Preface

This preface introduces the Arm® Compiler Migration and Compatibility Guide.

It contains the following:

• About this book on page 10.

About this book

The Arm® Compiler Migration and Compatibility Guide provides migration and compatibility information for users moving from older versions of Arm Compiler to Arm Compiler 6.

Using this book

This book is organized into the following chapters:

Chapter 1 Configuration and Support Information

Summarizes the support levels, and locales and FlexNet versions supported by the Arm compilation tools.

Chapter 2 Migrating from Arm® Compiler 5 to Arm® Compiler 6

Chapter 3 Migrating from armcc to armclang

Compares Arm Compiler 6 command-line options to older versions of Arm Compiler.

Chapter 4 Compiler Source Code Compatibility

Provides details of source code compatibility between Arm Compiler 6 and older armcc compiler versions.

Chapter 5 Migrating from armasm to the armclang integrated assembler

Describes how to migrate assembly code from armasm syntax to GNU syntax (used by armclang).

Glossary

The Arm® Glossary is a list of terms used in Arm documentation, together with definitions for those terms. The Arm Glossary does not contain terms that are industry standard unless the Arm meaning differs from the generally accepted meaning.

See the Arm® Glossary for more information.

Typographic conventions

italic

Introduces special terminology, denotes cross-references, and citations.

bold

Highlights interface elements, such as menu names. Denotes signal names. Also used for terms in descriptive lists, where appropriate.

monospace

Denotes text that you can enter at the keyboard, such as commands, file and program names, and source code.

<u>mono</u>space

Denotes a permitted abbreviation for a command or option. You can enter the underlined text instead of the full command or option name.

monospace italic

Denotes arguments to monospace text where the argument is to be replaced by a specific value.

monospace bold

Denotes language keywords when used outside example code.

<and>

Encloses replaceable terms for assembler syntax where they appear in code or code fragments. For example:

```
MRC p15, 0, <Rd>, <CRn>, <CRm>, <Opcode 2>
```

SMALL CAPITALS

Used in body text for a few terms that have specific technical meanings, that are defined in the *Arm® Glossary*. For example, IMPLEMENTATION DEFINED, IMPLEMENTATION SPECIFIC, UNKNOWN, and UNPREDICTABLE.

Feedback

Feedback on this product

If you have any comments or suggestions about this product, contact your supplier and give:

- The product name.
- The product revision or version.
- An explanation with as much information as you can provide. Include symptoms and diagnostic procedures if appropriate.

Feedback on content

If you have comments on content then send an e-mail to errata@arm.com. Give:

- The title *Arm Compiler Migration and Compatibility Guide*.
- The number 100068 0609 00 en.
- If applicable, the page number(s) to which your comments refer.

Arm also welcomes general suggestions for additions and improvements.

• A concise explanation of your comments.

Note
Arm tests the PDF only in Adobe Acrobat and Acrobat Reader, and cannot guarantee the quality of the
represented document when used with any other PDF reader.

Chapter 1 Configuration and Support Information

Summarizes the support levels, and locales and FlexNet versions supported by the Arm compilation tools.

It contains the following sections:

- 1.1 Support level definitions on page 1-13.
- 1.2 Compiler configuration information on page 1-16.

1.1 Support level definitions

This describes the levels of support for various Arm Compiler 6 features.

Arm Compiler 6 is built on Clang and LLVM technology. Therefore it has more functionality than the set of product features described in the documentation. The following definitions clarify the levels of support and guarantees on functionality that are expected from these features.

Arm welcomes feedback regarding the use of all Arm Compiler 6 features, and endeavors to support users to a level that is appropriate for that feature. You can contact support at https://developer.arm.com/support.

Identification in the documentation

All features that are documented in the Arm Compiler 6 documentation are product features, except where explicitly stated. The limitations of non-product features are explicitly stated.

Product features

Product features are suitable for use in a production environment. The functionality is well-tested, and is expected to be stable across feature and update releases.

- Arm endeavors to give advance notice of significant functionality changes to product features.
- If you have a support and maintenance contract, Arm provides full support for use of all product features.
- Arm welcomes feedback on product features.
- Any issues with product features that Arm encounters or is made aware of are considered for fixing in future versions of Arm Compiler.

In addition to fully supported product features, some product features are only alpha or beta quality.

Beta product features

Beta product features are implementation complete, but have not been sufficiently tested to be regarded as suitable for use in production environments.

Beta product features are indicated with [BETA].

- Arm endeavors to document known limitations on beta product features.
- Beta product features are expected to eventually become product features in a future release of Arm Compiler 6.
- Arm encourages the use of beta product features, and welcomes feedback on them.
- Any issues with beta product features that Arm encounters or is made aware of are considered for fixing in future versions of Arm Compiler.

Alpha product features

Alpha product features are not implementation complete, and are subject to change in future releases, therefore the stability level is lower than in beta product features.

Alpha product features are indicated with [ALPHA].

- Arm endeavors to document known limitations of alpha product features.
- Arm encourages the use of alpha product features, and welcomes feedback on them.
- Any issues with alpha product features that Arm encounters or is made aware of are considered for fixing in future versions of Arm Compiler.

Community features

Arm Compiler 6 is built on LLVM technology and preserves the functionality of that technology where possible. This means that there are additional features available in Arm Compiler that are not listed in the documentation. These additional features are known as community features. For information on these community features, see the *documentation for the Clang/LLVM project*.

Where community features are referenced in the documentation, they are indicated with [COMMUNITY].

- Arm makes no claims about the quality level or the degree of functionality of these features, except when explicitly stated in this documentation.
- · Functionality might change significantly between feature releases.
- Arm makes no guarantees that community features will remain functional across update releases, although changes are expected to be unlikely.

Some community features might become product features in the future, but Arm provides no roadmap for this. Arm is interested in understanding your use of these features, and welcomes feedback on them. Arm supports customers using these features on a best-effort basis, unless the features are unsupported. Arm accepts defect reports on these features, but does not guarantee that these issues will be fixed in future releases.

Guidance on use of community features

There are several factors to consider when assessing the likelihood of a community feature being functional:

• The following figure shows the structure of the Arm Compiler 6 toolchain:

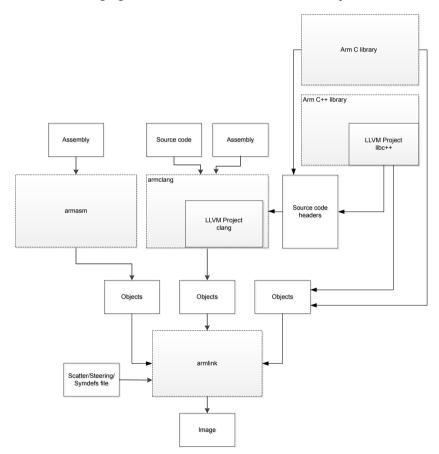

Figure 1-1 Integration boundaries in Arm Compiler 6.

The dashed boxes are toolchain components, and any interaction between these components is an integration boundary. Community features that span an integration boundary might have significant limitations in functionality. The exception to this is if the interaction is codified in one of the standards supported by Arm Compiler 6. See *Application Binary Interface (ABI) for the Arm*®

Architecture. Community features that do not span integration boundaries are more likely to work as expected.

- Features primarily used when targeting hosted environments such as Linux or BSD might have significant limitations, or might not be applicable, when targeting bare-metal environments.
- The Clang implementations of compiler features, particularly those that have been present for a long time in other toolchains, are likely to be mature. The functionality of new features, such as support for new language features, is likely to be less mature and therefore more likely to have limited functionality.

Unsupported features

With both the product and community feature categories, specific features and use-cases are known not to function correctly, or are not intended for use with Arm Compiler 6.

Limitations of product features are stated in the documentation. Arm cannot provide an exhaustive list of unsupported features or use-cases for community features. The known limitations on community features are listed in *Community features* on page 1-13.

List of known unsupported features

The following is an incomplete list of unsupported features, and might change over time:

- The Clang option -stdlib=libstdc++ is not supported.
- C++ static initialization of local variables is not thread-safe when linked against the standard C++ libraries. For thread-safety, you must provide your own implementation of thread-safe functions as described in *Standard C++ library implementation definition*.

- Use of C11 library features is unsupported.
- Any community feature that exclusively pertains to non-Arm architectures is not supported.
- Compilation for targets that implement architectures older than Armv7 or Armv6-M is not supported.
- The long double data type is not supported for AArch64 state because of limitations in the current Arm C library.
- Complex numbers are not supported because of limitations in the current Arm C library.

1.2 Compiler configuration information

Summarizes the locales and FlexNet versions supported by the Arm compilation tools.

FlexNet versions in the compilation tools

Different versions of Arm Compiler support different versions of FlexNet.

The FlexNet versions in the compilation tools are:

Table 1-1 FlexNet versions

Compilation tools version	Windows	Linux
Arm Compiler 6.7 and later	11.14.1.0	11.14.1.0
Arm Compiler 6.01 and later	11.12.1.0	11.12.1.0
Arm Compiler 6.00	11.10.1.0	11.10.1.0

Locale support in the compilation tools

Arm Compiler only supports the English locale.

Chapter 2 **Migrating from Arm® Compiler 5 to Arm® Compiler 6**

It contains the following sections:

- 2.1 Migration overview on page 2-18.
- 2.2 Toolchain differences on page 2-19.
- 2.3 Optimization differences on page 2-20.
- 2.4 Diagnostic messages on page 2-21.

2.1 Migration overview

Migrating from Arm Compiler 5 to Arm Compiler 6 requires the use of new command-line options and might also require changes to existing source files.

Arm Compiler 6 is based on the modern LLVM compiler framework. Arm Compiler 5 is not based on the LLVM compiler framework. Therefore migrating your project and source files from Arm Compiler 5 to Arm Compiler 6 requires you to be aware of:

- Differences in the command-line options when invoking the compiler.
- Differences in the adherence to language standards.
- Differences in compiler specific keywords, attributes, and pragmas.
- Differences in optimization and diagnostic behavior of the compiler.

Even though these differences exist between Arm Compiler 5 and Arm Compiler 6, it is possible to migrate your projects from Arm Compiler 5 to Arm Compiler 6 by modifying your command-line arguments and by changing your source code if required.

Arm Compiler 5 does not support processors based on Armv8 and later architectures. Migrating to Arm Compiler 6 enables you to generate highly efficient code for processors based on Armv8 and later architectures.

Related information

Migrating projects from Arm Compiler 5 to Arm Compiler 6.

2.2 Toolchain differences

Arm Compiler 5 and Arm Compiler 6 share many of the same compilation tools. However, the main difference between the two toolchains is the compiler tool armclang, which is based on Clang and LLVM.

The table lists the individual compilation tools and the toolchain they apply to.

Table 2-1 List of compilation tools

Arm Compiler 5	Arm Compiler 6	Function
armcc	armclang	Compiles C and C++ language source files, including inline assembly.
armcc	armclang	Preprocessor.
armasm	armasm	Assembles assembly language source files written in armasm syntax.
Not available	armclang. This is also called the armclang integrated assembler.	Assembles assembly language source files written in GNU assembly syntax.
fromelf	fromelf	Converts Arm ELF images to binary formats and can also generate textual information about the input image, such as its disassembly and its code and data size.
armlink	armlink	Combines the contents of one or more object files with selected parts of one or more object libraries to produce an executable program.
armar	armar	Enables sets of ELF object files to be collected together and maintained in archives or libraries.

Arm Compiler 6 uses the compiler tool armclang instead of armcc. The command-line options for armclang are different to the command-line options for armcc. These differences are described in 3.1 Migration of compiler command-line options from Arm® Compiler 5 to Arm® Compiler 6 on page 3-24.

Arm Compiler 6 provides armasm, which you can use use to assemble your existing assembly language source files that are written in armasm syntax. Arm recommends you write new assembly code using the GNU assembly syntax, which you can assemble using the armclang integrated assembler. You can also migrate existing assembly language source files from armasm syntax to GNU syntax, and then assemble them using the armclang integrated assembler. For more information see *Chapter 5 Migrating from armasm to the armclang integrated assembler* on page 5-57.

Related information

Migrating projects from Arm Compiler 5 to Arm Compiler 6.

2.3 Optimization differences

Arm Compiler 6 provides more performance optimization settings than are present in Arm Compiler 5. However, the optimizations that are performed at each optimization level might differ between the two toolchains.

The table compares the optimization settings and functions in Arm Compiler 5 and Arm Compiler 6.

Table 2-2 Optimization settings

Description	Arm Compiler 5	Arm Compiler 6
Optimization levels for performance.	• -Otime -O0	• -00
	• -Otime -O1	• -01
	• -Otime -O2	• -02
	• -Otime -O3	• -03
		• -Ofast
		• -Omax
Optimization levels for code size.	• -Ospace -00	• -0s
	• -Ospace -O1	• -0z
	• -0space -02	
	• -Ospace -O3	
Default	-Ospace -O2	-00
Best trade-off between image size, performance, and debug.	-Ospace -O2	-01
Highest optimization for performance	-Otime -O3	-Omax
Highest optimization for code size	-Ospace -O3	-Oz

Arm Compiler 6 provides an aggressive optimization setting, -Omax, which automatically enables a feature called Link Time Optimization. For more information, see *-flto*.

When using -Omax, armclang can perform link time optimizations that were not possible in Arm Compiler 5. These link time optimizations can expose latent bugs in the final image. Therefore, an image built with Arm Compiler 5 might have a different behavior to the image built with Arm Compiler 6.

For example, unused variables without the volatile keyword might be removed when using -Omax in Arm Compiler 6. If the unused variable is actually a volatile variable that requires the volatile keyword, then the removal of the variable can cause the generated image to behave unexpectedly. Since Arm Compiler 5 does not have this aggressive optimization setting, it might not have removed the unused variable, and the resulting image might behave as expected, and therefore the error in the code would be more difficult to detect

Related information

- -flto armclang option.
- -O armclang option.

Effect of the volatile keyword on compiler optimization.

Optimizing across modules with link time optimization.

2.4 Diagnostic messages

In general, armclang provides more precise and detailed diagnostic messages compared to armcc. Therefore you can expect to see more information about your code when using Arm Compiler 6, which can help you understand and fix your source more quickly.

armclang and armcc differ in the quality of diagnostic information they provide about your code. The following sections demonstrate some of the differences.

Assignment in condition

The following code is an example of armclang providing more precise information about your code. The error in this example is that the assignment operator, =, must be changed to the equality operator, ==.

```
main.cpp:
#include <stdio.h>
int main()
{
   int a = 0, b = 0;
   if (a = b)
   {
      printf("Right\n");
   }
   else
   {
      printf("Wrong\n");
   }
   return 0;
}
```

Compiling this example with Arm Compiler 5 gives the message:

```
"main.cpp", line 6: Warning: #1293-D: assignment in condition
if (a = b)
^
```

Compiling this example with Arm Compiler 6 gives the message:

armclang highlights the error in the code, and also suggests two different ways to resolve the error. The warning messages highlight the specific part which requires attention from the user.

Note -	_

When using armclang, it is possible to enable or disable specific warning messages. In the example above, you can enable this warning message using the -Wparentheses option, or disable it using the -Wno-parentheses option.

Automatic macro expansion

Another very useful feature of diagnostic messages in Arm Compiler 6, is the inclusion of notes about macro expansion. These notes provide useful context to help you understand diagnostic messages resulting from automatic macro expansion.

Consider the following code:

```
main.cpp:
#include <stdio.h>
#define LOG(PREFIX, MESSAGE) fprintf(stderr, "%s: %s", PREFIX, MESSAGE)
#define LOG_WARNING(MESSAGE) LOG("Warning", MESSAGE)
int main(void)
{
    LOG_WARNING(123);
}
```

The macro LOG_WARNING has been called with an integer argument. However, expanding the two macros, you can see that the fprintf function expects a string. When the macros are close together in the code it is easy to spot these errors. These errors are not easy to spot if they are defined in different part of the source code, or in other external libraries.

Compiling this example with Arm Compiler 5 armcc main.cpp gives the message:

```
main.cpp", line 8: Warning: #181-D: argument is incompatible with corresponding format
string conversion
    LOG_WARNING(123);
    ^
```

Compiling this example with Arm Compiler 6 armclang --target=arm-arm-none-eabi -march=armv8-a gives the message:

For more information, see 4.5 Diagnostics for pragma compatibility on page 4-51.

When starting the migration from Arm Compiler 5 to Arm Compiler 6, you can expect additional diagnostic messages because armclang does not recognize some of the pragmas, keywords, and attributes that were specific to armcc. When you replace the pragmas, keywords, and attributes from Arm Compiler 5 with their Arm Compiler 6 equivalents, the majority of these diagnostic messages disappear. You might require additional code changes if there is no direct equivalent for Arm Compiler 6. For more information see *Chapter 4 Compiler Source Code Compatibility* on page 4-39.

Chapter 3 **Migrating from armcc to armclang**

Compares Arm Compiler 6 command-line options to older versions of Arm Compiler.

It contains the following sections:

- 3.1 Migration of compiler command-line options from Arm® Compiler 5 to Arm® Compiler 6 on page 3-24.
- 3.2 Command-line options for preprocessing assembly source code on page 3-30.
- 3.3 Inline assembly with Arm® Compiler 6 on page 3-31.
- 3.4 Migrating architecture and processor names for command-line options on page 3-33.

3.1 Migration of compiler command-line options from Arm® Compiler 5 to Arm® Compiler 6

Arm Compiler 6 provides many command-line options, including most Clang command-line options and several Arm-specific options.

——Note ——
This topic includes descriptions of [COMMUNITY] features. See *Support level definitions* on page 1-13.

The following table describes the most common Arm Compiler 5 command-line options, and shows the equivalent options for Arm Compiler 6.

Additional information about command-line options is available:

- The armclang Reference Guide provides more detail about a number of command-line options.
- For a full list of Clang command-line options, see the Clang and LLVM documentation.

Table 3-1 Comparison of compiler command-line options in Arm Compiler 5 and Arm Compiler 6

Arm Compiler 5 option	Arm Compiler 6 option	Description	
allow_fpreg_for_nonfpdata, no_allow_fpreg_for_nonfpdata	<pre>[COMMUNITY] - mimplicit-float, -mno- implicit-float</pre>	Enables or disables the use of VFP and SIMD registers and data transfer instructions for non-VFP and non-SIMD data.	
apcs=/nointerwork	No equivalent.	Disables interworking between A32 and T32 code. Interworking is always enabled in Arm Compiler 6.	
apcs=/ropi apcs=/noropi	-fropi -fno-ropi	Enables or disables the generation of Read-Only Position-Independent (ROPI) code.	
apcs=/rwpi apcs=/norwpi	-frwpi -fno-rwpi	Enables or disables the generation of Read/Write Position-Independent (RWPI) code.	
arm	-marm	Targets the A32 instruction set. The compiler is permitted to generate both A32 and T32 code, but recognizes that A32 code preferred.	
arm_only	No equivalent.	Enforces A32 instructions only. The compiler does not generate T32 instructions.	
asm	-save-temps	Instructs the compiler to generate intermediate assembly files as well as object files.	
-с	-c	Performs the compilation step, but not the link step.	
c90	-xc -std=c90	Enables the compilation of C90 source code. -xc is a positional argument and only affects subsequent input files on the command-line. It is also only required if the input files do not have the appropriate file extension.	
c99	-xc -std=c99	Enables the compilation of C99 source code. -xc is a positional argument and only affects subsequent input files on the command-line. It is also only required if the input files do not have the appropriate file extension.	

Table 3-1 Comparison of compiler command-line options in Arm Compiler 5 and Arm Compiler 6 (continued)

Arm Compiler 5 option	Arm Compiler 6 option	Description	
cpp	-xc++ -std=c++03	Enables the compilation of C++03 source code.	
		-xc++ is a positional argument and only affects subsequent input files on the command-line. It is also only required if the input files do not have the appropriate file extension.	
		The default C++ language standard is different between Arm Compiler 5 and Arm Compiler 6.	
cpp11	-xc++ -std=c++11	Enables the compilation of C++11 source code.	
		-xc++ is a positional argument and only affects subsequent input files on the command-line.	
		The default C++ language standard is different between Arm Compiler 5 and Arm Compiler 6.	
cpp_compat	No equivalent.	Compiles C++ code to maximize binary compatibility.	
cpu 8-A.32	target=arm-arm- none-eabi - march=armv8-a	Targets Armv8-A and AArch32 state.	
cpu 8-A.64	target=aarch64-arm- none-eabi	Targets Armv8-A and AArch64 state. (Implies -march=armv8-a if -mcpu is not specified.)	
cpu 7-A	target=arm-arm- none-eabi - march=armv7-a	Targets the Armv7-A architecture.	
cpu=Cortex-M4	target=arm-arm- none-eabi - mcpu=cortex-m4	Targets the Cortex®-M4 processor.	
cpu=Cortex-A15	target=arm-arm- none-eabi - mcpu=cortex-a15	Targets the Cortex-A15 processor.	
-D	-D	Defines a preprocessing macro.	
depend	-MF	Specifies a filename for the makefile dependency rules.	
depend_dir	No equivalent. Use -MF to specify each dependency file individually.	Specifies the directory for dependency output files.	
depend_format=unix_escaped		Dependency file entries use UNIX-style path separators and escapes spaces with \. This is the default in Arm Compiler 6.	
depend_target	-MT	Changes the target name for the makefile dependency rule.	
diag_error	-Werror	Turn compiler warnings into errors.	
diag_suppress=foo	-Wno-foo	Suppress warning message <i>foo</i> . The error or warning codes might be different between Arm Compiler 5 and Arm Compiler 6.	
-E	-E	Executes only the preprocessor step.	

Table 3-1 Comparison of compiler command-line options in Arm Compiler 5 and Arm Compiler 6 (continued)

Arm Compiler 5 option	Arm Compiler 6 option	Description Sets the minimum size of an enumeration type. By default Arm Compiler 5 does not set a minimum size. By default Arm Compiler 6 uses -fno-short-enums to set the minimum size to 32-bit.	
enum_is_int	-fno-short-enums, - fshort-enums		
forceline	No equivalent.	Forces aggressive inlining of functions. Arm Compiler 6 automatically decides whether to inline functions depending on the optimization level.	
fpmode=std	-ffp-mode=std	Provides IEEE-compliant code with no IEEE exceptions, NaNs, and Infinities. Denormals are sign preserving. This is the default.	
fpmode=fast	-ffp-mode=fast	Similar to the default behavior, but also performs aggressive floating-point optimizations and therefore it is not IEEE-compliant.	
fpmode=ieee_full	-ffp-mode=full	Provides full IEEE support, including exceptions.	
fpmode=ieee_fixedfpmode=ieee_no_fenv	There are no supported equivalent options.	There might be community features that provide these IEEE floating-point modes.	
fpu For examplefpu=fpv5_d16	-mfpu For example - mfpu=fpv5-d16	Specifies the target FPU architecture. Note fpu=none checks the source code for floating-point operations, and if any are found it produces an errormfpu=none prevents the compiler from using hardware-based floating-point functions. If the compiler encounters floating-point types in the source code, it uses software-based floating-point library functions. The option values might be different. For example fpv5_d16 in Arm Compiler 5 is equivalent to fpv5-d16 in Arm Compiler 6, and targets the FPv5-D16 floating-point extension.	
-1	-I	Adds the specified directories to the list of places that are searched to find included files.	
ignore_missing_headers	-MG	Prints dependency lines for header files even if the header files are missing.	
inline	Default at -02 and -03.	There is no equivalent of theinline option. Arm Compiler 6 automatically decides whether to inline functions at optimization levels -02 and -03.	
-3	-isystem	Adds the specified directories to the list of places that are searched to find included system header files.	
-L	-Xlinker	Specifies command-line options to pass to the linker when a link step is being performed after compilation.	
licretry	No equivalent.	There is no equivalent of thelicretry option. The Arm Compiler 6 tools automatically retry failed attempts to obtain a license.	
list_macros	-E -dM	List all the macros that are defined at the end of the translation unit, including the predefined macros.	

Table 3-1 Comparison of compiler command-line options in Arm Compiler 5 and Arm Compiler 6 (continued)

Arm Compiler 5 option	Arm Compiler 6 option	Description	
littleend	-mlittle-endian	Generates code for little-endian data.	
lower_ropi,no_lower_ropi	-fropi-lowering, -fno-ropi-lowering	Enables or disables less restrictive C when generating Read-Only Position-Independent (ROPI) code. Note In Arm Compiler 5, whenacps=/ropi is specified,lower_ropi is not switched on by default. In Arm Compiler 6, when -fropi is specified, -fropi-lowering is switched on by default.	
lower_rwpi,no_lower_rwpi	-frwpi-lowering, -fno-rwpi-lowering	Enables or disables less restrictive C when generating Read-Write Position-Independent (RWPI) code.	
-м	-м	Instructs the compiler to produce a list of makefile dependency lines suitable for use by a make utility.	
md	-MD	Creates makefile dependency files, including the system header files. In Arm Compiler 5, this is equivalent tomddepend_system_headers.	
mdno_depend_system_headers	-MMD	Creates makefile dependency files, without the system header files.	
mm	-ММ	Creates a single makefile dependency file, without the system header files. In Arm Compiler 5, this is equivalent to -M no_depend_system_headers.	
no_exceptions	-fno-exceptions	Disables the generation of code needed to support C++ exceptions.	
-0	-0	Specifies the name of the output file.	
-Onum	-Onum	Specifies the level of optimization to be used when compiling source files.	
		The default for Arm Compiler 5 is -02. The default for Arm Compiler 6 is -00. For debug view in Arm Compiler 6, Arm recommends -01 rather than -00 for best trade-off between image size, performance, and debug.	
-Ospace	-0z / -0s	Performs optimizations to reduce image size at the expense of a possible increase in execution time.	
-Otime	This is the default.	Performs optimizations to reduce execution time at the expense of a possible increase in image size.	
		There is no equivalent of the -Otime option. Arm Compiler 6 optimizes for execution time by default, unless you specify the -Os or -Oz options.	
phony_targets	-MP	Emits dummy makefile rules.	
preinclude	-include	Include the source code of a specified file at the beginning of the compilation.	
relaxed_ref_def	-fcommon	Places zero-initialized definitions in a common block.	

Table 3-1 Comparison of compiler command-line options in Arm Compiler 5 and Arm Compiler 6 (continued)

Arm Compiler 5 option	Arm Compiler 6 option	Description	
-S	-S	Outputs the disassembly of the machine code generated by the compiler.	
		The output from this option differs between releases. Older Arm Compiler versions produce output with armasm syntax while Arm Compiler 6 produces output with GNU syntax.	
show_cmdline	-v	Shows how the compiler processes the command-line. The commands are shown normalized, and the contents of any via files are expanded.	
split_ldm	-fno-ldm-stm	Disables the generation of LDM and STM instructions.	
		Note that while the armccsplit_ldm option limits the size of generated LDM/STM instructions, the armclang -fno-ldm-stm option disables the generation of LDM and STM instructions altogether.	
split_sections	-ffunction-sections	Generates one ELF section for each function in the source file.	
		In Arm Compiler 6, -ffunction-sections is the default. Therefore, the merging of identical constants cannot be done by armclang. Instead, the merging is done by armlink.	
strict	-pedantic-errors	Generate errors if code violates strict ISO C and ISO C++.	
strict_warnings	-pedantic	Generate warnings if code violates strict ISO C and ISO C++.	
thumb	-mthumb	Targets the T32 instruction set.	
no_unaligned_access, unaligned_access	-mno-unaligned- access, -munaligned- access	Enables or disables unaligned accesses to data on Arm processors.	
use_frame_pointer, no_use_frame_pointer	-fno-omit-frame- pointer, -fomit-frame- pointer	Controls whether a register is used for storing stack frame pointers.	
vectorize	-fvectorize	Enables or disables the generation of Advanced SIMD vector	
no_vectorize	-fno-vectorize	instructions directly from C or C++ code.	
via	@file	Reads an additional list of compiler options from a file.	
vla	No equivalent.	Support for variable length arrays. Arm Compiler 6 automatically supports variable length arrays in accordance to the language standard.	
vsn	version	Displays version information and license details. In Arm Compiler 6 you can also usevsn.	
wchar16,wchar32	-fshort-wchar, -fno- short-wchar	Sets the size of wchar_t type. The default for Arm Compiler 5 iswchar16. The default for Arm Compiler 6 is -fno-short-wchar.

3.2 Command-line options for preprocessing assembly source code

The functionality of the --cpreproc and --cpreproc_opts command-line options in the version of armasm supplied with Arm Compiler 6 is different from the options used in earlier versions of armasm to preprocess assembly source code.

If you are using armasm to assemble source code that requires the use of the preprocessor, you must use both the --cpreproc and --cpreproc_opts options together. Also:

- As a minimum, you must include the armclang options --target and either -mcpu or -march in -- cpreproc_opts.
- The input assembly source must have an upper-case extension .s.

If you have existing source files, which require preprocessing, and that have the lower-case extension .s, then to avoid having to rename the files:

- 1. Perform the pre-processing step manually using the armclang -x assembler-with-cpp option.
- 2. Assemble the preprocessed file without using the --cpreproc and --cprepoc_opts options.

Example using armclang -x

This example shows the use of the armclang -x option.

```
armclang --target=aarch64-arm-none-eabi -march=armv8-a -x assembler-with-cpp -E test.s -o
test_preproc.s
armasm --cpu=8-A.64 test_preproc.s
```

Example using armasm --cpreproc opts

The options to the preprocessor in this example are --cpreproc_opts=--target=arm-arm-none-eabi,-mcpu=cortex-a9,-D,DEF1,-D,DEF2.

armasm --cpu=cortex-a9 --cpreproc --cpreproc opts=--target=arm-arm-none-eabi,-mcpu=cortex-a9,-D,DEF1,-D,DEF2 -I /path/to/includes1 -I /path/to/includes2 input.S

Ensure that you specify compatible architectures in the armclang options --target, -mcpu or -march, and the armasm --cpu option.

- -mcpu armclang option.
- --target armclang option.
- -x armclang option.

Preprocessing assembly code.

3.3 Inline assembly with Arm® Compiler 6

Inline assembly in Arm Compiler 6 must be written in GNU assembly syntax. Inline assembly in Arm Compiler 5 is written in armasm syntax. If you have inline assembly written in armasm syntax, you must modify this to use GNU assembly syntax.

In Arm Compiler 5:

- You can use C variable names directly inside inline assembly statements.
- You do not have direct access to physical registers. You must use C or C++ variables names as operands, and the compiler maps them to physical register. You must set the value of these variables before you read them within an inline assembly statement.
- If you use register names in inline assembly code, they are treated as C or C++ variables. They do not necessarily relate to the physical register of the same name. If the register name is not declared as a C or C++ variable, the compiler generates a warning.

In Arm Compiler 6:

- You cannot use C or C++ variable names directly inside inline assembly statements. You can map the physical registers to C or C++ variable names using operand mapping and constraints.
- You have direct access to physical registers. There is no need to set the value of the registers before
 you read them within inline assembly statements.
- If you use register names in inline assembly code, they are the physical register of the same name.

In Arm Compiler 6 you cannot use C variable names directly within inline assembly. However, the GNU assembly syntax in Arm Compiler 6 provides a way for mapping input and output operands to C variable names.

Arm Compiler 5 optimizes inline assembly, but Arm Compiler 6 emits it exactly as written.

For more information on writing inline assembly using __asm in armclang, see __asm.

For more information on GNU assembly syntax, see 5.2 Overview of differences between armasm and GNU syntax assembly code on page 5-63.

Inline assembly example in Arm® Compiler 5

The example below shows inline assembly code in Arm Compiler 5.

```
foo.c:
int add(int i, int j)
{
    int res;
        asm
        (
        "ADD res, i, j \t\n"
        "SUB res, i, res \t\n"
    );
    return res;
}
```

The example below shows an alternative syntax for inline assembly code in Arm Compiler 5.

Compile foo.c using armcc:

```
armcc foo.c -c -S -o foo.s
```

Arm Compiler 5 converts the example inline assembly code to:

```
foo.s:

add PROC

ADD r1,r0,r1

SUB r0,r0,r1

BX lr

ENDP
```

Inline assembly example in Arm® Compiler 6

The example below shows the equivalent inline assembly code in Arm Compiler 6.

```
foo.c:
int add(int i, int j)
{
  int res = 0;
    _asm
    (
        "ADD %[result], %[input_i], %[input_j] \t\n"
        "SUB %[result], %[input_i], %[result] \t\n"
        : [result] "=&r" (res)
        : [input_i] "r" (i), [input_j] "r" (j)
    );
  return res;
}
```

Compile foo.c using armclang with optimization level -01:

```
armclang foo.c --target=arm-arm-none-eabi -march=armv8-a -O1 -c -S -o foo.s
```

Arm Compiler 6 converts the example inline assembly code to:

Note —

Arm Compiler 6 supports inline assembly using the _asm or asm keywords. However the asm keyword is accepted only when:

- Used within C++ language source files.
- Used within C language source files without strict ISO C Standard compliance. For example, asm is accepted when using -std=gnu11.

3.4 Migrating architecture and processor names for command-line options

There are minor differences between the architecture and processor names that Arm Compiler 6 recognizes, and the names that Arm Compiler 5 recognizes. Within Arm Compiler 6, there are differences in the architecture and processor names that armclang recognizes and the names that armasm, armlink, and fromelf recognize. This topic shows the differences in the architecture and processor names for the different tools in Arm Compiler 5 and Arm Compiler 6.

The tables show the documented --cpu options in Arm Compiler 5 and their corresponding options for

migrating your Arm Compiler 5 command-line options to Arm Compiler 6.

Note

Note

Note

The tables assume the default floating-point unit derived from the --cpu option in Arm Compiler 5.
However, in Arm Compiler 6, armclang selects different defaults for floating-point unit (VFP) and Advanced SIMD. Therefore, the tables also show how to use the armclang -mfloat-abi and -mfpu options to be compatible with the default floating-point unit in Arm Compiler 5. The tables do not provide an exhaustive list.

Table 3-2 Architecture selection in Arm Compiler 5 and Arm Compiler 6

armcc, armlink, armasm, and fromelf option in Arm Compiler 5	armclang option in Arm Compiler 6	armlink, armasm, and fromelf option in Arm Compiler 6	Architecture description

Enabling or disabling architectural features in Arm® Compiler 6

Arm Compiler 6, by default, automatically enables or disables certain architectural features such as the floating-point unit, Advanced SIMD, and Cryptographic extensions depending on the specified architecture or processor. For a list of architectural features, see -mcpu in the *armclang Reference Guide*. You can override the defaults using other options.

For armclang:

- For AArch64 targets, you must use either -march or -mcpu to specify the architecture or processor and the required architectural features. You can use +[no]feature with -march or -mcpu to override any architectural feature.
- For AArch32 targets, you must use either -march or -mcpu to specify the architecture or processor and the required architectural features. You can use -mfloat-abi to override floating-point linkage. You can use -mfpu to override floating-point unit, Advanced SIMD, and Cryptographic extensions. You can use +[no]feature with -march or -mcpu to override certain other architectural features.

For armasm, armlink, and fromelf, you must use the --cpu option to specify the architecture or processor and the required architectural features. You can use --fpu to override the floating-point unit and floating-point linkage. The --cpu option is not mandatory for armlink and fromelf, but is mandatory for armasm.

_____ Note _____

- In Arm Compiler 5, if you use the armcc --fpu=none option, the compiler generates an error if it detects floating-point code. This behavior is different in Arm Compiler 6. If you use the armclang mfpu=none option, the compiler automatically uses software floating-point libraries if it detects any floating-point code. You cannot use the armlink --fpu=none option to link object files created using armclang.
- To link object files created using the armclang -mfpu=none option, you must set armlink --fpu to an
 option that supports software floating-point linkage, for example --fpu=SoftVFP, rather than using -fpu=none.

Chapter 4 Compiler Source Code Compatibility

Provides details of source code compatibility between Arm Compiler 6 and older armcc compiler versions.

It contains the following sections:

- 4.1 Language extension compatibility: keywords on page 4-40.
- 4.2 Language extension compatibility: attributes on page 4-43.
- 4.3 Language extension compatibility: pragmas on page 4-45.
- 4.4 Language extension compatibility: intrinsics on page 4-48.
- 4.5 Diagnostics for pragma compatibility on page 4-51.
- 4.6 C and C++ implementation compatibility on page 4-53.
- 4.7 Compatibility of C++ objects on page 4-55.

4.1 Language extension compatibility: keywords

Arm Compiler 6 provides support for some keywords that are supported in Arm Compiler 5.
Note
This topic includes descriptions of [COMMUNITY] features. See <i>Support level definitions</i> on page 1-13.
The following table lists some of the commonly used keywords that are supported by Arm Compiler 5 and shows whether Arm Compiler 6 supports them usingattribute Replace any instances of these
keywords in your code with the recommended alternative where available or use inline assembly
instructions.
Note
This is not an exhaustive list of all keywords.

Table 4-1 Keyword language extensions in Arm Compiler 5 and Arm Compiler 6

Keyword supported by Arm Compiler 5	Recommended Arm Compiler 6 keyword or alternative
align(x)	attribute((aligned(x)))
alignof	alignof
ALIGNOF	alignof
Embedded assembly usingasm	Arm Compiler 6 does not support theasm keyword on function definitions and declarations for embedded assembly. Instead, you can write embedded assembly using theattribute((naked)) function attribute. Seeattribute((naked)).
const	attribute((const))
attribute((const))	attribute((const))
forceinline	attribute((always_inline))
global_reg	Use inline assembler instructions or equivalent routine.
inline(x)	inline The use of this depends on the language mode.
int64	No equivalent. However, you can use long long. When you use long long in C90 mode, the compiler gives: • a warning. • an error, if you also use -pedantic-errors.
INTADDR	[COMMUNITY]None. There is community support for this as a Clang builtin.
irq	attribute((interrupt)). This is not supported in AArch64.

Table 4-1 Keyword language extensions in Arm Compiler 5 and Arm Compiler 6 (continued)

Keyword supported by Arm Compiler 5	Recommended Arm Compiler 6 keyword or alternative
packed for removing padding within structures.	 _attribute((packed)). This provides limited functionality compared topacked: Theattribute((packed)) variable attribute applies to members of a structure or union, but it does not apply to variables that are not members of a struct or union. _attribute((packed)) is not a type qualifier. Taking the address of a packed member can result in unaligned pointers, and in most cases the compiler generates a warning. Arm recommends upgrading this warning to an error when migrating code that usespacked. To upgrade the warning to error, use the armclang option -Werror=name. The placement of the attribute is different from the placement ofpacked. If your legacy code contains typedefpacked struct, then replace it with: typedef structattribute((packed))
packed as a type qualifier for unaligned access.	unaligned. This provides limited functionality compared topacked type qualifier. Theunaligned type qualifier can be used over a structure only when using typedef or when declaring a structure variable. This limitation does not apply when usingpacked in Arm Compiler 5. Therefore, there is currently no migration for legacy code that containspacked struct S{};.
pure	attribute((const))
smc	Use inline assembler instructions or equivalent routine.
softfp	attribute((pcs("aapcs")))
svc	Use inline assembler instructions or equivalent routine.
svc_indirect	Use inline assembler instructions or equivalent routine.
svc_indirect_r7	Use inline assembler instructions or equivalent routine.
thread	thread
value_in_regs	attribute((value_in_regs))
weak	attribute((weak))
writeonly	No equivalent.

 Note ———

The $_$ const keyword was supported by older versions of armcc. The equivalent for this keyword in Arm Compiler 5 and Arm Compiler 6 is $_$ attribute $_$ ((const)).

Migrating the __packed keyword from Arm® Compiler 5 to Arm® Compiler 6

The __packed keyword in Arm Compiler 5 has the effect of:

- Removing the padding within structures.
- Qualifying the variable for unaligned access.

Arm Compiler 6 does not support __packed, but supports __attribute__((packed)) and __unaligned keyword. Depending on the use, you might need to replace __packed with both __attribute__((packed)) and __unaligned. The following table shows the migration paths for various uses of __packed.

Table 4-2 Migrating the __packed keyword

Arm Compiler 5	Arm Compiler 6		
packed int x;	unaligned int x;		
packed int *x;	unaligned int *x;		
int *packed x;	<pre>int *unaligned x;</pre>		
unaligned int *packed x;	unaligned int *unaligned x;		
<pre>typedefpacked struct S{} s;</pre>	packed struct S{} s; typedefunaligned structattribute((packed)) S{} s;		
packed struct S{};	There is currently no migration. Use a typedef instead.		
packed struct S{} s;	unaligned structattribute((packed)) S{} s;		
	Subsequent declarations of variables of type struct S must useunaligned, for exampleunaligned struct S s2.		
struct S{packed int a;}	struct S {attribute((packed))unaligned int a;}

- 4.2 Language extension compatibility: attributes on page 4-43.
- 4.3 Language extension compatibility: pragmas on page 4-45.

Related information

-W.

4.2 Language extension compatibility: attributes

Arm Compiler 6 provides support for some function, variable, and type attributes that were supported in Arm Compiler 5. Other attributes are not supported, or have an alternate implementation.

The following attributes are supported by Arm Compiler 5 and Arm Compiler 6. These attributes do not require modification in your code:

__attribute__((aligned(x)))
__attribute__((always_inline))
__attribute__((const))
__attribute__((deprecated))
__attribute__((noinline))
__declspec(noinline)
__attribute__((nonnull))
__attribute__((noreturn))
__declspec(noreturn)
__attribute__((nothrow))
__attribute__((nothrow))
__attribute__((pcs("calling convention")))
__attribute__((pure))
__attribute__((section("name")))
__Note______

Section names must be unique. You must not use the same section name for another section or symbol. Only symbols that require the same section type can use the same section name.

__attribute__((unused))__attribute__((used))____Note_____

In Arm Compiler 6, functions marked with __attribute__((used)) can still be removed by linker unused section removal. To prevent the linker from removing these sections, you can use either the --keep=symbol or the --no_remove armlink options. In Arm Compiler 5, functions marked with __attribute__((used)) are not removed by the linker.

- __attribute__((visibility))
- __attribute__((weak))
- __attribute__((weakref))

Though Arm Compiler 6 supports certain __declspec attributes, Arm recommends using __attribute_ where available.

Table 4-3 Support for __declspec attributes

decIspec supported by Arm Compiler 5	Recommended Arm Compiler 6 alternative	
declspec(dllimport)	None. There is no support for BPABI linking models.	
declspec(dllexport)	None. There is no support for BPABI linking models.	
declspec(noinline)	attribute((noinline))	
declspec(noreturn)	attribute((noreturn))	
declspec(nothrow)	attribute((nothrow))	
declspec(notshared)	None. There is no support for BPABI linking models.	
declspec(thread)	thread	

Migrating __attribute__((at(address))) and zero-initialized __attribute__((section("name"))) from Arm® Compiler 5 to Arm® Compiler 6

Arm Compiler 5 supports the following attributes, which Arm Compiler 6 does not support:

- __attribute__((at(address))) to specify the absolute address of a function or variable.
- __attribute__((at(address), zero_init)) to specify the absolute address of a zero-initialized variable.
- __attribute__((section(name), zero_init)) to place a zero-initialized variable in a zero-initialized section with the given name.
- __attribute__((zero_init)) to generate an error if the variable has an initializer.

The following table shows migration paths for these features using Arm Compiler 6 supported features:

Table 4-4 Migrating __attribute__((at(address))) and zero-initialized __attribute__((section("name")))

Arm Compiler 5 attribute	Arm Compiler 6 attribute	Description
attribute((at(address)))	attribute((section(".ARMataddress")))	armlink in Arm Compiler 6 still supports the placement of sections in the form of .ARMat_address
attribute((at(address), zero_init))	attribute((section(".bss.ARMat_address")))	armlink in Arm Compiler 6 supports the placement of zero-initialized sections in the form of .bss.ARMat_address. The .bss prefix is case sensitive and must be all lowercase.
attribute((section(name), zero_init))	attribute((section(".bss.name")))	name is a name of your choice. The .bss prefix is case sensitive and must be all lowercase.
attribute((zero_init))	Arm Compiler 6 by default places zero-initialized variables in a .bss section. However, there is no equivalent to generate an error when you specify an initializer.	Arm Compiler 5 generates an error if the variable has an initializer. Otherwise, it places the zero-initialized variable in a .bss section.

4.1 Language extension compatibility: keywords on page 4-40.

4.3 Language extension compatibility: pragmas on page 4-45.

Related information

armlink User Guide: Placing at sections at a specific address.

4.3 Language extension compatibility: pragmas

Arm Compiler 6 provides support for some pragmas that are supported in Arm Compiler 5. Other pragmas are not supported, or must be replaced with alternatives.

The following table lists some of the commonly used pragmas that are supported by Arm Compiler 5 but are not supported by Arm Compiler 6. Replace any instances of these pragmas in your code with the recommended alternative.

Table 4-5 Pragma language extensions that must be replaced

Pragma supported by Arm Compiler 5	Recommended Arm Compiler 6 alternative
#pragma import (symbol)	asm(".global <i>symbol</i> \n\t");
<pre>#pragma anon_unions #pragma no_anon_unions</pre>	In C, anonymous structs and unions are a C11 extension which is enabled by default in armclang. If you specify the -pedantic option, the compiler emits warnings about extensions do not match the specified language standard. For example: armclangtarget=aarch64-arm-none-eabi -c -pedanticstd=c90 test.c test.c:3:5: warning: anonymous structs are a C11 extension [-Wc11-extensions]
	In C++, anonymous unions are part of the language standard, and are always enabled. However, anonymous structs and classes are an extension. If you specify the - pedantic option, the compiler emits warnings about anonymous structs and classes. For example:
	armclangtarget=aarch64-arm-none-eabi -c -pedantic -xc++ test.c test.c:3:5: warning: anonymous structs are a GNU extension [-Wgnu-anonymous-struct] Introducing anonymous unions, struct and classes using a typedef is a separate extension in armclang, which must be enabled using the -fms-extensions option.
#pragma arm #pragma thumb	armclang does not support switching instruction set in the middle of a file. You can use the command-line options -marm and -mthumb to specify the instruction set of the whole file.
#pragma arm section	#pragma clang section In Arm Compiler 5, the section types you can use this pragma with are rodata, rwdata, zidata, and code. In Arm Compiler 6, the equivalent section types are rodata, data, bss, and text respectively.
<pre>#pragma diag_default #pragma diag_suppress #pragma diag_remark #pragma diag_warning</pre>	The following pragmas provide equivalent functionality for diag_suppress, diag_warning, and diag_error: • #pragma clang diagnostic ignored "-Wmultichar" • #pragma clang diagnostic warning "-Wmultichar" • #pragma clang diagnostic error "-Wmultichar"
#pragma diag_error	Note that these pragmas use armclang diagnostic groups, which do not have a precise mapping to armcc diagnostic tags. armclang has no equivalent to diag_default or diag_remark. diag_default can be replaced by wrapping the change of diagnostic level with #pragma clang diagnostic push and #pragma clang diagnostic pop, or by manually returning the diagnostic to the default level.
	There is an additional diagnostic level supported in armclang, fatal, which causes compilation to fail without processing the rest of the file. You can set this as follows:
	#pragma clang diagnostic fatal "-Wmultichar"

Table 4-5 Pragma language extensions that must be replaced (continued)

Pragma supported by Arm Compiler 5	Recommended Arm Compiler 6 alternative
#pragma exceptions_unwind	armclang does not support these pragmas.
#pragma no_exceptions_unwind	Use theattribute((nothrow)) function attribute instead.
#pragma GCC system_header	This pragma is supported by both armcc and armclang, but #pragma clang system_header is the preferred spelling in armclang for new code.
#pragma hdrstop	armclang does not support these pragmas.
#pragma no_pch	
<pre>#pragma import(use_no_semihosting) #pragma</pre>	armclang does not support these pragmas. However, in C code, you can replace these pragmas with:
<pre>import(use_no_semihosting_swi)</pre>	asm(".globaluse_no_semihosting\n\t");
<pre>#pragma inline #pragma no_inline</pre>	armclang does not support these pragmas. However, inlining can be disabled on a perfunction basis using theattribute((noinline)) function attribute.
	The default behavior of both armcc and armclang is to inline functions when the compiler considers this worthwhile, and this is the behavior selected by using #pragma inline in armcc. To force a function to be inlined in armclang, use theattribute((always_inline)) function attribute.
<pre>#pragma Onum #pragma Ospace #pragma Otime</pre>	armclang does not support changing optimization options within a file. Instead these must be set on a per-file basis using command-line options.
<pre>#pragma pop #pragma push</pre>	armclang does not support these pragmas. Therefore, you cannot push and pop the state of all supported pragmas.
#pragila pusii	However, you can push and pop the state of the diagnostic pragmas and the state of the pack pragma.
	To control the state of the diagnostic pragmas, use #pragma clang diagnostic push and #pragma clang diagnostic pop.
	To control the state of the pack pragma, use #pragma pack(push) and #pragma pack(pop).
<pre>#pragma softfp_linkage</pre>	armclang does not support this pragma. Instead, use theattribute((pcs("aapcs"))) function attribute to set the calling convention on a per-function basis, or use the -mfloat-abi=soft command-line option to set the calling convention on a per-file basis.
<pre>#pragma no_softfp_linkage</pre>	armclang does not support this pragma. Instead, use theattribute((pcs("aapcs-vfp"))) function attribute to set the calling convention on a per-function basis, or use the -mfloat-abi=hard command-line option to set the calling convention on a per-file basis.
<pre>#pragma unroll[(n)] #pragma unroll_completely</pre>	armclang supports these pragmas. The default for #pragma unroll (that is, with no iteration count specified) differs between armclang and armcc: With armclang, the default is to fully unroll a loop. With armcc, the default is #pragma unroll(4).

armclang Reference Guide: #pragma unroll[(n)], #pragma unroll_completely.

4.4 Language extension compatibility: intrinsics

Arm Compiler 6 provides support for some intrinsics that are supported in Arm Compiler 5.

Note

This topic includes descriptions of [COMMUNITY] features. See *Support level definitions* on page 1-13.

The following table lists some of the commonly used intrinsics that are supported by Arm Compiler 5 and shows whether Arm Compiler 6 supports them or provides an alternative. If there is no support Arm Compiler 6, you must replace them with suitable inline assembly instructions or calls to the standard library. To use the intrinsic in Arm Compiler 6, you must include the appropriate header file. For more information on the ACLE intrinsics, see the *Arm® C Language Extensions*.

Note

• This is not an exhaustive list of all the intrinsics.

• The intrinsics provided in <arm_compat.h> are only supported for AArch32.

Table 4-6 Compiler intrinsic support in Arm Compiler 6

Intrinsic in Arm Compiler 5	Function	Support in Arm Compiler 6	Header file for Arm Compiler 6
breakpoint	Inserts a BKPT instruction.	Yes	arm_compat.h
cdp	Inserts a coprocessor instruction.	Yes. In Arm Compiler 6, the equivalent intrinsic isarm_cdp.	arm_acle.h
clrex	Inserts a CLREX instruction.	No	-
clz	Inserts a CLZ instruction or equivalent routine.	Yes	arm_acle.h
current_pc	Returns the program counter at this point.	Yes	arm_compat.h
current_sp	Returns the stack pointer at this point.	Yes	arm_compat.h
isb	Inserts ISB or equivalent.	Yes	arm_acle.h
disable_fiq	Disables FIQ interrupts (Armv7 architecture only). Returns previous value of FIQ mask.	Yes	arm_compat.h
disable_irq	Disable IRQ interrupts. Returns previous value of IRQ mask.	Yes	arm_compat.h
dmb	Inserts a DMB instruction or equivalent.	Yes	arm_acle.h
dsb	Inserts a DSB instruction or equivalent.	Yes	arm_acle.h
enable_fiq	Enables fast interrupts.	Yes	arm_compat.h
enable_irq	Enables IRQ interrupts.	Yes	arm_compat.h
fabs	Inserts a VABS or equivalent code sequence.	No. Arm recommends using the standard C library function fabs().	-
fabsf	Single precision version offabs.	No. Arm recommends using the standard C library function fabsf().	-

Table 4-6 Compiler intrinsic support in Arm Compiler 6 (continued)

Intrinsic in Arm Compiler 5	Function	Support in Arm Compiler 6	Header file for Arm Compiler 6
force_stores	Flushes all external variables visible from this function, if they have been changed.	Yes	arm_compat.h
ldrex	Inserts an appropriately sized Load Exclusive instruction.	No. This intrinsic is deprecated in ACLE 2.0.	-
ldrexd	Inserts an LDREXD instruction.	No. This intrinsic is deprecated in ACLE 2.0.	-
ldrt	Inserts an appropriately sized user-mode load instruction.	No	-
memory_changed	Is similar toforce_stores, but also reloads the values from memory.	Yes	arm_compat.h
nop	Inserts a NOP or equivalent instruction that will not be optimized away. It also inserts a sequence point, and scheduling barrier for side-effecting function calls.	Yes	arm_acle.h
pld	Inserts a PLD instruction, if supported.	Yes	arm_acle.h
pldw	Inserts a PLDW instruction, if supported (Armv7 architecture with MP).	No. Arm recommends usingpldx described in the ACLE document.	arm_acle.h
pli	Inserts a PLI instruction, if supported.	Yes	arm_acle.h
promise	Compiler assertion that the expression always has a nonzero value. It is an assert if asserts are enabled.	[COMMUNITY] No. However,promise is a community feature.	-
qadd	Inserts a saturating add instruction, if supported.	Yes	arm_acle.h
qdbl	Inserts instructions equivalent to qadd(val,val), if supported.	Yes	arm_acle.h
qsub	Inserts a saturating subtract, or equivalent routine, if supported.	Yes	arm_acle.h
rbit	Inserts a bit reverse instruction.	Yes	arm_acle.h
rev	Insert a REV, or endian swap instruction.	Yes	arm_acle.h
return_address	Returns value of LR when returning from current function, without inhibiting optimizations like inlining or tailcalling.	No. Arm recommends using inline assembly instructions.	-
ror	Insert an ROR instruction.	Yes	arm_acle.h
schedule_barrier	Create a sequence point without effecting memory or inserting NOP instructions. Functions with side effects cannot move past the new sequence point.	Yes	arm_compat.h
semihost	Inserts an SVC or BKPT instruction.	Yes	arm_compat.h
sev	Insert a SEV instruction. Error if the SEV instruction is not supported.	Yes	arm_acle.h
sqrt	Inserts a VSQRT instruction on targets with a VFP coprocessor.	No	-

Table 4-6 Compiler intrinsic support in Arm Compiler 6 (continued)

Intrinsic in Arm Compiler 5	Function	Support in Arm Compiler 6 Heade	
sqrtf single precision version ofsqrt. N		No	-
ssat	Inserts an SSAT instruction. Error if the SSAT instruction is not supported.	Yes	arm_acle.h
strex	Inserts an appropriately sized Store Exclusive instruction.	No. This intrinsic is deprecated in ACLE 2.0.	-
strexd	Inserts a doubleword Store Exclusive instruction.	No. This intrinsic is deprecated in ACLE 2.0.	-
strt	Insert an appropriately sized STRT instruction.	No	-
swp	Inserts an appropriately sized SWP instruction.	[COMMUNITY] Yes. However,swp is not recommended.	arm_acle.h
usat	Inserts a USAT instruction. Error if the USAT instruction is not supported.	Yes	arm_acle.h
wfe	Inserts a WFE instruction. Error if the WFE instruction is not supported.	Yes	arm_acle.h
wfi	Inserts a WFI instruction. Error if the WFI instruction is not supported.	Yes	arm_acle.h
yield	Inserts a YIELD instruction. Error if the YIELD instruction is not supported.	Yes	arm_acle.h
ARMv6 SIMD intrinsics Inserts an Armv6 SIMD instruction.		No	-
Solutions and 2 global variable flags specified in ETSI G729 used for speech encoding. These are provided in the Arm headers in dspfns.h.		No	-
C55x intrinsics Emulation of selected TI C55x compiler intrinsics.		No	-
vfp_status	Reads the FPSCR.	Yes	arm_compat.h
FMA intrinsics	Intrinsics for fused-multiply-add on the Cortex-M4 or Cortex-A5 processor in c99 mode.	No	-
Named register variables	Allows direct manipulation of a system register as if it were a C variable.	No. To access FPSCR, use thevfp_status intrinsic or inline assembly instructions.	-

4.5 Diagnostics for pragma compatibility

Older armcc compiler versions supported many pragmas which are not supported by armclang, but which could change the semantics of code. When armclang encounters these pragmas, it generates diagnostic messages.

The following table shows which diagnostics are generated for each pragma type, and the diagnostic group to which that diagnostic belongs. armclang generates diagnostics as follows:

- Errors indicate use of an armcc pragma which could change the semantics of code.
- Warnings indicate use of any other armcc pragma which is ignored by armclang.
- Pragmas other than those listed are silently ignored.

Table 4-7 Pragma diagnostics

Pragma supported by older compiler versions	Default diagnostic type	Diagnostic group
#pragma anon_unions	Warning	armcc-pragma-anon-unions
#pragma no_anon_unions	Warning	armcc-pragma-anon-unions
#pragma arm	Error	armcc-pragma-arm
<pre>#pragma arm section [section_type_list]</pre>	Error	armcc-pragma-arm
<pre>#pragma diag_default tag[,tag,]</pre>	Error	armcc-pragma-diag
<pre>#pragma diag_error tag[,tag,]</pre>	Error	armcc-pragma-diag
<pre>#pragma diag_remark tag[,tag,]</pre>	Warning	armcc-pragma-diag
<pre>#pragma diag_suppress tag[,tag,]</pre>	Warning	armcc-pragma-diag
<pre>#pragma diag_warning tag[,tag,]</pre>	Warning	armcc-pragma-diag
#pragma exceptions_unwind	Error	armcc-pragma-exceptions-unwind
#pragma no_exceptions_unwind	Error	armcc-pragma-exceptions-unwind
#pragma GCC system_header	None	-
#pragma hdrstop	Warning	armcc-pragma-hdrstop
#pragma import symbol_name	Error	armcc-pragma-import
#pragma inline	Warning	armcc-pragma-inline
#pragma no_inline	Warning	armcc-pragma-inline
#pragma no_pch	Warning	armcc-pragma-no-pch
#pragma O <i>num</i>	Warning	armcc-pragma-optimization
#pragma once	None	-
#pragma Ospace	Warning	armcc-pragma-optimization
#pragma Otime	Warning	armcc-pragma-optimization
#pragma pack	None	-
#pragma pop	Error	armcc-pragma-push-pop
#pragma push	Error	armcc-pragma-push-pop
#pragma softfp_linkage	Error	armcc-pragma-softfp-linkage
#pragma no_softfp_linkage	Error	armcc-pragma-softfp-linkage
#pragma thumb	Error	armcc-pragma-thumb

Table 4-7 Pragma diagnostics (continued)

Pragma supported by older compiler versions	Default diagnostic type	Diagnostic group
#pragma weak symbol	None	-
<pre>#pragma weak symbol1 = symbol2</pre>	None	-

In addition to the above diagnostic groups, there are the following additional diagnostic groups:

armcc-pragmas

Contains all of the above diagnostic groups.

unknown-pragmas

Contains diagnostics about pragmas which are not known to armclang, and are not in the above table.

pragmas

Contains all pragma-related diagnostics, including armcc-pragmas and unknown-pragmas.

Any non-fatal armclang diagnostic group can be ignored, upgraded, or downgraded using the following command-line options:

Suppress a group of diagnostics:

-Wno-diag-group

Upgrade a group of diagnostics to warnings:

-Wdiag-group

Upgrade a group of diagnostics to errors:

-Werror=diag-group

Downgrade a group of diagnostics to warnings:

-Wno-error=diag-group

4.6 C and C++ implementation compatibility

Arm Compiler 6 C and C++ implementation details differ from previous compiler versions.

The following table describes the C and C++ implementation detail differences.

Table 4-8 C and C++ implementation detail differences

Feature	Older versions of Arm Compiler	Arm Compiler 6	
Integer operations			
Shifts	int shifts > 0 && < 127	Warns when shift amount > width of type.	
	<pre>int left_shifts > 31 == 0</pre>	You can use the -Wshift-count-overflow option to	
	<pre>int right_shifts > 31 == 0</pre>	suppress this warning.	
	(for unsigned or positive)		
	<pre>int right_shifts > 31 == -1</pre>		
	(for negative)		
	long long shifts > 0 && < 63		
Integer division	Checks that the sign of the remainder matches the sign of the numerator	The sign of the remainder is not necessarily the same as the sign of the numerator.	
Floating-point operation	s		
Default standard	IEEE 754 standard, rounding to nearest representable value, exceptions disabled by default.	All facilities, operations, and representations guaranteed by the IEEE standard are available in single and double- precision. Modes of operation can be selected dynamically at runtime.	
		This is equivalent to thefpmode=ieee_full option in older versions of Arm Compiler.	
#pragma STDC FP_CONTRACT	#pragma STDC FP_CONTRACT	Might affect code generation.	
Unions, enums and struc	ts		
Enum packing Enums are implemented in the smallest integral type of the correct sign to hold the range of the enum values, except for when compiling in C++ mode with enum_is_int. By default enums are implemented as int, we used when required.		By default enums are implemented as int, with long long used when required.	
in containers is sufficient to con		A container is an object, aligned as the declared type. Its size is sufficient to contain the bit-field, but might be smaller or larger than the bit-field declared type.	
Signedness of plain bit-	Unsigned.	Signed.	
fields	Plain bit-fields declared without either the signed or unsigned qualifiers default to unsigned. Thesigned_bitfields option treats plain bit-fields as signed.	Plain bit-fields declared without either the signed or unsigned qualifiers default to signed . There is no equivalent to either thesigned_bitfields orno_signed_bitfields options.	

Table 4-8 C and C++ implementation detail differences (continued)

Feature	Older versions of Arm Compiler	Arm Compiler 6
Casting between integers and pointers	No change of representation	Converting a signed integer to a pointer type with greater bit width sign-extends the integer.
		Converting an unsigned integer to a pointer type with greater bit width zero-extends the integer.
Misc C		
sizeof(wchar_t)	2 bytes	4 bytes
size_t	Defined as unsigned int, 32-bit.	Defined as unsigned int in 32-bit architectures, and <sign><type> 64-bit in 64-bit architectures.</type></sign>
ptrdiff_t	Defined as signed int, 32-bit.	Defined as unsigned int in 32-bit architectures, and <sign><type> 64-bit in 64-bit architectures.</type></sign>
Misc C++		
C++ library Implicit inclusion Alternative template	Rogue Wave Standard C++ Library If compilation requires a template definition from a template declared in a header file xyz.h, the compiler implicitly includes the file xyz.cc or xyz.CC. When performing referencing context	Note Note Note Note When the C++ library is used in source code, there is limited compatibility between object code created with Arm Compiler 6 and object code created with Arm Compiler 5. This also applies to indirect use of the C++ library, for example memory allocation or exception handling. Not supported.
lookup algorithms	lookups, name lookup matches against names from the instantiation context as well as from the template definition context.	
Exceptions	Off by default, function unwinding on withexceptions by default.	On by default in C++ mode.
Translation		
Diagnostics messages format	<pre>source-file, line-number : severity : error-code : explanation</pre>	source-file:line-number:char-number: description [diagnostic-flag]
Environment		
Physical source file bytes interpretation	Current system locale dependent or set using thelocale command-line option.	UTF-8

4.7 Compatibility of C++ objects

The compatibility of C++ objects compiled with Arm Compiler 5 depends on the C++ libraries used.

Compatibility with objects compiled using Rogue Wave standard library headers

Arm Compiler 6 does not support binary compatibility with objects compiled using the Rogue Wave standard library include files.

There are warnings at link time when objects are mixed. L6869W is reported if an object requests the Rogue Wave standard library. L6870W is reported when using an object that is compiled with Arm Compiler 5 with exceptions support.

The impact of mixing objects that have been compiled against different C++ standard library headers might include:

- · Undefined symbol errors.
- Increased code size.
- Possible runtime errors.

If you have Arm Compiler 6 objects that have been compiled with the legacy -stdlib=legacy_cpplib option then these objects use the Rogue Wave standard library and therefore might be incompatible with objects created using Arm Compiler 6.4 or later. To resolve these issues, you must recompile all object files with Arm Compiler 6.4 or later.

Compatibility with C++ objects compiled using Arm® Compiler 5

The choice of C++ libraries at link time must match the choice of C++ include files at compile time for all input objects. Arm Compiler 5 objects that use the Rogue Wave C++ libraries are not compatible with Arm Compiler 6 objects. Arm Compiler 5 objects that use C++ but do not make use of the Rogue Wave header files can be compatible with Arm Compiler 6 objects that use libc++ but this is not guaranteed.

Arm recommends using Arm Compiler 6 for building the object files.

Compatibility of arrays of objects compiled using Arm® Compiler 5

Arm Compiler 6 is not compatible with objects from Arm Compiler 5 that use operator new[] and delete[]. Undefined symbol errors result at link time because Arm Compiler 6 does not provide the helper functions that Arm Compiler 5 depends on. For example:

```
construct.cpp:

class Foo
{
public:
    Foo() : x_(new int) { *x_ = 0; }
    void setX(int x) { *x_ = x; }
    ~Foo() { delete x_; }
private:
    int* x_;
};

void func(void)
{
    Foo* array;
    array = new Foo [10];
    array[0].setX(1);
    delete[] array;
}
```

If you build this example with the Arm Compiler 5 compiler, armcc, and link with the Arm Compiler 6 linker, armlink, using:

```
armcc -c construct.cpp -Ospace -O1 --cpu=cortex-a9 armlink construct.o -o construct.axf
```

the linker reports:

		aeabi_vec_delete (referred from construct.o)aeabi_vec_new_cookie_nodtor (referred from construct.o).	

To resolve these linker errors, you must use the Arm Compiler 6 compiler, armclang, to compile all C++ files that use the new[] and delete[] operators.

You do not have to specify --stdlib=libc++ for armlink, because this is the default and only option in Arm Compiler 6.4, and later.

Chapter 5

Migrating from armasm to the armclang integrated assembler

Describes how to migrate assembly code from armasm syntax to GNU syntax (used by armclang).

It contains the following sections:

- 5.1 Migration of assembler command-line options from armasm to the armclang integrated assembler on page 5-58.
- 5.2 Overview of differences between armasm and GNU syntax assembly code on page 5-63.
- *5.3 Comments* on page 5-65.
- 5.4 Labels on page 5-66.
- 5.5 Numeric local labels on page 5-67.
- 5.6 Functions on page 5-69.
- *5.7 Sections* on page 5-70.
- 5.8 Symbol naming rules on page 5-72.
- 5.9 Numeric literals on page 5-73.
- *5.10 Operators* on page 5-74.
- *5.11 Alignment* on page 5-75.
- 5.12 PC-relative addressing on page 5-76.
- 5.13 A32 and T32 instruction substitutions on page 5-77.
- 5.14 A32 and T32 pseudo-instructions on page 5-79.
- 5.15 Conditional directives on page 5-80.
- 5.16 Data definition directives on page 5-81.
- 5.17 Instruction set directives on page 5-83.
- 5.18 Miscellaneous directives on page 5-84.
- 5.19 Symbol definition directives on page 5-86.
- 5.20 Migration of armasm macros to integrated assembler macros on page 5-87.

5.1 Migration of assembler command-line options from armasm to the armclang integrated assembler

Arm Compiler 6 provides many command-line options, including most Clang command-line options as well as several Arm-specific options.

Note	
This topic includes descriptions of [COMMUNITY] features. See Support level definitions on pa	ge 1-13

—— Note ———

The following GNU assembly directives are [COMMUNITY] features:

- .eabi_attribute Tag_ABI_PCS_RO_data, value
- .eabi_attribute Tag_ABI_PCS_R9_use, value
- .eabi_attribute Tag_ABI_PCS_RW_data, value
- .eabi_attribute Tag_ABI_VFP_args, value
- .eabi_attribute Tag_CPU_unaligned_access, value
- .ident
- .protected
- .section .note.GNU-stack, "x"
- -Wa,--noexecstack
- -Wa,-L
- -Wa,-defsym,symbol=value

The following table describes the most common armasm command-line options, and shows the equivalent options for the armclang integrated assembler.

Additional information about command-line options is available:

- The armclang Reference Guide provides more detail about a number of command-line options.
- For a full list of Clang command-line options, consult the Clang and LLVM documentation.

Table 5-1 Comparison of command-line options in armasm and the armclang integrated assembler

armasm option	armclang integrated assembler option	Description
arm_only	No equivalent.	Enforces A32 instructions only.
apcs=/nointerwork	No equivalent.	Specifies that the code in the input file can interwork between A32 and T32 safely. Interworking is always enabled in Arm Compiler 6.
apcs=/ropi, apcs=/noropi	No direct equivalent.	With armasm, the options specify whether the code in the input file is Read-Only Position-Independent (ROPI) code. With the armclang integrated assembler, use the GNU assembly .eabi_attribute directive instead. To specify that the code is ROPI code, use the directive as follows: .eabi_attribute Tag_ABI_PCS_RO_data, 1 The code is marked as not ROPI code by default.

Table 5-1 Comparison of command-line options in armasm and the armclang integrated assembler (continued)

armasm option	armclang integrated assembler option	Description
apcs=/rwpi, apcs=/norwpi	No direct equivalent.	With armasm, the options specify whether the code in the input file is <i>Read-Write Position-Independent</i> (RWPI) code.
upes-/ nor wp1		With the armclang integrated assembler, use the GNU assembly .eabi_attribute directive instead.
		To specify that the code is RWPI code, use the directive as follows:
		<pre>.eabi_attribute Tag_ABI_PCS_R9_use, 1 .eabi_attribute Tag_ABI_PCS_RW_data, 2</pre>
		The code is marked as not RWPI code by default.
apcs=/hardfp, apcs=/softfp	No direct equivalent.	With armasm, the options set attributes in the object file to request hardware or software floating-point linkage.
		With the armclang integrated assembler, use the GNU assembly .eabi_attribute directive instead.
		To request hardware floating-point linkage, use the directive as follows:
		.eabi_attribute Tag_ABI_VFP_args, 1
		To request software floating-point linkage, use the directive as follows:
		.eabi_attribute Tag_ABI_VFP_args, 0
checkreglist, diag_warning=1206	This is the default.	Generates warnings if register lists in LDM and STM instructions are not provided in increasing register number order.
		This warning cannot be suppressed or upgraded to an error.
comment_section,	No direct equivalent.	With armasm, the option controls the inclusion of a comment section .comment in object files.
no_commenc_section		With the armclang integrated assembler, use the GNU assembly .ident directive to manually add a comment section.
debug,	-g	Instructs the assembler to generate DWARF debug tables.
-g		With armasm, the default format for debug tables is DWARF 3. Named local labels are not preserved in the object file, unless thekeep option is used.
		With the armclang integrated assembler, the default format for debug tables is DWARF 4. Named local labels are always preserved in the object file. See the entry forkeep in this table for details.
diag_warning=1645	No equivalent.	With armasm, the option enables warnings about instruction substitutions.
		With the armclang integrated assembler, instruction substitution support is limited. Where it is not supported, the assembler generates an error message.
		Use the armasm warning when migrating code to find instructions being substituted and perform the substitution manually.

Table 5-1 Comparison of command-line options in armasm and the armclang integrated assembler (continued)

armasm option	armclang integrated assembler option	Description
diag_warning=1763	No equivalent.	With armasm, the option enables warnings about automatic generation of IT blocks when assembling T32 code (formerly Thumb code).
		With the armclang integrated assembler, automatic generation of IT blocks is disabled by default. The assembler generates an error message when assembling conditional instructions without an enclosing IT block. To enable automatic generation of IT blocks, use the command-line option -mimplicit-it=always or -mimplicit-it=thumb.
dllexport_all	No direct equivalent.	With armasm, the option gives all exported global symbols STV_PROTECTED visibility in ELF rather than STV_HIDDEN, unless overridden by source directives.
		With the armclang integrated assembler, use the GNU assembly .protected directive to manually give exported symbols STV_PROTECTED visibility.
execstack, no_execstack	-Wa, noexecstack No direct equivalent for	With armasm, the option generates a .note.GNU-stack section marking the stack as either executable or non-executable.
no_execstack	execstack.	With the armclang integrated assembler, the equivalent option can be used to generate a .note.GNU-stack section marking the stack as non-executable.
		To generate such a section and mark the stack as executable, use the GNU assembly .section directive as follows:
		.section .note.GNU-stack, "x"
		The command-line option -Wa,noexecstack overrides the use of the .section directive.
keep	No direct equivalent.	With armasm, the option instructs the assembler to keep named local labels in the symbol table of the object file, for use by the debugger.
		With the armclang integrated assembler, named local labels defined without using the GNU assembly local symbol name prefix .L are always preserved in the object file.
		Use the command-line option -Wa, -L to automatically preserve all named local labels defined using the GNU assembly local symbol name prefix.
-М	-M	Instructs the assembler to produce a list of makefile dependency lines suitable for use by a make utility. It only includes dependencies visible to the preprocessor. The option does not include files added using the INCBIN, INCLUDE, or GET directives with armasm, or the GNU assembly .incbin or .include directives with the armclang integrated assembler.
		outputs the makefile dependency lines to the file specified. An object file is not produced.

Table 5-1 Comparison of command-line options in armasm and the armclang integrated assembler (continued)

armclang integrated assembler option	Description
- MM	Creates a single makefile dependency file, without the system header files. It only includes dependencies visible to the preprocessor. The option does not include files added using the INCBIN, INCLUDE, or GET directives with armasm, or the GNU assembly .incbin or .include directives with the armclang integrated assembler. Note With the armclang integrated assembler, using this option with -o outputs the makefile dependency file to the file specified. An object file is not produced.
This is the default.	Gives all exported and imported global symbols STV_DEFAULT visibility in ELF rather than STV_HIDDEN, unless overridden using source directives.
-Wa,-defsym,symbol=value	With armasm, the option instructs the assembler to pre-execute one of the SETA, SETL, or SETS directives as specified using <i>directive</i> .
	With the armclang integrated assembler, the option instructs the assembler to pre-define the symbol symbol with the value value. This GNU assembly .set directive can be used to change this value in the file being assembled.
No direct equivalent.	With armasm, the options instruct the assembler to set an attribute in the object file to enable or disable the use of unaligned accesses.
	With the armclang integrated assembler, use the GNU assembly .eabi_attribute directive instead.
	To enable the use of unaligned access, use the directive as follows:
	.eabi_attribute Tag_CPU_unaligned_access, 1
	To disable the use of unaligned access, use the directive as follows:
	<pre>.eabi_attribute Tag_CPU_unaligned_access, 0</pre>
No direct equivalent.	With armasm, the option enables instructions for architectures other than the target architecture to be assembled without error. With the armclang integrated assembler, use the GNU assembly .inst directive to generate such instructions.
	-MM This is the default. -Wa,-defsym,symbol=value No direct equivalent.

5.2 Overview of differences between armasm and GNU syntax assembly code

armasm (for assembling legacy assembly code) uses armasm syntax assembly code.

armclang aims to be compatible with GNU syntax assembly code (that is, the assembly code syntax supported by the GNU assembler, as).

If you have legacy assembly code that you want to assemble with armclang, you must convert that assembly code from armasm syntax to GNU syntax.

The specific instructions and order of operands in your UAL syntax assembly code do not change during this migration process.

However, you need to make changes to the syntax of your assembly code. These changes include:

- The directives in your code.
- The format of labels, comments, and some types of literals.
- Some symbol names.
- The operators in your code.

The following examples show simple, equivalent, assembly code in both armasm and GNU syntax.

armasm syntax

```
; Simple armasm syntax example
; Iterate round a loop 10 times, adding 1 to a register each time.
         AREA ||.text||, CODE, READONLY, ALIGN=2
main PROC
                   w5,#0x64
         MOV
                                  ; W5 = 100
         MOV
                   w4.#0
                                  ; W4 = 0
; branch to test_loop
                   test_loop
loop
                                  ; Add 1 to W5
; Add 1 to W4
         ΔDD
                   w5,w5,#1
         ADD
                   w4,w4,#1
test_loop
         .
CMP
                                  ; if W4 < 10, branch back to loop
                   w4,#0xa
         BLT
                   loop
         ENDP
         END
```

GNU syntax

```
// Simple GNU syntax example 5.3 Comments on page 5-65
^{\prime\prime} // Iterate round a loop 10 times, adding 1 to a register each time.
        .section .text,"ax"
                             // 5.7 Sections on page 5-70
        .balign 4
                             main:
       MO\/
                w5,#0x64
       MOV
                w4,#0
                test_loop
       В
loop:
                              // Add 1 to W5
       ΔDD
                w5,w5,#1
       ADD
                w4,w4,#1
                              // Add 1 to W4
test_loop:
CMP
                              // if W4 < 10, branch back to loop
                w4,#0xa
       BLT
        .end
                              // 5.18 Miscellaneous directives on page 5-84
```

Related information

About the Unified Assembler Language.

5.3 Comments

A comment identifies text that the assembler ignores.

armasm syntax

A comment is the final part of a source line. The first semicolon on a line marks the beginning of a comment except where the semicolon appears inside a string literal.

The end of the line is the end of the comment. A comment alone is a valid line.

For example:

```
; This whole line is a comment; As is this line

myProc: PROC

MOV r1, #16; Load R0 with 16
```

GNU syntax

GNU syntax assembly code provides two different methods for marking comments:

• The /* and */ markers identify multiline comments:

```
/* This is a comment
that spans multiple
lines */
```

• The // marker identifies the remainder of a line as a comment:

```
MOV R0,#16 // Load R0 with 16
```

Related information

GNU Binutils - Using as: Comments.

armasm User Guide: Syntax of source lines in assembly language.

5.4 Labels

Labels are symbolic representations of addresses. You can use labels to mark specific addresses that you want to refer to from other parts of the code.

armasm syntax

A label is written as a symbol beginning in the first column. A label can appear either in a line on its own, or in a line with an instruction or directive. Whitespace separates the label from any following instruction or directive:

```
MOV R0,#16
loop SUB R0,R0,#1 ; "loop" is a label
CMP R0,#0
BGT loop
```

GNU syntax

A label is written as a symbol that either begins in the first column, or has nothing but whitespace between the first column and the label. A label can appear either in a line on its own, or in a line with an instruction or directive. A colon ":" follows the label (whitespace is allowed between the label and the colon):

```
MOV R0,#16
loop: // "loop" label on its own line
SUB R0,R0,#1
CMP R0,#0
BGT loop

MOV R0,#16
loop: SUB R0,R0,#1 // "loop" label in a line with an instruction
CMP R0,#0
BGT loop
```

Related references

5.5 Numeric local labels on page 5-67.

Related information

GNU Binutils - Using as: Labels.

5.5 Numeric local labels

Numeric local labels are a type of label that you refer to by a number rather than by name. Unlike other labels, the same numeric local label can be used multiple times and the same number can be used for more than one numeric local label.

armasm syntax

A numeric local label is a number in the range 0-99, optionally followed by a scope name corresponding to a ROUT directive.

Numeric local labels follow the same syntax as all other labels.

Refer to numeric local labels using the following syntax:

```
%[F|B][A|T]n[routname]
```

Where:

- F and B instruct the assembler to search forwards and backwards respectively. By default, the
 assembler searches backwards first, then forwards.
- A and T instruct the assembler to search all macro levels or only the current macro level respectively. By default, the assembler searches all macros from the current level to the top level, but does not search lower level macros.
- *n* is the number of the numeric local label in the range 0-99.
- routname is an optional scope label corresponding to a ROUT directive. If routname is specified in either a label or a reference to a label, the assembler checks it against the name of the nearest preceding ROUT directive. If it does not match, the assembler generates an error message and the assembly fails.

For example, the following code implements an incrementing loop:

```
MOV r4,#1 ; r4=1
1 ; Local label
ADD r4,r4,#1 ; Increment r4
CMP r4,#0x5 ; if r4 < 5...
BLT %b1 ; ...branch backwards to local label "1"
```

Here is the same example using a ROUT directive to restrict the scope of the local label:

```
Start of "routA" scope
routA
         ROUT
         MOV
                   r4,#1
                                  r4=1
1routA
                                  Local label
         ADD
                   r4,r4,#1
                                 Increment r4
         CMP
                   r4,#0x9
                                 if r4 < 9.
                                  ...branch backwards to local label "1routA"
         BLT
                   %b1routA
routB
                                  Start of "routB" scope (and therefore end of "routA" scope)
         ROUT
```

GNU syntax

A numeric local label is a number in the range 0-99.

Numeric local labels follow the same syntax as all other labels.

Refer to numeric local labels using the following syntax:

 $n\{f|b\}$

Where:

- *n* is the number of the numeric local label in the range 0-99.
- f and b instruct the assembler to search forwards and backwards respectively. There is no default. You must specify one of f or b.

For example, the following code implements an incrementing loop:

CMP r4	,#0x5 // if	r4 < 5		
BLT 1b) //	branch backwards to	o local label	"1"

— Note —

GNU syntax assembly code does not provide mechanisms for restricting the scope of local labels.

5.6 Functions

Assemblers can identify the start of a function when producing DWARF call frame information for ELF.

armasm syntax

The FUNCTION directive marks the start of a function. PROC is a synonym for FUNCTION.

The ENDFUNC directive marks the end of a function. ENDP is a synonym for ENDFUNC.

For example:

```
myproc PROC
; Procedure body
ENDP
```

GNU syntax

Use the .type directive to identify symbols as functions. For example:

```
.type myproc, "function"
myproc:
  // Procedure body
```

GNU syntax assembly code provides the .func and .endfunc directives. However, these are not supported by armclang uses the .size directive to set the symbol size:

```
.type myproc, "function"
myproc:
  // Procedure body
.Lmyproc_end0:
  .size myproc, .Lmyproc_end0-myproc
```

—— Note ———

Functions must be typed to link properly.

Related information

GNU Binutils - Using as: .type.

armasm User Guide: FUNCTION or PROC. armasm User Guide: ENDFUNC or ENDP.

5.7 Sections

Sections are independent, named, indivisible chunks of code or data that are manipulated by the linker.

armasm syntax

The AREA directive instructs the assembler to assemble a new code or data section.

Section attributes within the AREA directive provide information about the section. Available section attributes include the following:

- CODE specifies that the section contains machine instructions.
- READONLY specifies that the section must not be written to.
- ALIGN=n specifies that the section is aligned on a 2^n byte boundary

For example:

AREA mysection, CODE, READONLY, ALIGN=3

Note ———

The ALIGN attribute does not take the same values as the ALIGN directive. ALIGN=n (the AREA attribute) aligns on a 2^n byte boundary. ALIGN n (the ALIGN directive) aligns on an n-byte boundary.

GNU syntax

The .section directive instructs the assembler to assemble a new code or data section.

Flags provide information about the section. Available section flags include the following:

- a specifies that the section is allocatable.
- x specifies that the section is executable.
- w specifies that the section is writable.
- s specifies that the section contains null-terminated strings.

For example:

- Note

```
.section mysection, "ax"
```

Not all armasm syntax AREA attributes map onto GNU syntax .section flags. For example, the armasm syntax ALIGN attribute corresponds to the GNU syntax .balign directive, rather than a .section flag:

```
.section mysection,"ax"
.balign 8
```

When using Arm Compiler 5, section names do not need to be unique. Therefore, you could use the same section name to create different section types.

Arm Compiler 6 does not support multiple sections with the same section name. Therefore you must ensure that the different section types have unique names. You must not use the same section name for another section or symbol. If you use the same section name for a different section type, the armclang integrated assembler merges the sections and gives the merged section the flags of the first section with that name.

```
// stores both the code and data in one section
// uses the flags from the first section
    .section "sectionX", "ax"
    mov r0, r0
    .section "sectionX", "a", %progbits
    .word 0xdeadbeef

// stores both the code and data in one section
// uses the flags from the first section
    .section "sectionY", "a", %progbits
    .word 0xdeadbeef
```

```
.section "sectionY", "ax"
mov r0, r0
```

When you assemble the above example code with:

```
armclang --target=arm-arm-none-eabi -c -march=armv8-m.main example_sections.s
```

The armclang integrated assembler:

- merges the two sections named sectionX into one section with the flags "ax".
- merges the two sections named sectionY into one section with the flags "a", %progbits.

Related information

GNU Binutils - Using as: .section. GNU Binutils - Using as: .align. armasm User Guide: AREA.

5.8 Symbol naming rules

armasm syntax assembly code and GNU syntax assembly code use similar, but different naming rules for symbols.

Symbol naming rules which are common to both armasm syntax and GNU syntax include:

- Symbol names must be unique within their scope.
- Symbol names are case-sensitive, and all characters in the symbol name are significant.
- Symbols must not use the same name as built-in variable names or predefined symbol names.

Symbol naming rules which differ between armasm syntax and GNU syntax include:

- armasm syntax symbols must start with a letter or the underscore character "_".
 - GNU syntax symbols must start with a letter, the underscore character "_", or a period ".".
- armasm syntax symbols use double bars to delimit symbol names containing non-alphanumeric characters (except for the underscore):

```
IMPORT ||Image$$ARM LIB STACKHEAP$$ZI$$Limit||
```

GNU syntax symbols do not require double bars:

.global Image\$\$ARM_LIB_STACKHEAP\$\$ZI\$\$Limit

5.9 Numeric literals

armasm syntax assembly and GNU syntax assembly provide different methods for specifying some types of numeric literal.

Implicit shift operations

armasm syntax assembly allows immediate values with an implicit shift operation. For example, the MOVK instruction takes a 16-bit operand with an optional left shift. armasm accepts the instruction MOVK x1, #0x40000, converting the operand automatically to MOVK x1, #0x4, LSL #16.

GNU syntax assembly expects immediate values to be presented as encoded. The instruction MOVK x1, #0x40000 results in the following message: error: immediate must be an integer in range [0, 65535].

Hexadecimal literals

armasm syntax assembly provides two methods for specifying hexadecimal literals, the prefixes "&" and "0x".

For example, the following are equivalent:

```
ADD r1, #0xAF
ADD r1, #&AF
```

GNU syntax assembly only supports the "0x" prefix for specifying hexadecimal literals. Convert any "&" prefixes to "0x".

n base-n-digits format

armasm syntax assembly lets you specify numeric literals using the following format:

n_base-n-digits

For example:

- 2_1101 is the binary literal 1101 (13 in decimal).
- 8 27 is the octal literal 27 (23 in decimal).

GNU syntax assembly does not support the $n_{\text{base-}n\text{-digits}}$ format. Convert all instances to a supported numeric literal form.

For example, you could convert:

```
ADD r1, #2_1101

to:

ADD r1, #13

or:

ADD r1, #0xD
```

Related information

GNU Binutils - Using as: Integers.

armasm User Guide: Syntax of numeric literals.

5.10 Operators

armasm syntax assembly and GNU syntax assembly provide different methods for specifying some operators.

The following table shows how to translate armasm syntax operators to GNU syntax operators.

Table 5-2 Operator translation

armasm syntax operator	GNU syntax operator
:OR:	1
:EOR:	٨
:AND:	&
:NOT:	~
:SHL:	<<
:SHR:	>>
:LOR:	П
:LAND:	&&
:ROL:	No GNU equivalent
:ROR:	No GNU equivalent

Related information

armasm User Guide: Addition, subtraction, and logical operators.

5.11 Alignment

Data and code must be aligned to appropriate boundaries.

For example, The T32 pseudo-instruction ADR can only load addresses that are word aligned, but a label within T32 code might not be word aligned. You must use an alignment directive to ensure four-byte alignment of an address within T32 code.

An alignment directive aligns the current location to a specified boundary by padding with zeros or NOP instructions.

armasm syntax

armasm syntax assembly provides the ALIGN n directive, where n specifies the alignment boundary in bytes. For example, the directive ALIGN 128 aligns addresses to 128-byte boundaries.

armasm syntax assembly also provides the PRESERVE8 directive. The PRESERVE8 directive specifies that the current file preserves eight-byte alignment of the stack.

GNU syntax

GNU syntax assembly provides the .balign n directive, which uses the same format as ALIGN.

Convert all instances of ALIGN n to .balign n.

 Note	

GNU syntax assembly also provides the .align n directive. However, the format of n varies from system to system. The .balign directive provides the same alignment functionality as .align with a consistent behavior across all architectures.

Convert all instances of PRESERVE8 to .eabi_attribute Tag_ABI_align_preserved, 1.

Related information

GNU Binutils - Using as: ARM Machine Directives.

GNU Binutils - Using as: .align. GNU Binutils - Using as: .balign.

armasm User Guide: REQUIRE8 and PRESERVE8.

armasm User Guide: ALIGN.

5.12 PC-relative addressing

armasm syntax assembly and GNU syntax assembly provide different methods for performing PC-relative addressing.

armasm syntax

armasm syntax assembly provides the symbol {pc} to let you specify an address relative to the current instruction.

For example:

ADRP x0, {pc}

GNU syntax

GNU syntax assembly does not support the {pc} symbol. Instead, it uses the special dot "." character, as follows:

ADRP x0, .

Related information

GNU Binutils - Using as: The Special Dot Symbol. armasm User Guide: Register-relative and PC-relative expressions.

5.13 A32 and T32 instruction substitutions

In certain circumstances, if the value of an Operand2 constant is not available with a given instruction, but its logical inverse or negation is available, then armasm can produce an equivalent instruction with the inverted or negated constant. The armclang integrated assembler provides limited support for such substitutions.

Substitutions when using armasm

More information about the syntax of Operand2 constants is available in the *armasm User Guide*. The following table shows the instruction substitutions supported by armasm, based on the values of Operand2 constants for the A32 and T32 instruction sets. The equivalent instructions shown can be used manually with the armclang integrated assembler for instructions where automatic substitution is not supported.

Table 5-3 A32 and T32 instruction substitutions supported by armasm

A32 and T32 instruction	Equivalent instruction	Constant substitution method
ADC{S}{cond} {Rd}, Rn, #constant	SBC{S}{cond} {Rd}, Rn, #~constant	Logical inversion
ADD{S}{cond} {Rd}, Rn, #constant	SUB{S}{cond} {Rd}, Rn, #-constant	Negation
AND{S}{cond} Rd, Rn, #constant	BIC{S}{cond} Rd, Rn, #~constant	Logical inversion
BIC{S}{cond} Rd, Rn, #constant	AND{S}{cond} Rd, Rn, #~constant	Logical inversion
CMP{cond} Rn, #constant	CMN{cond} Rn, #-constant	Negation
CMN{cond} Rn, #constant	CMP{cond} Rn, #-constant	Negation
MOV{S}{cond} Rd, #constant	MVN{S}{cond} Rd, #~constant	Logical inversion
MVN{S}{cond} Rd, #constant	MOV{S}{cond} Rd, #~constant	Logical inversion
ORN{S}{cond} Rd, Rn, #constant	ORR{S}{cond} Rd, Rn, #~constant	Logical inversion
(T32 only)	(T32 only)	
ORR{S}{cond} Rd, Rn, #constant	ORN{S}{cond} Rd, Rn, #~constant	Logical inversion
(T32 only)	(T32 only)	
SBC{S}{cond} {Rd}, Rn, #constant	ADC{S}{cond} {Rd}, Rn, #~constant	Logical inversion
SUB{S}{cond} {Rd}, Rn, #constant	ADD{S}{cond} {Rd}, Rn, #-constant	Negation

To find instruction substitutions in code assembled using armasm, use the command-line option -- diag_warning=1645.

Substitutions when using armclang integrated assembler

The armclang integrated assembler is also able to produce valid equivalent instructions through substitution, by inverting or negating the specified immediate value. This applies to both assembly language source files and to inline assembly code in C and C++ language source files.

You can disable this substitution using the -mno-neg-immediates armclang option.

5.14 A32 and T32 pseudo-instructions

armasm supports several A32 and T32 pseudo-instructions. The support for the pseudo-instructions varies with the armclang integrated assembler.

More information about the A32 and T32 pseudo-instructions is available in the *armasm User Guide*. The following table shows how to migrate the pseudo-instructions for use with the armclang integrated assembler:

Table 5-4 A32 and T32 pseudo-instruction migration

A32 and T32 pseudo- instruction	armclang integrated assembler equivalent	
ADRL{cond} Rd, label	No equivalent.	
	Use an ADR instruction if Label is within the supported offset range.	
	Use an LDR pseudo-instruction if <i>Label</i> is outside the supported offset range for an ADR instruction.	
CPY{cond} Rd, Rm	mov{cond} Rd, Rm	
LDR{cond}{.W} Rt, =expr	Identical.	
LDR{cond}{.W} Rt, =Label_expr	Identical.	
MOV32{cond} Rd, expr	Use the following instruction sequence:	
	<pre>movw{cond} Rd, #:lower16:expr movt{cond} Rd, #:upper16:expr</pre>	
NEG{cond} Rd, Rm	rsbs{cond} Rd, Rm, #0	
UND{cond}{.W} {#expr}	Use the following instruction for the A32 instruction set:	
	$udf\{c\}\{q\}$ {#}imm	
	Use the following instruction for the T32 instruction set with 8-bit encoding:	
	$udf\{c\}\{q\}$ {#}imm	
	Use the following instruction for the T32 instruction set with 16-bit encoding:	
	udf{c}.w {#}imm

5.15 Conditional directives

Conditional directives specify conditions that control whether or not to assemble a sequence of assembly code.

The following table shows how to translate armasm syntax conditional directives to GNU syntax directives:

Table 5-5 Conditional directive translation

armasm syntax directive	GNU syntax directive
IF	.if family of directives
IF :DEF:	.ifdef
IF :LNOT::DEF:	.ifndef
ELSE	.else
ELSEIF	.elseif
ENDIF	.endif

In addition to the change in directives shown, the following syntax differences apply:

• In armasm syntax, the conditional directives can use forward references. This is possible as armasm is a two-pass assembler. In GNU syntax, forward references are not supported, as the armclang integrated assembler only performs one pass over the main text.

If a forward reference is used with the .ifdef directive, the condition will always fail implicitly. Similarly, if a forward reference is used with the .ifndef directive, the condition will always pass implicitly.

• In armasm syntax, the maximum total nesting depth for directive structures such as IF...ELSE...ENDIF is 256. In GNU syntax, this limit is not applicable.

5.16 Data definition directives

Data definition directives allocate memory, define data structures, and set initial contents of memory.

The following table shows how to translate armasm syntax data definition directives to GNU syntax directives:

Note

This list only contains examples of common data definition assembly directives. It is not exhaustive.

Table 5-6 Data definition directives translation

armasm syntax directive	GNU syntax directive	Description	
DCB	.byte	Allocate one-byte blocks of memory, and specify the initial contents.	
DCW	.hword	Allocate two-byte blocks of memory, and specify the initial contents.	
DCD	.word	Allocate four-byte blocks of memory, and specify the initial contents.	
DCI	.inst	Allocate a block of memory in the code, and specify the opcode. In A32 code, this is a four-byte block. In T32 code, this can be a two-byte or four-byte blockinst.n allocates a two-byte block and .inst.w allocates a four-byte block.	
DCQ	.quad	Allocate eight-byte blocks of memory, and specify the initial contents.	
SPACE	.org	Allocate a zeroed block of memory. The armasm syntax SPACE directive allocates a zeroed block of memory with the specified size. The GNU assembly .org directive zeroes the memory up to the given address. The address must be greater than the address at which the directive is placed. The following example shows the armasm syntax and GNU syntax methods of creating a 100-byte zeroed block of memory using these directives: ; armasm syntax implementation start_address SPACE 0x100 // GNU syntax implementation start_address: .org start address + 0x100	
		If label arithmetic is not required, the GNU assembly .space directive can be used instead of the .org directive. However, Arm recommends using the .org directive wherever possible.	

The following examples show how to rewrite a vector table in both armasm and GNU syntax.

armasm syntax	GNU syntax
Vectors LDR PC, Reset_Addr LDR PC, Undefined_Addr LDR PC, SVC_Addr LDR PC, Prefetch_Addr B. ; Reserved vector LDR PC, IRQ_Addr LDR PC, IRQ_Addr LDR PC, FIQ_Addr Reset_Addr DCD Reset_Handler Undefined_Addr DCD Undefined_Handler SVC_Addr DCD SVC_Handler Prefetch_Addr DCD Prefetch_Handler Abort_Addr DCD Abort_Handler IRQ_Addr DCD IRQ_Handler FIQ_Addr DCD FIQ_Handler	Vectors: ldr pc, Reset_Addr ldr pc, Undefined_Addr ldr pc, SVC_Addr ldr pc, Prefetch_Addr ldr pc, Prefetch_Addr ldr pc, IRQ_Addr ldr pc, IRQ_Addr ldr pc, FIQ_Addr . balign 4 Reset_Addr: . word Reset_Handler Undefined_Addr: . word Undefined_Handler SVC_Addr: . word SVC_Handler Prefetch_Addr: . word Prefetch_Handler Abort_Addr: . word Abort_Handler IRQ_Addr: . word IRQ_Handler FIQ_Addr: word FIQ_Handler

5.17 Instruction set directives

Instruction set directives instruct the assembler to interpret subsequent instructions as either A32 or T32 instructions.

The following table shows how to translate armasm syntax instruction set directives to GNU syntax directives:

Table 5-7 Instruction set directives translation

armasm syntax directive	GNU syntax directive	Description
ARM or CODE32	.arm or .code 32	Interpret subsequent instructions as A32 instructions.
THUMB or CODE16	.thumb or .code 16	Interpret subsequent instructions as T32 instructions.

Related information

GNU Binutils - Using as: ARM Machine Directives. armasm User Guide: ARM or CODE32 directive.

armasm User Guide: CODE16 directive. armasm User Guide: THUMB directive.

5.18 Miscellaneous directives

Miscellaneous directives perform a range of different functions.

The following table shows how to translate armasm syntax miscellaneous directives to GNU syntax directives:

Table 5-8 Miscellaneous directives translation

armasm syntax directive	GNU syntax directive	Description
foo EQU 0x1C	.equ foo, 0x1C	Assigns a value to a symbol. Note the rearrangement of operands.
EXPORT StartHere	.global StartHere .type StartHere, @function	Declares a symbol that can be used by the linker (that is, a symbol that is visible to the linker).
GLOBAL StartHere		armasm automatically determines the types of exported symbols. However, armclang requires that you explicitly specify the types of exported symbols using the .type directive.
		If the .type directive is not specified, the linker outputs warnings of the form:
		Warning: L6437W: Relocation #RELA:1 in test.o(.text) with respect to symbol
		Warning: L6318W: test.o(.text) contains branch to a non-code symbol symbol.
GET file	.include file	Includes a file within the file being assembled.
INCLUDE file		
IMPORT foo	.global foo	Provides the assembler with a name that is not defined in the current assembly.
INCBIN	.incbin	Partial support, armclang does not fully support .incbin.
INFO n, "string"	.warning "string"	The INFO directive supports diagnostic generation on either pass of the assembly (specified by <i>n</i>). The .warning directive does not let you specify a particular pass, as the armclang integrated assembler only performs one pass.
ENTRY	armlinkentry=location	The ENTRY directive declares an entry point to a program. armclang does not provide an equivalent directive. Use armlinkentry=location to specify the entry point directly to the linker, rather than defining it in the assembly code.
END	.end	Marks the end of the assembly file.
PRESERVE8	.eabi_attribute Tag_ABI_align_preserved, 1	Emits a build attribute which guarantees that the functions in the file preserve 8-byte stack alignment. Note
		For armasm syntax assembly language source files, even if you do not specify the PRESERVE8 directive, armasm automatically emits the build attribute if all functions in the file preserve 8-byte stack alignment. For GNU syntax assembly language source files, the armclang integrated assembler does not automatically emit this build attribute. Therefore you must manually inspect and ensure that all functions in your GNU syntax assembly language source file preserve 8-byte stack alignment and then manually add the directive to the file.

5.19 Symbol definition directives

Symbol definition directives declare and set arithmetic, logical, or string variables.

The following table shows how to translate armasm syntax symbol definition directives to GNU syntax directives:

Note

This list only contains examples of common symbol definition directives. It is not exhaustive.

Table 5-9 Symbol definition directives translation

armasm syntax directive	GNU syntax directive	Description
LCLA var	No GNU equivalent	Declare a local arithmetic variable, and initialize its value to 0.
LCLL var	No GNU equivalent	Declare a local logical variable, and initialize its value to FALSE.
LCLS var	No GNU equivalent	Declare a local string variable, and initialize its value to a null string.
No armasm equivalent	.set var, 0	Declare a static arithmetic variable, and initialize its value to 0.
No armasm equivalent	.set var, FALSE	Declare a static logical variable, and initialize its value to FALSE.
No armasm equivalent	.set var, ""	Declare a static string variable, and initialize its value to a null string.
GBLA var	.global var	Declare a global arithmetic variable, and initialize its value to 0.
	.set var, 0	
GBLL var	.global var	Declare a global logical variable, and initialize its value to FALSE.
	.set var, FALSE	
GBLS var	.global var	Declare a global string variable, and initialize its value to a null string.
	.set var, ""	
var SETA expr	.set var, expr	Set the value of an arithmetic variable.
var SETL expr	.set var, expr	Set the value of a logical variable.
var SETS expr	.set var, expr	Set the value of a string variable.
foo RN 11	foo .req r11	Define an alias foo for register R11.
foo QN q5.I32	foo .qn q5.i32	Define an I32-typed alias foo for the quad-precision register Q5.
foo DN d2.I32	foo .dn d2.i32	Define an I32-typed alias foo for the double-precision register D2.

5.20 Migration of armasm macros to integrated assembler macros

The armclang integrated assembler provides similar macro features to those provided by armasm. The macro syntax is based on GNU assembler macro syntax.
Note
This topic includes descriptions of [COMMUNITY] features. See Support level definitions on page 1-13
Note
The following GNU assembly directives are [COMMUNITY] features:
• .macro and .endm
• .rept and .endr

Additional information about macro features is available:

- The armasm User Guide provides more detail about the macro directives supported, and examples of using macros.
- The GNU Binutils Using as document provides more detail about GNU assembly macro directives.

Macro directive features

.error

The following table describes the most common armasm macro directive features, and shows the equivalent features for the armclang integrated assembler.

Table 5-10 Comparison of macro directive features provided by armasm and the armclang integrated assembler

armasm feature	armclang integrated assembler feature	Description
MACRO, MEND directives	.macro, .endm directives	Directives to mark the start and end of the definition of a macro.
{\$label} macro parameter	Use a normal macro parameter.	Optionally define an internal label to use within the macro.
{\$cond} macro parameter	Use a normal macro parameter.	Optionally define a condition code to use within the macro.
{\$parameter{,\$param eter}} custom macro parameter specification	{parameter{:type} {,parameter{:type}}} custom macro parameter and parameter type specification	With armasm, any number of custom macro parameters can be defined. Unspecified parameters are substituted with an empty string. With the armclang integrated assembler, the custom macro parameters can optionally have a parameter type type. This can be either req or vararg. Unspecified parameters are substituted with an empty string. The req type specifies a required parameter. The assembler generates an error when instantiating a macro if a required parameter is missing and a default value is not available. The vararg type collects all remaining parameters as one parameter. It can only be used as the last parameter within the list of parameters for a given macro. Only one vararg parameter can be specified.
MEXIT directive	.exitm directive	Exit early from a macro definition.

Table 5-10 Comparison of macro directive features provided by armasm and the armclang integrated assembler (continued)

armasm feature	armclang integrated assembler feature	Description
IF,	.if family of directives,	The directives allow conditional assembly of instructions.
ELSE, ELIF,	and the .else, .elseif, .endif directives	With armasm, the conditional assembly directives use a logical expression that evaluates to either TRUE or FALSE as their controlling expression.
ENDIF conditional assembly directives		With the armclang integrated assembler, multiple variants of the GNU assembly .if directive are available, referred to as the .if family of directives.
		For the .if and .elseif directives, the controlling expression is a logical expression that evaluates to either TRUE or FALSE.
		For other directives in the .if family of directives, the controlling expression is an implicit part of the directive used, and varies for each such directive.
WHILE, WEND directives	.rept,	The directives allow a sequence of instructions or directives to be assembled repeatedly.
		With armasm, the WHILE directive uses a logical expression that evaluates to either TRUE or FALSE as its controlling expression. The sequence enclosed between a WHILE and WEND directive pair is assembled until the logical expression evaluates to FALSE.
		With the armclang integrated assembler, the GNU assembly .rept directive takes a fixed number of repetitions as a parameter. The sequence enclosed between a .rept and .endr directive pair is assembled the specified fixed number of times.
		To replicate the effect of using a logical expression to repeatedly assemble a code sequence, the .rept directive can be used within a macro. See the example provided later in this section.
ASSERT directive	Use a combination of the .if family of directives and the .error directive.	With armasm, the ASSERT directive generates an error message during assembly if a given assertion is false. A logical expression that evaluates to TRUE or FALSE is used as the assertion.
		With the armclang integrated assembler, this functionality can be achieved by using a GNU assembly directive from the .if family of directives to conditionally display an error message during assembly using the GNU assembly .error directive.
		Macros can be created to simplify this process. See the example provided later in this section.

Notable differences between armasm macro syntax and GNU macro syntax

The following syntax restrictions apply to GNU macro syntax in addition to the differences due to macro directives:

- In armasm macro syntax, using the pipe character | as the parameter value when instantiating a macro selects the default value of the parameter. In GNU macro syntax, leaving the parameter value empty when instantiating a macro selects the default value of the parameter. If a default value is not specified in the macro definition, an empty string is used.
- In armasm macro syntax, a dot can be used between a parameter and subsequent text, or another parameter, if a space is not required in the expansion. In GNU macro syntax, a set of parentheses ()

- can be used between a parameter and subsequent text, if a space is not required in the expansion. There is no need to separate a parameter from another subsequent parameter.
- Although the integrated assembler is case-insensitive to register names, the GNU assembly .ifc directive always performs a case-sensitive comparison. Manually check that the register names use the same case-sense when comparing them using the directive.

Migration of macro examples provided in the armasm User Guide

Table 5-11 NOT EQUALS assertion

```
armasm syntax implementation

ASSERT arg1 <> arg2

GNU syntax implementation

/* Helper macro to replicate ASSERT <> directive functionality from armasm.

Displays error if NE assertion fails. */
.macro assertNE arg1:req, arg2:req, message:req
.ifc \arg1, \arg2
.error "\message"
.endif
.endm
```

Table 5-12 Unsigned integer division macro

```
armasm syntax implementation
The macro takes the following parameters:
$Bot
          The register that holds the divisor.
$Top
          The register that holds the dividend before the instructions are executed. After the instructions are
          executed, it holds the remainder.
$Div
          The register where the quotient of the division is placed. It can be NULL ("") if only the remainder is
          required.
$Temp
          A temporary register used during the calculation.
            MACRO
                      $Div,$Top,$Bot,$Temp

                                                           less than divisor
```

MEND

GNU syntax implementation

The macro takes the following parameters:

Lab

A label to mark the start of the code. This parameter is required.

BotRegNum

The register number for the register that holds the divisor. This parameter is required.

TopRegNum

The register number for the register that holds the dividend before the instructions are executed. After the instructions are executed, it holds the remainder. This parameter is required.

DivRegNum

The register number for the register where the quotient of the division is placed. It can be NULL ("") if only the remainder is required. This parameter is optional.

TempRegNum

The register number for a temporary register used during the calculation. This parameter is required.

```
.macro DivMod Lab:req, DivRegNum, TopRegNum:req, BotRegNum:req, TempRegNum:req assertNE \TopRegNum, \BotRegNum, "Top and Bottom cannot be the same register" assertNE \TopRegNum, \TempRegNum, "Top and Temp cannot be the same register" assertNE \BotRegNum, \TempRegNum, "Bottom and Temp cannot be the same register"
     .ifnb \DivRegNum
           assertNE \DivRegNum, \TopRegNum, "Div and Top cannot be the same register" assertNE \DivRegNum, \BotRegNum, "Div and Bottom cannot be the same register"
           assertNE \DivRegNum, \TempRegNum, "Div and Temp cannot be the same register"
      .endif
\Lab:
                                                                      // Put divisor in r\TempRegNum
                 r\TempRegNum, r\BotRegNum
     mov
                                                         lsr #1 // double it until
                 r\TempRegNum, r\TopRegNum,
     cmp
90:
     mov1s
                 r\TempRegNum, r\TempRegNum, lsl #1 // 2 * r\TempRegNum > r\TopRegNum
                 r\TempRegNum, r\TopRegNum, lsr #1
90b // The 'b' means search backwards

     cmp
     h1s
     .ifnb \DivRegNum
           mov r\DivRegNum, #0
                                              // Initialize quotient
     .endif
91:
                 r\TopRegNum, r\TempRegNum
                                                                           // Can we subtract r\TempRegNum?
     cmn
                 r\TopRegNum, r\TopRegNum, r\TempRegNum // If we can, then do so
DivRegNum // Omit next instruction if r\DivRegNum is null
     subcs
     .ifnb \DivRegNum
          adc r\DivRegNum, r\DivRegNum, r\DivRegNum
                                                                           // Double r\DivRegNum
      .endif
     mov
                 r\TempRegNum, r\TempRegNum, lsr #1 // Halve r\TempRegNum
     cmp
                 r\TempRegNum, r\BotRegNum
                                                                      // and loop until
     bhs
                 91b
                                                                      // less than divisor
      .endm
```

Notable differences from the armasm syntax implementation:

- A custom macro, assertNE, is used instead of the armasm ASSERT directive.
- Register numbers are used instead of registers as parameters. This is because the GNU assembly .ifc directive used for the assertNE assertions treats its operands as case-sensitive.
- The GNU assembly .ifnb directive is used to check if the parameter DivRegNum has been defined. In the
 armasm syntax implementation, the armasm IF directive is used.

          diagnose
          diagnose "hello"
                                  ; Prints "default" at assembly-time
          diagnose |
```

GNU syntax implementation

Notable differences from the armasm syntax implementation:

- It is not possible to print a blank line at assembly-time using the GNU assembly .warning directive. Only a
 warning with an empty message can be printed.
- The format of the diagnostic message displayed is different between armasm and the armclang integrated assembler.

With armasm, the diagnostic messages displayed at assembly-time by the macro example are:

```
"macros_armasm.S", line 11:
"macros_armasm.S", line 12: hello
"macros_armasm.S", line 13: default
```

With the armclang integrated assembler, the diagnostic messages displayed at assembly-time by the macro example are:

Table 5-14 Conditional loop macro

armasm syntax implementation

The macro takes the following parameters:

\$counter

The assembly-time variable for the loop counter. This parameter is required. The {\$label} parameter for the MACRO directive has been used for this parameter. If a normal macro parameter is used, the parameter cannot be instantiated as a label.

\$N

The maximum number of iterations for the loop. This parameter is required.

\$decr

The loop decrement value. This parameter is optional.

do

The text to which \$counter is appended in each iteration of the loop. This parameter is required.

     FND
```

GNU syntax implementation

The macro takes the following parameters:

counter

The assembly-time variable for the loop counter. This parameter is required.

Ν

The maximum number of iterations for the loop. This parameter is required.

decr

The loop decrement value. This parameter is optional.

do

The text to which \counter is appended in each iteration of the loop. This parameter is required.

Note —

The order in which the GNU assembly.ifgt, .endif, .rept, and .endr directives are used is important. Including the .endr directive as a statement within the .ifgtendif structure produces an error. Similarly, placing the .endif directive outside the .reptendr structure produces an error.

The macro expansion produces the following code:

```
mov r0, #0xa
mov r0, #8
mov r0, #6
mov r0, #4
mov r0, #2
```

Notable differences from the armasm syntax implementation:

- In the armasm syntax implementation, the ASSERT directive is used to raise an error if a required parameter is missing. In the GNU syntax implementation, this can be achieved by using the parameter type req for required parameters in the macro definition.
- In the armasm syntax implementation, the macro instantiation uses a string as the value to the \$do parameter. The quotes are implicitly removed at assembly-time. Quotes are required as the parameter value contains spaces. In the GNU syntax implementation, this is achieved using the parameter type vararg for the \do parameter in the macro definition.
- In the GNU syntax implementation, the .reptendr structure is always evaluated \N times at assembly-time. This is because the .ifgtendif structure must be placed within the .reptendr structure. In the armasm syntax implementation, the WHILE...WEND structure is only evaluated the required number of times at assembly-time based on the controlling expression of the WHILE directive.
