory ordering semantics, as described in Load-Acquire, Store-Release. For information about addressing modes, see Load/Store addressing modes.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs and STLXP.

Assembler Symbols

<Ws>

Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.
1 If the operation fails to update memory.

<Wt1>

Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2>

Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt1>

Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2>

Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64_ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64_ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(datasize);

let dbytes : integer{} = datasize DIV 8;
let privileged : boolean = PSTATE.EL != EL0;
let ispair : boolean = FALSE;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, ispair, t, t2);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(datasize);
else
    let el1 : bits(datasize DIV 2) = X{}(t);
    let el2 : bits(datasize DIV 2) = X{}(t2);
    data = if BigEndian(accdesc.acctype) then el1::el2 else el2::el1;
end;
var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{datasize}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

        when Constraint_UNKNOWN =>    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXRH.

Assembler Symbols

<Ws>

Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the “Rs” field. The value returned is:

0 If the operation updates memory.
1 If the operation fails to update memory.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64_ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64_ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(16);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(16);
else
    data = X{16}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, 2, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{16}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);

C6.2.416 STR (register)

Store register (register)

This instruction calculates an address from a base register value and an offset register value, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about addressing modes, see Load/Store addressing modes.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.

```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;         // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let scale : integer{} = UInt(size);
let shift : integer{} = if S == '1' then scale else 0;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm>

When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm>

When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend>

Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount>

For the "32-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#2

For the "64-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#3

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the signed immediate byte offset, in the range -256 to 255, encoded in the “imm9” field.

<pimm>

Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var rt_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE =>    rt_unknown = FALSE;    // Value stored is original value
        when Constraint_UNKNOWN => rt_unknown = TRUE;     // Value stored is UNKNOWN
        when Constraint_UNDEF =>   EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>     EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;
```

C6.2.418 STRB (register)

Store register byte (register)

This instruction calculates an address from a base register value and an offset register value, and stores a byte from a 32-bit register to the calculated address. For information about addressing modes, see Load/Store addressing modes.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.

31 30	29 27	26	25 24	23 22	21	20 16	15 13	12	11 10	9 5	4 0
0 0	1 1 1	0	0 0	0 0	1	Rm	option	S	1 0	Rn	Rt
size		VR		opc							

Encoding for the Extended register variant

Applies when `(option != 011)`

```
STRB  <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the Shifted register variant

Applies when `(option == 011)`

```
STRB  <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;         // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = 0;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm>

When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm>

When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend>

Is the index extend specifier, encoded in “option”:

option	<extend>
010	UXTW

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<extend>
110	SXTW
111	SXTX

<amount>

Is the index shift amount, it must be #0, encoded in “S” as 0 if omitted, or as 1 if present.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{8}(address, accdesc) = X{8}(t);
```

C6.2.419 STRH (immediate)

Store register halfword (immediate)

This instruction stores the least significant halfword of a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index, Pre-index, and Unsigned offset

Post-index

31	30	29	28	27	26	25	24	23	22	21	20 … 12	11	10	9 … 5	4 … 0
0	1	1	1	1	0	0	0	0	0	0	imm9	0	1	Rn	Rt
size					VR			opc							

Encoding

```
STRH  <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
let wback : boolean = TRUE;
let postindex : boolean = TRUE;
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index

31	30	29	28	27	26	25	24	23	22	21	20 … 12	11	10	9 … 5	4 … 0
0	1	1	1	1	0	0	0	0	0	0	imm9	1	1	Rn	Rt
size					VR			opc							

Encoding

```
STRH  <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
let wback : boolean = TRUE;
let postindex : boolean = FALSE;
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset

31	30	29	28	27	26	25	24	23	22	21 … 10	9 … 5	4 … 0
0	1	1	1	1	0	0	1	0	0	imm12	Rn	Rt
size					VR			opc				

Encoding

```
STRH  <Wt>, [<Xn|SP>{, #<pimm>}]
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
let wback : boolean = FALSE;
let postindex : boolean = FALSE;
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 1);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STRH (immediate).

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the signed immediate byte offset, in the range -256 to 255, encoded in the “imm9” field.

<pimm>

Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the “imm12” field as <pimm>/2.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var rt_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE =>    rt_unknown = FALSE;    // Value stored is original value
        when Constraint_UNKNOWN => rt_unknown = TRUE;     // Value stored is UNKNOWN
        when Constraint_UNDEF =>   EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>     EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
var data : bits(16);
if rt_unknown then
    data = ARBITRARY : bits(16);
else
    data = X{16}(t);
end;

Mem{16}(address, accdesc) = data;

if wback then
    if postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

C6.2.420 STRH (register)

Store register halfword (register)

This instruction calculates an address from a base register value and an offset register value, and stores a halfword from a 32-bit register to the calculated address. For information about addressing modes, see Load/Store addressing modes.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.

31 30	29 28	27	26	25	24	23 22	21	20 16	15 13	12	11 10	9 5	4 0
0 1	1 1	1	0	0	0	0 0	1	Rm	option	S	1 0	Rn	Rt
size			VR			opc							

Encoding

```
STRH  <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;         // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm>

When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm>

When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend>

Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<amount>

Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#1

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{16}(address, accdesc) = X{16}(t);
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.421 STSET, STSETL

Atomic bit set on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- `STSET` does not have release semantics.
- `STSETL` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDSET, LDSETA, LDSETAL, LDSETL. This means:

- The encodings in this description are named to match the encodings of LDSET, LDSETA, LDSETAL, LDSETL.
- The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C6.2.424 STSHH

Store shared hint

This instruction signals to the memory system that if the next instruction in program order generates an explicit write effect, then it is to a location that one or more other threads of execution will observe, and there is a performance benefit to ensuring that the updated value from the write to that location propagates to those other observers with minimal latency.

The thread of execution on the other observers might be polling the location using load or Load-Exclusive instructions, or may have executed a `PRFM IR` instruction targeting the location.

System

(FEAT_PCDPHINT)

31–29	28–26	25–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 0	0 1 1 0 (CRm)	0 0 x (op2)	1 1 1 1 1

Encoding

```
STSHH  <policy>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PCDPHINT) then EndOfDecode(Decode_NOP); end;
let stream : boolean = op2[0] == '1';
```

Assembler Symbols

<policy>

`<policy>` is one of:

KEEP Signals to the memory system that there may be a performance benefit to retaining the updated location in the local cache of the updating PE.

STRM Signals to the memory system that there may be a performance benefit to ensuring the updated location is not retained in the local cache of the updating PE.

op2<0>	<policy>
0	KEEP
1	STRM

Operation

```
Hint_StoreShared(stream);
```

C6.2.425 STSMAX, STSMAXL

Atomic signed maximum on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- `STSMAX` does not have release semantics.
- `STSMAXL` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL. This means:

- The encodings in this description are named to match the encodings of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL.
- The description of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C6.2.426 STSMAXB, STSMAXLB

Atomic signed maximum on byte, without return

This instruction atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- `STSMAXB` does not have release semantics.
- `STSMAXLB` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB. This means:

- The encodings in this description are named to match the encodings of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB.
- The description of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C6.2.433 STTNP

Store unprivileged pair of registers, with non-temporal hint

This instruction calculates an address from a base register value and an immediate offset, and stores two 64-bit doublewords to the calculated address, from two registers. For information about addressing modes, see Load/Store addressing modes. For information about non-temporal pair instructions, see Load/Store non-temporal pair.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Signed offset

STTP has the same CONSTRAINED UNPREDICTABLE behavior as STP. For information about this CONSTRAINED UNPREDICTABLE behavior, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STP.

Assembler Symbols

<Xt1>

Is the 64-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.

<Xt2>

Is the 64-bit name of the second general-purpose register to be transferred, encoded in the “Rt2” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Load/store register pair (post-indexed)” and “Load/store register pair (pre-indexed)” variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the “imm7” field as <imm>/8.

For the “Load/store register pair (offset)” variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the “imm7” field as <imm>/8.

Shared Decode

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let scale : integer{} = 2 + UInt(opc[1]);
let datasize : integer{} = 64;
let offset : bits(64) = LSL(SignExtend{64}(imm7), scale);
let tagchecked : boolean = wback || n != 31;

var rt_unknown : boolean = FALSE;

if wback && (t == n || t2 == n) && n != 31 then

C6.2.438 STTSET, STTSETL

Atomic bit set unprivileged, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- `STTSET` does not have release semantics.
- `STTSETL` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDTSET, LDTSETA, LDTSETAL, LDTSETL. This means:

- The encodings in this description are named to match the encodings of LDTSET, LDTSETA, LDTSETAL, LDTSETL.
- The description of LDTSET, LDTSETA, LDTSETAL, LDTSETL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C6.2.439 STTXR

Store unprivileged exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `STTXR` is equivalent to `STXR`.

For information about addressing modes, see Load/Store addressing modes.

        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

STTXR has the same CONSTRAINED UNPREDICTABLE behavior as STXR. For information about this CONSTRAINED UNPREDICTABLE behavior, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXR.

Assembler Symbols

<Ws>

Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the “Rs” field. The value returned is:

0 If the operation updates memory.
1 If the operation fails to update memory.

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64_ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64_ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(elsize);

let dbytes : integer{} = elsize DIV 8;
let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(elsize);
else
    data = X{elsize}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{elsize}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

C6.2.440 STUMAX, STUMAXL

Atomic unsigned maximum on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- `STUMAX` does not have release semantics.
- `STUMAXL` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL. This means:

- The encodings in this description are named to match the encodings of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.
- The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C6.2.441 STUMAXB, STUMAXLB

Atomic unsigned maximum on byte, without return

This instruction atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- `STUMAXB` does not have release semantics.
- `STUMAXLB` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB. This means:

- The encodings in this description are named to match the encodings of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB.
- The description of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

C6.2.442 STUMAXH, STUMAXLH

Atomic unsigned maximum on halfword, without return

This instruction atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- `STUMAXH` does not have release semantics.
- `STUMAXLH` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH. This means:

- The encodings in this description are named to match the encodings of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH.
- The description of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C6.2.446 STUR

Store register (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about addressing modes, see Load/Store addressing modes.

31	30	29	27	26	25	24	23	22	21	20	12	11	10	9	5	4	0
1	x	1	1 1	0	0	0	0	0	0	imm9		0	0	Rn		Rt	
	size			VR			opc										

Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STUR  <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STUR  <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 8 << scale;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

C6.2.447 STURB

Store register byte (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a byte to the calculated address, from a 32-bit register. For information about addressing modes, see Load/Store addressing modes.

31 30	29 28	27	26	25	24	23 22	21	20 … 12	11 10	9 … 5	4 … 0
0 0	1 1	1	0	0	0	0 0	0	imm9	0 0	Rn	Rt
size			VR			opc					

Encoding

```
STURB  <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 8;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);

C6.2.449 STXP

Store exclusive pair of registers

This instruction stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about addressing modes, see Load/Store addressing modes.

31	30	29						23	22	21	20	16	15	14	10	9	5	4	0
1	sz	0	0	1	0	0	0	0	0	1	Rs		0	Rt2		Rn		Rt	
									L				o0						

Encoding for the 32-bit variant

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs and STXP.

Assembler Symbols

<Ws>

Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.
1 If the operation fails to update memory.

<Wt1>

Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2>

Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt1>

Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2>

Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64_ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64_ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(datasize);

let dbytes : integer{} = datasize DIV 8;
let privileged : boolean = PSTATE.EL != EL0;
let ispair : boolean = FALSE;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, ispair, t, t2);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(datasize);
else
    let el1 : bits(datasize DIV 2) = X{}(t);
    let el2 : bits(datasize DIV 2) = X{}(t2);
    data = if BigEndian(accdesc.acctype) then el1::el2 else el2::el1;
end;
var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, dbytes, accdesc) then

C6.2.450 STXR

Store exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores.

For information about addressing modes, see Load/Store addressing modes.

31	30	29						23	22	21	20			16	15	14				10	9			5	4			0
1	x	0	0	1	0	0	0	0	0	0	Rs				0	(1)	(1)	(1)	(1)	(1)	Rn				Rt			
size									L						o0	Rt2												

Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STXR  <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STXR  <Ws>, <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 8 << UInt(size);
let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

Assembler Symbols

<Ws>

Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the “Rs” field. The value returned is:

0 If the operation updates memory.
1 If the operation fails to update memory.

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xt>

Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64_ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64_ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(elsize);

let dbytes : integer{} = elsize DIV 8;
let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(elsize);
else
    data = X{elsize}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
```

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Aborts

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

If `AArch64_ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(8);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(8);
else
    data = X{8}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, 1, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{8}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

C6.2.452 STXRH

Store exclusive register halfword

This instruction stores a halfword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic.

For information about addressing modes, see Load/Store addressing modes.

31	30	29	28	27	26	25	24	23	22	21	20 … 16	15	14 … 10	9 … 5	4 … 0
0	1	0	0	1	0	0	0	0	0	0	Rs	0	(1)(1)(1)(1)(1)	Rn	Rt
size									L			o0	Rt2		

Encoding

```
STXRH  <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXRH.

Assembler Symbols

<Ws>

Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the “Rs” field. The value returned is:

0 If the operation updates memory.
1 If the operation fails to update memory.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Wt>

Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64_ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64_ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(16);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(16);
else
    data = X{16}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, 2, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{16}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);

C6.2.455 STZGM

Store Allocation Tag and zero multiple

This instruction writes a naturally aligned block of N Allocation Tags and stores zero to the associated data locations, where the size of N is identified in DCZID_EL0.BS, and the Allocation Tag is taken from the source register bits<3:0>.

This instruction is UNDEFINED at EL0.

This instruction generates an Unchecked access.

Integer

(FEAT_MTE2)

31–28	27	26	25	24	23	22	21	20–12	11	10	9–5	4–0
1 1 0 1	1	0	0	1	0	0	1	0 0 0 0 0 0 0 0 0	0	0	Rn	Rt
					opc			imm9		op2		

Encoding

```
STZGM  <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE2) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose source register, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Operation

```
if PSTATE.EL == EL0 then Undefined(); end;

let data : bits(64) = X{64}(t);
let tag : bits(4) = data[3:0];
var address : bits(64);
if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let size : integer{} = 4 * 2 ^ UInt(DCZID_EL0().BS);
address = AlignDownSize(address, size);
let count : integer = size >> LOG2_TAG_GRANULE;
let stzgm : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescLDGSTG(MemOp_STORE, stzgm, t);

for i = 0 to count-1 do
    AArch64_MemTag(address, accdesc) = tag;
    Mem{8*TAG_GRANULE}(address, accdesc) = Zeros{8*TAG_GRANULE};
```

C6.2.456 SUB (extended register)

Subtract extended and scaled register

This instruction subtracts a sign-extended or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the `<Rm>` register can be a byte, halfword, word, or doubleword.

31	30	29	28	23	22	21	20	15	12	9	4
sf	1	0	0 1 0 1 1	0	0	1	Rm	option	imm3	Rn	Rd
	op	S			opt						

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUB  <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUB  <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let shift : integer{} = UInt(imm3) as integer{0..4};
let datasize : integer{} = 32 << UInt(sf);
let extend_type : ExtendType = DecodeRegExtend(option);
```

Assembler Symbols

<Wd|WSP>

Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Wn|WSP>

Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<extend>

For the “32-bit” variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<extend>
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If “Rd” or “Rn” is ‘11111’ (WSP) and “option” is ‘010’ then LSL is preferred, but may be omitted when “imm3” is ‘000’. In all other cases <extend> is required and must be UXTW when “option” is ‘010’.

For the “64-bit” variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If “Rd” or “Rn” is ‘11111’ (SP) and “option” is ‘011’ then LSL is preferred, but may be omitted when “imm3” is ‘000’. In all other cases <extend> is required and must be UXTX when “option” is ‘011’.

<amount>

Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the “imm3” field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xd|SP>

Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<R>

Is a width specifier, encoded in “option”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m>

Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the “Rm” field.

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = NOT ExtendReg{datasize}(m, extend_type, shift);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, '1');

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.457 SUB (immediate)

Subtract immediate value

This instruction subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register.

31	30	29	28	23	22	21	10	9	5	4	0
sf	1	0	1 0 0 0 1 0		sh	imm12		Rn		Rd	
	op	S									

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUB  <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUB  <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);

let imm : bits(24) = if sh == '0' then Zeros{12}::imm12 else imm12::Zeros{12};
```

Assembler Symbols

<Wd|WSP>

Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Wn|WSP>

Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

<imm>

Is an unsigned immediate, in the range 0 to 4095, encoded in the “imm12” field.

<shift>

Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #12

<Xd|SP>

Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn|SP>

Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = NOT ZeroExtend{datasize}(imm);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, '1');

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

C6.2.458 SUB (shifted register)

Subtract optionally-shifted register

This instruction subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

This instruction is used by the alias NEG (shifted register).

31	30	29	28	23 22	21	20	15	9	4
sf	1	0	0 1 0 1 1	shift	0	Rm	imm6	Rn	Rd
	op	S							

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUB  <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUB  <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if shift == '11' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount>

For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
NEG (shifted register)	Rn == '11111'

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = NOT ShiftReg{datasize}(m, shift_type, shift_amount);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, '1');

X{datasize}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

C6.2.459 SUBG

Subtract with tag

This instruction subtracts an immediate value scaled by the Tag Granule from the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

Integer

(FEAT_MTE)

Encoding

```
SUBG  <Xd|SP>, <Xn|SP>, #<uimm6>, #<uimm4>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let tag_offset : bits(4) = imm4;
let offset : bits(64) = LSL(ZeroExtend{64}(imm6), LOG2_TAG_GRANULE);
```

Assembler Symbols

<Xd|SP>

Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

<uimm6>

Is an unsigned immediate, a multiple of 16 in the range 0 to 1008, encoded in the “imm6” field.

<uimm4>

Is an unsigned immediate, in the range 0 to 15, encoded in the “imm4” field.

Operation

```
let operand1 : bits(64) = if n == 31 then SP{64}() else X{64}(n);
let start_tag : bits(4) = AArch64_AllocationTagFromAddress(operand1);
let exclude : bits(16) = GCR_EL1().Exclude;
let rtag : bits(4) = AArch64_ChooseNonExcludedTagOrZero(start_tag, tag_offset, exclude);
var result : bits(64);

(result, -) = AddWithCarry{64}(operand1, NOT offset, '1');

result = AArch64_AddressWithAllocationTag(result, rtag);

if d == 31 then
    SP{64}() = result;

C6.2.462 SUBPT

Subtract checked pointer

This instruction subtracts an optionally-shifted register value from a base address register value, and writes the result to the destination register. The optionally-shifted register value is treated as the offset.

If the operation would have generated a result where the most significant 8 bits of the result register differ from the most significant 8 bits of the base register, then the result is modified such that it is likely to be non-canonical when used as an address.

Integer

(FEAT_CPA)

31	30	29	28	27 25	24 21	20 16	15 13	12 10	9 5	4 0
1	1	0	1	1 0 1	0 0 0 0	Rm	0 0 1	imm3	Rn	Rd
sf	op	S								

Encoding

```
SUBPT  <Xd|SP>, <Xn|SP>, <Xm>{, LSL #<amount>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CPA) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let shift : integer = UInt(imm3);
```

Assembler Symbols

<Xd|SP>

Is the 64-bit name of the general-purpose destination register or stack pointer, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the first general-purpose source register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

<amount>

Is the left shift amount, in the range 0 to 7, defaulting to 0, encoded in the “imm3” field.

Operation

```
var result : bits(64);
let base : bits(64) = if n == 31 then SP{64}() else X{64}(n);
let offset : bits(64) = LSL(X{64}(m), shift);

result = base - offset;
result = PointerAddCheck(result, base);

if d == 31 then
    SP{64}() = result;
else

C6.2.463 SUBS (extended register)

Subtract extended and scaled register, setting flags

This instruction subtracts a sign-extended or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the `<Rm>` register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMP (extended register).

31	30	29	28				24	23	22	21	20		16	15		13	12		10	9		5	4		0
sf	1	1	0	1	0	1	1	0	0	1	Rm			option			imm3			Rn			Rd		
op		S						opt																	

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUBS  <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUBS  <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let shift : integer{} = UInt(imm3) as integer{0..4};
let datasize : integer{} = 32 << UInt(sf);
let extend_type : ExtendType = DecodeRegExtend(option);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn|WSP>

Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<extend>

For the “32-bit” variant: is the extension to be applied to the second source operand, encoded in “option”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If “Rn” is ‘11111’ (WSP) and “option” is ‘010’ then LSL is preferred, but may be omitted when “imm3” is ‘000’. In all other cases <extend> is required and must be UXTW when “option” is ‘010’.

For the “64-bit” variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If “Rn” is ‘11111’ (SP) and “option” is ‘011’ then LSL is preferred, but may be omitted when “imm3” is ‘000’. In all other cases <extend> is required and must be UXTX when “option” is ‘011’.

<amount>

Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the “imm3” field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<R>

Is a width specifier, encoded in “option”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m>

Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
CMP (extended register)	Rd == '11111'

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = NOT ExtendReg{datasize}(m, extend_type, shift);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, '1');

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Applies when `(sf == 0)`

```
SUBS  <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUBS  <Xd>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);

let imm : bits(24) = if sh == '0' then Zeros{12}::imm12 else imm12::Zeros{12};
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn|WSP>

Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

<imm>

Is an unsigned immediate, in the range 0 to 4095, encoded in the “imm12” field.

<shift>

Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #12

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

Alias Conditions

Alias	Is preferred when
CMP (immediate)	Rd == '11111'

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = NOT ZeroExtend{datasize}(imm);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, '1');

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.465 SUBS (shifted register)

Subtract optionally-shifted register, setting flags

This instruction subtracts an optionally-shifted register value from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the aliases CMP (shifted register) and NEGS.

31	30	29	28	24	23 22	21	20	16	15	10	9	5	4	0
sf	1	1	0 1 0 1 1		shift	0	Rm		imm6		Rn		Rd	
	op	S												

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUBS  <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUBS  <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if shift == '11' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount>

For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
CMP (shifted register)	Rd == '11111'
NEGS	Rn == '11111' && Rd != '11111'

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = NOT ShiftReg{datasize}(m, shift_type, shift_amount);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, '1');

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

C6.2.466 SVC

Supervisor call

This instruction causes an exception to be taken to EL1.

On executing an `SVC` instruction, the PE records the exception as a Supervisor Call exception in ESR_ELx, using the EC syndrome value `0x15`, and the value of the immediate argument.

31–29	28–26	25–24	23–21	20–5	4–2	1–0
1 1 0	1 0 1	0 0	0 0 0	imm16	0 0 0	0 1
			opc		op2	LL

Encoding

```
SVC  #<imm>
```

Decode for this encoding

```
let imm : bits(16) = imm16;
```

Assembler Symbols

<imm>

Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

Operation

```
AArch64_CheckForSVCTrap(imm);
AArch64_CallSupervisor(imm);
```

C6.2.467 SWP, SWPA, SWPAL, SWPL

Swap word or doubleword in memory

This instruction atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR` or `XZR`, `SWPA` and `SWPAL` load from memory with acquire semantics.
  - `SWPL` and `SWPAL` store to memory with release semantics.
  - `SWP` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

C6.2.471 SWPT, SWPTA, SWPTAL, SWPTL

Swap unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR` or `XZR`, `SWPTA` and `SWPTAL` load from memory with acquire semantics.
  - `SWPTL` and `SWPTAL` store to memory with release semantics.
  - `SWPT` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Assembler Symbols

<Ws>

Is the 32-bit name of the general-purpose register to be stored, encoded in the “Rs” field.

<Wt>

Is the 32-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xs>

Is the 64-bit name of the general-purpose register to be stored, encoded in the “Rs” field.

<Xt>

Is the 64-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.

Operation

```
var address : bits(64);
var data : bits(datasize);
var store_value : bits(datasize);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_SWP, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

store_value = X{datasize}(s);

// Irrelevant when not executing CAS
let comparevalue : bits(datasize) = ARBITRARY : bits(datasize);
data = MemAtomic{datasize}(address, comparevalue, store_value, accdesc);

X{regsize}(t) = ZeroExtend{regsize}(data);
```

C6.2.472 SXTB

Signed extend byte

This instruction extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 … 23	22	21 … 16	15 … 10	9 … 5	4 … 0
sf	0 0	1 0 0 1 1 0	N	0 0 0 0 0 0	0 0 0 1 1 1	Rn	Rd
	opc			immr	imms		

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
SXTB  <Wd>, <Wn>
```

is equivalent to

```
SBFM  <Wd>, <Wn>, #0, #7
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
SXTB  <Xd>, <Wn>
```

is equivalent to

```
SBFM  <Xd>, <Xn>, #0, #7
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

Non-Confidential

C6.2.473 SXTH

Sign extend halfword

This instruction extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 … 23	22	21 … 16	15 … 10	9 … 5	4 … 0
sf	0 0 (opc)	1 0 0 1 1 0	N	0 0 0 0 0 0 (immr)	0 0 1 1 1 1 (imms)	Rn	Rd

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
SXTH  <Wd>, <Wn>
```

is equivalent to

```
SBFM  <Wd>, <Wn>, #0, #15
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
SXTH  <Xd>, <Wn>
```

is equivalent to

```
SBFM  <Xd>, <Xn>, #0, #15
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

C6.2.474 SXTW

Sign extend word

This instruction sign-extends a word to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 26	25 23	22	21 16	15 10	9 5	4 0
1	0 0	1 0 0	1 1 0	1	0 0 0 0 0 0	0 1 1 1 1 1	Rn	Rd
sf	opc			N	immr	imms		

Encoding

```
SXTW  <Xd>, <Wn>
```

is equivalent to

```
SBFM  <Xd>, <Xn>, #0, #31
```

and is always the preferred disassembly.

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

C6.2.475 SYS

System instruction

For more information, see op0 == `0b01`, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions for the encodings of System instructions.

This instruction is used by the aliases APAS, AT, BRB, CFP, COSP, CPP, DC, DVP, GCSPOPCX, GCSPOPX, GCSPUSHM, GCSPUSHX, GCSSS1, IC, TLBI, and TRCIT.

31–29	28–26	25–22	21	20–19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0	0	0 1	op1	CRn	CRm	op2	Rt
			L						

Encoding

```
SYS  #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}
```

Decode for this encoding

```
let t : integer       = UInt(Rt);
let sys_op0 : bits(2) = '01';
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<op1>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

<Cn>

Is a name ‘Cn’, with ‘n’ in the range 0 to 15, encoded in the “CRn” field.

<Cm>

Is a name ‘Cm’, with ‘m’ in the range 0 to 15, encoded in the “CRm” field.

<op2>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

<Xt>

Is the 64-bit name of the optional general-purpose source register, defaulting to ‘11111’, encoded in the “Rt” field.

Alias Conditions

Alias	Is preferred when
APAS	`op1 == '110' && CRn == '0111' && CRm == '0000' && op2 == '000'`

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alias	Is preferred when

C6.2.476 SYSL

System instruction with result

For more information, see op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions for the encodings of System instructions.

This instruction is used by the aliases GCSPOPM and GCSSS2.

31–29	28–26	25–22	21	20–19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0	1 (L)	0 1	op1	CRn	CRm	op2	Rt

Encoding

```
SYSL  <Xt>, #<op1>, <Cn>, <Cm>, #<op2>
```

Decode for this encoding

```
let t : integer       = UInt(Rt);
let sys_op0 : bits(2) = '01';
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rt” field.

<op1>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

<Cn>

Is a name ‘Cn’, with ‘n’ in the range 0 to 15, encoded in the “CRn” field.

<Cm>

Is a name ‘Cm’, with ‘m’ in the range 0 to 15, encoded in the “CRm” field.

<op2>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

Alias Conditions

Alias	Is preferred when
GCSPOPM	op1 == '011' && CRn == '0111' && CRm == '0111' && op2 == '001'
GCSSS2	op1 == '011' && CRn == '0111' && CRm == '0111' && op2 == '011'

C6.2.477 SYSP

128-bit system instruction

For more information, see op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions for the encodings of System instructions.

This instruction is used by the alias TLBIP.

System

(FEAT_SYSINSTR128)

31–29	28–26	25–22	21	20–19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 1	0	0 1	op1	CRn	CRm	op2	Rt
			L						

Encoding

```
SYSP  #<op1>, <Cn>, <Cm>, #<op2>{, <Xt1>, <Xt2>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SYSINSTR128) then EndOfDecode(Decode_UNDEF); end;
if Rt[0] == '1' && Rt != '11111' then EndOfDecode(Decode_UNDEF); end;

let t : integer       = UInt(Rt);
let t2 : integer      = if t == 31 then 31 else t + 1;
let sys_op0 : bits(2) = '01';
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<op1>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

<Cn>

Is a name ‘Cn’, with ‘n’ in the range 0 to 15, encoded in the “CRn” field.

<Cm>

Is a name ‘Cm’, with ‘m’ in the range 0 to 15, encoded in the “CRm” field.

<op2>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

<Xt1>

Is the 64-bit name of the first optional general-purpose source register, defaulting to ‘11111’, encoded in the “Rt” field.

<Xt2>

Is the 64-bit name of the second optional general-purpose source register, defaulting to ‘11111’, encoded as “Rt” +1. Defaults to ‘11111’ if “Rt” = ‘11111’.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alias Conditions

Alias	Is preferred when
TLBIP	CRn IN {'100x'} && SysOp128(op1, CRn, CRm, op2) == Sys_TLBIP

Operation

```
AArch64_SysInstr128(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t, t2);
```

C6.2.478 TBNZ

Test bit and branch if nonzero

This instruction compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

31	30	29	28	26	25	24	23	19	18	5	4	0
b5	0	1	1	0 1	1	1	b40		imm14		Rt	
						op						

Encoding

```
TBNZ  <R><t>, #<imm>, <label>
```

Decode for this encoding

```
let t : integer = UInt(Rt);

let datasize : integer{} = 32 << UInt(b5);
let bit_pos : integer = UInt(b5::b40);
let offset : bits(64) = SignExtend{}(imm14::'00');
```

Assembler Symbols

<R>

Is a width specifier, encoded in “b5”:

b5	<R>
0	W
1	X

In assembler source code an ‘X’ specifier is always permitted, but a ‘W’ specifier is permitted only when the bit number is less than 32.

<t>

Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the “Rt” field.

<imm>

Is the bit number to be tested, in the range 0 to 63, encoded in “b5:b40”.

<label>

Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as “imm14” times 4.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
let operand : bits(datasize) = X{datasize}(t);
let branch_conditional : boolean = TRUE;
if operand[bit_pos] != '0' then
    BranchTo{64}(PC64() + offset, BranchType_DIR, branch_conditional);
else
    BranchNotTaken(BranchType_DIR, branch_conditional);
end;
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.479 TBZ

Test bit and branch if zero

This instruction compares the value of a test bit with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

31	30	29	28	26	25	24	23 19	18 5	4 0
b5	0	1	1	0 1	1	0	b40	imm14	Rt
						op			

Encoding

```
TBZ  <R><t>, #<imm>, <label>
```

Decode for this encoding

```
let t : integer = UInt(Rt);

let datasize : integer{} = 32 << UInt(b5);
let bit_pos : integer = UInt(b5::b40);
let offset : bits(64) = SignExtend{}(imm14::'00');
```

Assembler Symbols

<R>

Is a width specifier, encoded in “b5”:

b5	<R>
0	W
1	X

In assembler source code an ‘X’ specifier is always permitted, but a ‘W’ specifier is permitted only when the bit number is less than 32.

<t>

Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the “Rt” field.

<imm>

Is the bit number to be tested, in the range 0 to 63, encoded in “b5:b40”.

<label>

Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as “imm14” times 4.

C6.2.480 TLBI

TLB invalidate operation

For more information, see op0 == `0b01`, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31–29	28–26	25–22	21	20–19	18–16	15–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0	0 (L)	0 1	op1	1 0 0 x (CRn)	CRm	op2	Rt

Encoding

```
TLBI  <tlbi_op>{, <Xt>}
```

is equivalent to

```
SYS  #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp(op1, CRn, CRm, op2) == Sys_TLBI`.

Assembler Symbols

<tlbi_op>

Is a TLBI operation name, as listed for the TLBI system instruction group, encoded in “op1:CRn:CRm:op2”:

op1	CRn	CRm	op2	<tlbi_op>	Architectural Feature	Description
000	1000	0001	000	VMALLE1OS	FEAT_TLBIOS	For more information, see TLBI VMALLE1OS, TLBI VMALLE1OSNXS.

<Xt>

Is the 64-bit name of the optional general-purpose source register, defaulting to ‘11111’, encoded in the “Rt” field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.481 TLBIP

TLB invalidate pair operation

For more information, see op0 == `0b01`, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions.

This is an alias of SYSP. This means:

- The encodings in this description are named to match the encodings of SYSP.
- The description of SYSP gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_SYSINSTR128)

31 29	28 26	25 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0	1 0 1	0 1 0 1	0	0 1	op1	1 0 0 x	CRm	op2	Rt
			L			CRn			

Encoding

```
TLBIP  <tlbip_op>{, <Xt1>, <Xt2>}
```

is equivalent to

```
SYSP  #<op1>, <Cn>, <Cm>, #<op2>{, <Xt1>, <Xt2>}
```

and is the preferred disassembly when `SysOp128(op1, CRn, CRm, op2) == Sys_TLBIP`.

Assembler Symbols

<tlbip_op>

Is a TLBIP operation name, as listed for the TLBIP system pair instruction group, encoded in “op1:CRn:CRm:op2”:

C6.2.482 TRCIT

Trace instrumentation

This instruction generates an instrumentation trace packet that contains the value of the provided register.

For more information, see TRCIT, Trace Instrumentation.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_ITE)

31 29	28 26	25 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0	1 0 1	0 1 0 0	0	0 1	0 1 1	0 1 1 1	0 0 1 0	1 1 1	Rt
			L		op1	CRn	CRm	op2	

Encoding

```
TRCIT  <Xt>
```

is equivalent to

```
SYS  #3, C7, C2, #7, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose source register, encoded in the “Rt” field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.483 TSB

Trace synchronization barrier

This instruction is a barrier that synchronizes the trace operations of instructions, see Trace Synchronization Barrier (TSB). For information about the synchronization behavior when a `DSB` instruction follows a `TSB` instruction in program order, see:

- Trace synchronization and memory barriers.
- Synchronization in self-hosted trace.

If FEAT_TRF is not implemented, this instruction executes as a `NOP`.

System

(FEAT_TRF)

31–29	28–26	25–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 0	0 0 1 0 (CRm)	0 1 0 (op2)	1 1 1 1 1

Encoding

```
TSB  CSYNC
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_TRF) then EndOfDecode(Decode_NOP); end;
```

Operation

```
CheckTSBTrap();

TraceSynchronizationBarrier();
```

C6.2.484 TST (immediate)

Test bits (immediate)

This instruction performs a bitwise AND between a register value and an immediate value, and discards the results. It updates the condition flags based on the result.

This is an alias of ANDS (immediate). This means:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	1 1	1 0 0 1 0 0	N	immr	imms	Rn	1 1 1 1 1
	opc						Rd

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
TST  <Wn>, #<imm>
```

is equivalent to

```
ANDS  WZR, <Wn>, #<imm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
TST  <Xn>, #<imm>
```

is equivalent to

```
ANDS  XZR, <Xn>, #<imm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<imm>

Is the bitmask immediate. For encoding information, see Logical (immediate).

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of ANDS (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of ANDS (immediate) gives the operational information for this instruction.

Non-Confidential

C6.2.485 TST (shifted register)

Test (shifted register)

This instruction performs a bitwise AND between a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ANDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 … 24	23 22	21	20 … 16	15 … 10	9 … 5	4 … 0
sf	1 1 (opc)	0 1 0 1 0	shift	0 (N)	Rm	imm6	Rn	1 1 1 1 1 (Rd)

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
TST  <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ANDS  WZR, <Wn>, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
TST  <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ANDS  XZR, <Xn>, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of ANDS (shifted register) gives the operational information for this instruction.

C6.2.486 UBFIZ

Unsigned bitfield insert in zeros

This instruction copies a bitfield of `<width>` bits from the least significant bits of the source register to bit position `<lsb>` of the destination register, setting the destination bits above and below the bitfield to zero.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	1 0	1 0 0 1 1 0	N	immr	imms	Rn	Rd

opc

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
UBFIZ  <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM  <Wd>, <Wn>, #(-<lsb>  MOD  32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
UBFIZ  <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM  <Xd>, <Xn>, #(-<lsb>  MOD  64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<lsb>

For the “32-bit” variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.

For the “64-bit” variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<width>

For the “32-bit” variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the “64-bit” variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.487 UBFM

Unsigned bitfield move

This instruction is usually accessed using one of its aliases, which are always preferred for disassembly.

If `<imms>` is greater than or equal to `<immr>`, this copies a bitfield of (`<imms>`-`<immr>`+1) bits starting from bit position `<immr>` in the source register to the least significant bits of the destination register.

If `<imms>` is less than `<immr>`, this copies a bitfield of (`<imms>`+1) bits from the least significant bits of the source register to bit position (regsize-`<immr>`) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases, the destination bits below and above the bitfield are set to zero.

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	1 0	1 0 0 1 1 0	N	immr	imms	Rn	Rd
	opc						

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
UBFM  <Wd>, <Wn>, #<immr>, #<imms>
```

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
UBFM  <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
if sf == '1' && N != '1' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && (N != '0' || immr[5] != '0' || imms[5] != '0') then
    EndOfDecode(Decode_UNDEF);
end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let r : integer = UInt(immr);

var wmask : bits(datasize);
var tmask : bits(datasize);
(wmask, tmask) = DecodeBitMasks{datasize}(N, imms, immr, FALSE);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<immr>

For the “32-bit” variant: is the right rotate amount, in the range 0 to 31, encoded in the “immr” field.

For the “64-bit” variant: is the right rotate amount, in the range 0 to 63, encoded in the “immr” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<imms>

For the “32-bit” variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the “imms” field.

For the “64-bit” variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the “imms” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Alias Conditions

Alias	Of variant	Is preferred when
LSL (immediate)	32-bit	imms != '011111' && UInt(imms) + 1 == UInt(immr)
LSL (immediate)	64-bit	imms != '111111' && UInt(imms) + 1 == UInt(immr)
LSR (immediate)	32-bit	imms == '011111'
LSR (immediate)	64-bit	imms == '111111'
UBFIZ		UInt(imms) < UInt(immr)
UBFX		BFXPreferred(sf, opc<1>, imms, immr)
UXTB		immr == '000000' && imms == '000111'
UXTH		immr == '000000' && imms == '001111'

Operation

```
let src : bits(datasize) = X{}(n);

// Perform bitfield move on low bits
let bot : bits(datasize) = ROR(src, r) AND wmask;

// Combine extension bits and result bits
X{datasize}(d) = bot AND tmask;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.488 UBFX

Unsigned bitfield extract

This instruction copies a bitfield of `<width>` bits starting from bit position `<lsb>` in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to zero.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28 23	22	21 16	15 10	9 5	4 0
sf	1 0	1 0 0 1 1 0	N	immr	imms	Rn	Rd
	opc						

Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
UBFX  <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM  <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc[1], imms, immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
UBFX  <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM  <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc[1], imms, immr)`.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<lsb>

For the “32-bit” variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.

For the “64-bit” variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.

<width>

For the “32-bit” variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the “64-bit” variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

C6.2.489 UDF

Permanently undefined

This instruction generates an Undefined Instruction exception (ESR_ELx.EC = `0b000000`). The encodings for `UDF` used in this section are defined as permanently UNDEFINED.

31	30	29	28			25	24								16	15																0
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	imm16																

Encoding

```
UDF  #<imm>
```

Decode for this encoding

```
// The imm16 field is ignored by hardware.
EndOfDecode(Decode_UNDEF);
```

Assembler Symbols

<imm>

is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field. The PE ignores the value of this constant.

Operation

```
// No operation.
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.490 UDIV (quotient)

Unsigned divide

This instruction divides the first unsigned source register value by the second unsigned source register value, and writes the result to the destination register. Dividing by zero writes the value zero to the destination register. The condition flags are not affected.

31	30	29	28	21	20	16	15	11	10	9	5	4	0
sf	0	0	1 1 0 1 0 1 1 0		Rm		0 0 0 0 1		0	Rn		Rd	
		S							o1				

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
UDIV  <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
UDIV  <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let dividend : integer = UInt(operand1);
let divisor : integer = UInt(operand2);

var result : integer;
if divisor == 0 then
    result = 0;
else
    result = dividend DIVRM divisor;
end;

X{datasize}(d) = result[datasize-1:0];
```

Non-Confidential

C6.2.491 UMADDL

Unsigned multiply-add long

This instruction multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMULL (32-bit).

31	30 29	28	27 25	24	23	22 21	20 16	15	14 10	9 5	4 0
1	0 0	1	1 0 1	1	1	0 1	Rm	0	Ra	Rn	Rd
sf	op54				U			o0			

Encoding

```
UMADDL  <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Xa>

Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the “Ra” field.

Alias Conditions

Alias	Is preferred when
UMULL (32-bit)	Ra == '11111'

Operation

```
let operand1 : bits(32) = X{32}(n);
let operand2 : bits(32) = X{32}(m);
let operand3 : bits(64) = X{64}(a);

let result : integer = UInt(operand3) + UInt(operand1) * UInt(operand2);

X{64}(d) = result[63:0];
```

C6.2.494 UMIN (immediate)

Unsigned minimum (immediate)

This instruction determines the unsigned minimum of the source register value and immediate, and writes the result to the destination register.

Integer

(FEAT_CSSC)

31	30	29	28						22	21			18	17						10	9				5	4					0
sf	0	0	1	0	0	0	1	1	1	0	0	1	1	imm8							Rn					Rd					
op		S										opc																			

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
UMIN  <Wd>, <Wn>, #<uimm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
UMIN  <Xd>, <Xn>, #<uimm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let imm : integer = UInt(imm8);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<uimm>

Is an unsigned immediate, in the range 0 to 255, encoded in the “imm8” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = Min(UInt(operand1), imm);

X{datasize}(d) = result[datasize-1:0];
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.495 UMIN (register)

Unsigned minimum (register)

This instruction determines the unsigned minimum of the two source register values and writes the result to the destination register.

Integer

(FEAT_CSSC)

31	30	29	28							21	20				16	15						10	9				5	4				0
sf	0	0	1	1	0	1	0	1	1	0	Rm					0	1	1	0	1	1		Rn					Rd				
		S																	opcode													

Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
UMIN  <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
UMIN  <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

C6.2.496 UMNEGL

Unsigned multiply-negate long

This instruction multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This is an alias of UMSUBL. This means:

- The encodings in this description are named to match the encodings of UMSUBL.
- The description of UMSUBL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28	27 25	24	23	22 21	20 16	15	14 10	9 5	4 0
1	0 0	1	1 0 1	1	1	0 1	Rm	1	1 1 1 1 1	Rn	Rd
sf	op54				U			o0	Ra		

Encoding

```
UMNEGL  <Xd>, <Wn>, <Wm>
```

is equivalent to

```
UMSUBL  <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

The description of UMSUBL gives the operational pseudocode for this instruction.

Operational Information

The description of UMSUBL gives the operational information for this instruction.

Non-Confidential

C6.2.497 UMSUBL

Unsigned multiply-subtract long

This instruction multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMNEGL.

31	30 29	28	27 25	24	23	22 21	20 16	15	14 10	9 5	4 0
1	0 0	1	1 0 1	1	1	0 1	Rm	1	Ra	Rn	Rd
sf	op54				U			o0			

Encoding

```
UMSUBL  <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Xa>

Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the “Ra” field.

Alias Conditions

Alias	Is preferred when
UMNEGL	Ra == '11111'

Operation

```
let operand1 : bits(32) = X{32}(n);
let operand2 : bits(32) = X{32}(m);
let operand3 : bits(64) = X{64}(a);

let result : integer = UInt(operand3) - UInt(operand1) * UInt(operand2);

X{64}(d) = result[63:0];
```

C6.2.498 UMULH

Unsigned multiply high

This instruction multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.

31	30 29	28	27 25	24	23	22 21	20 16	15	14 10	9 5	4 0
1	0 0	1	1 0 1	1	1	1 0	Rm	0	(1)(1)(1)(1)(1)	Rn	Rd
sf	op54				U			o0	Ra		

Encoding

```
UMULH  <Xd>, <Xn>, <Xm>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn>

Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

```
let operand1 : bits(64) = X{64}(n);
let operand2 : bits(64) = X{64}(m);

let result : integer = UInt(operand1) * UInt(operand2);

X{64}(d) = result[127:64];
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.499 UMULL (32-bit)

Unsigned multiply long

This instruction multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This is an alias of UMADDL. This means:

- The encodings in this description are named to match the encodings of UMADDL.
- The description of UMADDL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30 29	28	27 25	24	23	22 21	20 16	15	14 10	9 5	4 0
1	0 0	1	1 0 1	1	1	0 1	Rm	0	1 1 1 1 1	Rn	Rd
sf	op54				U			o0	Ra		

Encoding

```
UMULL  <Xd>, <Wn>, <Wm>
```

is equivalent to

```
UMADDL  <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn>

Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Wm>

Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

The description of UMADDL gives the operational pseudocode for this instruction.

Operational Information

The description of UMADDL gives the operational information for this instruction.

C6.2.502 WFE

Wait for event

This instruction is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the `SEV` instruction on any PE in the multiprocessor system. For more information, see Wait For Event mechanism and Send event.

As described in Wait For Event mechanism and Send event, the execution of a `WFE` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.

31–29	28–26	25–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 0	0 0 0 0 (CRm)	0 1 0 (op2)	1 1 1 1 1

Encoding

```
WFE
```

Decode for this encoding

```
// Empty.
```

Operation

```
Hint_WFE();
```

C6.2.503 WFET

Wait for event with timeout

This instruction provides a hint that the PE can enter a low-power state and remain there until either a local timeout event or a wakeup event occurs. Wakeup events include the event signaled as a result of executing the `SEV` instruction on any PE in the multiprocessor system. For more information, see Wait For Event mechanism and Send event.

As described in Wait For Event mechanism and Send event, the execution of a `WFET` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.

System

(FEAT_WFxT)

31–29	28–26	25–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 0 1	0 0 0 0 (CRm)	0 0 0 (op2)	Rd

Encoding

```
WFET  <Xt>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_WFxT) then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
```

Assembler Symbols

<Xt>

Is the 64-bit name of the general-purpose source register, encoded in the “Rd” field.

Operation

```
let localtimeout : integer = UInt(X{64}(d));

if Halted() && ConstrainUnpredictableBool(Unpredictable_WFxTDEBUG) then
    ExecuteAsNOP();
end;

Hint_WFET(localtimeout);
```

C6.2.508 YIELD

Yield

This instruction is a hint instruction. Software with a multithreading capability can use a `YIELD` instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction, see The YIELD instruction.

31–29	28–26	25–12	11–8	7–5	4–0
1 1 0	1 0 1	0 1 0 0 0 0 0 0 1 1 0 0 1 0	0 0 0 0 (CRm)	0 0 1 (op2)	1 1 1 1 1

Encoding

```
YIELD
```

Chapter C7
A64 Advanced SIMD and Floating-point Instruction Descriptions

This chapter describes the A64 Advanced SIMD and floating-point instructions.

It contains the following sections:

- About the A64 Advanced SIMD and floating-point instructions
- Alphabetical list of A64 Advanced SIMD and floating-point instructions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C7.1 About the A64 Advanced SIMD and floating-point instructions

Alphabetical list of A64 Advanced SIMD and floating-point instructions gives full descriptions of the A64 instructions that are in the following instruction groups:

- Loads and store instructions associated with the SIMD and floating-point registers.
- Data processing instructions with SIMD and floating-point registers.

A64 instruction set encoding in the A64 Instruction Encodings chapter provides an overview of the instruction encodings as part of an instruction class within a functional group.

The rest of this section is a general description of the SIMD and floating-point instructions. It contains the following subsections:

- Register size
- Output element control
- Data types
- Condition flags and related instructions

C7.1.1 Register size

A64 provides a comprehensive set of packed Single Instruction Multiple Data (SIMD) and scalar operations using data held in the 32 entry 128-bit wide SIMD and floating-point register file.

Each SIMD and floating-point register can be used to hold:

- A single scalar value of the floating-point or integer type.
- A 64-bit wide vector containing one or more elements.
- A 128-bit wide vector containing two or more elements.

Where the entire 128-bit wide register is not fully utilized, the vector or scalar quantity is held in the least significant bits of the register, with the most significant bits being cleared to zero on a write, see Advanced SIMD vector formats.

The following instructions can insert data into individual elements within a SIMD and floating-pointer register without clearing the remaining bits to zero:

- Insert vector element from another vector element or general-purpose register, `INS`.
- Load structure into a single lane, for example `LD3`.
- All second-part narrowing operations, for example `SHRN2`.

C7.1.2 Output element control

When FEAT_AFP is implemented, the FPCR.NEP bit controls how output elements are determined for the scalar Advanced SIMD instructions for elements other than the lowest element of the vector.

If FPCR.NEP == 1, the following instructions determine output elements as follows:

- The 3-input floating-point scalar versions of FMLA (by element) and FMLS (by element) take output elements other than the lowest element from the <Hd>, <Sd>, or <Dd> register.
- The 3-input floating-point FMADD, FMSUB, FNMADD, and FNMSUB instructions take output elements other than the lowest element from the <Ha>, <Sa>, or <Da> register.
- The 2-input floating-point scalar versions of FCMGE (register), FCMGT (register), FCMEQ (register), FACGE, FACGT, take output elements other than the lowest element from the <Hm>, <Sm>, or <Dm> register.
- The 2-input floating-point scalar versions of FMULX, FRECPS, FRSQRTS, FABD, FMUL (by element), FMUL (scalar), FDIV (scalar), FADD (scalar), FSUB (scalar), FMAX (scalar), FMIN (scalar), FMAXNM (scalar), FMINNM (scalar), FNMUL (scalar), take output elements other than the lowest element from the <Hn>, <Sn>, or <Dn> register.

- For 1-input floating-point scalar versions of the instructions FCVTNS (vector), FCVTMS (vector), FCVTAS (vector), FCVTPS (vector), SCVTF (vector, integer), UCVTF (vector, integer) FCVTZS (vector, integer), FCVTZU (vector, integer), FCVTNU (vector), FCVTMU (vector), FCVTAU (vector), FCVTPU (vector), SCVTF (vector, fixed-point), UCVTF (vector, fixed-point), FCVTZS (vector, fixed-point), FCVTZU (vector, fixed-point), SCVTF (scalar, integer), UCVTF (scalar, integer), SCVTF (scalar, fixed-point), UCVTF (scalar, fixed-point), BFCVT, FCVT, `FCVTXN`, FRECPE, FRECPX, FRSQRTE, FABS (scalar), FNEG (scalar), FSQRT (scalar), FRINTN (scalar), FRINTP (scalar), FRINTM (scalar), FRINTZ (scalar), FRINTA (scalar), FRINTI (scalar), FRINTX (scalar), FRINT32Z (scalar), FRINT32X (scalar), FRINT64Z (scalar), FRINT64X (scalar), take output elements other than the lowest element from the <Hd>, <Sd>, or <Dd> register.

C7.1.3 Data types

The A64 instruction set provides support for arithmetic, conversion, and bitwise operations on:

- Half-precision, single-precision, and double-precision floating-points.
- Signed and unsigned integers.
- Polynomials over {0, 1}.
- When FEAT_FCMA is implemented, complex numbers.

For all AArch64 floating-point operations, including SIMD operations, the rounding mode and exception trap handling are controlled by the FPCR.

Note

- AArch32 Advanced SIMD operations always use Arm standard floating-point arithmetic, regardless of the rounding mode specified by the AArch64 FPCR or the AArch32 FPSCR.
- In AArch64 state, floating-point multiply-add operations are always performed as fused operations, but AArch32 state provides both fused and chained multiply-add instructions.

In addition to operations that consume and produce values of the same width and type, the A64 instruction set supports SIMD and scalar operations that produce a wider or narrower vector result:

- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the A64 instruction set provides a second-part operation, for example `SHRN2`, that can pack the result of a second operation into the upper part of the same destination register.
- Where a SIMD operation widens a 64-bit vector to a 128-bit vector, the A64 instruction set provides a second-part operation, for example `SMLAL2`, that can extract the source from the upper 64 bits of the source registers.

All SIMD operations that could produce side-effects that are not limited to the destination SIMD and floating-point register, for example a potential update of FPSR.Q or FPSR.IDC, have a dedicated scalar variant to support the use of SIMD with loops requiring specialized head or tail handling, or both.

C7.1.4 Condition flags and related instructions

The A64 instruction set provides support for flag setting and conditional operations on the SIMD and floating-point register file:

- Floating-point `FCSEL` and `FCCMP` instructions are equivalent to the integer `CSEL` and `CCMP` instructions.
- Floating-point `FCMP`, `FCMPE`, `FCCMP`, and `FCCMP` instructions set the PSTATE.{N, Z, C, V} flags based on the result of the floating-point comparison.
- Floating-point `FJCVTZS` instruction sets the PSTATE.Z flag if the result of the conversion, when converted back to a double-precision floating-point number, gives precisely the same value as the original. Other PSTATE flags are cleared by this instruction.
- Floating-point and integer instructions provide a means of producing either a scalar or a vector mask based on a comparison in a SIMD and floating-point register, for example `FCMEQ`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

`FCMP` and `FCMPE` differ from the A32/T32 `VCMP` and `VCMPE` instructions, which use the dedicated FPSCR.NZCV field for the result. A64 instructions store the result of an `FCMP` or `FCMPE` operation in the PSTATE.{N, Z, C, V} field.
If FEAT_FlagM2 is implemented, base instructions XAFLAG and AXFLAG convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format. See Table C6-1.

C7.2.1 ABS

Absolute value (vector)

This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register. If the value in an element of the source vector is the most negative value, the result for that element is the same as the value in that element of the source vector.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

Assembler Symbols

<d>

Is the number of the SIMD&FP destination register, encoded in the “Rd” field.

<n>

Is the number of the SIMD&FP source register, encoded in the “Rn” field.

<Vd>

Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<Vn>

Is the name of the SIMD&FP source register, encoded in the “Rn” field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(datasize) = V{}(n);
var result : bits(datasize);
var element : integer;

for e = 0 to elements-1 do
    element = SInt(operand[e*:esize]);
    element = Abs(element);
    result[e*:esize] = element[esize-1:0];
end;

V{datasize}(d) = result;
```

Operational Information

C7.2.3 ADDHN, ADDHN2

Add returning high narrow

This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are truncated. For rounded results, see RADDHN.

The `ADDHN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `ADDHN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

(FEAT_AdvSIMD)

Non-Confidential

C7.2.5 ADDP (vector)

Add pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.10 AESMC

AES mix columns

This instruction reads a 16-byte state array from the source vector and performs a single round of the MixColumns() transformation on the state array in accordance with the AES standard. The updated state array is placed in the destination vector.

C7.2.11 AND (vector)

Bitwise AND (vector)

This instruction performs a bitwise AND between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.13 BF1CVTL, BF1CVTL2, BF2CVTL, BF2CVTL2

8-bit floating-point convert to BFloat16 (vector)

This instruction converts each 8-bit floating-point element from the lower or upper half of the source vector to BFloat16 while downscaling the value, and places the results in the 16-bit elements of the destination vector. `BF1CVTL` and `BF2CVTL` convert the elements from the lower half of the source vector while scaling the values by $2^{-\text{UInt(FPMR.LSCALE[5:0])}}$ and $2^{-\text{UInt(FPMR.LSCALE2[5:0])}}$, respectively. `BF1CVTL2` and `BF2CVTL2` convert the elements from the upper half of the source vector while scaling the values by $2^{-\text{UInt(FPMR.LSCALE[5:0])}}$ and $2^{-\text{UInt(FPMR.LSCALE2[5:0])}}$, respectively.

The 8-bit floating-point encoding format for `BF1CVTL` and `BF1CVTL2` is selected by FPMR.F8S1. The 8-bit floating-point encoding format for `BF2CVTL` and `BF2CVTL2` is selected by FPMR.F8S2.

C7.2.15 BFCVTN, BFCVTN2

Single-precision convert to BFloat16 (vector)

This instruction reads each single-precision element in the SIMD&FP source vector, converts each value to BFloat16 format, and writes the results in the lower or upper half of the SIMD&FP destination vector. The result elements are half the width of the source elements.

The `BFCVTN` instruction writes the half-width results to the lower half of the 128-bit SIMD&FP destination vector and clears the upper half to zero. The `BFCVTN2` instruction writes the results to the upper half of the 128-bit SIMD&FP destination vector without affecting the lower half.

C7.2.16 BFDOT (by element)

BFloat16 dot product to single-precision (vector, by element)

This instruction delimits the source vectors into pairs of BFloat16 elements. The BFloat16 pair within the second source vector is specified using an immediate index. The index range is from 0 to 3 inclusive.

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, this instruction:

- Performs an unfused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second source vector. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Honors FPCR.AH when generating a default NaN result, otherwise disables alternative floating point behaviors, as if FPCR.AH is 0.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, then this instruction:

- Performs a fused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second source vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as governed by FPCR.RMode, FPCR.FZ, FPCR.AH, and FPCR.FIZ.

Irrespective of FEAT_EBF16 and FPCR.EBF, this instruction:

- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

C7.2.20 BFMMLA (widening)

BFloat16 matrix multiply-accumulate to single-precision

This instruction multiplies the 2x4 matrix of BFloat16 values held in the first source vector by the 4x2 matrix of BFloat16 values in the second source vector.

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, this instruction:

- Calculates the intermediate single-precision results as a sum of two unfused sum-of-products using two pairs of adjacent BFloat16 values from each of the source vectors, and then rounds the results before accumulation into the 2x2 matrix of single-precision results in the destination vector. This is equivalent to accumulating a 4-way dot product per destination element.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Honors FPCR.AH when generating a default NaN result, otherwise disables alternative floating point behaviors, as if FPCR.AH is 0.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, this instruction:

- Calculates the intermediate single-precision results as a sum of two fused sum-of-products using two pairs of adjacent BFloat16 values from each of the source vectors, and then rounds the results before accumulation into the 2x2 matrix of single-precision results in the destination vector. This is equivalent to accumulating a 4-way dot product per destination element.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as governed by FPCR.RMode, FPCR.FZ, FPCR.AH, and FPCR.FIZ.

Irrespective of FEAT_EBF16 and FPCR.EBF, this instruction:

- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

Assembler Symbols

<Vd>

Is the name of the SIMD&FP third source and destination register, encoded in the “Rd” field.

<Vn>

Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm>

Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let op1 : bits(128) = V{}(n);
let op2 : bits(128) = V{}(m);
let acc : bits(128) = V{}(d);

V{128}(d) = BFMatMulAddH(acc, op1, op2, FPCR());
```

Operational Information

Arm expects that the `BFMMLA` instruction will deliver a peak BFloat16 multiply throughput that is at least as high as can be achieved using two `BFDOT` (vector) instructions, with a goal that it should have significantly higher throughput.

C7.2.21 BIC (vector, immediate)

Bitwise bit clear (vector, immediate)

This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise AND between each result and the complement of an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Shifted immediate

(FEAT_AdvSIMD)

31	30	29	28									19	18	17	16	15			12	11	10	9	8	7	6	5	4	0

C7.2.30 CMGE (register)

Compare signed greater than or equal (vector)

This instruction compares each vector element in the first source SIMD&FP register with the corresponding vector element in the second source SIMD&FP register and if the first signed integer value is greater than or equal to the second signed integer value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.36 CMLE (zero)

Compare signed less than or equal to zero (vector)

This instruction reads each vector element in the source SIMD&FP register and if the signed integer value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.44 EXT

Extract vector from pair of vectors

This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

Figure C7-1 EXT doubleword operation for Q = 0 and imm4<2:0> = 3

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.45 F1CVTL, F1CVTL2, F2CVTL, F2CVTL2

8-bit floating-point convert to half-precision (vector)

This instruction converts each 8-bit floating-point element from the lower or upper half of the source vector to half-precision while downscaling the value, and places the results in the 16-bit elements of the destination vector. `F1CVTL` and `F2CVTL` convert the elements from the lower half of the source vector while scaling the values by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$ and $2^{-\text{UInt(FPMR.LSCALE2[3:0])}}$, respectively. `F1CVTL2` and `F2CVTL2` convert the elements from the upper half of the source vector while scaling the values by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$ and $2^{-\text{UInt(FPMR.LSCALE2[3:0])}}$, respectively.

The 8-bit floating-point encoding format for `F1CVTL` and `F1CVTL2` is selected by FPMR.F8S1. The 8-bit floating-point encoding format for `F2CVTL` and `F2CVTL2` is selected by FPMR.F8S2.

C7.2.46 FABD

Floating-point absolute difference (vector)

This instruction subtracts the floating-point values in the elements of the second source SIMD&FP register, from the corresponding floating-point values in the elements of the first source SIMD&FP register, places the absolute value of each result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

Scalar half-precision

C7.2.49 FACGE

Floating-point absolute compare greater than or equal (vector)

This instruction compares the absolute value of each floating-point value in the first source SIMD&FP register with the absolute value of the corresponding floating-point value in the second source SIMD&FP register and if the first value is greater than or equal to the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

C7.2.50 FACGT

Floating-point absolute compare greater than (vector)

This instruction compares the absolute value of each vector element in the first source SIMD&FP register with the absolute value of the corresponding vector element in the second source SIMD&FP register and if the first value is greater than the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

C7.2.54 FADDP (vector)

Floating-point add pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.55 FAMAX

Floating-point absolute maximum

This instruction determines the maximum absolute value from floating-point elements of the first source vector and the corresponding floating-point elements of the second source vector, and places the results in the corresponding elements of the destination vector.

The behavior is as follows:

- Alternate floating-point behaviors do not apply, as if FPCR.AH is 0.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN derived as follows:
  - If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
  - Otherwise, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a NaN, the result is the default NaN, with the sign bit set to 0.
- Denormalized inputs and results are never flushed to zero, as if FPCR.{FZ, FZ16, FIZ} are all 0.
- Denormalized inputs never generate an Input Denormal floating-point exception.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision

C7.2.56 FAMIN

Floating-point absolute minimum

This instruction determines the minimum absolute value from floating-point elements of the first source vector and the corresponding floating-point elements of the second source vector, and places the results in the corresponding elements of the destination vector.

The behavior is as follows:

- Alternate floating-point behaviors do not apply, as if FPCR.AH is 0.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN derived as follows:
  - If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
  - Otherwise, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a NaN, the result is the default NaN, with the sign bit set to 0.
- Denormalized inputs and results are never flushed to zero, as if FPCR.{FZ, FZ16, FIZ} are all 0.
- Denormalized inputs never generate an Input Denormal floating-point exception.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision

C7.2.57 FCADD

Floating-point complex add

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following calculation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.58 FCCMP

Floating-point conditional quiet compare (scalar)

This instruction, if the condition passes, has the following behavior:

- This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.{N, Z, C, V} flags.
- This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.
- This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

If the condition does not pass, then the comparison is not performed and the PSTATE.{N, Z, C, V} flags are set to the flag bit specifier.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Non-Confidential

Operation

```
AArch64_CheckFPEnabled();

let operand1 : bits(datasize) = V{}(n);
let operand2 : bits(datasize) = V{}(m);

if ConditionHolds(condition) then
    let signal_all_nans : boolean = FALSE;
    flags = FPCompare{datasize}(operand1, operand2, signal_all_nans, FPCR());
end;

PSTATE.[N,Z,C,V] = flags;
```

Operational Information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, >, or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2), and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction that is dependent on the NZCV condition flags written by this instruction might be significantly delayed.

C7.2.59 FCCMPE

Floating-point conditional signaling compare (scalar)

This instruction, if the condition passes, has the following behavior:

- This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.{N, Z, C, V} flags.
- This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.
- This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

If the condition does not pass, then the comparison is not performed and the PSTATE.{N, Z, C, V} flags are set to the flag bit specifier.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.60 FCMEQ (register)

Floating-point compare equal (vector)

This instruction compares each floating-point value from the first source SIMD&FP register, with the corresponding floating-point value from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

C7.2.61 FCMEQ (zero)

Floating-point compare equal to zero (vector)

This instruction reads each floating-point value in the source SIMD&FP register and if the value is equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

Scalar half-precision

C7.2.66 FCMLA (by element)

Floating-point complex multiply accumulate (by element)

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following calculation on complex numbers from the first source register and the destination register with the specified complex number from the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.69 FCMLT (zero)

Floating-point compare less than zero (vector)

This instruction reads each floating-point value in the source SIMD&FP register and if the value is less than zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

Scalar half-precision

C7.2.70 FCMP

Floating-point quiet compare (scalar)

This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE.{N, Z, C, V} flags.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

For the “Double-precision, zero” variant: is the 64-bit name of the SIMD&FP source register, encoded in the “Rn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64_CheckFPEnabled();

let operand1 : bits(datasize) = V{}(n);
let operand2 : bits(datasize) = if cmp_with_zero then FPZero{datasize}('0') else V{datasize}(m);

PSTATE.[N,Z,C,V] = FPCompare{datasize}(operand1, operand2, signal_all_nans, FPCR());
```

Operational Information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, >, or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2), and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction that is dependent on the NZCV condition flags written by this instruction might be significantly delayed.

C7.2.71 FCMPE

Floating-point signaling compare (scalar)

This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE.{N, Z, C, V} flags.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.74 FCVTAS (vector)

Floating-point convert to signed integer, rounding to nearest with ties to away (vector)

This instruction converts each element in a vector from a floating-point value to a signed integer value using the Round to Nearest with Ties to Away rounding mode and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

C7.2.75 FCVTAS (scalar)

Floating-point convert to signed integer, rounding to nearest with ties to away (scalar)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round to Nearest with Ties to Away rounding mode, and writes the result to the general-purpose destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.80 FCVTL, FCVTL2

Floating-point convert to higher precision long (vector)

This instruction reads each element in a vector in the SIMD&FP source register, converts each value to double the precision of the source element using the rounding mode that is determined by the FPCR, and writes each result to the equivalent element of the vector in the SIMD&FP destination register.

Where the operation lengthens a 64-bit vector to a 128-bit vector, the `FCVTL2` variant operates on the elements in the top 64 bits of the source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector single-precision and double-precision

C7.2.81 FCVTMS (vector)

Floating-point convert to signed integer, rounding toward minus infinity (vector)

This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Minus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

Scalar half-precision

C7.2.85 FCVTMU (scalar)

Floating-point convert to unsigned integer, rounding toward minus infinity (scalar)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round towards Minus Infinity rounding mode, and writes the result to the general-purpose destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.87 FCVTN, FCVTN2 (double to single-precision, single to half-precision)

Floating-point convert to lower precision narrow (vector)

This instruction reads each vector element in the SIMD&FP source register, converts each result to half the precision of the source element, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The rounding mode is determined by the FPCR.

`FCVTN` writes the vector to the lower half of the destination register and clears the upper half. `FCVTN2` writes the vector to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.90 FCVTNS (vector)

Floating-point convert to signed integer, rounding to nearest with ties to even (vector)

This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

Scalar half-precision

C7.2.91 FCVTNS (scalar)

Floating-point convert to signed integer, rounding to nearest with ties to even (scalar)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round to Nearest rounding mode, and writes the result to the general-purpose destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.92 FCVTNS (scalar SIMD&FP)

Floating-point convert to signed integer, rounding to nearest with ties to even (scalar SIMD&FP)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round to Nearest with Ties to Even rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.93 FCVTNU (vector)

Floating-point convert to unsigned integer, rounding to nearest with ties to even (vector)

This instruction converts a scalar or each element in a vector from a floating-point value to an unsigned integer value using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

Scalar half-precision

C7.2.98 FCVTPS (scalar SIMD&FP)

Floating-point convert to signed integer, rounding toward plus infinity (scalar SIMD&FP)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round toward Plus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.102 FCVTXN, FCVTXN2

Floating-point convert to lower precision narrow, rounding to odd (vector)

This instruction reads each double-precision element in the source SIMD&FP register, converts each value to single-precision format using the Round to Odd rounding mode, and writes the results to the destination SIMD&FP register.

Note

This instruction uses the Round to Odd rounding mode, which is not defined by the IEEE 754-2008 standard. This rounding mode ensures that if the result of the conversion is inexact, the least significant bit of the mantissa is forced to 1. This rounding mode enables a floating-point value to be converted to a lower precision format using an intermediate precision format while avoiding double rounding errors. For example, a 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value by first using this instruction to produce a 32-bit value and then using another instruction with the wanted rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

The Vector variant of `FCVTXN` writes the half-width results to the lower half of the destination register and clears the upper half to 0. `FCVTXN2` writes the half-width results to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.104 FCVTZS (vector, integer)

Floating-point convert to signed integer, rounding toward zero (vector)

This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

Scalar half-precision

C7.2.109 FCVTZU (vector, integer)

Floating-point convert to unsigned integer, rounding toward zero (vector)

This instruction converts a scalar or each element in a vector from a floating-point value to an unsigned integer value using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

Scalar half-precision

C7.2.110 FCVTZU (scalar, fixed-point)

Floating-point convert to unsigned fixed-point, rounding toward zero (scalar)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit fixed-point unsigned integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.115 FDOT (8-bit floating-point to half-precision, by element)

8-bit floating-point dot product to half-precision (vector, by element)

This instruction calculates the fused sum-of-products of a pair of 8-bit floating-point values held in each 16-bit element of the first source vector and a pair of 8-bit floating-point values in an indexed 16-bit element of the second source vector. The half-precision sum-of-products are scaled by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$, before being destructively added without intermediate rounding to the corresponding half-precision elements of the destination vector.

The 8-bit floating-point groups within the second source vector are specified using an immediate index.

The 8-bit floating-point encoding format for the elements of the first source vector is selected by FPMR.F8S1. The 8-bit floating-point encoding format for the elements of the second source vector is selected by FPMR.F8S2.

C7.2.119 FJCVTZS

Floating-point JavaScript convert to signed fixed-point, rounding toward zero

This instruction converts the double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register. If the result is too large to be represented as a signed 32-bit integer, then the result is the integer modulo 2^{32}, as held in a 32-bit signed integer.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Double-precision to 32-bit

(FEAT_JSCVT)

Encoding

```
FJCVTZS  <Wd>, <Dn>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_JSCVT) then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Dn>

Is the 64-bit name of the SIMD&FP source register, encoded in the “Rn” field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let fltval : bits(64) = V{}(n);

var intval : bits(32);
var z : bit;
(intval, z) = FPToFixedJS(fltval, FPCR());

X{32}(d) = intval;
PSTATE.[N,Z,C,V] = '0'::z::'00';

C7.2.120 FMADD

Floating-point fused multiply-add (scalar)

This instruction multiplies the values of the first two SIMD&FP source registers, adds the product to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.121 FMAX (vector)

Floating-point maximum (vector)

This instruction compares corresponding vector elements in the two source SIMD&FP registers, places the larger of each of the two floating-point values into a vector, and writes the vector to the destination SIMD&FP register.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN derived as follows:
  - If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
  - Otherwise, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.122 FMAX (scalar)

Floating-point maximum (scalar)

This instruction compares the two source SIMD&FP registers, and writes the larger of the two floating-point values to the destination SIMD&FP register.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either value is a NaN, the result is a quiet NaN derived as follows:
  - If at least one value is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN value.
  - Otherwise, the result is a quiet NaN derived from the first NaN value.
- When FPCR.DN is 1, if either value is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both values are zeros, regardless of the sign of either zero, the result is the second value.
- If either value is a NaN, regardless of the value of FPCR.DN, the result is the second value.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.123 FMAXNM (vector)

Floating-point maximum number (vector)

This instruction compares corresponding vector elements in the two source SIMD&FP registers, writes the larger of the two floating-point values into a vector, and writes the vector to the destination SIMD&FP register.

The behavior is as follows:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the quiet NaN element is ignored and the result is the numeric element.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN derived as follows:
  - If FPCR.AH is 0:
    - — If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
    - — Otherwise, the result is a quiet NaN derived from the first NaN element.
  - If FPCR.AH is 1, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.125 FMAXNMP (scalar)

Floating-point maximum number of pair of elements (scalar)

This instruction compares two vector elements in the source SIMD&FP register and writes the largest of the floating-point values as a scalar to the destination SIMD&FP register.

The behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the quiet NaN element is ignored and the result is the numeric element.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN derived as follows:
  - If FPCR.AH is 0:
    - — If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
    - — Otherwise, the result is a quiet NaN derived from the first NaN element.
  - If FPCR.AH is 1, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.126 FMAXNMP (vector)

Floating-point maximum number pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

The behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the quiet NaN element is ignored and the result is the numeric element.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN derived as follows:
  - If FPCR.AH is 0:
    - — If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
    - — Otherwise, the result is a quiet NaN derived from the first NaN element.
  - If FPCR.AH is 1, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.127 FMAXNMV

Floating-point maximum number across vector

This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

The behavior is as follows:

- Negative zero compares less than positive zero.
- If one value is numeric and the other is a quiet NaN, the quiet NaN value is ignored and the result is the numeric value.
- When FPCR.DN is 0, if either value is a signaling NaN or if both values are NaNs, the result is a quiet NaN derived as follows:
  - If FPCR.AH is 0:
    - If at least one value is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN value.
    - Otherwise, the result is a quiet NaN derived from the first NaN value.
  - If FPCR.AH is 1, the result is a quiet NaN derived from the first NaN value.
- When FPCR.DN is 1, if either value is a signaling NaN or if both values are NaNs, the result is default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision

C7.2.128 FMAXP (scalar)

Floating-point maximum of pair of elements (scalar)

This instruction compares two vector elements in the source SIMD&FP register and writes the largest of the floating-point values as a scalar to the destination SIMD&FP register.

When FPCR.AH is 0, the behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN derived as follows:
  - If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
  - Otherwise, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows for each pairwise operation:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision

C7.2.129 FMAXP (vector)

Floating-point maximum pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, writes the larger of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

When FPCR.AH is 0, the behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN derived as follows:
  - If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
  - Otherwise, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows for each pairwise operation:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.130 FMAXV

Floating-point maximum across vector

This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either value is a NaN, the result is a quiet NaN derived as follows:
  - If at least one value is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN value.
  - Otherwise, the result is a quiet NaN derived from the first NaN value.
- When FPCR.DN is 1, if either value is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both values are zeros, regardless of the sign of either zero, the result is the second value.
- If either value is a NaN, regardless of the value of FPCR.DN, the result is the second value.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision

C7.2.133 FMINNM (vector)

Floating-point minimum number (vector)

This instruction compares corresponding vector elements in the two source SIMD&FP registers, writes the smaller of the two floating-point values into a vector, and writes the vector to the destination SIMD&FP register.

The behavior is as follows:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the quiet NaN element is ignored and the result is the numeric element.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN derived as follows:
  - If FPCR.AH is 0:
    - — If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
    - — Otherwise, the result is a quiet NaN derived from the first NaN element.
  - If FPCR.AH is 1, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.134 FMINNM (scalar)

Floating-point minimum number (scalar)

This instruction compares the first and second source SIMD&FP register values, and writes the smaller of the two floating-point values to the destination SIMD&FP register.

The behavior is as follows:

- Negative zero compares less than positive zero.
- If one value is numeric and the other is a quiet NaN, the quiet NaN value is ignored and the result is the numeric value.
- When FPCR.DN is 0, if either value is a signaling NaN or if both values are NaNs, the result is a quiet NaN derived as follows:
  - If FPCR.AH is 0:
    - If at least one value is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN value.
    - Otherwise, the result is a quiet NaN derived from the first NaN value.
  - If FPCR.AH is 1, the result is a quiet NaN derived from the first NaN value.
- When FPCR.DN is 1, if either value is a signaling NaN or if both values are NaNs, the result is default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.135 FMINNMP (scalar)

Floating-point minimum number of pair of elements (scalar)

This instruction compares two vector elements in the source SIMD&FP register and writes the smallest of the floating-point values as a scalar to the destination SIMD&FP register.

The behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the quiet NaN element is ignored and the result is the numeric element.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN derived as follows:
  - If FPCR.AH is 0:
    - — If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
    - — Otherwise, the result is a quiet NaN derived from the first NaN element.
  - If FPCR.AH is 1, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.136 FMINNMP (vector)

Floating-point minimum number pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of floating-point values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

The behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the quiet NaN element is ignored and the result is the numeric element.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN derived as follows:
  - If FPCR.AH is 0:
    - — If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
    - — Otherwise, the result is a quiet NaN derived from the first NaN element.
  - If FPCR.AH is 1, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.138 FMINP (scalar)

Floating-point minimum of pair of elements (scalar)

This instruction compares two vector elements in the source SIMD&FP register and writes the smallest of the floating-point values as a scalar to the destination SIMD&FP register.

When FPCR.AH is 0, the behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN derived as follows:
  - If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
  - Otherwise, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows for each pairwise operation:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.139 FMINP (vector)

Floating-point minimum pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, writes the smaller of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

When FPCR.AH is 0, the behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN derived as follows:
  - If at least one element is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN element.
  - Otherwise, the result is a quiet NaN derived from the first NaN element.
- When FPCR.DN is 1, if either element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows for each pairwise operation:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Floating-point minimum across vector

This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either value is a NaN, the result is a quiet NaN derived as follows:
  - If at least one value is a signaling NaN, the result is a quiet NaN derived from the first signaling NaN value.
  - Otherwise, the result is a quiet NaN derived from the first NaN value.
- When FPCR.DN is 1, if either value is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both values are zeros, regardless of the sign of either zero, the result is the second value.
- If either value is a NaN, regardless of the value of FPCR.DN, the result is the second value.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision

C7.2.141 FMLA (by element)

Floating-point fused multiply-add to accumulator (by element)

This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the results in the vector elements of the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision, Scalar, single-precision and double-precision, Vector, half-precision, and Vector, single-precision and double-precision

C7.2.143 FMLAL, FMLAL2 (by element)

Floating-point fused multiply-add long to accumulator (by element)

This instruction multiplies the half-precision vector elements in the first source SIMD&FP register by the specified half-precision value in the second source SIMD&FP register, and accumulates the intermediate product without rounding to the corresponding single-precision vector element of the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4, it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

It has encodings from 2 classes: FMLAL and FMLAL2

C7.2.145 FMLALB, FMLALT (by element)

8-bit floating-point multiply-add to half-precision (vector, by element)

This instruction widens the even-numbered (bottom) or odd-numbered (top) 8-bit elements in the first source vector and the indexed element from the second source vector to half-precision format and multiplies the corresponding elements. The intermediate products are scaled by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$, before being destructively added without intermediate rounding to the half-precision elements of the destination vector that overlap with the corresponding 8-bit floating-point elements in the first source vector.

The 8-bit floating-point encoding format for the elements of the first source vector is selected by FPMR.F8S1. The 8-bit floating-point encoding format for the elements of the second source vector is selected by FPMR.F8S2.

C7.2.149 FMLS (by element)

Floating-point fused multiply-subtract from accumulator (by element)

This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and subtracts the results from the vector elements of the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision, Scalar, single-precision and double-precision, Vector, half-precision, and Vector, single-precision and double-precision

Scalar, half-precision

C7.2.150 FMLS (vector)

Floating-point fused multiply-subtract from accumulator (vector)

This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, negates the product, adds the result to the corresponding vector element of the destination SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision

C7.2.151 FMLSL, FMLSL2 (by element)

Floating-point fused multiply-subtract long from accumulator (by element)

This instruction multiplies the negated half-precision vector elements in the first source SIMD&FP register by the specified half-precision value in the second source SIMD&FP register, and accumulates the intermediate product without rounding to the corresponding single-precision vector element of the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4, it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

It has encodings from 2 classes: FMLSL and FMLSL2

C7.2.152 FMLSL, FMLSL2 (vector)

Floating-point fused multiply-subtract long from accumulator (vector)

This instruction negates the half-precision values in the vector of one SIMD&FP register, multiplies these with the corresponding half-precision values in another vector, and accumulates the intermediate product without rounding to the corresponding single-precision vector element of the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4, it is mandatory for all implementations to support it.

C7.2.153 FMMLA (widening, 8-bit floating-point to half-precision)

8-bit floating-point matrix multiply-accumulate to half-precision

This instruction multiplies the 2×4 matrix of 8-bit floating-point values held in each 64-bit segment of the first source vector by the 4×2 matrix of 8-bit floating-point values in the corresponding segment of the second source vector. The intermediate half-precision results, calculated as a fused sum-of-products using four adjacent 8-bit floating-point values from each of the source vectors, are scaled by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$ before being destructively added without intermediate rounding to the 2x2 half-precision matrix in the corresponding segment of the destination vector. This is equivalent to accumulating 4-way dot product per destination element.

The 8-bit floating-point encoding format for the elements of the first source vector is selected by FPMR.F8S1. The 8-bit floating-point encoding format for the elements of the second source vector is selected by FPMR.F8S2.

Advanced SIMD

C7.2.154 FMMLA (widening, 8-bit floating-point to single-precision)

8-bit floating-point matrix multiply-accumulate to single-precision

This instruction multiplies the 2×8 matrix of 8-bit floating-point values held in the first source vector by the 8×2 matrix of 8-bit floating-point values in the second source vector. The intermediate single-precision results, calculated as a fused sum-of-products using eight adjacent 8-bit floating-point values from each of the source vectors, are scaled by $2^{-\mathrm{UInt(FPMR.LSCALE)}}$ before being destructively added without intermediate rounding to the 2x2 single-precision matrix in the destination vector. This is equivalent to accumulating 8-way dot product per destination element.

The 8-bit floating-point encoding format for the elements of the first source vector is selected by FPMR.F8S1. The 8-bit floating-point encoding format for the elements of the second source vector is selected by FPMR.F8S2.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

<Sn>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Rn” field.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

<Vd>

Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<Dn>

Is the 64-bit name of the SIMD&FP source register, encoded in the “Rn” field.

<Vn>

Is the name of the SIMD&FP source register, encoded in the “Rn” field.

Operation

```
AArch64_CheckFPEnabled();

var fltval : bits(fltsize);
var intval : bits(intsize);

case op of
    when FPConvOp_MOV_FtoI =>
        fltval = Vpart{fltsize}(n, part);
        X{intsize}(d) = ZeroExtend{intsize}(fltval);
    when FPConvOp_MOV_ItoF =>
        intval = X{intsize}(n);
        Vpart{fltsize}(d, part) = intval[fltsize-1:0];
    otherwise =>
        unreachable;
end;
```

Operational Information

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction that is dependent on the general-purpose register written by this instruction might be significantly delayed.

C7.2.159 FMSUB

Floating-point fused multiply-subtract (scalar)

This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, adds that to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.160 FMUL (by element)

Floating-point multiply (by element)

This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision, Scalar, single-precision and double-precision, Vector, half-precision, and Vector, single-precision and double-precision

Scalar, half-precision

C7.2.163 FMULX (by element)

Floating-point multiply extended (by element)

This instruction multiplies the floating-point values in the vector elements in the first source SIMD&FP register by the specified floating-point value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If one value is zero and the other value is infinite, the result is 2.0. In this case, the result is negative if only one of the values is negative, otherwise the result is positive.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision, Scalar, single-precision and double-precision, Vector, half-precision, and Vector, single-precision and double-precision

Assembler Symbols

<Hd>

Is the 16-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

<Hn>

Is the 16-bit name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm>

For the “Scalar, half-precision” and “Vector, half-precision” variants: is the name of the second SIMD&FP source register, in the range V0 to V15, encoded in the “Rm” field.

For the “Scalar, single-precision and double-precision” and “Vector, single-precision and double-precision” variants: is the name of the second SIMD&FP source register, encoded in the “M:Rm” fields.

<index>

For the “Scalar, half-precision” and “Vector, half-precision” variants: is the element index, in the range 0 to 7, encoded in the “H:L:M” fields.

For the “Scalar, single-precision and double-precision” and “Vector, single-precision and double-precision” variants: is the element index, encoded in “sz:L:H”:

C7.2.164 FMULX

Floating-point multiply extended

This instruction multiplies corresponding floating-point values in the vectors of the two source SIMD&FP registers, places the resulting floating-point values in a vector, and writes the vector to the destination SIMD&FP register.

If one value is zero and the other value is infinite, the result is 2.0. In this case, the result is negative if only one of the values is negative, otherwise the result is positive.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision, Scalar single-precision and double-precision, Vector half-precision, and Vector single-precision and double-precision

Scalar half-precision

C7.2.169 FNMUL (scalar)

Floating-point multiply-negate (scalar)

This instruction multiplies the floating-point values of the two source SIMD&FP registers, and writes the negation of the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.173 FRINT32X (vector)

Floating-point round to 32-bit integer, using current rounding mode (vector)

This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values that fit into a 32-bit integer size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

A zero input returns a zero result with the same sign. When one of the result values is not numerically equal to the corresponding input value, an Inexact exception is raised. When an input is infinite, NaN or out-of-range, the instruction returns for the corresponding result value the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.174 FRINT32X (scalar)

Floating-point round to 32-bit integer, using current rounding mode (scalar)

This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value that fits into a 32-bit integer size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

A zero input returns a zero result with the same sign. When the result value is not numerically equal to the input value, an Inexact exception is raised. When the input is infinite, NaN or out-of-range, the instruction returns the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.175 FRINT32Z (vector)

Floating-point round to 32-bit integer toward zero (vector)

This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values that fit into a 32-bit integer size using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A zero input returns a zero result with the same sign. When one of the result values is not numerically equal to the corresponding input value, an Inexact exception is raised. When an input is infinite, NaN or out-of-range, the instruction returns for the corresponding result value the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.181 FRINTA (vector)

Floating-point round to integral, to nearest with ties to away (vector)

This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.183 FRINTI (vector)

Floating-point round to integral, using current rounding mode (vector)

This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision

C7.2.190 FRINTP (scalar)

Floating-point round to integral, toward plus infinity (scalar)

This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round towards Plus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.191 FRINTX (vector)

Floating-point round to integral exact, using current rounding mode (vector)

This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

When a result value is not numerically equal to the corresponding input value, an Inexact exception is raised. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.198 FSQRT (vector)

Floating-point square root (vector)

This instruction calculates the square root for each vector element in the source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.202 INS (element)

Insert vector element from another vector element

This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (element).

Advanced SIMD

0	1	1	0	1 1 1	0 0	0 0	imm5	0	imm4	1	Rn	Rd
	Q	op										

Encoding

```
INS  <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if imm5 == 'x0000' then EndOfDecode(Decode_UNDEF); end;
let size : integer{} = LowestSetBitNZ(imm5[3:0]);

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let dst_index : integer = UInt(imm5[4:size+1]);
let src_index : integer = UInt(imm4[3:size]);
let idxdsize : integer{} = 64 << UInt(imm4[3]);
// imm4[size-1:0] is IGNORED
let esize : integer{} = 8 << size;
```

Assembler Symbols

<Vd>

Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<Ts>

Is an element size specifier, encoded in “imm5”:

imm5	<Ts>
x0000	RESERVED
xxxx1	B
xxx10	H

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

imm5	<Ts>
xx100	S
x1000	D

<index1>

Is the destination element index encoded in “imm5”:

imm5	<index1>
x0000	RESERVED
xxxx1	UInt(imm5<4:1>)
xxx10	UInt(imm5<4:2>)
xx100	UInt(imm5<4:3>)
x1000	UInt(imm5<4>)

<Vn>

Is the name of the SIMD&FP source register, encoded in the “Rn” field.

<index2>

Is the source element index encoded in “imm5:imm4”:

imm5	<index2>
x0000	RESERVED
xxxx1	UInt(imm4)
xxx10	UInt(imm4<3:1>)
xx100	UInt(imm4<3:2>)
x1000	UInt(imm4<3>)

Unspecified bits in “imm4” are ignored but should be set to zero by an assembler.

Alias Conditions

Alias	Is preferred when
MOV (element)	Unconditionally

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(idxdsize) = V{idxdsize}(n);
var result : bits(128) = V{128}(d);

result[dst_index*:esize] = operand[src_index*:esize];
V{128}(d) = result;
```

C7.2.203 INS (general)

Insert vector element from general-purpose register

This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (from general).

Advanced SIMD

(FEAT_AdvSIMD)

31	30	29	28	27 25	24 23	22 21	20 16	15	14 11	10	9 5	4 0
0	1	0	0	1 1 1	0 0	0 0	imm5	0	0 0 1 1	1	Rn	Rd
	Q	op							imm4			

Encoding

```
INS  <Vd>.<Ts>[<index>], <R><n>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if imm5 == 'x0000' then EndOfDecode(Decode_UNDEF); end;
let size : integer{} = LowestSetBitNZ(imm5[3:0]);

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let index : integer = UInt(imm5[4:size+1]);
let esize : integer{} = 8 << size;
```

Assembler Symbols

<Vd>

Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<Ts>

Is an element size specifier, encoded in “imm5”:

imm5	<Ts>
x0000	RESERVED
xxxx1	B
xxx10	H
xx100	S
x1000	D

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<index>

Is the element index encoded in “imm5”:

imm5	<index>
x0000	RESERVED
xxxx1	UInt(imm5<4:1>)
xxx10	UInt(imm5<4:2>)
xx100	UInt(imm5<4:3>)
x1000	UInt(imm5<4>)

<R>

Is the width specifier for the general-purpose source register, encoded in “imm5”:

imm5	<R>
x0000	RESERVED
xxxx1	W
xxx10	W
xx100	W
x1000	X

<n>

Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the “Rn” field.

Alias Conditions

Alias	Is preferred when
MOV (from general)	Unconditionally

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let element : bits(esize) = X{esize}(n);
var result : bits(128) = V{128}(d);

result[index*:esize] = element;
V{128}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = TRUE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	1D
11	1	2D

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<Vt3>

Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<Vt4>

Is the name of the fourth SIMD&FP register to be transferred, encoded as “Rt” plus 3 modulo 32.

<imm>

For the “One register, immediate offset” variant: is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#8

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Q	<imm>
1	#16

For the “Two registers, immediate offset” variant: is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#16
1	#32

For the “Three registers, immediate offset” variant: is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#24
1	#48

For the “Four registers, immediate offset” variant: is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#32
1	#64

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

Shared Decode

```
let datasize : integer{} = 64 << UInt(Q);
let esize : integer{} = 8 << UInt(size);
let elements : integer = datasize DIV esize;

var rpt : integer;                 // number of iterations
let selem : integer = 1;           // structure elements

case opcode of
    when '0010' => rpt = 4;    // LD/ST1 (4 registers)

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
var t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = TRUE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	1D
11	1	2D

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

Is the post-index immediate offset, encoded in “size”:

size	<imm>
00	#1
01	#2
10	#4
11	#8

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

C7.2.207 LD2 (multiple structures)

Load multiple 2-element structures to two registers

This instruction loads multiple 2-element structures from memory and writes the result to the two SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see LD3 (multiple structures).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

(FEAT_AdvSIMD)

31	30	29 28	27	26	25	24 23	22	21 16	15 12	11 10	9 5	4 0
0	Q	0 0	1	1	0	0 0	1	0 0 0 0 0 0	1 0 0 0	size	Rn	Rt
							L		opcode			

Encoding

```
LD2  { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = ARBITRARY : integer;
let wback : boolean = FALSE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Post-index

(FEAT_AdvSIMD)

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = TRUE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

Is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#16
1	#32

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

C7.2.210 LD3 (multiple structures)

Load multiple 3-element structures to three registers

This instruction loads multiple 3-element structures from memory and writes the result to the three SIMD&FP registers, with de-interleaving.

Figure C7-2 de-interleaving of an LD3.16 (multiple 3-element structures) instruction

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

(FEAT_AdvSIMD)

let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Vt3>

Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

Is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#24
1	#48

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

Shared Decode

```
let datasize : integer{} = 64 << UInt(Q);
let esize : integer{} = 8 << UInt(size);
let elements : integer = datasize DIV esize;

let rpt : integer = 1;                  // number of iterations
let selem : integer = 3;            // structure elements

// .1D format only permitted with LD1 & ST1
if size::Q == '110' && selem != 1 then EndOfDecode(Decode_UNDEF); end;
```

Operation

C7.2.212 LD3R

Load single 3-element structure and replicate to all lanes of three registers

This instruction loads a 3-element structure from memory and replicates the structure to all the lanes of the three SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

(FEAT_AdvSIMD)

Encoding

```
LD3R  { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
var t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = ARBITRARY : integer;
let wback : boolean = FALSE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Post-index

(FEAT_AdvSIMD)

Encoding for the Immediate offset variant

Applies when `(Rm == 11111)`

```
LD3R  { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <imm>
```

Encoding for the Register offset variant

Applies when `(Rm != 11111)`

```
LD3R  { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
var t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = TRUE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	1D
11	1	2D

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<Vt3>

Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

Is the post-index immediate offset, encoded in “size”:

size	<imm>
00	#3
01	#6
10	#12
11	#24

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<Vt3>

Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<Vt4>

Is the name of the fourth SIMD&FP register to be transferred, encoded as “Rt” plus 3 modulo 32.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

Is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#32

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Q	<imm>
1	#64

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

Shared Decode

```
let datasize : integer{} = 64 << UInt(Q);
let esize : integer{} = 8 << UInt(size);
let elements : integer = datasize DIV esize;

let rpt : integer = 1;                  // number of iterations
let selem : integer = 4;            // structure elements

// .1D format only permitted with LD1 & ST1
if size::Q == '110' && selem != 1 then EndOfDecode(Decode_UNDEF); end;
```

Operation

```
AArch64_CheckFPAdvSIMDEnabled();

C7.2.214 LD4 (single structure)

Load single 4-element structure to one lane of four registers

This instruction loads a 4-element structure from memory and writes the result to the corresponding elements of the four SIMD&FP registers without affecting the other bits of the registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

(FEAT_AdvSIMD)

Encoding for the 8-bit variant

Applies when `(opcode == 001)`

```
LD4  { <Vt>.B, <Vt2>.B, <Vt3>.B, <Vt4>.B }[<index>], [<Xn|SP>]
```

Encoding for the 16-bit variant

Applies when `(opcode == 011 && size == x0)`

```
LD4  { <Vt>.H, <Vt2>.H, <Vt3>.H, <Vt4>.H }[<index>], [<Xn|SP>]
```

Encoding for the 32-bit variant

Applies when `(opcode == 101 && size == 00)`

```
LD4  { <Vt>.S, <Vt2>.S, <Vt3>.S, <Vt4>.S }[<index>], [<Xn|SP>]
```

Encoding for the 64-bit variant

Applies when `(opcode == 101 && S == 0 && size == 01)`

```
LD4  { <Vt>.D, <Vt2>.D, <Vt3>.D, <Vt4>.D }[<index>], [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
var t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = ARBITRARY : integer;
let wback : boolean = FALSE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

C7.2.215 LD4R

Load single 4-element structure and replicate to all lanes of four registers

This instruction loads a 4-element structure from memory and replicates the structure to all the lanes of the four SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

(FEAT_AdvSIMD)

Encoding

```
LD4R  { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
var t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = ARBITRARY : integer;
let wback : boolean = FALSE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Post-index

(FEAT_AdvSIMD)

Encoding for the Immediate offset variant

Applies when `(Rm == 11111)`

```
LD4R  { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>
```

Encoding for the Register offset variant

Applies when `(Rm != 11111)`

```
LD4R  { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
var t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = TRUE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	1D
11	1	2D

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<Vt3>

Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<Vt4>

Is the name of the fourth SIMD&FP register to be transferred, encoded as “Rt” plus 3 modulo 32.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

Is the post-index immediate offset, encoded in “size”:

size	<imm>
00	#4

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

size	<imm>
01	#8
10	#16
11	#32

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

C7.2.216 LDAP1 (SIMD&FP)

Load-acquire RCpc one single-element structure to one lane of one register

This instruction loads a single-element structure from memory and writes the result to the specified lane of the SIMD&FP register without affecting the other bits of the register.

The instruction has memory ordering semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.217 LDAPUR (SIMD&FP)

Load-acquire RCpc SIMD&FP register (unscaled offset)

This instruction loads a SIMD&FP register from memory. The address that is used for the load is calculated from a base register value and an optional immediate offset.

The instruction has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Unscaled offset

Assembler Symbols

<Bt>

Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

<Ht>

Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<St>

Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<Dt>

Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<Qt>

Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 8 << scale;
let tagchecked : boolean = n != 31;
```

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
var address : bits(64);
let accdesc : AccessDescriptor = CreateAccDescASIMDAcqRel(MemOp_LOAD, tagchecked);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

V{datasize}(t) = Mem{datasize}(address, accdesc);
```

C7.2.218 LDBFADD, LDBFADDA, LDBFADDAL, LDBFADDL

Atomic BFloat16 add

This instruction atomically loads a 16-bit value from memory, adds it to the BFloat16 value held in a register, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- `LDBFADDA` and `LDBFADDAL` load from memory with acquire semantics.
- `LDBFADDL` and `LDBFADDAL` store to memory with release semantics.
- `LDBFADD` has neither acquire nor release semantics.

This instruction:

- Disables alternative floating-point behaviors, as if FPCR.AH is 0.
- Generates only the default NaN, as if FPCR.DN is 1.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

C7.2.223 LDFADD, LDFADDA, LDFADDAL, LDFADDL

Atomic floating-point add

This instruction atomically loads a 16-bit, 32-bit, or 64-bit value from memory, performs a floating-point add with the value held in a register, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- `LDFADDA` and `LDFADDAL` load from memory with acquire semantics.
- `LDFADDL` and `LDFADDAL` store to memory with release semantics.
- `LDFADD` has neither acquire nor release semantics.

This instruction:

- Disables alternative floating-point behaviors, as if FPCR.AH is 0.
- Generates only the default NaN, as if FPCR.DN is 1.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

C7.2.224 LDFMAX, LDFMAXA, LDFMAXAL, LDFMAXL

Atomic floating-point maximum

This instruction atomically loads a 16-bit, 32-bit, or 64-bit value from memory, calculates the floating-point maximum with the value held in a register, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- `LDFMAXA` and `LDFMAXAL` load from memory with acquire semantics.
- `LDFMAXL` and `LDFMAXAL` store to memory with release semantics.
- `LDFMAX` has neither acquire nor release semantics.

This instruction:

- Disables alternative floating-point behaviors, as if FPCR.AH is 0.
- Generates only the default NaN, as if FPCR.DN is 1.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

Assembler Symbols

<Hs>

Is the 16-bit name of the SIMD&FP register holding the data value to be operated on with the contents of the memory location, encoded in the “Rs” field.

<Ht>

Is the 16-bit name of the SIMD&FP register to be loaded, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Ss>

Is the 32-bit name of the SIMD&FP register holding the data value to be operated on with the contents of the memory location, encoded in the “Rs” field.

<St>

Is the 32-bit name of the SIMD&FP register to be loaded, encoded in the “Rt” field.

<Ds>

Is the 64-bit name of the SIMD&FP register holding the data value to be operated on with the contents of the memory location, encoded in the “Rs” field.

<Dt>

Is the 64-bit name of the SIMD&FP register to be loaded, encoded in the “Rt” field.

Operation

```
AArch64_CheckFPEnabled();
var address : bits(64);
var value : bits(datasize);
var data : bits(datasize);
let accdesc : AccessDescriptor = CreateAccDescFPAtomicOp(MemAtomicOp_FPMINNM, acquire,
                                                         release, tagchecked);

value = V{datasize}(s);
if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

// Irrelevant when not executing CAS
let comparevalue : bits(datasize) = ARBITRARY : bits(datasize);
data = MemAtomic{datasize}(address, comparevalue, value, accdesc);

V{datasize}(t) = data;
```

C7.2.228 LDNP (SIMD&FP)

Load pair of SIMD&FP registers, with non-temporal hint

This instruction loads a pair of SIMD&FP registers from memory, issuing a hint to the memory system that the access is non-temporal. The address that is used for the load is calculated from a base register value and an optional immediate offset.

For information about non-temporal pair instructions, see Load/Store SIMD and Floating-point non-temporal pair.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Signed offset

(FEAT_FP)

31 30	29 27	26	25 23	22	21 15	14 10	9 5	4 0
opc	1 0 1	1	0 0 0	1	imm7	Rt2	Rn	Rt
		VR		L				

Encoding for the 32-bit variant

Applies when `(opc == 00)`

```
LDNP  <St1>, <St2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 01)`

<imm>

For the “32-bit” variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the “imm7” field as <imm>/4.

For the “64-bit” variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the “imm7” field as <imm>/8.

For the “128-bit” variant: is the optional signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the “imm7” field as <imm>/16.

<Dt1>

Is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<Dt2>

Is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

<Qt1>

Is the 128-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<Qt2>

Is the 128-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

Shared Decode

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF); end;

Assembler Symbols

<St1>

Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<St2>

Is the 32-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Post-index 32-bit” and “Pre-index 32-bit” variants: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the “imm7” field as <imm>/4.

For the “Post-index 64-bit” and “Pre-index 64-bit” variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the “imm7” field as <imm>/8.

For the “Post-index 128-bit” and “Pre-index 128-bit” variants: is the signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, encoded in the “imm7” field as <imm>/16.

For the “Signed offset 32-bit” variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the “imm7” field as <imm>/4.

For the “Signed offset 64-bit” variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the “imm7” field as <imm>/8.

For the “Signed offset 128-bit” variant: is the optional signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the “imm7” field as <imm>/16.

<Dt1>

Is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<Dt2>

Is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

<Qt1>

Is the 128-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<Qt2>

Is the 128-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
