Bits [63:17]  

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0  IFAR is valid.

0b1  IFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a synchronous External abort other than a synchronous External abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.

This field resets to an architecturally UNKNOWN value.

Bits [15:13]  

Reserved, RES0.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of External aborts.

In an implementation that does not provide any classification of External aborts, this bit is RES0.
For aborts other than External aborts this bit always returns 0.
This field resets to an architecturally UNKNOWN value.

**Bit [11]**

Reserved, RES0.

**FS[4], bit [10]**

This field is bit[4] of FS[4:0].

- **0b00001** PC alignment fault.
- **0b00010** Debug exception.
- **0b00011** Access flag fault, level 1.
- **0b00101** Translation fault, level 1.
- **0b00110** Access flag fault, level 2.
- **0b00111** Translation fault, level 2.
- **0b01000** Synchronous External abort, not on translation table walk.
- **0b01001** Domain fault, level 1.
- **0b01011** Domain fault, level 2.
- **0b01100** Synchronous External abort, on translation table walk, level 1.
- **0b01101** Permission fault, level 1.
- **0b01110** Synchronous External abort, on translation table walk, level 2.
- **0b01111** Permission fault, level 2.
- **0b10000** TLB conflict abort.
- **0b10100** IMPLEMENTATION DEFINED fault (Lockdown fault).
- **0b11001** When FEAT_RAS is not implemented Synchronous parity or ECC error on memory access, not on translation table walk.

- **0b11100** When FEAT_RAS is not implemented Synchronous parity or ECC error on translation table walk, level 1.

- **0b11110** When FEAT_RAS is not implemented Synchronous parity or ECC error on translation table walk, level 2.

All other values are reserved.
For more information about the lookup level associated with a fault, see *The level associated with MMU faults on a Short-descriptor translation table lookup on page G5-6070*.

The FS field is split as follows:
- FS[4] is IFSR32_EL2[10].
- FS[3:0] is IFSR32_EL2[3:0].

This field resets to an architecturally UNKNOWN value.

**LPAE, bit [9]**

On taking a Data Abort exception, this bit is set as follows:

- **0b0** Using the Short-descriptor translation table formats.
- **0b1** Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.
This field resets to an architecturally UNKNOWN value.

**Bits [8:4]**

Reserved, RES0.
FS[3:0], bits [3:0]
This field is bits[3:0] of FS[4:0].

When TTBCR.EAE == 1:

FnV, bit [16]
Far not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 IFAR is valid.
0b1 IFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a synchronous External abort other than a synchronous External abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.
This field resets to an architecturally UNKNOWN value.

ExT, bit [12]
External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of External aborts.

In an implementation that does not provide any classification of External aborts, this bit is RES0.
For aborts other than External aborts this bit always returns 0.
This field resets to an architecturally UNKNOWN value.

LPAE, bit [9]
On taking a Data Abort exception, this bit is set as follows:

0b0 Using the Short-descriptor translation table formats.
0b1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.
This field resets to an architecturally UNKNOWN value.

Bits [8:6]
Reserved, RES0.
STATUS, bits [5:0]

Fault status bits. Possible values of this field are:
- 0b000000 Address size fault in translation table base register.
- 0b000001 Address size fault, level 1.
- 0b000010 Address size fault, level 2.
- 0b000011 Address size fault, level 3.
- 0b000101 Translation fault, level 1.
- 0b000110 Translation fault, level 2.
- 0b000111 Translation fault, level 3.
- 0b001001 Access flag fault, level 1.
- 0b001010 Access flag fault, level 2.
- 0b001011 Access flag fault, level 3.
- 0b001101 Permission fault, level 1.
- 0b001110 Permission fault, level 2.
- 0b001111 Permission fault, level 3.
- 0b010000 Synchronous External abort, not on translation table walk.
- 0b010101 Synchronous External abort on translation table walk, level 1.
- 0b010110 Synchronous External abort on translation table walk, level 2.
- 0b010111 Synchronous External abort on translation table walk, level 3.

**0b011000 When FEAT_RAS is not implemented** Synchronous parity or ECC error on memory access, not on translation table walk.

**0b011101 When FEAT_RAS is not implemented** Synchronous parity or ECC error on memory access on translation table walk, level 1.

**0b011110 When FEAT_RAS is not implemented** Synchronous parity or ECC error on memory access on translation table walk, level 2.

**0b011111 When FEAT_RAS is not implemented** Synchronous parity or ECC error on memory access on translation table walk, level 3.

- 0b100001 PC alignment fault.
- 0b10010 Debug exception.
- 0b110000 TLB conflict abort.

All other values are reserved.

When the RAS Extension is implemented, 0b011000, 0b011101, 0b011110, and 0b011111, are reserved.

For more information about the lookup level associated with a fault, see *The level associated with MMU faults on a Long-descriptor translation table lookup on page G5-6072.*

This field resets to an architecturally UNKNOWN value.

### Accessing the IFSR32_EL2

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, IFSR32_EL2

<table>

D13.2.86 ISR_EL1, Interrupt Status Register

The ISR_EL1 characteristics are:

**Purpose**

Shows the pending status of the IRQ, FIQ, or SError interrupt.

When executing at EL2, EL3 or Secure EL1 when SCR_EL3.EEL2 == 0b0, this shows the pending status of the physical IRQ, FIQ, or SError interrupts.

When executing at either Non-secure EL1 or at Secure EL1 when SCR_EL3.EEL2 == 0b1:

- If the HCR_EL2.{IMO,FMO,AMO} bit has a value of 1, the corresponding ISR_EL1.{I,F,A} bit shows the pending status of the virtual IRQ, FIQ, or SError.
- If the HCR_EL2.{IMO,FMO,AMO} bit has a value of 0, the corresponding ISR_EL1.{I,F,A} bit shows the pending status of the physical IRQ, FIQ, or SError.

**Configurations**

AArch64 System register ISR_EL1[31:0] is architecturally mapped to AArch32 System register ISR[31:0].

**Attributes**

ISR_EL1 is a 64-bit register.

**Field descriptions**

The ISR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>9</td>

</tr>
</tbody>
</table>

**Bits [63:9]**

Reserved, RES0.

**A, bit [8]**

SError interrupt pending bit.

0b0  No pending SError.
0b1  An SError interrupt is pending.

If the SError interrupt is edge-triggered, this field is cleared to zero when the physical SError interrupt is taken.

**I, bit [7]**

IRQ pending bit. Indicates whether an IRQ interrupt is pending:

0b0  No pending IRQ.
0b1  An IRQ interrupt is pending.

**F, bit [6]**

FIQ pending bit. Indicates whether an FIQ interrupt is pending.

0b0  No pending FIQ.
0b1  An FIQ interrupt is pending.

**Bits [5:0]**

Reserved, RES0.
Accessing the ISR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, ISR_EL1

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>

D13.2.87  LORC_EL1, LORegion Control (EL1)

The LORC_EL1 characteristics are:

**Purpose**

Enables and disables LORegions, and selects the current LORegion descriptor.

**Configurations**

This register is present only when FEAT_LOR is implemented. Otherwise, direct accesses to LORC_EL1 are UNDEFINED.

If no LORegion descriptors are supported by the PE, then this register is res0.

**Attributes**

LORC_EL1 is a 64-bit register.

**Field descriptions**

The LORC_EL1 bit assignments are:

![Field Diagram]

**Bits [63:10]**

Reserved, RES0.

**DS, bits [9:2]**

Descriptor Select. Selects the current LORegion descriptor accessed by LORSA_EL1, LOREA_EL1, and LORN_EL1.

The number of LORegion descriptors in IMPLEMENTATION DEFINED. The maximum number of LORegion descriptors supported is 256. If the number is less than 256, then bits[63:M+2] are RES0, where M is Log2(Number of LORegion descriptors supported by the implementation).

If this field points to an LORegion descriptor that is not supported by an implementation, then the registers LORN_EL1, LOREA_EL1, and LORSA_EL1 are RES0.

This field resets to an architecturally UNKNOWN value.

**Bit [1]**

Reserved, RES0.

**EN, bit [0]**

Enable. Indicates whether LORegions are enabled.

\[ 0:0 \]

Disabled. Memory accesses do not match any LORegions.

\[ 1:1 \]

Enabled. Memory accesses may match a LORegion.

This bit is permitted to be cached in a TLB.

This field resets to 0.

**Accessing the LORC_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, LORC_EL1

D13.2.88 LOREA_EL1, LORegion End Address (EL1)

The LOREA_EL1 characteristics are:

**Purpose**

Holds the physical address of the end of the LORegion described in the current LORegion descriptor selected by LORC_EL1.DS.

**Configurations**

This register is present only when FEAT_LOR is implemented. Otherwise, direct accesses to LOREA_EL1 are UNDEFINED.

This register is RES0 if any of the following apply:

- No LORegion descriptors are supported by the PE.
- LORC_EL1.DS points to a LORegion that is not supported by the PE.

**Attributes**

LOREA_EL1 is a 64-bit register.

**Field descriptions**

The LOREA_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>52</th>
<th>48</th>
<th>47</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>

D13.2.89  **LORID_EL1, LORegionID (EL1)**

The LORID_EL1 characteristics are:

**Purpose**

Indicates the number of LORegions and LORegion descriptors supported by the PE.

**Configurations**

This register is present only when FEAT_LOR is implemented. Otherwise, direct accesses to LORID_EL1 are UNDEFINED.

If no LORegion descriptors are implemented, then the registers LORC_EL1, LORN_EL1, LOREA_EL1, and LORSA_EL1 are RES0.

**Attributes**

LORID_EL1 is a 64-bit register.

**Field descriptions**

The LORID_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:24]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>LD, bits [23:16]</td>
<td>Number of LORegion descriptors supported by the PE. This is an 8-bit binary number.</td>
</tr>
<tr>
<td>Bits [15:8]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>LR, bits [7:0]</td>
<td>Number of LORegions supported by the PE. This is an 8-bit binary number.</td>
</tr>
</tbody>
</table>

**Note**

If LORID_EL1 indicates that no LORegions are implemented, then LoadLOAcquire and StoreLORelease will behave as LoadAcquire and StoreRelease.

**Accessing the LORID_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, LORID_EL1**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>

elif PSTATE.EL == EL3 then
   return LORID_EL1;
D13.2.90  LORN_EL1, LORegion Number (EL1)

The LORN_EL1 characteristics are:

**Purpose**

Holds the number of the LORegion described in the current LORegion descriptor selected by LORC_EL1.DS.

**Configurations**

This register is present only when FEAT_LOR is implemented. Otherwise, direct accesses to LORN_EL1 are UNDEFINED.

This register is RES0 if any of the following apply:

- No LORegion descriptors are supported by the PE.
- LORC_EL1.DS points to a LORegion that is not supported by the PE.

**Attributes**

LORN_EL1 is a 64-bit register.

**Field descriptions**

The LORN_EL1 bit assignments are:

```
63 8 7 0
<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Num</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Any of the fields in this register are permitted to be cached in a TLB.

**Bits [63:8]**

Reserved, RES0.

**Num, bits [7:0]**

Number of the LORegion described in the current LORegion descriptor selected by LORC_EL1.DS.

The maximum number of LORegions supported by the PE is 256. If the maximum number is less than 256, then bits[8:N] are RES0, where N is \( \log_2(\text{Number of LORegions supported by the PE}) \).

If this field points to a LORegion that is not supported by the PE, then the current LORegion descriptor does not match any LORegion.

This field resets to an architecturally UNKNOWN value.

**Accessing the LORN_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRS <Xt>, LORN_EL1
```

<table>
<thead>
<tr>

D13.2.91 LORSA_EL1, LORegion Start Address (EL1)

The LORSA_EL1 characteristics are:

**Purpose**

Indicates whether the current LORegion descriptor selected by LORC_EL1.DS is enabled, and holds the physical address of the start of the LORegion.

**Configurations**

This register is present only when FEAT_LOR is implemented. Otherwise, direct accesses to LORSA_EL1 are **UNDEFINED**.

This register is **RES0** if any of the following apply:

- No LORegion descriptors are supported by the PE.
- LORC_EL1.DS points to a LORegion that is not supported by the PE.

**Attributes**

LORSA_EL1 is a 64-bit register.

**Field descriptions**

The LORSA_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Width</th>
<th>Field Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-52</td>
<td>Reserved, <strong>RES0</strong></td>
<td></td>
</tr>
<tr>
<td>51-48</td>
<td>SA[51:48], bits <strong>[51:48]</strong></td>
<td></td>
</tr>
<tr>
<td>47-16</td>
<td><strong>SA[47:16]</strong></td>
<td></td>
</tr>
<tr>
<td>15-1</td>
<td>Reserved, <strong>RES0</strong></td>
<td></td>
</tr>
</tbody>
</table>

Any of the fields in this register are permitted to be cached in a TLB.

**Bits [63:52]**

Reserved, **RES0**.

**SA[51:48], bits [51:48]**

*When FEAT_LPA is implemented:*

This field resets to an architecturally **UNKNOWN** value.

*Otherwise:*

Reserved, **RES0**.

**SA[47:16], bits [47:16]**

Bits [47:16] of the start physical address of the LORegion described in the current LORegion descriptor selected by LORC_EL1.DS. Bits[15:0] of this address are defined to be 0x0000. For implementations with fewer than 48 bits, the upper bits of this field are **RES0**.

When FEAT_LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, SA[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, SA[51:48] are **RES0**.

This field resets to an architecturally **UNKNOWN** value.

**Bits [15:1]**

Reserved, **RES0**.
Valid, bit [0]  
Indicates whether the current LORegion Descriptor is enabled.

0b0  Disabled
0b1  Enabled

This field resets to 0.

Accessing the LORSA_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.92 MAIR_EL1, Memory Attribute Indirection Register (EL1)

The MAIR_EL1 characteristics are:

**Purpose**

Provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations at EL1.

**Configurations**

AArch64 System register MAIR_EL1[31:0] is architecturally mapped to AArch32 System register PRRR[31:0] when TTBCR.EAE == 0.

AArch64 System register MAIR_EL1[31:0] is architecturally mapped to AArch32 System register MAIR0[31:0] when TTBCR.EAE == 1.

AArch64 System register MAIR_EL1[63:32] is architecturally mapped to AArch32 System register NMRR[31:0] when TTBCR.EAE == 0.

AArch64 System register MAIR_EL1[63:32] is architecturally mapped to AArch32 System register MAIR1[31:0] when TTBCR.EAE == 1.

**Attributes**

MAIR_EL1 is a 64-bit register.

**Field descriptions**

The MAIR_EL1 bit assignments are:

```
63  56  48  40  32  24  16  8  7  0
| Attr7 | Attr6 | Attr5 | Attr4 | Attr3 | Attr2 | Attr1 | Attr0 |
```

MAIR_EL1 is permitted to be cached in a TLB.

**Attr<n>, bits [8n+7:8n], for n = 0 to 7**

Attr is encoded as follows:

<table>
<thead>
<tr>
<th>Attr</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000dd00</td>
<td>Device memory. See encoding of 'dd' for the type of Device memory.</td>
</tr>
<tr>
<td>0b0000ddxx, (xx != 00)</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>0booooiili, (oooo != 0000 and iiii != 0000)</td>
<td>Normal memory. See encoding of 'oooo' and 'iiii' for the type of Normal Memory.</td>
</tr>
<tr>
<td>0b11110000</td>
<td>If FEAT_MTE is implemented, then: Tagged Normal Memory. Inner+Outer Write-Back Non-transient memory, Inner+Outer Read-Allocate, Inner+Outer Write-Allocate. Otherwise, UNPREDICTABLE.</td>
</tr>
<tr>
<td>0bxxxx0000, (xxxx != 0000 and xxxx != 1111)</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>
'dd' is encoded as follows:

<table>
<thead>
<tr>
<th>dd</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Device-nGnRnE memory</td>
</tr>
<tr>
<td>0b01</td>
<td>Device-nGnRE memory</td>
</tr>
<tr>
<td>0b10</td>
<td>Device-nGRE memory</td>
</tr>
<tr>
<td>0b11</td>
<td>Device-GRE memory</td>
</tr>
</tbody>
</table>

'o0oo' is encoded as follows:

<table>
<thead>
<tr>
<th>'o0oo'</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>See encoding of Attr</td>
</tr>
<tr>
<td>0b00RW, RW not0b00</td>
<td>Normal memory, Outer Write-Through Transient</td>
</tr>
<tr>
<td>0b0100</td>
<td>Normal memory, Outer Non-cacheable</td>
</tr>
<tr>
<td>0b01RW, RW not0b00</td>
<td>Normal memory, Outer Write-Back Transient</td>
</tr>
<tr>
<td>0b10RW</td>
<td>Normal memory, Outer Write-Through Non-transient</td>
</tr>
<tr>
<td>0b11RW</td>
<td>Normal memory, Outer Write-Back Non-transient</td>
</tr>
</tbody>
</table>

'R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

'iiii' is encoded as follows:

<table>
<thead>
<tr>
<th>'iiii'</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>See encoding of Attr</td>
</tr>
<tr>
<td>0b00RW, RW not0b00</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0b0100</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>0b01RW, RW not0b00</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>0b10RW</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>0b11RW</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

'R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in 'o0oo' and 'iiii' fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>0b1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.
Accessing the MAIR_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic MAIR_EL1 or MAIR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, MAIR_EL1**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>

D13.2.93   MAIR_EL2, Memory Attribute Indirection Register (EL2)

The MAIR_EL2 characteristics are:

**Purpose**

Provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations at EL2.

**Configurations**

AArch64 System register MAIR_EL2[31:0] is architecturally mapped to AArch32 System register HMAIR0[31:0].

AArch64 System register MAIR_EL2[63:32] is architecturally mapped to AArch32 System register HMAIR1[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

MAIR_EL2 is a 64-bit register.

**Field descriptions**

The MAIR_EL2 bit assignments are:

```
   63  56  48  40  32  24  16  8  7  0
Attr7 Attr6 Attr5 Attr4 Attr3 Attr2 Attr1 Attr0
```

MAIR_EL2 is permitted to be cached in a TLB.

**Attr<><n>, bits [8n+7:8n], for n = 0 to 7**

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where AttrIndx[2:0] gives the value of \(<n>\) in Attr<><n>.

Attr is encoded as follows:

<table>
<thead>
<tr>
<th>Attr</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000dd00</td>
<td>Device memory. See encoding of 'dd' for the type of Device memory.</td>
</tr>
<tr>
<td>0b0000ddxx</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>0booooiii, (oooo != 0000 and iii != 0000)</td>
<td>Normal memory. See encoding of 'oooo' and 'iii' for the type of Normal Memory.</td>
</tr>
<tr>
<td>0b11110000</td>
<td>If FEAT_MTE is implemented, then: Tagged Normal Memory. Inner+Outer Write-Back Non-transient memory, Inner+Outer Read-Allocate, Inner+Outer Write-Allocate. Otherwise, UNPREDICTABLE.</td>
</tr>
<tr>
<td>0bxxxx@000, (xxxx != 0000 and xxxx != 1111)</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>
'dd' is encoded as follows:

<table>
<thead>
<tr>
<th>dd</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Device-nGnRnE memory</td>
</tr>
<tr>
<td>0b01</td>
<td>Device-nGnRE memory</td>
</tr>
<tr>
<td>0b10</td>
<td>Device-nGRE memory</td>
</tr>
<tr>
<td>0b11</td>
<td>Device-GRE memory</td>
</tr>
</tbody>
</table>

'oooo' is encoded as follows:

<table>
<thead>
<tr>
<th>'oooo'</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>See encoding of Attr</td>
</tr>
<tr>
<td>0b00RW</td>
<td>Normal memory, Outer Write-Through Transient</td>
</tr>
<tr>
<td>0b0000</td>
<td>Normal memory, Outer Write-Through Non-transient</td>
</tr>
<tr>
<td>0b01RW</td>
<td>Normal memory, Outer Write-Back Transient</td>
</tr>
<tr>
<td>0b011RW</td>
<td>Normal memory, Outer Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

'iiii' is encoded as follows:

<table>
<thead>
<tr>
<th>'iiii'</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>See encoding of Attr</td>
</tr>
<tr>
<td>0b00RW</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0b0000</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>0b01RW</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>0b011RW</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in 'oooo' and 'iiii' fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>0b1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.
Accessing the MAIR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic MAIR_EL2 or MAIR_EL1 is not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, MAIR_EL2**

<table>

D13.2.95 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

**Purpose**

Provides identification information for the PE, including an implementer code for the device and a device ID number.

**Configurations**

AArch64 System register MIDR_EL1[31:0] is architecturally mapped to AArch32 System register MIDR[31:0].

AArch64 System register MIDR_EL1[31:0] is architecturally mapped to External register MIDR_EL1[31:0].

**Attributes**

MIDR_EL1 is a 64-bit register.

**Field descriptions**

The MIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Hex Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:32] RES0</td>

<td>Applied Micro Circuits Corporation</td>
</tr>
</tbody>
</table>
Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

**Variant, bits [23:20]**

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

**Architecture, bits [19:16]**

Architecture version. For A-profile, the defined values are:

- 0b0001  Armv4.
- 0b0010  Armv4T.
- 0b0011  Armv5 (obsolete).
- 0b0100  Armv5T.
- 0b0101  Armv5TE.
- 0b0110  Armv5TEJ.
- 0b0111  Armv6.
- 0b1111  Architectural features are individually identified in the ID_* registers, see [ID registers on page K15-8181](#).

All other values are reserved.

**PartNum, bits [15:4]**

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the device.

**Accessing the MIDR_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, MIDR_EL1**

D13.2.96 MPIDR_EL1, Multiprocessor Affinity Register

The MPIDR_EL1 characteristics are:

**Purpose**

In a multiprocessor system, provides an additional PE identification mechanism for scheduling purposes.

**Configurations**

AArch64 System register MPIDR_EL1[31:0] is architecturally mapped to AArch32 System register MPIDR[31:0].

In a uniprocessor system Arm recommends that each Aff<n> field of this register returns a value of 0.

**Attributes**

MPIDR_EL1 is a 64-bit register.

**Field descriptions**

The MPIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Field descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-40</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>39-32</td>
<td>Affinity level 3.</td>
</tr>
<tr>
<td>31</td>
<td>Reserved, RES1.</td>
</tr>
<tr>
<td>30</td>
<td>U</td>
</tr>
<tr>
<td>29-25</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>24</td>
<td>MT</td>
</tr>
<tr>
<td>23</td>
<td></td>
</tr>
<tr>
<td>15-8</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:40]**

Reserved, RES0.

**Aff3, bits [39:32]**

Affinity level 3. See the description of Aff0 for more information.

Aff3 is not supported in AArch32 state.

**Bit [31]**

Reserved, RES1.

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

- 0b0: Processor is part of a multiprocessor system.
- 0b1: Processor is part of a uniprocessor system.

**Bits [29:25]**

Reserved, RES0.

**MT, bit [24]**

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of Aff0 for more information about affinity levels. The possible values of this bit are:

- 0b0: Performance of PEs at the lowest affinity level, or PEs with MPIDR_EL1.MT set to 1, different affinity level 0 values, and the same values for affinity level 1 and higher, is largely independent.
Performance of PEs at the lowest affinity level, or PEs with MPIDR_EL1.MT set to 1, different affinity level 0 values, and the same values for affinity level 1 and higher, is very interdependent.

**Aff2, bits [23:16]**
Affinity level 2. See the description of Aff0 for more information.

**Aff1, bits [15:8]**
Affinity level 1. See the description of Aff0 for more information.

**Aff0, bits [7:0]**
Affinity level 0. This is the affinity level that is most significant for determining PE behavior. Higher affinity levels are increasingly less significant in determining PE behavior. The assigned value of the MPIDR.{Aff2, Aff1, Aff0} or MPIDR_EL1.{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

### Accessing the MPIDR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRS <Xt>, MPIDR_EL1 \]

```

```
D13.2.97  MVFR0_EL1, AArch32 Media and VFP Feature Register 0

The MVFR0_EL1 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR1_EL1 and MVFR2_EL1.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D13-2867.

**Configurations**

AArch64 System register MVFR0_EL1[31:0] is architecturally mapped to AArch32 System register MVFR0[31:0].

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

**Attributes**

MVFR0_EL1 is a 64-bit register.

**Field descriptions**

The MVFR0_EL1 bit assignments are:

*When AArch32 is supported at any Exception level:*

<table>
<thead>

</tbody>
</table>
FPsqrt, bits [23:20]
Square Root. Indicates whether the floating-point implementation provides support for the ARMv6 VFP square root operations. Defined values are:

0b0000   Not supported in hardware.
0b0001   Supported.

All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0001.
The VSQRT.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VSQRT.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPDivide, bits [19:16]
Indicates whether the floating-point implementation provides support for VFP divide operations. Defined values are:

0b0000   Not supported in hardware.
0b0001   Supported.

All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0001.
The VDIV.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VDIV.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPTrap, bits [15:12]
Floating Point Exception Trapping. Indicates whether the floating-point implementation provides support for exception trapping. Defined values are:

0b0000   Not supported.
0b0001   Supported.

All other values are reserved.
A value of 0b0001 indicates that, when the corresponding trap is enabled, a floating-point exception generates an exception.

FPDP, bits [11:8]
Double Precision. Indicates whether the floating-point implementation provides support for double-precision operations. Defined values are:

0b0000   Not supported in hardware.
0b0001   Supported, VFPv2.
0b0010   Supported, VFPv3, VFPv4, or Armv8. VFPv3 and Armv8 add an instruction to load a double-precision floating-point constant, and conversions between double-precision and fixed-point values.

All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0010.
A value of 0b0001 or 0b0010 indicates support for all VFP double-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

• VSQRT.F64 is only available if the Square root field is 0b0001.
• VDIV.F64 is only available if the Divide field is 0b0001.
• Conversion between double-precision and single-precision is only available if the single-precision field is nonzero.
FPSP, bits [7:4]

Single Precision. Indicates whether the floating-point implementation provides support for single-precision operations. Defined values are:

- 0b0000  Not supported in hardware.
- 0b0001  Supported, VFPv2.
- 0b0010  Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a single-precision floating-point constant, and conversions between single-precision and fixed-point values.

All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0010.

A value of 0b0001 or 0b0010 indicates support for all VFP single-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F32 is only available if the Square root field is 0b0001.
- VDIV.F32 is only available if the Divide field is 0b0001.
- Conversion between double-precision and single-precision is only available if the double-precision field is nonzero.

SIMDReg, bits [3:0]

Advanced SIMD registers. Indicates whether the Advanced SIMD and floating-point implementation provides support for the Advanced SIMD and floating-point register bank. Defined values are:

- 0b0000  The implementation has no Advanced SIMD and floating-point support.
- 0b0001  The implementation includes floating-point support with 16 x 64-bit registers.
- 0b0010  The implementation includes Advanced SIMD and floating-point support with 32 x 64-bit registers.

All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0010.

Otherwise:

UNKNOWN, bits [63:0]

Reserved, UNKNOWN.

D13.2.98 MVFR1_EL1, AArch32 Media and VFP Feature Register 1

The MVFR1_EL1 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR0_EL1 and MVFR2_EL1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D13-2867.

**Configurations**

AArch64 System register MVFR1_EL1[31:0] is architecturally mapped to AArch32 System register MVFR1[31:0].

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

**Attributes**

MVFR1_EL1 is a 64-bit register.

**Field descriptions**

The MVFR1_EL1 bit assignments are:

*When AArch32 is supported at any Exception level:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>

<tr>
<td>19</td>
<td>FPFPB</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**SIMDFMAC, bits [31:28]**

Advanced SIMD Fused Multiply-Accumulate. Indicates whether the Advanced SIMD implementation provides fused multiply accumulate instructions. Defined values are:

- 0b0000: Not implemented.
- 0b0001: Implemented.

All other values are reserved.

In Armv8-A, the permitted values are 0b0000 and 0b0001.

The Advanced SIMD and floating-point implementations must provide the same level of support for these instructions.

**FPHP, bits [27:24]**

Floating Point Half Precision. Indicates the level of half-precision floating-point support. Defined values are:

- 0b0000: Not supported.
- 0b0001: Floating-point half-precision conversion instructions are supported for conversion between single-precision and half-precision.
0b0010  As for 0b0001, and adds instructions for conversion between double-precision and half-precision.

0b0011  As for 0b0010, and adds support for half-precision floating-point arithmetic.

All other values are reserved.

In Armv8-A, the permitted values are:

- 0b0000 in an implementation without floating-point support.
- 0b0010 in an implementation with floating-point support that does not include the FEAT_FP16 extension.
- 0b0011 in an implementation with floating-point support that includes the FEAT_FP16 extension.

The level of support indicated by this field must be equivalent to the level of support indicated by the SIMDHP field, meaning the permitted values are:

<table>
<thead>
<tr>
<th>Half Precision instructions supported</th>
<th>FPHP</th>
<th>SIMDHP</th>
</tr>
</thead>
<tbody>
<tr>
<td>No support</td>
<td>0b0000</td>
<td>0b0000</td>

<td>0b0001</td>
</tr>
<tr>
<td>Conversions and arithmetic</td>
<td>0b0011</td>
<td>0b0010</td>
</tr>
</tbody>
</table>

SIMDHP, bits [23:20]

Advanced SIMD Half Precision. Indicates the level of half-precision floating-point support. Defined values are:

- 0b0000  Not supported.
- 0b0001  SIMD half-precision conversion instructions are supported for conversion between single-precision and half-precision.
- 0b0010  As for 0b0001, and adds support for half-precision floating-point arithmetic.

All other values are reserved.

In Armv8-A, the permitted values are:

- 0b0000 in an implementation without SIMD floating-point support.
- 0b0010 in an implementation with SIMD floating-point support that does not include the FEAT_FP16 extension.
- 0b0011 in an implementation with SIMD floating-point support that includes the FEAT_FP16 extension.

The level of support indicated by this field must be equivalent to the level of support indicated by the FPHP field, meaning the permitted values are:

<table>
<thead>
<tr>
<th>Half Precision instructions supported</th>
<th>FPHP</th>
<th>SIMDHP</th>
</tr>
</thead>
<tbody>
<tr>
<td>No support</td>
<td>0b0000</td>
<td>0b0000</td>
</tr>
<tr>
<td>Conversions only</td>
<td>0b0010</td>
<td>0b0001</td>
</tr>
<tr>
<td>Conversions and arithmetic</td>
<td>0b0011</td>
<td>0b0010</td>
</tr>
</tbody>
</table>

SIMDSP, bits [19:16]

Advanced SIMD Single Precision. Indicates whether the Advanced SIMD and floating-point implementation provides single-precision floating-point instructions. Defined values are:

- 0b0000  Not implemented.
- 0b0001  Implemented. This value is permitted only if the SIMDInt field is 0b0001.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.

**SIMDInt, bits [15:12]**

Advanced SIMD Integer. Indicates whether the Advanced SIMD and floating-point implementation provides integer instructions. Defined values are:

- 0b0000: Not implemented.
- 0b0001: Implemented.

All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.

**SIMDLS, bits [11:8]**

Advanced SIMD Load/Store. Indicates whether the Advanced SIMD and floating-point implementation provides load/store instructions. Defined values are:

- 0b0000: Not implemented.
- 0b0001: Implemented.

All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.

**FPDNaN, bits [7:4]**

Default NaN mode. Indicates whether the floating-point implementation provides support only for the Default NaN mode. Defined values are:

- 0b0000: Not implemented, or hardware supports only the Default NaN mode.
- 0b0001: Hardware supports propagation of NaN values.

All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.

**FPFtZ, bits [3:0]**

Flush to Zero mode. Indicates whether the floating-point implementation provides support only for the Flush-to-Zero mode of operation. Defined values are:

- 0b0000: Not implemented, or hardware supports only the Flush-to-Zero mode of operation.
- 0b0001: Hardware supports full denormalized number arithmetic.

All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.

Otherwise:

**UNKNOWN, bits [63:0]**

Reserved, UNKNOWN.

**Accessing the MVFR1_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, MVFR1_EL1

if PSTATE.EL == EL0 then
    if IsFeatureImplemented("FEAT_IDST") then
        if EL2Enabled() && HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);

D13.2.100 PAR_EL1, Physical Address Register

The PAR_EL1 characteristics are:

Purpose

Returns the output address (OA) from an Address translation instruction that executed successfully, or fault information if the instruction did not execute successfully.

Configurations

AArch64 System register PAR_EL1[63:0] is architecturally mapped to AArch32 System register PAR[63:0].

Attributes

PAR_EL1 is a 64-bit register.

Field descriptions

The PAR_EL1 bit assignments are:

**When PAR_EL1.F == 0:**

<table>
<thead>
<tr>
<th>63</th>
<th>56–55</th>
<th>52–51</th>
<th>48–47</th>
<th>12–11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATTR</td>
<td>RES0</td>
<td>PA[51:48]</td>
<td>PA[47:12]</td>
<td>NS</td>
<td>SH</td>
<td>RES0</td>
<td>F</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

On a successful conversion, the PAR_EL1 can return a value that indicates the resulting attributes, rather than the values that appear in the translation table descriptors. More precisely:

- The PAR_EL1.{ATTR, SH} fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the translation table descriptors.
- See the PAR_EL1.NS bit description for constraints on the value it returns.

**ATTR, bits [63:56]**

Memory attributes for the returned output address. This field uses the same encoding as the Attr<n> fields in MAIR_EL1, MAIR_EL2, and MAIR_EL3.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

This field resets to an architecturally UNKNOWN value.

**Bits [55:52]**

Reserved, RES0.

**PA[51:48], bits [51:48]**

*When FEAT_LPA is implemented:*

Extension to PA[47:12]. See PA[47:12] for more details.

This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

PA[47:12], bits [47:12]
Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[47:12].
When FEAT_LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, the PA[51:48] bits form the upper part of the address value. Otherwise the PA[51:48] bits are RES0. For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.
This field resets to an architecturally UNKNOWN value.

Bit [11]
Reserved, RES1.

IMPLEMENTATION DEFINED, bit [10]
IMPLEMENTATION DEFINED.
This field resets to an architecturally UNKNOWN value.

NS, bit [9]
Non-secure. The NS attribute for a translation table entry from a Secure translation regime.
For a result from a Secure translation regime, when SCR_EL3.EEL2 is 1, this bit reflects the Security state of the intermediate physical address space of the translation for the instructions:
• In AArch64 state: AT S1E1R, AT S1E1W, AT S1E1RP, AT S1E1WP, AT S1E0R, and AT S1E0W.
• In AArch32 state: ATS1CPR, ATS1CPW, ATS1CPRP, ATS1CPWP, ATS1CUR, and ATS1CUW.
Otherwise, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.
For a result from a Non-secure translation regime, this bit is UNKNOWN.
This field resets to an architecturally UNKNOWN value.

SH, bits [8:7]
Shareability attribute, for the returned output address. Permitted values are:
0b00 Non-shareable.
0b10 Outer Shareable.
0b11 Inner Shareable.
The value 0b01 is reserved.

--- Note ---
This field returns the value 0b10 for:
• Any type of Device memory.
• Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.
This field resets to an architecturally UNKNOWN value.

Bits [6:1]
Reserved, RES0.
F, bit [0]
Indicates whether the instruction performed a successful address translation.
0b0 Address translation completed successfully.
This field resets to an architecturally UNKNOWN value.

When PAR_EL1.F == 1:

IMPLEMENTATION DEFINED, bits [51:48]
IMPLEMENTATION DEFINED.
This field resets to an architecturally UNKNOWN value.

Bits [47:12]
Reserved, RES0.

Bit [11]
Reserved, RES1.

Bit [10]
Reserved, RES0.

S, bit [9]
Indicates the translation stage at which the translation aborted:
0b0 Translation aborted because of a fault in the stage 1 translation.
0b1 Translation aborted because of a fault in the stage 2 translation.
This field resets to an architecturally UNKNOWN value.

PTW, bit [8]
If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.
This field resets to an architecturally UNKNOWN value.
Bit [7]

Reserved, RES0.

FST, bits [6:1]

Fault status code, as shown in the Data Abort ESR encoding.

- 0b000000  Address size fault, level 0 of translation or translation table base register.
- 0b000001  Address size fault, level 1.
- 0b000010  Address size fault, level 2.
- 0b000011  Address size fault, level 3.
- 0b000100  Translation fault, level 0.
- 0b000101  Translation fault, level 1.
- 0b000110  Translation fault, level 2.
- 0b000111  Translation fault, level 3.
- 0b001001  Access flag fault, level 1.
- 0b001010  Access flag fault, level 2.
- 0b001011  Access flag fault, level 3.
- 0b001101  Permission fault, level 1.
- 0b001110  Permission fault, level 2.
- 0b001111  Permission fault, level 3.
- 0b010100  Synchronous External abort on translation table walk or hardware update of translation table, level 0.
- 0b010101  Synchronous External abort on translation table walk or hardware update of translation table, level 1.
- 0b010110  Synchronous External abort on translation table walk or hardware update of translation table, level 2.
- 0b010111  Synchronous External abort on translation table walk or hardware update of translation table, level 3.
- 0b011100 When FEAT_RAS is not implemented  Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.
- 0b011101 When FEAT_RAS is not implemented  Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.
- 0b011110 When FEAT_RAS is not implemented  Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.
- 0b011111 When FEAT_RAS is not implemented  Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.
- 0b100000 TLB conflict abort.
- 0b110001 When FEAT_HAFDBS is implemented  Unsupported atomic hardware update fault.
- 0b111101 When EL1 is capable of using AArch32  Section Domain fault, from an AArch32 stage 1 EL1&0 translation regime using Short-descriptor translation table format.
- 0b111110 When EL1 is capable of using AArch32  Page Domain fault, from an AArch32 stage 1 EL1&0 translation regime using Short-descriptor translation table format.

This field resets to an architecturally UNKNOWN value.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

- 0b1  Address translation aborted.

This field resets to an architecturally UNKNOWN value.

### D13.2.101 REVIDR_EL1, Revision ID Register

The REVIDR_EL1 characteristics are:

**Purpose**
Provides implementation-specific minor revision information.

**Configurations**
AArch64 System register REVIDR_EL1[31:0] is architecturally mapped to AArch32 System register REVIDR[31:0].

If REVIDR_EL1 has the same value as MIDR_EL1, then its contents have no significance.

**Attributes**
REVIDR_EL1 is a 64-bit register.

**Field descriptions**
The REVIDR_EL1 bit assignments are:

D13.2.102 RGSR_EL1, Random Allocation Tag Seed Register.

The RGSR_EL1 characteristics are:

**Purpose**

Random Allocation Tag Seed Register.

**Configurations**

This register is present only when FEAT_MTE is implemented and ID_AA64PFR1_EL1.MTE != 0b0001. Otherwise, direct accesses to RGSR_EL1 are UNDEFINED.

When GCR_EL1.RRND==0b1, updates to RGSR_EL1 are implementation-specific.

**Attributes**

RGSR_EL1 is a 64-bit register.

**Field descriptions**

The RGSR_EL1 bit assignments are:

D13.2.103 RMR_EL1, Reset Management Register (EL1)

The RMR_EL1 characteristics are:

**Purpose**

When this register is implemented:

- A write to the register at EL1 can request a Warm reset.
- If EL1 can use all Execution states, this register specifies the Execution state that the PE boots into on a Warm reset.

**Configurations**

AArch64 System register RMR_EL1[31:0] is architecturally mapped to AArch32 System register RMR[31:0] when the highest implemented Exception level is EL1.

This register is present only when the highest implemented Exception level is EL1. Otherwise, direct accesses to RMR_EL1 are UNDEFINED.

When EL1 is the highest implemented Exception level:

- If EL1 can use all Execution states then this register must be implemented.
- If EL1 cannot use AArch32 then it is IMPLEMENTATION DEFINED whether the register is implemented.

**Attributes**

RMR_EL1 is a 64-bit register.

**Field descriptions**

The RMR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>62</td>
<td>Reserved.</td>
</tr>
<tr>
<td>61</td>
<td>Reserved.</td>
</tr>
<tr>
<td>1</td>
<td>Reset Request. Setting this bit to 1 requests a Warm reset. This field resets to 0.</td>
</tr>
<tr>
<td>0</td>
<td>AArch64.</td>
</tr>
</tbody>
</table>

**When EL1 is capable of using AArch32:**

When EL1 can use AArch32, determines which Execution state the PE boots into after a Warm reset:

- 0b0  AArch32.
- 0b1  AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL1 can only use AArch64 state, this bit is RAO/WI.

When implemented as a RW field, this field resets to 1 on a Cold reset.
Otherwise:
Reserved, RAO/WI.

Accessing the RMR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

\[\text{MRS } <Xt>, \text{ RMR_EL1}\]

\[
\begin{array}{cccccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
0b11 & 0b000 & 0b1100 & 0b0000 & 0b010 \\
\end{array}
\]

if PSTATE_EL == EL1 && IsHighestEL(EL1) then

\end{array}
\]

if PSTATE_EL == EL1 && IsHighestEL(EL1) then
RMR_EL1 = X[t];
else
UNDEFINED;
D13.2.104   **RMR_EL2, Reset Management Register (EL2)**

The RMR_EL2 characteristics are:

**Purpose**

When this register is implemented:

- A write to the register at EL2 can request a Warm reset.
- If EL2 can use all Execution states, this register specifies the Execution state that the PE boots into on a Warm reset.

**Configurations**

AArch64 System register RMR_EL2[31:0] is architecturally mapped to AArch32 System register HRMR[31:0] when the highest implemented Exception level is EL2.

This register is present only when the highest implemented Exception level is EL2. Otherwise, direct accesses to RMR_EL2 are **UNDEFINED**.

When EL2 is the highest implemented Exception level:

- If EL2 can use all Execution states then this register must be implemented.
- If EL2 cannot use AArch32 then it is **IMPLEMENTATION DEFINED** whether the register is implemented.

**Attributes**

RMR_EL2 is a 64-bit register.

**Field descriptions**

The RMR_EL2 bit assignments are:

63 62 61 60 59 58 57 56 55 54 53 52 51 50 49 48 47 46 45 44 43 42 41 40 39 38 37 36 35 34 33 32 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

\end{array}
\]

if PSTATE.EL == EL3 && IsHighestEL(EL3) then
RMR_EL3 = X[t];
else
UNDEFINED;
D13.2.106 RNDR, Random Number

The RNDR characteristics are:

**Purpose**
Random Number. Returns a 64-bit random number which is reseeded from the True Random Number source at an IMPLEMENTATION DEFINED rate.
If the hardware returns a genuine random number, PSTATE.NZCV is set to 0b0000.
If the instruction cannot return a genuine random number in a reasonable period of time, PSTATE.NZCV is set to 0b0100 and the data value returned is 0.
RNDR is a read-only register.

**Configurations**
This register is present only when FEAT_RNG is implemented. Otherwise, direct accesses to RNDR are UNDEFINED.

**Attributes**
RNDR is a 64-bit register.

**Field descriptions**
The RNDR bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

  return RNDR;
elif PSTATE_EL == EL2 then
  return RNDR;
elif PSTATE_EL == EL3 then
  return RNDR;
```
D13.2.107  RNDRRS, Reseeded Random Number

The RNDRRS characteristics are:

**Purpose**

- Reseeded Random Number. Returns a 64-bit random number which is reseeded from the True Random Number source immediately before the read of the random number.
- If the hardware returns a genuine random number, PSTATE.NZCV is set to 0b0000.
- If the instruction cannot return a genuine random number in a reasonable period of time, PSTATE.NZCV is set to 0b0100 and the data value returned is 0.

RNDRRS is a read-only register.

**Configurations**

This register is present only when FEAT_RNG is implemented. Otherwise, direct accesses to RNDRRS are UNDEFINED.

**Attributes**

RNDRRS is a 64-bit register.

**Field descriptions**

The RNDRRS bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RNDRRS</td>
<td>Reseeded Random Number. Returns a 64-bit Random Number which is reseeded from the True Random Number source immediately before this read. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the RNDRRS**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, RNDRRS**

```
if PSTATE.EL == EL0 then
  return RNDRRS;
elsif PSTATE.EL == EL1 then
  return RNDRRS;
elsif PSTATE.EL == EL2 then

elsif PSTATE.EL == EL3 then
  return RNDRRS;
```
D13.2.108 RVBAR_EL1, Reset Vector Base Address Register (if EL2 and EL3 not implemented)

The RVBAR_EL1 characteristics are:

**Purpose**

If EL1 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

**Configurations**

This register is present only when the highest implemented Exception level is EL1. Otherwise, direct accesses to RVBAR_EL1 are UNDEFINED.

**Attributes**

RVBAR_EL1 is a 64-bit register.

**Field descriptions**

The RVBAR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Reset Address, The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.</td>
</tr>
</tbody>
</table>

**Accessing the RVBAR_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, RVBAR_EL1**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>

<td>0b0000</td>
<td>0b001</td>
</tr>
</tbody>
</table>

if PSTATE_EL == EL1 && IsHighestEl(EL1) then
    return RVBAR_EL1;
else
    UNDEFINED;
D13.2.109 RVBAR_EL2, Reset Vector Base Address Register (if EL3 not implemented)

The RVBAR_EL2 characteristics are:

Purpose

If EL2 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

Configurations

This register is present only when the highest implemented Exception level is EL2. Otherwise, direct accesses to RVBAR_EL2 are UNDEFINED.

Attributes

RVBAR_EL2 is a 64-bit register.

Field descriptions

The RVBAR_EL2 bit assignments are:

![RVBAR_EL2 Bit Assignments Diagram]

Bits [63:0]

Reset Address. The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.

Accessing the RVBAR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, RVBAR_EL2**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>

elsif PSTATE.EL == EL2 && IsHighestEL(EL2) then
    return RVBAR_EL2;
else
    UNDEFINED;
D13.2.110 RVBAR_EL3, Reset Vector Base Address Register (if EL3 implemented)

The RVBAR_EL3 characteristics are:

**Purpose**

If EL3 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

**Configurations**

This register is present only when EL3 is implemented. Otherwise, direct accesses to RVBAR_EL3 are UNDEFINED.

Only implemented if the highest Exception level implemented is EL3.

**Attributes**

RVBAR_EL3 is a 64-bit register.

**Field descriptions**

The RVBAR_EL3 bit assignments are:

![Diagram of RVBAR_EL3 bit assignments]

**Bits [63:0]**

Reset Address. The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.

**Accessing the RVBAR_EL3**

### D13.2.112 SCR_EL3, Secure Configuration Register

The SCR_EL3 characteristics are:

**Purpose**

Defines the configuration of the current Security state. It specifies:
- The Security state of EL0, EL1, and EL2. The Security state is either Secure or Non-secure.
- The Execution state at lower Exception levels.
- Whether IRQ, FIQ, SError interrupts, and External abort exceptions are taken to EL3.
- Whether various operations are trapped to EL3.

**Configurations**

AArch64 System register SCR_EL3[31:0] can be mapped to AArch32 System register SCR[31:0], but this is not architecturally mandated.

This register is present only when EL3 is implemented. Otherwise, direct accesses to SCR_EL3 are UNDEFINED.

**Attributes**

SCR_EL3 is a 64-bit register.

**Field descriptions**

The SCR_EL3 bit assignments are:

**Bits [63:36]**

Reserved, RES0.

**AMVOFFEN, bit [35]**

*When FEAT_AMUV1p1 is implemented:*

Activity Monitors Virtual Offsets Enable.

0b0 Accesses to AMEVCNTVOFF0<el2> and AMEVCNTVOFF1<el2> at EL2 are trapped to EL3. Indirect reads of the virtual offset registers are zero.
Accesses to AMEVCNTVOFF0<el2> and AMEVCNTVOFF1<el2> are not affected by this field.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**Bit [34]**

Reserved, RES0.

**TWDEDEL, bits [33:30]**

*When FEAT_TWED is implemented:*

TWE Delay. A 4-bit unsigned number that, when SCR_EL3.TWEDEn is 1, encodes the minimum delay in taking a trap of WFE caused by SCR_EL3.TWE as \(2^{\text{TWDEDEL}} \times 8\) cycles.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**TWEDEn, bit [29]**

*When FEAT_TWED is implemented:*

TWE Delay Enable. Enables a configurable delayed trap of the WFE instruction caused by SCR_EL3.TWE.

\(0b0\) The delay for taking a WFE trap is IMPLEMENTATION DEFINED.

\(0b1\) The delay for taking a WFE trap is at least the number of cycles defined in SCR_EL3.TWDEDEL.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**ECVEn, bit [28]**

*When FEAT_ECV is implemented:*

ECV Enable. Enables access to the CNTPOFF_EL2 register.

\(0b0\) EL2 accesses to CNTPOFF_EL2 are trapped to EL3, and the value of CNTPOFF_EL2 is treated as 0 for all purposes other than direct reads or writes to the register from EL3.

\(0b1\) EL2 accesses to CNTPOFF_EL2 are not trapped to EL3 by this mechanism.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**FGTEn, bit [27]**

*When FEAT_FGT is implemented:*

Enables access to the Fine-Grained Traps registers: HAFGRTR_EL2, HDFGRTR_EL2, HDFGWTR_EL2, HFGTR_EL2, HFGITR_EL2 and HFGWTR_EL2.

\(0b0\) EL2 Accesses to HAFGRTR_EL2, HDFGRTR_EL2, HDFGWTR_EL2, HFGTR_EL2, HFGITR_EL2 and HFGWTR_EL2 registers are trapped to EL3, and those registers behave as if all bits are set to 0.

\(0b1\) EL2 Accesses to HAFGRTR_EL2, HDFGRTR_EL2, HDFGWTR_EL2, HFGTR_EL2, HFGITR_EL2 and HFGWTR_EL2 registers are not trapped to EL3 by this mechanism.

Traps caused by accesses to the fine-grained trap registers are reported using an ESR_ELx.EC value of 0x18 and its associated ISS.
ATA, bit [26]

When FEAT_MTE is implemented:
Allocation Tag Access. Controls access at EL2, EL1 and EL0 to Allocation Tags.
When access is prevented:
  • Instructions which Load or Store data are Unchecked.
  • Instructions which Load or Store Allocation Tags treat the Allocation Tag as RAZ/WI.
  • Instructions which insert Logical Address Tags into addresses treat the Allocation Tag used to generate the Logical Address Tag as 0.
  • Cache maintenance instructions which invalidate Allocation Tags from caches behave as the equivalent Clean and Invalidate operation on Allocation Tags.
  • MRS and MSR instructions at EL1 and EL2 using GCR_EL1, RGSR_EL1, TFSR_EL1, TFSR_EL2 or TFSRE0_EL1 that are not UNDEFINED or trapped to a lower Exception level are trapped to EL3.
  • MRS and MSR instructions at EL2 using TFSR_EL1 that are not UNDEFINED are trapped to EL3.

- 0b0 Access is prevented.
- 0b1 Access is not prevented.

This field is permitted to be cached in a TLB.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

EnSCXT, bit [25]

When FEAT_CSV2 is implemented:
Enable access to the SCXTNUM_EL2, SCXTNUM_EL1, and SCXTNUM_EL0 registers. The defined values are:

- 0b0 EL2, EL1 and EL0 access to SCXTNUM_EL0, EL2 and EL1 access to SCXTNUM_EL1, EL2 access to SCXTNUM_EL2 registers are disabled by this mechanism, causing an exception to EL3, and the values of these registers to be treated as 0.
- 0b1 This control does not cause accesses to SCXTNUM_EL0, SCXTNUM_EL1, SCXTNUM_EL2 to be trapped.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [24:22]
Reserved, RES0.

FIEN, bit [21]

When FEAT_RASv1p1 is implemented:
Fault Injection enable. Trap accesses to the registers ERXPFGCDN_EL1, ERXPFGCTL_EL1, and ERXPFGF_EL1 from EL1 and EL2 to EL3, reported using an ESR_ELx.EC value of 0x18.

- 0b0 Accesses to the specified registers from EL1 and EL2 generate a Trap exception to EL3.
- 0b1 This control does not cause any instructions to be trapped.

If EL3 is not implemented, the Effective value of SCR_EL3.FIEN is 0b1.
If ERRIDR_EL1.NUM is zero, meaning no error records are implemented, or no error record accessible using System registers is owned by a node that implements the RAS Common Fault Injection Model Extension, then this bit might be RES0.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

### NMEA, bit [20]

**When FEAT_DoubleFault is implemented:**

Non-maskable External Aborts. When SCR_EL3.EA == 1, controls whether PSTATE.A masks SError interrupts at EL3.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>If SCR_EL3.EA == 1, asserted SError interrupts are not taken at EL3 if PSTATE.A == 1.</td>
</tr>
<tr>
<td>0b1</td>
<td>If SCR_EL3.EA == 1, asserted SError interrupts are taken at EL3 regardless of the value of PSTATE.A.</td>
</tr>
</tbody>
</table>

When SCR_EL3.EA == 0:

- Asserted SError interrupts are not taken at EL3 regardless of the value of PSTATE.A and this field.
- This field is ignored and its Effective value is 0.

This field resets to 0.

**Otherwise:**

Reserved, RES0.

### EASE, bit [19]

**When FEAT_DoubleFault is implemented:**

External aborts to SError interrupt vector.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Synchronous External abort exceptions taken to EL3 are taken to the appropriate synchronous exception vector offset from VBAR_EL3.</td>
</tr>
<tr>
<td>0b1</td>
<td>Synchronous External abort exceptions taken to EL3 are taken to the appropriate SError interrupt vector offset from VBAR_EL3.</td>
</tr>
</tbody>
</table>

This field resets to 0.

**Otherwise:**

Reserved, RES0.

### EEL2, bit [18]

**When FEAT_SEL2 is implemented:**

Secure EL2 Enable.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>All behaviors associated with Secure EL2 are disabled. All registers, including timer registers, defined by FEAT_SEL2 are UNDEFINED, and those timers are disabled.</td>
</tr>
<tr>
<td>0b1</td>
<td>All behaviors associated with Secure EL2 are enabled.</td>
</tr>
</tbody>
</table>

When the value of this bit is 1, then:

- When SCR_EL3.NS == 0, the SCR_EL3.RW bit is treated as 1 for all purposes other than reading or writing the register.
- If Secure EL1 is using AArch32, then any of the following operations, executed in Secure EL1, is trapped to Secure EL2, using the EC value of ESR_EL2.EC== 0x3:
  - A read or write of the SCR.
  - A read or write of the NSACR.
  - A read or write of the MVBAR.
  - A read or write of the SDCR.
Execution of an ATS12NSO** instruction.

- If Secure EL1 is using AArch32, then any of the following operations, executed in Secure EL1, is trapped to Secure EL2 using the EC value of $ESR_{EL2}.EC = 0x0$:
  - Execution of an SRS instruction that uses $R13_{mon}$.
  - Execution of an MRS (Banked register) or MSR (Banked register) instruction that would access $SPSR_{mon}$, $R13_{mon}$, or $R14_{mon}$.

**Note**
If the Effective value of $SCR_{EL3}.EEL2$ is 0, then these operations executed in Secure EL1 using AArch32 are trapped to EL3.

In a Secure only implementation that does not implement EL3 but implements EL2, behaves as if $SCR_{EL3}.EEL2 = 1$.

This bit is permitted to be cached in a TLB.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**API, bit [17]**

*When FEAT_SEL2 is implemented and FEAT_PAuth is implemented:*

Controls the use of the following instructions related to Pointer Authentication. Traps are reported using an $ESR_{ELx}.EC$ value of 0x0:

- PACGA, which is always enabled.
- AUTDA, AUTDB, AUTDZA, AUTDZB, AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZA, AUTIZB, PACDA, PACDB, PACDZA, PACDZB, PACIA, PACIA1716, PACIASP, PACIAZ, PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZA, PACIZB, RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ, ERETAA, ERETAB, LDRAA and LDRAB when:
  - In EL0, when $HCR_{EL2}.TGE = 0$ or $HCR_{EL2}.E2H = 0$, and the associated $SCTLR_{EL1}.En<<N><M>> = 1$.
  - In EL0, when $HCR_{EL2}.TGE = 1$ and $HCR_{EL2}.E2H = 1$, and the associated $SCTLR_{EL2}.En<<N><M>> = 1$.
  - In EL1, when the associated $SCTLR_{EL1}.En<<N><M>> = 1$.
  - In EL2, when the associated $SCTLR_{EL2}.En<<N><M>> = 1$.

**Note**
The use of any instruction related to pointer authentication in any Exception level except EL3 when the instructions are enabled are trapped to EL3 unless they are trapped to EL2 as a result of the $HCR_{EL2}.API$ bit.

- **0b0** This control does not cause any instructions to be trapped.

An instruction is trapped only if Pointer Authentication is enabled for that instruction, for more information, see *System register control of pointer authentication* on page D5-2533.

**Note**
If FEAT_PAuth is implemented but EL3 is not implemented, the system behaves as if this bit is 1.

This field resets to an architecturally UNKNOWN value.

*When FEAT_SEL2 is not implemented and FEAT_PAuth is implemented:*

Controls the use of instructions related to Pointer Authentication:

- PACGA.
D13.2 General system control registers

- AUTDA, AUTDB, AUTDZA, AUTDZB, AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZA, AUTIZB, PACDA, PACDB, PACDZA, PACDZB, PACIA, PACIA1716, PACIASP, PACIAZ, PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZA, PACIZ, RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ, ERETAA, ERETAB, LDRAA and LDRAB when:
  - In Non-secure EL0, when HCR_EL2.TGE == 0 or HCR_EL2.E2H == 0, and the associated SCTLR_EL1.En<N><M> == 1.
  - In Non-secure EL0, when HCR_EL2.TGE == 1 and HCR_EL2.E2H == 1, and the associated SCTLR_EL2.En<N><M> == 1.
  - In Secure EL0, when the associated SCTLR_EL2.En<N><M> == 1.
  - In Secure or Non-secure EL1, when the associated SCTLR_EL1.En<N><M> == 1.
  - In EL2, when the associated SCTLR_EL2.En<N><M> == 1.

0b0 The use of any instruction related to pointer authentication in any Exception level except EL3 when the instructions are enabled are trapped to EL3 unless they are trapped to EL2 as a result of the HCR_EL2.API bit.

0b1 This control does not cause any instructions to be trapped.

--- Note ---

If FEAT_PAuth is implemented but EL3 is not implemented, the system behaves as if this bit is 1.

---

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, res0.

**APK, bit [16]**

When FEAT_PAuth is implemented:

Trap registers holding "key" values for Pointer Authentication. Traps accesses to the following registers, using an ESR_ELx.EC value of 0x18, from EL1 or EL2 to EL3 unless they are trapped to EL2 as a result of the HCR_EL2.APK bit or other traps:

- APIAKeyLo_EL1, APIAKeyHi_EL1, APIBKeyLo_EL1, APIBKeyHi_EL1.
- APDAKeyLo_EL1, APDAKeyHi_EL1, APDBKeyLo_EL1, APDBKeyHi_EL1.
- APGAKeyLo_EL1, and APGAKeyHi_EL1.

0b0 Access to the registers holding "key" values for pointer authentication from EL1 or EL2 are trapped to EL3 unless they are trapped to EL2 as a result of the HCR_EL2.APK bit or other traps.

0b1 This control does not cause any instructions to be trapped.

For more information, see System register control of pointer authentication on page D5-2533.

--- Note ---

If FEAT_PAuth is implemented but EL3 is not implemented, the system behaves as if this bit is 1.

---

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, res0.
TERR, bit [15]

When FEAT_RAS is implemented:

Trap Error record accesses. Accesses to the RAS ERR* and RAS ERX* registers from EL1 and EL2 to EL3 are trapped as follows:

- Accesses from EL1 and EL2 using AArch64 to the following registers are trapped and reported using an ESR_ELx.EC value of 0x18:
  - ERRIDR_EL1, ERRSELR_EL1, ERXADDR_EL1, ERXCTLR_EL1, ERXFR_EL1, ERXMISC0_EL1, ERXMISC1_EL1, and ERXSTATUS_EL1.
- If FEAT_RASv1p1 is implemented, accesses from EL1 and EL2 using AArch64 to ERXMISC2_EL1, and ERXMISC3_EL1, are trapped and reported using an ESR_ELx.EC value of 0x18.
- Accesses from EL1 and EL2 using AArch32, to the following registers are trapped and reported using an ESR_ELx.EC value of 0x03:
  - ERRIDR, ERRSELR, ERXADDR, ERXADDR2, ERXCTLR, ERXCTLR2, ERXFR, ERXFR2, ERXMISC0, ERXMISC1, ERXMISC2, ERXMISC3, and ERXSTATUS.
- If FEAT_RASv1p1 is implemented, accesses from EL1 and EL2 using AArch32 to the following registers are trapped and reported using an ESR_ELx.EC value of 0x03:
  - ERXMISC4, ERXMISC5, ERXMISC6, and ERXMISC7.

0b0 This control does not cause any instructions to be trapped.

0b1 Accesses to the specified registers from EL1 and EL2 generate a Trap exception to EL3.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLOR, bit [14]

When FEAT_LOR is implemented:

Trap LOR registers. Traps accesses to the LORSA_EL1, LOREA_EL1, LORN_EL1, LORC_EL1, and LORID_EL1 registers from EL1 and EL2 to EL3, unless the access has been trapped to EL2.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 and EL2 accesses to the LOR registers that are not UNDEFINED are trapped to EL3, unless it is trapped HCR_EL2.TLOR.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TWE, bit [13]

Traps EL2, EL1, and EL0 execution of WFE instructions to EL3, from both Security states and both Execution states, reported using an ESR_ELx.EC value of 0x01.

0b0 This control does not cause any instructions to be trapped.

0b1 Any attempt to execute a WFE instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWE, HCR.TWE, SCTLR_EL1.nTWE, SCTLR_EL2.nTWE, or HCR_EL2.TWE.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.
Note
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about when WFE instructions can cause the PE to enter a low-power state, see *Wait for Event mechanism and Send event* on page D1-2391.

This field resets to an architecturally UNKNOWN value.

TWI, bit [12]
Traps EL2, EL1, and EL0 execution of WFI instructions to EL3, from both Security states and both Execution states, reported using an ESR_ELx.EC value of 0x01.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>This control does not cause any instructions to be trapped.</td>
</tr>
<tr>
<td>0b1</td>
<td>Any attempt to execute a WFI instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWI, HCR.TWI, SCTLR_EL1.nTWI, SCTLR_EL2.nTWI, or HCR_EL2.TWI.</td>
</tr>
</tbody>
</table>

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

Note
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about when WFI instructions can cause the PE to enter a low-power state, see *Wait For Interrupt* on page D1-2394.

This field resets to an architecturally UNKNOWN value.

ST, bit [11]
Traps Secure EL1 accesses to the Counter-timer Physical Secure timer registers to EL3, from AArch64 state only, reported using an ESR_ELx.EC value of 0x18.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Secure EL1 using AArch64 accesses to the CNTPS.TVAL_EL1, CNTPS.CTL_EL1, and CNTPS.CV_EL1 are trapped to EL3 when Secure EL2 is disabled. If Secure EL2 is enabled, the behavior is as if the value of this field was 0b1.</td>
</tr>
<tr>
<td>0b1</td>
<td>This control does not cause any instructions to be trapped.</td>
</tr>
</tbody>
</table>

Note
Accesses to the Counter-timer Physical Secure timer registers are always enabled at EL3. These registers are not accessible at EL0.

This field resets to an architecturally UNKNOWN value.

RW, bit [10]
*When AArch32 is supported at any Exception level:*
Execution state control for lower Exception levels.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Lower levels are all AArch32.</td>
</tr>
<tr>
<td>0b1</td>
<td>The next lower level is AArch64. If EL2 is present:</td>
</tr>
<tr>
<td></td>
<td>• EL2 is AArch64.</td>
</tr>
<tr>
<td></td>
<td>• EL2 controls EL1 and EL0 behaviors.</td>
</tr>
</tbody>
</table>
If EL2 is not present:
- EL1 is AArch64.
- EL0 is determined by the Execution state described in the current process state when executing at EL0.

If AArch32 state is not supported by the implementation at EL2 and AArch32 state is not supported by the implementation at EL1, then this bit is RAO/WI.

If AArch32 state is supported by the implementation at EL1, SCR_EL3.NS == 1 and AArch32 state is not supported by the implementation at EL2, the Effective value of this bit is 1.

If AArch32 state is supported by the implementation at EL1, FEAT_SEL2 is implemented and SCR_EL3.{EEL2, NS} == {1, 0}, the Effective value of this bit is 1.

This bit is permitted to be cached in a TLB.
This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RAO/WI.

**SIF, bit [9]**

*When FEAT_SEL2 is implemented:*
Secure instruction fetch. When the PE is in Secure state, this bit disables instruction fetch from memory marked in the first stage of translation as being Non-secure. The possible values for this bit are:

- 0b0 Secure state instruction fetches from memory marked in the first stage of translation as being Non-secure are permitted.
- 0b1 Secure state instruction fetches from memory marked in the first stage of translation as being Non-secure are not permitted.

This bit is permitted to be cached in a TLB.
This field resets to an architecturally UNKNOWN value.

*Otherwise:*
Secure instruction fetch. When the PE is in Secure state, this bit disables instruction fetch from Non-secure memory.

- 0b0 Secure state instruction fetches from Non-secure memory are permitted.
- 0b1 Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.
This field resets to an architecturally UNKNOWN value.

**HCE, bit [8]**

Hypervisor Call instruction enable. Enables HVC instructions at EL3 and, if EL2 is enabled in the current Security state, at EL2 and EL1, in both Execution states, reported using an ESR_ELx.EC value of 0x00.

- 0b0 HVC instructions are UNDEFINED.
- 0b1 HVC instructions are enabled at EL3, EL2, and EL1.

**Note**
HVC instructions are always UNDEFINED at EL0 and, if Secure EL2 is disabled, at Secure EL1. Any resulting exception is taken from the current Exception level to the current Exception level.

If EL2 is not implemented, this bit is RES0.
This field resets to an architecturally UNKNOWN value.
SMD, bit [7]
Secure Monitor Call disable. Disables SMC instructions at EL1 and above, from both Security states and both Execution states, reported using an ESR_ELx.EC value of 0x00.

\[ \begin{align*}
\text{0b0} & \quad \text{SMC instructions are enabled at EL3, EL2 and EL1.} \\
\text{0b1} & \quad \text{SMC instructions are UNDEFINED.}
\end{align*} \]

--- Note ---
SMC instructions are always UNDEFINED at EL0. Any resulting exception is taken from the current Exception level to the current Exception level.
If HCR_EL2.TSC or HCR.TSC traps attempted EL1 execution of SMC instructions to EL2, that trap has priority over this disable.

This field resets to an architecturally UNKNOWN value.

Bit [6]
Reserved, RES0.

Bits [5:4]
Reserved, RES1.

EA, bit [3]
External Abort and SError interrupt routing.

\[ \begin{align*}
\text{0b0} & \quad \text{When executing at Exception levels below EL3, External aborts and SError interrupts are not taken to EL3.} \\
& \quad \text{In addition, when executing at EL3:} \\
& \quad \quad \text{SErrror interrupts are not taken.} \\
& \quad \quad \text{External aborts are taken to EL3.} \\
\text{0b1} & \quad \text{When executing at any Exception level, External aborts and SError interrupts are taken to EL3.}
\end{align*} \]

For more information, see Asynchronous exception routing on page D1-2358.
This field resets to an architecturally UNKNOWN value.

FIQ, bit [2]
Physical FIQ Routing.

\[ \begin{align*}
\text{0b0} & \quad \text{When executing at Exception levels below EL3, physical FIQ interrupts are not taken to EL3.} \\
& \quad \text{When executing at EL3, physical FIQ interrupts are not taken.} \\
\text{0b1} & \quad \text{When executing at any Exception level, physical FIQ interrupts are taken to EL3.}
\end{align*} \]

For more information, see Asynchronous exception routing on page D1-2358.
This field resets to an architecturally UNKNOWN value.

IRQ, bit [1]
Physical IRQ Routing.

\[ \begin{align*}
\text{0b0} & \quad \text{When executing at Exception levels below EL3, physical IRQ interrupts are not taken to EL3.} \\
& \quad \text{When executing at EL3, physical IRQ interrupts are not taken.} \\
\text{0b1} & \quad \text{When executing at any Exception level, physical IRQ interrupts are taken to EL3.}
\end{align*} \]

For more information, see Asynchronous exception routing on page D1-2358.
This field resets to an architecturally UNKNOWN value.
NS, bit [0]

Non-secure bit.

\[ b0 \] Indicates that EL0 and EL1 are in Secure state.
\[ b1 \] Indicates that Exception levels lower than EL3 are in Non-secure state, and so memory accesses from those Exception levels cannot access Secure memory.

When SCR_EL3.{EEL2, NS} == {1, 0}, then EL2 is using AArch64 and in Secure state.

This field resets to an architecturally UNKNOWN value.

**Accessing the SCR_EL3**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, SCR_EL3**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1</td>
<td>0b10</td>
<td>0b0001</td>
<td>0b0001</td>
<td>0b000</td>
</tr>
</tbody>
</table>

```plaintext
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    return SCR_EL3;
```

**MSR SCR_EL3, <Xt>**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1</td>
<td>0b10</td>
<td>0b0001</td>
<td>0b0001</td>
<td>0b000</td>
</tr>
</tbody>
</table>

```plaintext
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    SCR_EL3 = X[t];
```
### D13.2.113 SCTLR_EL1, System Control Register (EL1)

The SCTLR_EL1 characteristics are:

**Purpose**

Provides top level control of the system, including its memory system, at EL1 and EL0.

**Configurations**

AArch64 System register SCTLR_EL1[31:0] is architecturally mapped to AArch32 System register SCTLR[31:0].

**Attributes**

SCTLR_EL1 is a 64-bit register.

**Field descriptions**

The SCTLR_EL1 bit assignments are:

**Bits [63:50]**

Reserved, RES0.

**TWDEl**, bits [49:46]

*When FEAT_TWED is implemented:*

TWE Delay. A 4-bit unsigned number that, when SCTLR_EL1.TWEDEn is 1, encodes the minimum delay in taking a trap of WFE caused by SCTLR_EL1.nTWE as $2^{(TWDEl + 8)}$ cycles.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.
TWEDEn, bit [45]

When FEAT_TWED is implemented:

TWE Delay Enable. Enables a configurable delayed trap of the WFE instruction caused by SCTLR_EL1.nTWE.

0b0  The delay for taking a WFE trap is IMPLEMENTATION DEFINED.
0b1  The delay for taking a WFE trap is at least the number of cycles defined in SCTLR_EL1.TWEDEL.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

DSSBS, bit [44]

When FEAT_SSBS is implemented:

Default PSTATE.SSBS value on Exception Entry. The defined values are:

0b0  PSTATE.SSBS is set to 0 on an exception to EL1.
0b1  PSTATE.SSBS is set to 1 on an exception to EL1.

In a system where the PE resets into EL1, this field resets to an IMPLEMENTATION DEFINED value.

Otherwise:
Reserved, RES0.

ATA, bit [43]

When FEAT_MTE is implemented:

Allocation Tag Access in EL1. When SCR_EL3.ATA=1 and HCR_EL2.ATA=1, controls EL1 access to Allocation Tags.
When access to Allocation Tags is prevented:
- Instructions which Load or Store data are Unchecked.
- Instructions which Load or Store Allocation Tags treat the Allocation Tag as RAZ/WI.
- Instructions which insert Logical Address Tags into addresses treat the Allocation Tag used to generate the Logical Address Tag as 0.
- Cache maintenance instructions which invalidate Allocation Tags from caches behave as the equivalent Clean and Invalidate operation on Allocation Tags.

0b0  Access to Allocation Tags is prevented.
0b1  Access to Allocation Tags is not prevented.

This bit is permitted to be cached in a TLB.
In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

ATA0, bit [42]

When FEAT_MTE is implemented:

Allocation Tag Access in EL0. When SCR_EL3.ATA=1, HCR_EL2.ATA=1, and HCR_EL2.{E2H,TGE} != {1,1}, controls EL0 access to Allocation Tags.
When access to Allocation Tags is prevented:
- Instructions which Load or Store data are Unchecked.
- Instructions which Load or Store Allocation Tags treat the Allocation Tag as RAZ/WI.
- Instructions which insert Logical Address Tags into addresses treat the Allocation Tag used to generate the Logical Address Tag as 0.
• Cache maintenance instructions which invalidate Allocation Tags from caches behave as the equivalent Clean and Invalidate operation on Allocation Tags.

0b0  Access to Allocation Tags is prevented.
0b1  Access to Allocation Tags is not prevented.

This field is permitted to be cached in a TLB.

--- Note ---
Software may change this control bit on a context switch.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

TCF, bits [41:40]
When FEAT_MTE is implemented:
Tag Check Fault in EL1. Controls the effect of Tag Check Faults due to Loads and Stores in EL1.

0b00  Tag Check Faults have no effect on the PE.
0b01  Tag Check Faults cause a synchronous exception.
0b10  Tag Check Faults are asynchronously accumulated.

The value 0b11 is reserved.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

TCF0, bits [39:38]
When FEAT_MTE is implemented:
Tag Check Fault in EL0. When HCR_EL2.[E2H,TGE] !={1,1}, controls the effect of Tag Check Faults due to Loads and Stores in EL0.

0b00  Tag Check Faults have no effect on the PE.
0b01  Tag Check Faults cause a synchronous exception.
0b10  Tag Check Faults are asynchronously accumulated.

The value 0b11 is reserved.

--- Note ---
Software may change this control bit on a context switch.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

ITFSB, bit [37]
When FEAT_MTE is implemented:
When synchronous exceptions are not being generated by Tag Check Faults which are generated for Loads and Stores in EL0 or EL1, controls the auto-synchronization of Tag Check Faults into TFSRE0_EL1 and TFSR_EL1.

0b0  Tag Check Faults are not synchronized on entry to EL1.
0b1  Tag Check Faults are synchronized on entry to EL1.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.
**BT1, bit [36]**

*When FEAT_BTI is implemented:*

PAC Branch Type compatibility at EL1.

- **0b0** When the PE is executing at EL1, PACIASP and PACIBSP are compatible with PSTATE.BTYPE == 0b11.
- **0b1** When the PE is executing at EL1, PACIASP and PACIBSP are not compatible with PSTATE.BTYPE == 0b11.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**BT0, bit [35]**

*When FEAT_BTI is implemented:*

PAC Branch Type compatibility at EL0.

- **0b0** When the PE is executing at EL0, PACIASP and PACIBSP are compatible with PSTATE.BTYPE == 0b11.
- **0b1** When the PE is executing at EL0, PACIASP and PACIBSP are not compatible with PSTATE.BTYPE == 0b11.

When HCR_EL2.E2H == 1 && HCR_EL2.TGE == 1, the value of the SCTLR_EL1.BT0 has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**Bits [34:32]**

Reserved, RES0.

**EnIA, bit [31]**

*When FEAT_PAuth is implemented:*

Controls enabling of pointer authentication (using the APIAKey_EL1 key) of instruction addresses in the EL1&0 translation regime.

For more information, see [System register control of pointer authentication on page D5-2533](#).

- **0b0** Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is not enabled.
- **0b1** Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is enabled.

---

**Note**

This field controls the behavior of the AddPACIA and AuthIA pseudocode functions. Specifically, when the field is 1, AddPACIA returns a copy of a pointer to which a pointer authentication code has been added, and AuthIA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.
EnIB, bit [30]

When FEAT_PAuth is implemented:

- Controls enabling of pointer authentication (using the APIBKey_EL1 key) of instruction addresses in the EL1&0 translation regime.

For more information, see System register control of pointer authentication on page D5-2533.

0b0  Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is not enabled.

0b1  Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is enabled.

--- Note ---

This field controls the behavior of the AddPACIB and AuthIB pseudocode functions. Specifically, when the field is 1, AddPACIB returns a copy of a pointer to which a pointer authentication code has been added, and AuthIB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

--- Note ---

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LSMAOE, bit [29]

When FEAT_LSMAOC is implemented:

- Load Multiple and Store Multiple Atomicity and Ordering Enable.

0b0  For all memory accesses at EL0, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.

0b1  The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL0 is as defined for Armv8.0.

This bit is permitted to be cached in a TLB.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1,1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

nTLSMD, bit [28]

When FEAT_LSMAOC is implemented:

- No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory.

0b0  All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.

0b1  All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.

This bit is permitted to be cached in a TLB.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1,1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.
EnDA, bit [27]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication (using the APDAKey_EL1 key) of instruction addresses in the EL1&0 translation regime.

For more information, see System register control of pointer authentication on page D5-2533.

0b0  Pointer authentication (using the APDAKey_EL1 key) of data addresses is not enabled.
0b1  Pointer authentication (using the APDAKey_EL1 key) of data addresses is enabled.

Note

This field controls the behavior of the AddPACDA and AuthDA pseudocode functions. Specifically, when the field is 1, AddPACDA returns a copy of a pointer to which a pointer authentication code has been added, and AuthDA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UCI, bit [26]

Traps EL0 execution of cache maintenance instructions, to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from AArch64 state only, reported using an ESR_ELx.EC value of 0x18.

This applies to DC CVAU, DC CIVAC, DC CVAC, DC CVAP, and IC IVAU.

If FEAT_DPB2 is implemented, this trap also applies to DC CVADP.

If FEAT_MTE is implemented, this trap also applies to DC CIGVAC, DC CIGDVAC, DC CGVAC, DC CGDVAC, DC CGVAP, and DC CGDVAP.

If FEAT_DPB2 and FEAT_MTE are implemented, this trap also applies to DC CGVADP and DC CGDVADP.

0b0  Execution of the specified instructions at EL0 using AArch64 is trapped.
0b1  This control does not cause any instructions to be trapped.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

If the Point of Coherency is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean, or clean and invalidate instruction that operates by VA to the point of coherency can be trapped when the value of this control is 1.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

EE, bit [25]

Endianness of data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime.

The possible values of this bit are:

0b0  Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are little-endian.
0b1  Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are big-endian.
If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to an IMPLEMENTATION DEFINED value.

**E0E, bit [24]**

Endianness of data accesses at EL0.

The possible values of this bit are:

0b0  Explicit data accesses at EL0 are little-endian.

0b1  Explicit data accesses at EL0 are big-endian.

If an implementation only supports Little-endian accesses at EL0 then this bit is RES0. This option is not permitted when SCTLR_EL1.EE is RES1.

If an implementation only supports Big-endian accesses at EL0 then this bit is RES1. This option is not permitted when SCTLR_EL1.EE is RES0.

This bit has no effect on the endianness of LDTR, LDTRH, LDTRSH, LDTRSW, STTR, and STTRH instructions executed at EL1.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**SPAN, bit [23]**

*When FEAT_PAN is implemented:*

Set Privileged Access Never, on taking an exception to EL1.

0b0  PSTATE.PAN is set to 1 on taking an exception to EL1.

0b1  The value of PSTATE.PAN is left unchanged on taking an exception to EL1.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES1.

**EIS, bit [22]**

*When FEAT_ExS is implemented:*

Exception Entry is Context Synchronizing. The defined values are:

0b0  The taking of an exception to EL1 is not a context synchronizing event.

0b1  The taking of an exception to EL1 is a context synchronizing event.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this bit has no effect on execution at EL0.

If SCTLR_EL1.EIS is set to 0b0:

- Indirect writes to ESR_EL1, FAR_EL1, SPSR_EL1, ELR_EL1 are synchronized on exception entry to EL1, so that a direct read of the register after exception entry sees the indirectly written value caused by the exception entry.
- Memory transactions, including instruction fetches, from an Exception level always use the translation resources associated with that translation regime.
- Exception Catch debug events are synchronous debug events.
- DCPS* and DRPS instructions are context synchronization events.

The following are not affected by the value of SCTLR_EL1.EIS:
- Changes to the PSTATE information on entry to EL1.
- Behavior of accessing the banked copies of the stack pointer using the SP register name for loads, stores and data processing instructions.
- Exit from Debug state.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES1.

**IESB, bit [21]**

*When FEAT_IESB is implemented:*
Implicit Error Synchronization event enable. Possible values are:

0b0  Disabled.

0b1  An implicit error synchronization event is added:
  - At each exception taken to EL1.
  - Before the operational pseudocode of each *ERET* instruction executed at EL1.

When the PE is in Debug state, the effect of this field is CONSTRAINED UNPREDICTABLE, and its Effective value might be 0 or 1 regardless of the value of the field. If the Effective value of the field is 1, then an implicit error synchronization event is added after each DCPSx instruction taken to EL1 and before each DRPS instruction executed at EL1, in addition to the other cases where it is added.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**TSCXT, bit [20]**

*When FEAT_CSV2 is implemented:*
Trap EL0 Access to the SCXTNUM_EL0 register, when EL0 is using AArch64. The defined values are:

0b0  EL0 access to SCXTNUM_EL0 is not disabled by this mechanism.

0b1  EL0 access to SCXTNUM_EL0 is disabled, causing an exception to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.

The value of SCXTNUM_EL0 is treated as 0.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1,1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES1.

**WXN, bit [19]**
Write permission implies XN (Execute-never). For the EL1&0 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

0b0  This control has no effect on memory access permissions.

0b1  Any region that is writable in the EL1&0 translation regime is forced to XN for accesses from software executing at EL1 or EL0.

This bit applies only when SCTLR_EL1.M bit is set.

The WXN bit is permitted to be cached in a TLB.
When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**nTWE, bit [18]**

Traps EL0 execution of WFE instructions to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from both Execution states, reported using an ESR_ELx.EC value of 0x01.

- 0b0 Any attempt to execute a WFE instruction at EL0 is trapped, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0b1 This control does not cause any instructions to be trapped.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**Bit [17]**

Reserved, RES0.

**nTWI, bit [16]**

Traps EL0 execution of WFI instructions to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from both Execution states, reported using an ESR_ELx.EC value of 0x01.

- 0b0 Any attempt to execute a WFI instruction at EL0 is trapped, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0b1 This control does not cause any instructions to be trapped.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**UCT, bit [15]**

Traps EL0 accesses to the CTR_EL0 to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from AArch64 state only, reported using an ESR_ELx.EC value of 0x18.

- 0b0 Accesses to the CTR_EL0 from EL0 using AArch64 are trapped.
- 0b1 This control does not cause any instructions to be trapped.
When FEAT_VHE is implemented, and the value of HCR_EL2.\{E2H, TGE\} is \{1, 1\}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

DZE, bit [14]

Traps EL0 execution of DC ZVA instructions to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from AArch64 state only, reported using an ESR_ELx.EC value of 0x18.

If FEAT_MTE is implemented, this trap also applies to DC GVA and DC GZVA.

0b0 Any attempt to execute an instruction that this trap applies to at EL0 using AArch64 is trapped.

Reading DCZID_EL0.DZP from EL0 returns 1, indicating that the instructions this trap applies to are not supported.

0b1 This control does not cause any instructions to be trapped.

When FEAT_VHE is implemented, and the value of HCR_EL2.\{E2H, TGE\} is \{1, 1\}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

EnDB, bit [13]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication (using the APDBKey_EL1 key) of instruction addresses in the EL1&0 translation regime.

For more information, see System register control of pointer authentication on page D5-2533.

0b0 Pointer authentication (using the APDBKey_EL1 key) of data addresses is not enabled.

0b1 Pointer authentication (using the APDBKey_EL1 key) of data addresses is enabled.

Note

This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. Specifically, when the field is 1, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

I, bit [12]

Stage 1 instruction access Cacheability control, for accesses at EL0 and EL1:

0b0 All instruction access to Stage 1 Normal memory from EL0 and EL1 are Stage 1 Non-cacheable.

If the value of SCTLR_EL1.M is 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

0b1 This control has no effect on the Stage 1 Cacheability of instruction access to Stage 1 Normal memory from EL0 and EL1.

If the value of SCTLR_EL1.M is 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

When the value of the HCR_EL2.DC bit is 1, then instruction access to Normal memory from EL0 and EL1 are Cacheable regardless of the value of the SCTLR_EL1.I bit.

When FEAT_VHE is implemented, and the value of HCR_EL2.\{E2H, TGE\} is \{1, 1\}, this bit has no effect on the PE.
In a system where the PE resets into EL1, this field resets to 0.

**EOS, bit [11]**

*When FEAT_ExS is implemented:*

Exception Exit is Context Synchronizing. The defined values are:

- **0b0**: An exception return from EL1 is not a context synchronizing event
- **0b1**: An exception return from EL1 is a context synchronizing event

When **FEAT_VHE** is implemented, and the value of **HCR_EL2.{E2H, TGE}** is \{1,1\}, this bit has no effect on execution at EL0.

If SCTLR_EL1.EOS is set to **0b0**:

- Memory transactions, including instruction fetches, from an Exception level always use the translation resources associated with that translation regime.
- Exception Catch debug events are synchronous debug events.
- DCPS* and DRPS instructions are context synchronization events.

The following are not affected by the value of SCTLR_EL1.EOS:

- The indirect write of the PSTATE and PC values from SPSR_EL1 and ELR_EL1 on exception return is synchronized.
- Behavior of accessing the banked copies of the stack pointer using the SP register name for loads, stores and data processing instructions.
- Exit from Debug state.

In a system where the PE resets into EL1, this field resets to an architecturally **UNKNOWN** value.

**Otherwise:**

Reserved, RES1.

**EnRCTX, bit [10]**

*When FEAT_SPECRES is implemented:*

Enable EL0 Access to the following instructions:

- AArch32 CFPRCTX, DVPRCTX and CPPRCTX instructions.
- AArch64 CFP RCTX, DVP RCT and CPP RCTX instructions.

The defined values are:

- **0b0**: EL0 access to these instructions is disabled, and these instructions are trapped to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.
- **0b1**: EL0 access to these instructions is enabled.

When **FEAT_VHE** is implemented, and the value of **HCR_EL2.{E2H, TGE}** is \{1,1\}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally **UNKNOWN** value.

**Otherwise:**

Reserved, RES0.

**UMA, bit [9]**

User Mask Access. Traps EL0 execution of MSR and MRS instructions that access the PSTATE.{D, A, I, F} masks to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from AArch64 state only, reported using an ESR_ELx.EC value of 0x18.

- **0b0**: Any attempt at EL0 using AArch64 to execute an MSR, MSR(register), or MSR(immediate) instruction that accesses the DAIF is trapped.
- **0b1**: This control does not cause any instructions to be trapped.

When **FEAT_VHE** is implemented, and the value of **HCR_EL2.{E2H, TGE}** is \{1,1\}, this bit has no effect on execution at EL0.
In a system where the PE resets into EL1, this field resets to an architecturally **UNKNOWN** value.

**SED, bit [8]**

*When EL0 is capable of using AArch32:*

SETEND instruction disable. Disables SETEND instructions at EL0 using AArch32.

0b0  SETEND instruction execution is enabled at EL0 using AArch32.

0b1  SETEND instructions are **UNDEFINED** at EL0 using AArch32 and any attempt at EL0 to access a SETEND instruction generates an exception to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, reported using an ESR_ELx.EC value of 0x00.

If the implementation does not support mixed-endian operation at any Exception level, this bit is **RES1**.

When **FEAT_VHE** is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally **UNKNOWN** value.

*Otherwise:*

Reserved, **RES1**.

**ITD, bit [7]**

*When EL0 is capable of using AArch32:*

IT Disable. Disables some uses of IT instructions at EL0 using AArch32.

0b0  All IT instruction functionality is enabled at EL0 using AArch32.

0b1  Any attempt at EL0 using AArch32 to execute any of the following is **UNDEFINED** and generates an exception, reported using an ESR_ELx.EC value of 0x00, to EL1 or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1:

* All encodings of the IT instruction with hw1[3:0]!=1000.
* All encodings of the subsequent instruction with the following values for hw1:
  * 0b11xxxxxxxxxxxxxx: All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
  * 0b1011xxxxxxxxxxxx: All instructions in 'Miscellaneous 16-bit instructions' in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile, section F3.2.5.
  * 0b10100xxxxxxxxx: ADD Rd, PC, #imm
  * 0b01001xxxxxxxxxx: LDR Rd, [PC, #imm]
  * 0b0100x1xx1111xxx: ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
  * 0b010001xx1xxxx1111: ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers unpredictable cases with BLX Rn.

These instructions are always **UNDEFINED**, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

It is **IMPLEMENTATION** **DEFINED** whether the IT instruction is treated as:

* A 16-bit instruction, that can only be followed by another 16-bit instruction.
* The first half of a 32-bit instruction.

This means that, for the situations that are **UNDEFINED**, either the second 16-bit instruction or the 32-bit instruction is **UNDEFINED**.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is **CONSTRAINED UNPREDICTABLE**. For more information see *Changes to an ITD control by an instruction in an IT block on page E1-3998.*
ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAZ/WI.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES1.

nAA, bit [6]

When FEAT_LSE2 is implemented:
Non-aligned access. This bit controls generation of Alignment faults at EL1 and EL0 under certain conditions.

0b0 LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAR, LDARH, LDARL, LDARRH, STLLR, STLLRH, STLUR, STLURH, and STLURH generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes for accesses.

0b1 This control bit does not cause LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAR, LDARH, LDARL, LDARRH, STLLR, STLLRH, STLUR, STLURH, or STLURH to generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

CP15BEN, bit [5]

When EL0 is capable of using AArch32:
System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==0b1111) encoding space from EL0:

0b0 EL0 using AArch32: EL0 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is UNDEFINED and generates an exception to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1. The exception is reported using an ESR_ELx.EC value of 0x00.

0b1 EL0 using AArch32: EL0 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is enabled.

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAZ/WI.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SA0, bit [4]

SP Alignment check enable for EL0. When set to 1, if a load or store instruction executed at EL0 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see SP alignment checking on page D1-2327.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.
SA, bit [3]

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL1 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see SP alignment checking on page D1-2327.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

C, bit [2]

Stage 1 Cacheability control, for data accesses.

0b0              All data access to Stage 1 Normal memory from EL0 and EL1, and all Normal memory accesses from unified cache to the EL1&0 Stage 1 translation tables, are treated as Stage 1 Non-cacheable.

0b1              This control has no effect on the Stage 1 Cacheability of:
                    • Data access to Normal memory from EL0 and EL1.
                    • Normal memory accesses to the EL1&0 Stage 1 translation tables.

When the value of the HCR_EL2.DC bit is 1, the PE ignores SCTLR.C. This means that Non-secure EL0 and Non-secure EL1 data accesses to Normal memory are Cacheable.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL1 and EL0.

0b0              Alignment fault checking disabled when executing at EL1 or EL0.
                    Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

0b1              Alignment fault checking enabled when executing at EL1 or EL0.
                    All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

M, bit [0]

MMU enable for EL1&0 stage 1 address translation.

0b0              EL1&0 stage 1 address translation disabled.
                    See the SCTLR_EL1.I field for the behavior of instruction accesses to Normal memory.

0b1              EL1&0 stage 1 address translation enabled.

If the value of HCR_EL2.{DC, TGE} is not {0, 0} then in Non-secure state the PE behaves as if the value of the SCTLR_EL1.M field is 0 for all purposes other than returning the value of a direct read of the field.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to 0.
### Accessing the SCTLR_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic SCTLR_EL1 or SCTLR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

#### MRS <Xt>, SCTLR_EL1

D13.2.114 SCTLR_EL2, System Control Register (EL2)

The SCTLR_EL2 characteristics are:

**Purpose**

Provides top level control of the system, including its memory system, at EL2.

When FEAT_VHE is implemented, and the value of HCR_EL2.E2H, TGE is \{1, 1\}, these controls apply also to execution at EL0.

**Configurations**

AArch64 System register SCTLR_EL2[31:0] is architecturally mapped to AArch32 System register HSCTLR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

SCTLR_EL2 is a 64-bit register.

**Field descriptions**

The SCTLR_EL2 bit assignments are:

*When HCR_EL2.E2H != 1 or HCR_EL2.TGE != 1:*

This format applies in all Armv8.0 implementations, and from Armv8.1 when the Effective value of HCR_EL2.{E2H, TGE} != \{1, 1\}.

**Bits [63:45]**

Reserved, RES0.

**DSSBS, bit [44]**

*When FEAT_SSBS is implemented:*

Default PSTATE.SSBS value on Exception Entry.

- **0b0** PSTATE.SSBS is set to 0 on an exception to EL2.
- **0b1** PSTATE.SSBS is set to 1 on an exception to EL2.

In a system where the PE resets into EL2, this field resets to an IMPLEMENTATION DEFINED value.
**ATA, bit [43]**

When FEAT_MTE is implemented:

Allocation Tag Access. When SCR_EL3.ATA=1, controls EL2 access to Allocation Tags.

When access to Allocation Tags is prevented:

- Instructions that Load or Store data are Unchecked.
- Instructions that Load or Store Allocation Tags treat the Allocation Tag as RAZ/WI.
- Instructions that insert Logical Address Tags into addresses treat the Allocation Tag used to generate the Logical Address Tag as 0.
- Cache maintenance instructions that invalidate Allocation Tags from caches behave as the equivalent Clean and Invalidate operation on Allocation Tags.

- **0b0** Access to Allocation Tags is prevented.
- **0b1** Access to Allocation Tags is not prevented.

This bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bit [42]**

Reserved, RES0.

**TCF, bits [41:40]**

When FEAT_MTE is implemented:

Tag Check Fault. Controls the effect of Tag Check Faults due to Loads and Stores in EL2.

- **0b00** Tag Check Faults have no effect on the PE.
- **0b01** Tag Check Faults cause a synchronous exception.
- **0b10** Tag Check Faults are asynchronously accumulated.

The value **0b11** is reserved.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bits [39:38]**

Reserved, RES0.

**ITFSB, bit [37]**

When FEAT_MTE is implemented:

When synchronous exceptions are not being generated by Tag Check Faults, which are generated for Loads and Stores in EL0, EL1 or EL2, controls the auto-synchronization of Tag Check Faults into TFSRE0_EL1, TFSR_EL1, and TFSR_EL2.

- **0b0** Tag Check Faults are not synchronized on entry to EL2.
- **0b1** Tag Check Faults are synchronized on entry to EL2.

**Otherwise:**

Reserved, RES0.
BT, bit [36]

When **FEAT_BTI** is implemented:

PAC Branch Type compatibility at EL2.

0b0 When the PE is executing at EL2, PACIASP and PACIBSP are compatible with PSTATE.BTYPE == 0b11.

0b1 When the PE is executing at EL2, PACIASP and PACIBSP are not compatible with PSTATE.BTYPE == 0b11.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [35:32]

Reserved, RES0.

EnIA, bit [31]

When **FEAT_PAuth** is implemented:

Controls enabling of pointer authentication (using the APIAKey_EL1 key) of instruction addresses in the EL2&0 translation regime.

For more information, see System register control of pointer authentication on page D5-2533.

0b0 Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is not enabled.

0b1 Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is enabled.

Note

This field controls the behavior of the AddPACIA and AuthIA pseudocode functions. Specifically, when the field is 1, AddPACIA returns a copy of a pointer to which a pointer authentication code has been added, and AuthIA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnIB, bit [30]

When **FEAT_PAuth** is implemented:

Controls enabling of pointer authentication (using the APIBKey_EL1 key) of instruction addresses in the EL2&0 translation regime.

For more information, see System register control of pointer authentication on page D5-2533.

0b0 Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is not enabled.

0b1 Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is enabled.

Note

This field controls the behavior of the AddPACIB and AuthIB pseudocode functions. Specifically, when the field is 1, AddPACIB returns a copy of a pointer to which a pointer authentication code has been added, and AuthIB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**D13.2 General system control registers**

When **FEAT_PAuth** is implemented:

- Controls enabling of pointer authentication (using the APDAKey_EL1 key) of instruction addresses in the EL2&0 translation regime.
- For more information, see *System register control of pointer authentication on page D5-2533.*

</tr>
</tbody>
</table>

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an **IMPLEMENTATION DEFINED** value.

Bit [24]

Reserved, RES0.

Bit [23]

Reserved, RES1.

**EIS, bit [22]**

When **FEAT_ExS** is implemented:

- Exception entry is a context synchronization event. The defined values are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>The taking of an exception to EL2 is not a context synchronization event.</td>
</tr>
</tbody>
</table>
The taking of an exception to EL2 is a context synchronization event.

If SCTLR_EL2.EIS is set to 0b0:

1. Indirect writes to ESR_EL2, FAR_EL2, SPSR_EL2, ELR_EL2, and HPFAR_EL2 are synchronized on exception entry to EL2, so that a direct read of the register after exception entry sees the indirectly written value caused by the exception entry.
2. Memory transactions, including instruction fetches, from an Exception level always use the translation resources associated with that translation regime.
3. Exception Catch debug events are synchronous debug events.
4. DCPS* and DRPS instructions are context synchronization events.

The following are not affected by the value of SCTLR_EL2.EIS:

1. Changes to the PSTATE information on entry to EL2.
2. Behavior of accessing the banked copies of the stack pointer using the SP register name for loads, stores, and data processing instructions.
3. Exit from Debug state.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES1.

IESB, bit [21]

*When FEAT_IESB is implemented:*

Implicit Error Synchronization event enable.

- 0b0  Disabled.
- 0b1  An implicit error synchronization event is added:
  - At each exception taken to EL2.
  - Before the operational pseudocode of each ERET instruction executed at EL2.

When the PE is in Debug state, the effect of this field is CONSTRAINED UNPREDICTABLE, and its Effective value might be 0 or 1 regardless of the value of the field. If the Effective value of the field is 1, then an implicit error synchronization event is added after each DCPSx instruction taken to EL2 and before each DRPS instruction executed at EL2, in addition to the other cases where it is added.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

Bit [20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL2 or EL2&0 translation regime, this bit can force all memory regions that are writable to be treated as XN:

- 0b0  This control has no effect on memory access permissions.
- 0b1  Any region that is writable in the EL2 or EL2&0 translation regime is forced to XN for accesses from software executing at EL2.

This bit applies only when SCTLR_EL2.M bit is set.
The WXN bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Bit [18]

Reserved, RES1.
Bit [17]
Reserved, RES0.

Bit [16]
Reserved, RES1.

Bits [15:14]
Reserved, RES0.

EnDB, bit [13]

When FEAT_PAuth is implemented:
Controls enabling of pointer authentication (using the APDBKey_EL1 key) of instruction addresses in the EL2&0 translation regime.
For more information, see System register control of pointer authentication on page D5-2533.

0b0 Pointer authentication (using the APDBKey_EL1 key) of data addresses is not enabled.
0b1 Pointer authentication (using the APDBKey_EL1 key) of data addresses is enabled.

Note
This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. Specifically, when the field is 1, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

I, bit [12]
Instruction access Cacheability control, for accesses at EL2:

0b0 All instruction accesses to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache.
If the value of SCTLR_EL2.M is 0, instruction accesses from stage 1 of the EL2 or EL2&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

0b1 This control has no effect on the Cacheability of instruction access to Normal memory from EL2.
If the value of SCTLR_EL2.M is 0, instruction accesses from stage 1 of the EL2 or EL2&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0 or EL3 translation regimes.
In a system where the PE resets into EL2, this field resets to 0.

EOS, bit [11]

When FEAT_ExS is implemented:
Exception exit is a context synchronization Event.

0b0 An exception return from EL2 is not a context synchronization event.
0b1 An exception return from EL2 is a context synchronization event.

If SCTLR_EL2.EOS is set to 0b0:
- Memory transactions, including instruction fetches, from an Exception level always use the translation resources associated with that translation regime.
- Exception Catch debug events are synchronous debug events.
- DCPS* and DRPS instructions are context synchronization events.
The following are not affected by the value of SCTLR_EL2.EOS:

- The indirect write of the PSTATE and PC values from SPSR_EL2 and ELR_EL2 on exception return is synchronized.
- Behavior of accessing the banked copies of the stack pointer using the SP register name for loads, stores, and data processing instructions.
- Exit from Debug state.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES1.

**Bits [10:7]**

Reserved, RES0.

**nAA, bit [6]**

*When FEAT_LSE2 is implemented:*

Non-aligned access. This bit controls generation of Alignment faults at EL2 under certain conditions.

- **0b0** LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLR, STLRH, STLUR, and STLURH generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes for accesses.
- **0b1** This control bit does not cause LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLR, STLRH, STLUR, or STLURH to generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bits [5:4]**

Reserved, RES1.

**SA, bit [3]**

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL2 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then an SP alignment fault exception is generated. For more information, see *SP alignment checking on page D1-2327.*

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**C, bit [2]**

Cacheability control, for data accesses.

- **0b0** All data accesses to Normal memory from EL2, and all Normal memory accesses to the EL2 translation tables, are Non-cacheable for all levels of data and unified cache.
- **0b1** This control has no effect on the Cacheability of:
  - Data access to Normal memory from EL2.
  - Normal memory accesses to the EL2 translation tables.

This bit has no effect on the EL1&0 or EL3 translation regimes.

In a system where the PE resets into EL2, this field resets to 0.

**A, bit [1]**

Alignment check enable. This is the enable bit for Alignment fault checking at EL2:

- **0b0** Alignment fault checking disabled when executing at EL2.
Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

<table>

In a system where the PE resets into EL2, this field resets to an architecturally **UNKNOWN** value.

### When \( \text{HCR\_EL2.E2H} == 1 \) and \( \text{HCR\_EL2.TGE} == 1 \):

![Diagram](attachment:register_diagram.png)

This format applies only from Armv8.1 when EL2 is enabled in the current Security state and \( \text{HCR\_EL2.\{E2H, TGE\}} == \{1, 1\} \).

#### Bits [63:50]

Reserved, **RES0**.

#### TWEDEL, bits [49:46]

*When FEAT\_TWED is implemented:*

TWE Delay. A 4-bit unsigned number that, when SCTL\_EL2.TWEDEn is 1, encodes the minimum delay in taking a trap of WFE caused by SCTL\_EL2.nTWE as \( 2^{(\text{TWEDEL} + 8)} \) cycles.

In a system where the PE resets into EL2, this field resets to an architecturally **UNKNOWN** value.
**Otherwise:**

Reserved, RES0.

**TWEDEn, bit [45]**

*When FEAT_TWED is implemented:*

TWE Delay Enable. Enables a configurable delayed trap of the WFE instruction caused by SCTLR_EL2.nTWE.

- **0b0** The delay for taking a WFE trap is IMPLEMENTATION DEFINED.
- **0b1** The delay for taking a WFE trap is at least the number of cycles defined in SCTLR_EL2.TWEDEL.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**DSSBS, bit [44]**

*When FEAT_SSBS is implemented:*

Default PSTATE.SSBS value on Exception Entry.

- **0b0** PSTATE.SSBS is set to 0 on an exception to EL2.
- **0b1** PSTATE.SSBS is set to 1 on an exception to EL2.

In a system where the PE resets into EL2, this field resets to an IMPLEMENTATION DEFINED value.

**Otherwise:**

Reserved, RES0.

**ATA, bit [43]**

*When FEAT_MTE is implemented:*

Allocation Tag Access in EL2. When SCR_EL3.ATA=1, controls EL2 access to Allocation Tags.

When access to Allocation Tags is prevented:

- Instructions which Load or Store data are Unchecked.
- Instructions which Load or Store Allocation Tags treat the Allocation Tag as RAZ/WI.
- Instructions which insert Logical Address Tags into addresses treat the Allocation Tag used to generate the Logical Address Tag as 0.
- Cache maintenance instructions which invalidate Allocation Tags from caches behave as the equivalent Clean and Invalidate operation on Allocation Tags.

- **0b0** Access to Allocation Tags is prevented.
- **0b1** Access to Allocation Tags is not prevented.

This bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**ATA0, bit [42]**

*When FEAT_MTE is implemented:*

Allocation Tag Access in EL0. When SCR_EL3.ATA=1, controls EL0 access to Allocation Tags.

When access to Allocation Tags is prevented:

- Instructions which Load or Store data are Unchecked.
- Instructions which Load or Store Allocation Tags treat the Allocation Tag as RAZ/WI.
- Instructions which insert Logical Address Tags into addresses treat the Allocation Tag used to generate the Logical Address Tag as 0.
• Cache maintenance instructions which invalidate Allocation Tags from caches behave as the equivalent Clean and Invalidate operation on Allocation Tags.

0b0  Access to Allocation Tags is prevented.
0b1  Access to Allocation Tags is not prevented.

This field is permitted to be cached in a TLB.

Note
Software may change this control bit on a context switch.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

TCF, bits [41:40]
When FEAT_MTE is implemented:
Tag Check Fault in EL2. Controls the effect of Tag Check Faults due to Loads and Stores in EL2.
0b00  Tag Check Faults have no effect on the PE.
0b01  Tag Check Faults cause a synchronous exception.
0b10  Tag Check Faults are asynchronously accumulated.

The value 0b11 is reserved.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

TCF0, bits [39:38]
When FEAT_MTE is implemented:
Tag Check Fault in EL0. Controls the effect of Tag Check Faults due to Loads and Stores in EL0.
0b00  Tag Check Faults have no effect on the PE.
0b01  Tag Check Faults cause a synchronous exception.
0b10  Tag Check Faults are asynchronously accumulated.

The value 0b11 is reserved.

Note
Software may change this control bit on a context switch.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

ITFSB, bit [37]
When FEAT_MTE is implemented:
When synchronous exceptions are not being generated by Tag Check Faults which are generated for Loads and Stores in EL0, EL1 or EL2, controls the auto-synchronization of Tag Check Faults into TFSR2_EL0, TFSR_EL1 and TFSR_EL2.
0b0  Tag Check Faults are not synchronized on entry to EL2.
0b1  Tag Check Faults are synchronized on entry to EL2.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
BT1, bit [36]

When FEAT_BTI is implemented:

PAC Branch Type compatibility at EL2.

0b0 When the PE is executing at EL2, PACIASP and PACIBSP are compatible with PSTATE.BTYPE == 0b11.

0b1 When the PE is executing at EL2, PACIASP and PACIBSP are not compatible with PSTATE.BTYPE == 0b11.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BT0, bit [35]

When FEAT_BTI is implemented:

PAC Branch Type compatibility at EL0.

0b0 When the PE is executing at EL0, PACIASP and PACIBSP are compatible with PSTATE.BTYPE == 0b11.

0b1 When the PE is executing at EL0, PACIASP and PACIBSP are not compatible with PSTATE.BTYPE == 0b11.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [34:32]

Reserved, RES0.

EnIA, bit [31]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication (using the APIAKey_EL1 key) of instruction addresses in the EL2&0 translation regime.

For more information, see System register control of pointer authentication on page D5-2533.

0b0 Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is not enabled.

0b1 Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is enabled.

Note

This field controls the behavior of the AddPACIA and AuthIA pseudocode functions. Specifically, when the field is 1, AddPACIA returns a copy of a pointer to which a pointer authentication code has been added, and AuthIA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnIB, bit [30]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication (using the APIBKey_EL1 key) of instruction addresses in the EL2&0 translation regime.
For more information, see System register control of pointer authentication on page D5-2533.

0b0  Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is not enabled.
0b1  Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is enabled.

Note
This field controls the behavior of the AddPACIB and AuthIB pseudocode functions. Specifically, when the field is 1, AddPACIB returns a copy of a pointer to which a pointer authentication code has been added, and AuthIB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

LSMAOE, bit [29]
When FEAT_LSMAOC is implemented:
Load Multiple and Store Multiple Atomicity and Ordering Enable.

0b0  For all memory accesses at EL0, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.
0b1  The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL0 is as defined for Armv8.0.

This bit is permitted to be cached in a TLB.
In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES1.

nTLSMD, bit [28]
When FEAT_LSMAOC is implemented:
No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory.

0b0  All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.
0b1  All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.

This bit is permitted to be cached in a TLB.
In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES1.

EnDA, bit [27]
When FEAT_PAuth is implemented:
Controls enabling of pointer authentication (using the APDAKey_EL1 key) of instruction addresses in the EL2&0 translation regime.

For more information, see System register control of pointer authentication on page D5-2533.

0b0  Pointer authentication (using the APDAKey_EL1 key) of data addresses is not enabled.
0b1  Pointer authentication (using the APDAKey_EL1 key) of data addresses is enabled.
This field controls the behavior of the AddPACDA and AuthDA pseudocode functions. Specifically, when the field is 1, AddPACDA returns a copy of a pointer to which a pointer authentication code has been added, and AuthDA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**UCI, bit [26]**

Traps execution of cache maintenance instructions at EL0 to EL2, from AArch64 state only. This applies to DC CVAU, DC CIVAC, DC CVAC, DC CVAP, and IC IVAU.

If FEAT_DPB2 is implemented, this trap also applies to DC CVADP.

If FEAT_MTE is implemented, this trap also applies to DC CIGVAC, DC CIGDVAC, DC CGVAC, DC CGDVAC, DC CGVAP, and DC CGDVAP.

If FEAT_DPB2 and FEAT_MTE are implemented, this trap also applies to DC CGVADP and DC CGDVADP.

- **0b0** Any attempt to execute an instruction that this trap applies to at EL0 using AArch64 is trapped to EL2.
- **0b1** This control does not cause any instructions to be trapped.

If the Point of Coherency is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean, or clean and invalidate instruction that operates by VA to the point of coherency can be trapped when the value of this control is 1.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**EE, bit [25]**

Endianness of data accesses at EL2, stage 1 translation table walks in the EL2 or EL2&0 translation regime, and stage 2 translation table walks in the EL2&0 translation regime.

The possible values of this bit are:

- **0b0** Explicit data accesses at EL2, stage 1 translation table walks in the EL2 or EL2&0 translation regime, and stage 2 translation table walks in the EL2&0 translation regime are little-endian.
- **0b1** Explicit data accesses at EL2, stage 1 translation table walks in the EL2 or EL2&0 translation regime, and stage 2 translation table walks in the EL2&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an IMPLEMENTATION DEFINED value.
**E0E, bit [24]**

Endianness of data accesses at EL0.
- 0b0: Explicit data accesses at EL0 are little-endian.
- 0b1: Explicit data accesses at EL0 are big-endian.

If an implementation only supports Little-endian accesses at EL0 then this bit is RES0. This option is not permitted when SCTLR_EL1.EE is RES1.

If an implementation only supports Big-endian accesses at EL0 then this bit is RES1. This option is not permitted when SCTLR_EL1.EE is RES0.

This bit has no effect on the endianness of LDTR, LDTRH, LDTRSH, LDTRSW, STTR, and STTRH instructions executed at EL1.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**SPAN, bit [23]**

Set Privileged Access Never, on taking an exception to EL2.
- 0b0: PSTATE.PAN is set to 1 on taking an exception to EL2.
- 0b1: The value of PSTATE.PAN is left unchanged on taking an exception to EL2.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**EIS, bit [22]**

*When FEAT_ExS is implemented:*

Exception Entry is a context synchronization event.
- 0b0: The taking of an exception to EL2 is not a context synchronization event.
- 0b1: The taking of an exception to EL2 is a context synchronization event.

If SCTLR_EL2.EIS is set to 0b0:
- Indirect writes to ESR_EL2, FAR_EL2, SPSR_EL2, ELR_EL2, HPFAR_EL2 are synchronized on exception entry to EL2, so that a direct read of the register after exception entry sees the indirectly written value caused by the exception entry.
- Memory transactions, including instruction fetches, from an Exception level always use the translation resources associated with that translation regime.
- Exception Catch debug events are synchronous debug events.
- DCPS* and DRPS instructions are context synchronization events.

The following are not affected by the value of SCTLR_EL2.EIS:
- Changes to the PSTATE information on entry to EL2.
- Behavior of accessing the banked copies of the stack pointer using the SP register name for loads, stores and data processing instructions.
- Exit from Debug state.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES1.

**IESB, bit [21]**

*When FEAT_IESB is implemented:*

Implicit Error Synchronization event Enable.
- 0b0: Disabled.
- 0b1: An implicit error synchronization event is added:
  - After each exception taken to EL2.
  - Before the operational pseudocode of each ERET instruction executed at EL2.
When the PE is in Debug state, the effect of this field is CONSTRAINED UNPREDICTABLE, and its Effective value might be 0 or 1 regardless of the value of the field. If the Effective value of the field is 1, then an implicit error synchronization event is added after each DCPSx instruction taken to EL2 and before each DRPS instruction executed at EL2, in addition to the other cases where it is added.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

### TSCXT, bit [20]

**When FEAT_CSV2 is implemented:**

- **0b0** EL0 access to SCXTNUM_EL0 is not disabled by this mechanism.
- **0b1** EL0 access to SCXTNUM_EL0 is disabled, causing an exception to EL2, and the SCXTNUM_EL0 value is treated as 0.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES1.

### WXN, bit [19]

Write permission implies XN (Execute-never). For the EL2 or EL2&0 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

- **0b0** This control has no effect on memory access permissions.
- **0b1** Any region that is writable in the EL2 or EL2&0 translation regime is forced to XN for accesses from software executing at EL2.

This bit applies only when SCTLR_EL2.M bit is set.

The WXN bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

### nTWE, bit [18]

Traps execution of WFE instructions at EL0 to EL2, from both Execution states.

- **0b0** Any attempt to execute a WFE instruction at EL0 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
- **0b1** This control does not cause any instructions to be trapped.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

--- **Note** ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

---

### Bit [17]

Reserved, RES0.

### nTWI, bit [16]

Traps execution of WFI instructions at EL0 to EL2, from both Execution states.

- **0b0** Any attempt to execute a WFI instruction at EL0 is trapped EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
0b1  This control does not cause any instructions to be trapped.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

UCT, bit [15]

Traps EL0 accesses to the CTR_EL0 to EL2, from AArch64 state only.
0b0  Accesses to the CTR_EL0 from EL0 using AArch64 are trapped to EL2.
0b1  This control does not cause any instructions to be trapped.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

DZE, bit [14]

Traps execution of DC ZVA instructions at EL0 to EL2, from AArch64 state only.
If FEAT_MTE is implemented, this trap also applies to DC GVA and DC GZVA.
0b0  Any attempt to execute an instruction that this trap applies to at EL0 using AArch64 is trapped to EL2. Reading DCZID_EL0.DZP from EL0 returns 1, indicating that the instructions that this trap applies to are not supported.
0b1  This control does not cause any instructions to be trapped.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

EnDB, bit [13]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication (using the APDBKey_EL1 key) of instruction addresses in the EL2&0 translation regime.
For more information, see System register control of pointer authentication on page D5-2533.
0b0  Pointer authentication (using the APDBKey_EL1 key) of data addresses is not enabled.
0b1  Pointer authentication (using the APDBKey_EL1 key) of data addresses is enabled.

--- Note ---

This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. Specifically, when the field is 1, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

---

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL2 and EL0:
0b0  All instruction access to Normal memory from EL2 and EL0 are Non-cacheable for all levels of instruction and unified cache.
If the value of SCTLR_EL2.M is 0, instruction accesses from stage 1 of the EL2&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
0b1  This control has no effect on the Cacheability of instruction access to Normal memory from EL2 and EL0.

If the value of SCTLR_EL2.M is 0, instruction accesses from stage 1 of the EL2&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL3 translation regimes.
In a system where the PE resets into EL2, this field resets to 0.

EOS, bit [11]

When FEAT_ExS is implemented:
Exception exit is a context synchronization event.

0b0  An exception return from EL2 is not a context synchronization event.
0b1  An exception return from EL2 is a context synchronization event.

If SCTLR_EL2.EOS is set to 0b0:
• Memory transactions, including instruction fetches, from an Exception level always use the translation resources associated with that translation regime.
• Exception Catch debug events are synchronous debug events.
• DCPS* and DRPS instructions are context synchronization events.

The following are not affected by the value of SCTLR_EL2.EOS:
• The indirect write of the PSTATE and PC values from SPSR_EL2 and ELR_EL2 on exception return is synchronized.
• Exception Catch debug events are synchronous debug events.
• DCPS* and DRPS instructions are context synchronization events.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES1.

EnRCTX, bit [10]

When FEAT_SPECRES is implemented:
Enable EL0 Access to the following instructions:
• AArch32 CFPRCTX, DVPRCTX and CPPRCTX instructions.
• AArch64 CFP RCTX, DVP RCT and CPP RCTX instructions.

The defined values are:
0b0  EL0 access to these instructions is disabled, and these instructions are trapped to EL1.
0b1  EL0 access to these instructions is enabled.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bit [9]
Reserved, RES0.

SED, bit [8]

When EL0 is capable of using AArch32:
SETEND instruction disable. Disables SETEND instructions at EL0 using AArch32.

0b0  SETEND instruction execution is enabled at EL0 using AArch32.
0b1  SETEND instructions are UNDEFINED at EL0 using AArch32.
If the implementation does not support mixed-endian operation at any Exception level, this bit is RES1.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES1.

**ITD, bit [7]**

When EL0 is capable of using AArch32:

IT Disable. Disables some uses of IT instructions at EL0 using AArch32.

0b0  All IT instruction functionality is enabled at EL0 using AArch32.
0b1  Any attempt at EL0 using AArch32 to execute any of the following is UNDEFINED:

- All encodings of the IT instruction with hw1[3:0]!={1000}.
- All encodings of the subsequent instruction with the following values for hw1:
  - 0b11xxxxxxxx: All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
  - 0b1011xxxxxxx: All instructions in 'Miscellaneous 16-bit instructions' in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile, section F3.2.5.
  - 0b10100xxxxxx: ADD Rd, PC, #imm
  - 0b01001xxxxxxxx: LDR Rd, [PC, #imm]
  - 0b01001xxxxxxx: ADD Rd, PC, #imm
  - 0b01001xxxxxx: ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
  - 0b010001x1xxx111xxx: ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn.

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:

- A 16-bit instruction, that can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information see Changes to an ITD control by an instruction in an IT block on page E1-3998.

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAZ/WI.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES1.

**nAA, bit [6]**

When FEAT_LSE2 is implemented:

Non-aligned access. This bit controls generation of Alignment faults at EL2 and EL0 under certain conditions.

0b0  LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLNR, STLLRH, and STLURH generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes for accesses.
0b1 This control bit does not cause LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAR, LDARH, LDLAR, LDLARH, STLRR, STLRRH, STLUR, STLURH, or STLRURH to generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**CP15BEN, bit [5]**

*When EL0 is capable of using AArch32:*

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==0b1111) encoding space from EL0:

0b0 EL0 using AArch32: EL0 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is UNDEFINED.

0b1 EL0 using AArch32: EL0 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is enabled.

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAO/WI.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**SA0, bit [4]**

SP Alignment check enable for EL0. When set to 1, if a load or store instruction executed at EL0 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see SP alignment checking on page D1-2327.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**SA, bit [3]**

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL2 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see SP alignment checking on page D1-2327.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**C, bit [2]**

Cacheability control, for data accesses.

0b0 All data access to Normal memory from EL2 and EL0, and all Normal memory accesses to the EL2&0 translation tables, are Non-cacheable for all levels of data and unified cache.

0b1 This control has no effect on the Cacheability of:

- Data access to Normal memory from EL2 and EL0.
- Normal memory accesses to the EL2&0 translation tables.

This bit has no effect on the EL3 translation regimes.

In a system where the PE resets into EL2, this field resets to 0.

**A, bit [1]**

Alignment check enable. This is the enable bit for Alignment fault checking at EL2 and EL0.

0b0 Alignment fault checking disabled when executing at EL2 and EL0.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

0b1 Alignment fault checking enabled when executing at EL2 and EL0.
All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

In a system where the PE resets into EL2, this field resets to an architecturally _UNKNOWN_ value.

**M, bit [0]**

MMU enable for EL2&0 stage 1 address translation. Possible values of this bit are:

- **0b0**: EL2&0 stage 1 address translation disabled.
  
  See the SCTLR_EL2.I field for the behavior of instruction accesses to Normal memory.

- **0b1**: EL2&0 stage 1 address translation enabled.

In a system where the PE resets into EL2, this field resets to 0.

### Accessing the SCTLR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic SCTLR_EL2 or SCTLR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, SCTLR_EL2**

D13.2.115  SCTLR_EL3, System Control Register (EL3)

The SCTLR_EL3 characteristics are:

**Purpose**

Provides top level control of the system, including its memory system, at EL3.

**Configurations**

This register is present only when EL3 is implemented. Otherwise, direct accesses to SCTLR_EL3 are UNDEFINED.

**Attributes**

SCTLR_EL3 is a 64-bit register.

**Field descriptions**

The SCTLR_EL3 bit assignments are:

<table>

**DSSBS, bit [44]**

*When FEAT_SSSBS is implemented:*

Default PSTATE.SSSBS value on Exception Entry.

- **0b0**: PSTATE.SSSBS is set to 0 on an exception to EL3.
- **0b1**: PSTATE.SSSBS is set to 1 on an exception to EL3.

In a system where the PE resets into EL3, this field resets to an IMPLEMENTATION DEFINED value.

**ATA, bit [43]**

*When FEAT_MTE is implemented:*

Allocation Tag Access in EL3. Controls EL3 access to Allocation Tags.
When access to Allocation Tags is prevented:

- Instructions which Load or Store data are Unchecked.
- Instructions which Load or Store Allocation Tags treat the Allocation Tag as RAZ/WI.
- Instructions which insert Logical Address Tags into addresses treat the Allocation Tag used to generate the Logical Address Tag as 0.
- Cache maintenance instructions which invalidate Allocation Tags from caches behave as the equivalent Clean and Invalidate operation on Allocation Tags.

0b0  Access to Allocation Tags is prevented.
0b1  Access to Allocation Tags is not prevented.

This bit is permitted to be cached in a TLB.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bit [42]
Reserved, RES0.

TCF, bits [41:40]

When FEAT_MTE is implemented:
Tag Check Fault in EL3. Controls the effect of Tag Check Faults due to Loads and Stores in EL3.
0b00  Tag Check Faults have no effect on the PE.
0b01  Tag Check Faults cause a synchronous exception.
0b10  Tag Check Faults are asynchronously accumulated.
The value 0b11 is reserved.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [39:38]
Reserved, RES0.

ITFSB, bit [37]

When FEAT_MTE is implemented:
When asynchronous exceptions are being generated by Tag Check Faults which are generated for Loads and Stores at any exception level, controls the auto-synchronisation of Tag Check Faults into TFSRE0_EL1 and TFSR_ELx
0b0  Tag Check Faults are not synchronized on entry to EL3.
0b1  Tag Check Faults are synchronized on entry to EL3.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

BT, bit [36]

When FEAT_BTI is implemented:
PAC Branch Type compatibility at EL3.
0b0  When the PE is executing at EL3, PACIASP and PACIBSP are compatible with PSTATE.BTYPE == 0b11.
0b1  When the PE is executing at EL3, PACIASP and PACIBSP are not compatible with PSTATE.BTYPE == 0b11.
In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**Bits [35:32]**
Reserved, RES0.

**EnIA, bit [31]**

*When FEAT_PAuth is implemented:*

Controls enabling of pointer authentication (using the APIAKey_EL1 key) of instruction addresses in the EL3 translation regime.

Possible values of this bit are:

- **0b0** Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is not enabled.
- **0b1** Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is enabled.

For more information, see *System register control of pointer authentication on page D5-2533.*

--- **Note** ---

This field controls the behavior of the AddPACIA and AuthIA pseudocode functions. Specifically, when the field is 1, AddPACIA returns a copy of a pointer to which a pointer authentication code has been added, and AuthIA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**EnIB, bit [30]**

*When FEAT_PAuth is implemented:*

Controls enabling of pointer authentication (using the APIBKey_EL1 key) of instruction addresses in the EL3 translation regime.

Possible values of this bit are:

- **0b0** Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is not enabled.
- **0b1** Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is enabled.

For more information, see *System register control of pointer authentication on page D5-2533.*

--- **Note** ---

This field controls the behavior of the AddPACIB and AuthIB pseudocode functions. Specifically, when the field is 1, AddPACIB returns a copy of a pointer to which a pointer authentication code has been added, and AuthIB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**Bits [29:28]**
Reserved, RES1.
EnDA, bit [27]

*When FEAT_PAuth is implemented:*

Controls enabling of pointer authentication (using the APDAKey_EL1 key) of instruction addresses in the EL3 translation regime.

- **0b0**: Pointer authentication (using the APDAKey_EL1 key) of data addresses is not enabled.
- **0b1**: Pointer authentication (using the APDAKey_EL1 key) of data addresses is enabled.

For more information, see *System register control of pointer authentication* on page D5-2533.

---

**Note**

This field controls the behavior of the AddPACDA and AuthDA pseudocode functions. Specifically, when the field is 1, AddPACDA returns a copy of a pointer to which a pointer authentication code has been added, and AuthDA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

---

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

Bit [26]

Reserved, RES0.

Bit [25]

Reserved, RES1.

EE, bit [25]

Endianness of data accesses at EL3, and stage 1 translation table walks in the EL3 translation regime.

- **0b0**: Explicit data accesses at EL3, and stage 1 translation table walks in the EL3 translation regime are little-endian.
- **0b1**: Explicit data accesses at EL3, and stage 1 translation table walks in the EL3 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

In a system where the PE resets into EL3, this field resets to an IMPLEMENTATION DEFINED value.

Bit [24]

Reserved, RES0.

Bit [23]

Reserved, RES1.

EIS, bit [22]

*When FEAT_ExS is implemented:*

Exception Entry is Context Synchronizing.

- **0b0**: The taking of an exception to EL3 is not a context synchronizing event.
- **0b1**: The taking of an exception to EL3 is a context synchronizing event.

If SCTLR_EL3.EIS is set to **0b0**:
- Indirect writes to ESR_EL3, FAR_EL3, SPSR_EL3, ELR_EL3 are synchronized on exception entry to EL3, so that a direct read of the register after exception entry sees the indirectly written value caused by the exception entry.
- Memory transactions, including instruction fetches, from an Exception level always use the translation resources associated with that translation regime.
Exception Catch debug events are synchronous debug events.
DCPS* and DRPS instructions are context synchronization events.

The following are not affected by the value of SCTL_EL3.EIS:
Changes to the PSTATE information on entry to EL3.
Behavior of accessing the banked copies of the stack pointer using the SP register name for loads, stores and data processing instructions.
Debug state exit.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES1.

**IESB, bit [21]**

When **FEAT_IESB** is implemented:
Implicit Error Synchronization event enable.

0b0  Disabled.
0b1  An implicit error synchronization event is added:
  - At each exception taken to EL3.
  - Before the operational pseudocode of each ERET instruction executed at EL3.

When the PE is in Debug state, the effect of this field is CONSTRAINED UNPREDICTABLE, and its Effective value might be 0 or 1 regardless of the value of the field. If the Effective value of the field is 1, then an implicit error synchronization event is added after each DCPSx instruction taken to EL3 and before each DRPS instruction executed at EL3, in addition to the other cases where it is added. When **FEAT_DoubleFault** is implemented, and the Effective value of SCR_EL3.NMEA is 1, this field is ignored and its Effective value is 1.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**Bit [20]**
Reserved, RES0.

**WXN, bit [19]**
Write permission implies XN (Execute-never). For the EL3 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

0b0  This control has no effect on memory access permissions.
0b1  Any region that is writable in the EL3 translation regime is forced to XN for accesses from software executing at EL3.

This bit applies only when SCTL_EL3.M bit is set.
The WXN bit is permitted to be cached in a TLB.
In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

**Bit [18]**
Reserved, RES1.

**Bit [17]**
Reserved, RES0.

**Bit [16]**
Reserved, RES1.
Bits [15:14]

Reserved, RES0.

EnDB, bit [13]

When FEAT_PAuth is implemented:
Controls enabling of pointer authentication (using the APDBKey_EL1 key) of instruction addresses in the EL3 translation regime.

0b0 Pointer authentication (using the APDBKey_EL1 key) of data addresses is not enabled.
0b1 Pointer authentication (using the APDBKey_EL1 key) of data addresses is enabled.

For more information, see System register control of pointer authentication on page D5-2533.

Note
This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. Specifically, when the field is 1, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

I, bit [12]

Instruction access Cacheability control, for accesses at EL3:

0b0 All instruction access to Normal memory from EL3 are Non-cacheable for all levels of instruction and unified cache.
If the value of SCTLR_EL3.M is 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
0b1 This control has no effect on the Cacheability of instruction access to Normal memory from EL3.
If the value of SCTLR_EL3.M is 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0, EL2, or EL2&0 translation regimes.
In a system where the PE resets into EL3, this field resets to 0.

EOS, bit [11]

When FEAT_ExS is implemented:
Exception Exit is Context Synchronizing.

0b0 An exception return from EL3 is not a context synchronizing event
0b1 An exception return from EL3 is a context synchronizing event

If SCTLR_EL3.EOS is set to 0b0:
• Memory transactions, including instruction fetches, from an Exception level always use the translation resources associated with that translation regime.
• Exception Catch debug events are synchronous debug events.
• DCPS* and DRPS instructions are context synchronization events.
The following are not affected by the value of SCTLR_EL3.EOS:
• The indirect write of the PSTATE and PC values from SPSR_EL3 and ELR_EL3 on exception return is synchronized.
• If the PE enters Debug state before the first instruction after an Exception return from EL3 to Non-secure state, any pending Halting debug event completes execution.
• The GIC behavior that allocates interrupts to FIQ or IRQ changes simultaneously with leaving the EL3 Exception level.
• Behavior of accessing the banked copies of the stack pointer using the SP register name for loads, stores and data processing instructions.
• Exit from Debug state.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

Bits [10:7]

Reserved, RES0.

nAA, bit [6]

When FEAT_LSE2 is implemented:

Non-aligned access. This bit controls generation of Alignment faults at EL3 under certain conditions.

\[
\begin{align*}
0b0 & : \text{LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLRR, STLRH, STLUR, and STLURH generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes for accesses.} \\
0b1 & : \text{This control bit does not cause LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLRR, STLRH, STLUR, or STLURH to generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes.}
\end{align*}
\]

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [5:4]

Reserved, RES1.

SA, bit [3]

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL3 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see SP alignment checking on page D1-2327.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

C, bit [2]

Cacheability control, for data accesses.

\[
\begin{align*}
0b0 & : \text{All data access to Normal memory from EL3, and all Normal memory accesses to the EL3 translation tables, are Non-cacheable for all levels of data and unified cache.} \\
0b1 & : \text{This control has no effect on the Cacheability of:} \\
& \quad \cdot \text{Data access to Normal memory from EL3.} \\
& \quad \cdot \text{Normal memory accesses to the EL3 translation tables.}
\end{align*}
\]

This bit has no effect on the EL1&0, EL2, or EL2&0 translation regimes.

In a system where the PE resets into EL3, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL3.

\[
\begin{align*}
0b0 & : \text{Alignment fault checking disabled when executing at EL3.}
\end{align*}
\]
Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

0b1 Alignment fault checking enabled when executing at EL3.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

**M, bit [0]**

MMU enable for EL3 stage 1 address translation. Possible values of this bit are:

0b0 EL3 stage 1 address translation disabled.

See the SCTLR_EL3.I field for the behavior of instruction accesses to Normal memory.

0b1 EL3 stage 1 address translation enabled.

In a system where the PE resets into EL3, this field resets to 0.

### Accessing the SCTLR_EL3

Accesses to this register use the following encodings in the System instruction encoding space:

#### MRS <Xt>, SCTLR_EL3

<table>
<thead>
<tr>
<th>op0</th>

```
D13.2.116 SCXTNUM_EL0, EL0 Read/Write Software Context Number

The SCXTNUM_EL0 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL0 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

Configurations

This register is present only when FEAT_CSV2 is implemented. Otherwise, direct accesses to SCXTNUM_EL0 are UNDEFINED.

Attributes

SCXTNUM_EL0 is a 64-bit register.

Field descriptions

The SCXTNUM_EL0 bit assignments are:

<table>

D13.2.118   SCXTNUM_EL2, EL2 Read/Write Software Context Number

The SCXTNUM_EL2 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL2 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

Configurations

This register is present only when FEAT_CSV2 is implemented. Otherwise, direct accesses to SCXTNUM_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

SCXTNUM_EL2 is a 64-bit register.

Field descriptions

The SCXTNUM_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Software Context Number. A number to identify the context within the EL2 exception level. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

Accessing the SCXTNUM_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic SCXTNUM_EL2 or SCXTNUM_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRS <Xt>, SCXTNUM_EL2}
\]

```
if PSTATE_EL == EL0 then
    UNDEFINED;
elsif PSTATE_EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elsif PSTATE_EL == EL2 then
    if Halted() && HaveEL(EL3) && EDSCR.SDD == '1' && boolean IMPLEMENTATION_DEFINED "EL3 trap priority when SDD == '1'" && SCR_EL3.EnSCXT == '0' then
        UNDEFINED;
    elsif HaveEL(EL3) && SCR_EL3.EnSCXT == '0' then
        if Halted() && EDSCR.SDD == '1' then
            UNDEFINED;
```

### D13.2.119 SCXTNUM_EL3, EL3 Read/Write Software Context Number

The SCXTNUM_EL3 characteristics are:

**Purpose**

Provides a number that can be used to separate out different context numbers with the EL3 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

**Configurations**

This register is present only when EL3 is implemented and FEAT_CSV2 is implemented. Otherwise, direct accesses to SCXTNUM_EL3 are UNDEFINED.

**Attributes**

SCXTNUM_EL3 is a 64-bit register.

**Field descriptions**

The SCXTNUM_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Software Context Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 to 0</td>
<td></td>

D13.2.120 TCR_EL1, Translation Control Register (EL1)

The TCR_EL1 characteristics are:

**Purpose**

The control register for stage 1 of the EL1&0 translation regime.

**Configurations**

AArch64 System register TCR_EL1[31:0] is architecturally mapped to AArch32 System register TTBCR[31:0].

AArch64 System register TCR_EL1[63:32] is architecturally mapped to AArch32 System register TTBCR2[31:0].

**Attributes**

TCR_EL1 is a 64-bit register.

**Field descriptions**

The TCR_EL1 bit assignments are:

Any of the bits in TCR_EL1, other than the A1 bit and the EPDx bits when they have the value 1, are permitted to be cached in a TLB.

**Bits [63:59]**

Reserved, RES0.

**TCMA1, bit [58]**

*When FEAT_MTE is implemented:*

Controls the generation of Unchecked accesses at EL1, and at EL0 if HCR_EL2.{E2H,TGE}!={1,1}, when address[59:55] = 0b11111.

0b0 This control has no effect on the generation of Unchecked accesses at EL1 or EL0.

0b1 All accesses at EL1 and EL0 are Unchecked.
Note
Software may change this control bit on a context switch.

Otherwise:
Reserved, RES0.

TCMA0, bit [57]

When FEAT_MTE is implemented:
Controls the generation of Unchecked accesses at EL1, and at EL0 if
HCR_EL2.{E2H,TGE}!={1,1}, when address[59:55] = 0b00000.

0b0 This control has no effect on the generation of Unchecked accesses at EL1 or EL0.
0b1 All accesses at EL1 and EL0 are Unchecked.

Note
Software may change this control bit on a context switch.

Otherwise:
Reserved, RES0.

E0PD1, bit [56]

When FEAT_E0PD is implemented:
Faulting control for Unprivileged access to any address translated by TTBR1_EL1.

0b0 Unprivileged access to any address translated by TTBR1_EL1 will not generate a fault by this mechanism.
0b1 Unprivileged access to any address translated by TTBR1_EL1 will generate a level 0 translation fault

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

E0PD0, bit [55]

When FEAT_E0PD is implemented:
Faulting control for Unprivileged access to any address translated by TTBR0_EL1.

0b0 Unprivileged access to any address translated by TTBR0_EL1 will not generate a fault by this mechanism.
0b1 Unprivileged access to any address translated by TTBR0_EL1 will generate a level 0 translation fault

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

NFD1, bit [54]

When FEAT_SVE is implemented:
Non-fault translation table walk disable for stage 1 translations using TTBR1_EL1.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault unprivileged access for a virtual address that is translated using TTBR1_EL1.

If SVE is implemented, the affected access types include:
• All accesses due to an SVE non-fault contiguous load instruction.
Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.

Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

For more information, see FEAT_SVE.

\[0b0\] Does not disable stage 1 translation table walks using TTBR1_EL1.

\[0b1\] A TLB miss on a virtual address that is translated using TTBR1_EL1 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

### NFD0, bit [53]

**When FEAT_SVE is implemented:**

Non-fault translation table walk disable for stage 1 translations using TTBR0_EL1.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault unprivileged access for a virtual address that is translated using TTBR0_EL1.

If SVE is implemented, the affected access types include:

- All accesses due to an SVE non-fault contiguous load instruction.
- Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
- Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

For more information, see FEAT_SVE.

\[0b0\] Does not disable stage 1 translation table walks using TTBR0_EL1.

\[0b1\] A TLB miss on a virtual address that is translated using TTBR0_EL1 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

### TBID1, bit [52]

**When FEAT_PAuth is implemented:**

Controls the use of the top byte of instruction addresses for address matching.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see *Address tagging in AArch64 state* on page D5-2528.

\[0b0\] TCR_EL1.TBI1 applies to Instruction and Data accesses.

\[0b1\] TCR_EL1.TBI1 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR1_EL1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

### TBID0, bit [51]

**When FEAT_PAuth is implemented:**

Controls the use of the top byte of instruction addresses for address matching.
For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see *Address tagging in AArch64 state* on page D5-2528.

\[0b0\] TCR_EL1.TBI0 applies to Instruction and Data accesses.

\[0b1\] TCR_EL1.TBI0 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL1.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HWU162, bit [50]**

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

\[0b0\] For translations using TTBR1_EL1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

\[0b1\] For translations using TTBR1_EL1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HWU161, bit [49]**

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

\[0b0\] For translations using TTBR1_EL1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

\[0b1\] For translations using TTBR1_EL1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HWU160, bit [48]**

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

\[0b0\] For translations using TTBR1_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

\[0b1\] For translations using TTBR1_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

HWU159, bit [47]

When FEAT_HPDS2 is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1
translation table Block or Page entry for translations using TTBR1_EL1.

0b0 For translations using TTBR1_EL1, bit[59] of each stage 1 translation table Block or
Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR1_EL1, bit[59] of each stage 1 translation table Block or
Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the
value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU062, bit [46]

When FEAT_HPDS2 is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1
translation table Block or Page entry for translations using TTBR0_EL1.

0b0 For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or
Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or
Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the
value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU061, bit [45]

When FEAT_HPDS2 is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1
translation table Block or Page entry for translations using TTBR0_EL1.

0b0 For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or
Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or
Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the
value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
HWU060, bit [44]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

0b0   For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1   For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU059, bit [43]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

0b0   For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1   For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD1, bit [42]

When FEAT_HPDS is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR1_EL1.

0b0   Hierarchical permissions are enabled.
0b1   Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.
This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD0, bit [41]

When FEAT_HPDS is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL1.

0b0   Hierarchical permissions are enabled.
0b1   Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.
This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
HD, bit [40]

When FEAT_HAFDBS is implemented:

- **0b0**: Stage 1 hardware management of dirty state disabled.
- **0b1**: Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.

This field resets to an architecturally **UNKNOWN** value.

Otherwise:

Reserved, **RES0**.

HA, bit [39]

When FEAT_HAFDBS is implemented:

- **0b0**: Stage 1 Access flag update disabled.
- **0b1**: Stage 1 Access flag update enabled.

This field resets to an architecturally **UNKNOWN** value.

Otherwise:

Reserved, **RES0**.

TBI1, bit [38]

Top Byte ignored. Indicates whether the top byte of an address is used for address match for the TTBR1_EL1 region, or ignored and used for tagged addresses.

- **0b0**: Top Byte used in the address calculation.
- **0b1**: Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by **TTBR1_EL1**. It has an effect whether the EL1&0 translation regime is enabled or not.

If FEAT_PAuth is implemented and TCR_EL1.TBID1 is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI1 is 1 and bit [55] of the target address to be stored to the PC is 1, then bits[63:56] of that target address are also set to 1 before the address is stored in the PC, in the following cases:
- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

This field resets to an architecturally **UNKNOWN** value.

TBI0, bit [37]

Top Byte ignored. Indicates whether the top byte of an address is used for address match for the TTBR0_EL1 region, or ignored and used for tagged addresses.

- **0b0**: Top Byte used in the address calculation.
- **0b1**: Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by **TTBR0_EL1**. It has an effect whether the EL1&0 translation regime is enabled or not.

If FEAT_PAuth is implemented and TCR_EL1.TBID0 is 1, then this field only applies to Data accesses.
Otherwise, if the value of TBI0 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.

**AS, bit [36]**

ASID Size.

- 0b0 8 bit - the upper 8 bits of TTBR0_EL1 and TTBR1_EL1 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.
- 0b1 16 bit - the upper 16 bits of TTBR0_EL1 and TTBR1_EL1 are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

This field resets to an architecturally UNKNOWN value.

**Bit [35]**

Reserved, RES0.

**IPS, bits [34:32]**

Intermediate Physical Address Size.

- 0b000 32 bits, 4GB.
- 0b001 36 bits, 64GB.
- 0b010 40 bits, 1TB.
- 0b011 42 bits, 4TB.
- 0b100 44 bits, 16TB.
- 0b101 48 bits, 256TB.
- 0b110 52 bits, 4PB.

All other values are reserved.

The reserved values behave in the same way as the 0b101 or 0b110 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

If the translation granule is not 64KB, the value 0b110 is treated as reserved.

It is IMPLEMENTATION DEFINED whether an implementation that does not implement FEAT_LPA supports setting the value of 0b110 for the 64KB translation granule size or whether setting this value behaves as the 0b101 encoding.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL1 are 0b0000.

This field resets to an architecturally UNKNOWN value.

**TG1, bits [31:30]**

Granule size for the TTBR1_EL1.

- 0b0 16KB.
- 0b1 4KB.
- 0b1 64KB.

Other values are reserved.
If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

**SH1, bits [29:28]**
Shareability attribute for memory associated with translation table walks using TTBR1_EL1.

- 0b00: Non-shareable.
- 0b10: Outer Shareable.
- 0b11: Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

This field resets to an architecturally UNKNOWN value.

**ORGN1, bits [27:26]**
Outer cacheability attribute for memory associated with translation table walks using TTBR1_EL1.

- 0b00: Normal memory, Outer Non-cacheable.
- 0b01: Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

**IRGN1, bits [25:24]**
Inner cacheability attribute for memory associated with translation table walks using TTBR1_EL1.

- 0b00: Normal memory, Inner Non-cacheable.
- 0b01: Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

**EPD1, bit [23]**
Translation table walk disable for translations using TTBR1_EL1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1_EL1. The encoding of this bit is:

- 0b0: Perform translation table walks using TTBR1_EL1.
- 0b1: A TLB miss on an address that is translated using TTBR1_EL1 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

**A1, bit [22]**
Selects whether TTBR0_EL1 or TTBR1_EL1 defines the ASID. The encoding of this bit is:

- 0b0: TTBR0_EL1.ASID defines the ASID.
- 0b1: TTBR1_EL1.ASID defines the ASID.

This field resets to an architecturally UNKNOWN value.

**T1SZ, bits [21:16]**
The size offset of the memory region addressed by TTBR1_EL1. The region size is $2^{(64-T1SZ)}$ bytes.
The maximum and minimum possible values for T1SZ depend on the level of translation table and
the memory translation granule size, as described in the AArch64 Virtual Memory System
Architecture chapter.
This field resets to an architecturally UNKNOWN value.

**TG0, bits [15:14]**
Granule size for the TTBR0_EL1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>4KB</td>
</tr>
<tr>
<td>0b01</td>
<td>64KB</td>
</tr>
<tr>
<td>0b10</td>
<td>16KB</td>
</tr>
</tbody>
</table>
Other values are reserved.
If the value is programmed to either a reserved value, or a size that has not been implemented, then
the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED
choice of the sizes that has been implemented for all purposes other than the value read back from
this register.
It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value
that corresponds to the size chosen.
This field resets to an architecturally UNKNOWN value.

**SH0, bits [13:12]**
Shareability attribute for memory associated with translation table walks using TTBR0_EL1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>0b10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>0b11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>
Other values are reserved. The effect of programming this field to a Reserved value is that behavior
is CONSTRAINED UNPREDICTABLE.
This field resets to an architecturally UNKNOWN value.

**ORGN0, bits [11:10]**
Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Normal memory, Outer Non-cacheable</td>
</tr>
<tr>
<td>0b01</td>
<td>Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable</td>
</tr>
<tr>
<td>0b10</td>
<td>Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable</td>
</tr>
<tr>
<td>0b11</td>
<td>Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable</td>
</tr>
</tbody>
</table>
This field resets to an architecturally UNKNOWN value.

**IRGN0, bits [9:8]**
Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>0b01</td>
<td>Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable</td>
</tr>
<tr>
<td>0b10</td>
<td>Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable</td>
</tr>
<tr>
<td>0b11</td>
<td>Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable</td>
</tr>
</tbody>
</table>
This field resets to an architecturally UNKNOWN value.

**EPD0, bit [7]**
Translation table walk disable for translations using TTBR0_EL1. This bit controls whether a
translation table walk is performed on a TLB miss, for an address that is translated using
TTBR0_EL1. The encoding of this bit is:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Perform translation table walks using TTBR0_EL1.</td>
</tr>
</tbody>
</table>
A TLB miss on an address that is translated using TTBR0_EL1 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

**Bit [6]**

Reserved, RES0.

**T0SZ, bits [5:0]**

The size offset of the memory region addressed by TTBR0_EL1. The region size is 2\(^{64-\text{T0SZ}}\) bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

### Accessing the TCR_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic TCR_EL1 or TCR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, TCR_EL1**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>

D13.2.121 TCR_EL2, Translation Control Register (EL2)

The TCR_EL2 characteristics are:

**Purpose**

The control register for stage 1 of the EL2, or EL2&0, translation regime:

- When the Effective value of HCR_EL2.E2H is 0, this register controls stage 1 of the EL2 translation regime, that supports a single VA range, translated using TTBR0_EL2.
- When the value of HCR_EL2.E2H is 1, this register controls stage 1 of the EL2&0 translation regime, that supports both:
  - A lower VA range, translated using TTBR0_EL2.
  - A higher VA range, translated using TTBR1_EL2.

**Configurations**

AArch64 System register TCR_EL2[31:0] is architecturally mapped to AArch32 System register HTCR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

TCR_EL2 is a 64-bit register.

**Field descriptions**

The TCR_EL2 bit assignments are:

*When HCR_EL2.E2H == 0:*

Any of the bits in TCR_EL2, other than the A1 bit and the EPDx bits when they have the value 1, are permitted to be cached in a TLB.

**Bits [63:32]**

Reserved, RES0.

**Bit [31]**

Reserved, RES1.
TCMA, bit [30]

When FEAT_MTE is implemented:

Controls the generation of Unchecked accesses at EL2 when address [59:56] = 0b0000.

0b0  This control has no effect on the generation of Unchecked accesses.
0b1  All accesses are Unchecked.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID, bit [29]

When FEAT_PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see Address tagging in AArch64 state on page D5-2528.

0b0  TCR_EL2.TBI applies to Instruction and Data accesses.
0b1  TCR_EL2.TBI applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU62, bit [28]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry.

0b0  Bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1  Bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU61, bit [27]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry.

0b0  Bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1  Bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
HWU60, bit [26]

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry.

- **0b0** Bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1** Bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU59, bit [25]

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry.

- **0b0** Bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1** Bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD, bit [24]

*When FEAT_HPDS is implemented:*

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL2.

- **0b0** Hierarchical permissions are enabled.
- **0b1** Hierarchical permissions are disabled.

_____ Note _____

In this case bit[61] (APTable[0]) and bit[59] (PXNTable) of the next level descriptor attributes are required to be ignored by the PE, and are no longer reserved, allowing them to be used by software.

When disabled, the permissions are treated as if the bits are zero.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [23]

Reserved, RES1.

HD, bit [22]

*When FEAT_HAFDBS is implemented:*

Hardware management of dirty state in stage 1 translations from EL2.

- **0b0** Stage 1 hardware management of dirty state disabled.
Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1. This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**HA, bit [21]**

*When FEAT_HAFDBS is implemented:*

Hardware Access flag update in stage 1 translations from EL2.

- **0b0** Stage 1 Access flag update disabled.
- **0b1** Stage 1 Access flag update enabled.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**TBI, bit [20]**

Top Byte Ignored. Indicates whether the top byte of an address is used for address match for the TTBR0_EL2 region, or ignored and used for tagged addresses.

For more information, see Address tagging in AArch64 state on page D5-2528.

- **0b0** Top Byte used in the address calculation.
- **0b1** Top Byte ignored in the address calculation.

This affects addresses generated in EL2 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL2. It has an effect whether the EL2, or EL2&0, translation regime is enabled or not.

If FEAT_PAuth is implemented and TCR_EL2.TBID is 1, then this field only applies to Data accesses.

If the value of TBI is 1, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL2.
- An exception taken to EL2.
- An exception return to EL2.

This field resets to an architecturally UNKNOWN value.

**Bit [19]**

Reserved, RES0.

**PS, bits [18:16]**

Physical Address Size.

- **0b000** 32 bits, 4GB.
- **0b001** 36 bits, 64GB.
- **0b010** 40 bits, 1TB.
- **0b011** 42 bits, 4TB.
- **0b100** 44 bits, 16TB.
- **0b101** 48 bits, 256TB.
- **0b110** 52 bits, 4PB.

All other values are reserved.

The reserved values behave in the same way as the **0b101** or **0b110** encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

If the translation granule is not 64KB, the value **0b110** is treated as reserved.
It is IMPLEMENTATION DEFINED whether an implementation that does not implement FEAT_LPA supports setting the value of 0b110 for the 64KB translation granule size or whether setting this value behaves as the 0b101 encoding.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL2 are 0b0000.

This field resets to an architecturally UNKNOWN value.

**TG0, bits [15:14]**
Granule size for the TTBR0_EL2.
- 0b00 4KB.
- 0b01 64KB.
- 0b10 16KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

**SH0, bits [13:12]**
Shareability attribute for memory associated with translation table walks using TTBR0_EL2.
- 0b00 Non-shareable.
- 0b10 Outer Shareable.
- 0b11 Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

This field resets to an architecturally UNKNOWN value.

**ORGN0, bits [11:10]**
Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL2.
- 0b00 Normal memory, Outer Non-cacheable.
- 0b01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

**IRGN0, bits [9:8]**
Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL2.
- 0b00 Normal memory, Inner Non-cacheable.
- 0b01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

**Bits [7:6]**
Reserved, RES0.
T0SZ, bits [5:0]

The size offset of the memory region addressed by TTBR0_EL2. The region size is \(2^{(64-T0SZ)}\) bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

When FEAT_VHE is implemented and HCR_EL2.E2H == 1:

This view of the register is only valid from Armv8.1 when HCR_EL2.E2H is 1.

Any of the bits in TCR_EL2 are permitted to be cached in a TLB.

Bits [63:59]

Reserved, RES0.

TCMA1, bit [58]

When FEAT_MTE is implemented:

Controls the generation of Unchecked accesses at EL2, and at EL0 if HCR_EL2.TGE=1, when address[59:55] = \(0\) \(\overline{1}1\)1111.

- 0b0 This control has no effect on the generation of Unchecked accesses at EL2 or EL0.
- 0b1 All accesses are Unchecked.

Note

Software may change this control bit on a context switch.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
TCMA0, bit [57]

*When FEAT_MTE is implemented:*

Controls the generation of Unchecked accesses at EL2, and at EL0 if HCR_EL2.TGE=1, when `address[59:55] = 0b00000`.

*0b0* This control has no effect on the generation of Unchecked accesses at EL2 or EL0.

*0b1* All accesses are Unchecked.

--- Note ---

Software may change this control bit on a context switch.

---

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

E0PD1, bit [56]

*When FEAT_E0PD is implemented:*

Faulting control for Unprivileged access to any address translated by TTBR1_EL2.

*0b0* Unprivileged access to any address translated by TTBR1_EL2 will not generate a fault by this mechanism.

*0b1* Unprivileged access to any address translated by TTBR1_EL2 will generate a level 0 translation fault

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

E0PD0, bit [55]

*When FEAT_E0PD is implemented:*

Faulting control for Unprivileged access to any address translated by TTBR0_EL2.

*0b0* Unprivileged access to any address translated by TTBR0_EL2 will not generate a fault by this mechanism.

*0b1* Unprivileged access to any address translated by TTBR0_EL2 will generate a level 0 translation fault

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

NFD1, bit [54]

*When FEAT_SVE is implemented:*

Non-fault translation table walk disable for stage 1 translations using TTBR1_EL2.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault unprivileged access for a virtual address that is translated using TTBR1_EL2.

If SVE is implemented, the affected access types include:

- All accesses due to an SVE non-fault contiguous load instruction.
- Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
- Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

For more information, see FEAT_SVE.

*0b0* Does not disable stage 1 translation table walks using TTBR1_EL2.
NFD0, bit [53]

When FEAT_SVE is implemented:

Non-fault translation table walk disable for stage 1 translations using TTBR0_EL2.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault unprivileged access for a virtual address that is translated using TTBR0_EL2.

If SVE is implemented, the affected access types include:

- All accesses due to an SVE non-fault contiguous load instruction.
- Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
- Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

For more information, see FEAT_SVE.

0b0 Does not disable stage 1 translation table walks using TTBR0_EL2.

0b1 A TLB miss on a virtual address that is translated using TTBR0_EL2 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID1, bit [52]

When FEAT_PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see Address tagging in AArch64 state on page D5-2528.

0b0 TCR_EL2.TBI1 applies to Instruction and Data accesses.

0b1 TCR_EL2.TBI1 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR1_EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID0, bit [51]

When FEAT_PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For more information, see Address tagging in AArch64 state on page D5-2528.

0b0 TCR_EL2.TBI0 applies to Instruction and Data accesses.

0b1 TCR_EL2.TBI0 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL2.

This field resets to an architecturally UNKNOWN value.
**D13.2 General system control registers**

---

**Otherwise:**
Reserved, RES0.

**HWU162, bit [50]**

**When FEAT_HPDS2 is implemented:**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

- **0b0**: For translations using TTBR1_EL2, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1**: For translations using TTBR1_EL2, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

---

**HWU161, bit [49]**

**When FEAT_HPDS2 is implemented:**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

- **0b0**: For translations using TTBR1_EL2, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1**: For translations using TTBR1_EL2, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

---

**HWU160, bit [48]**

**When FEAT_HPDS2 is implemented:**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

- **0b0**: For translations using TTBR1_EL2, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1**: For translations using TTBR1_EL2, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.
HWU159, bit [47]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

- 0b0 For translations using TTBR1_EL2, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- 0b1 For translations using TTBR1_EL2, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.

Otherwise:

Reserved, RES0.

HWU062, bit [46]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

- 0b0 For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- 0b1 For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0.

Otherwise:

Reserved, RES0.

HWU061, bit [45]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

- 0b0 For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- 0b1 For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0.

Otherwise:

Reserved, RES0.

HWU060, bit [44]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

- 0b0 For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1 For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU059, bit [43]

When FEAT_HPDS2 is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

0b0 For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HPD1, bit [42]

When FEAT_HPDS is implemented:
Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR1_EL2.

0b0 Hierarchical permissions are enabled.
0b1 Hierarchical permissions are disabled.
When disabled, the permissions are treated as if the bits are zero.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HPD0, bit [41]

When FEAT_HPDS is implemented:
Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL2.

0b0 Hierarchical permissions are enabled.
0b1 Hierarchical permissions are disabled.
When disabled, the permissions are treated as if the bits are zero.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HD, bit [40]

When FEAT_HAFDBS is implemented:
Hardware management of dirty state in stage 1 translations from EL2.

0b0 Stage 1 hardware management of dirty state disabled.
0b1 Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.
This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**HA, bit [39]**

*When FEAT_HAFDBS is implemented:*

Hardware Access flag update in stage 1 translations from EL2.

- 0b0: Stage 1 Access flag update disabled.
- 0b1: Stage 1 Access flag update enabled.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**TBI1, bit [38]**

Top Byte Ignored. Indicates whether the top byte of an address is used for address match for the TTBR1_EL2 region, or ignored and used for tagged addresses.

For more information, see *Address tagging in AArch64 state on page D5-2528.*

- 0b0: Top Byte used in the address calculation.
- 0b1: Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL2 using AArch64 where the address would be translated by tables pointed to by TTBR1_EL2. It has an effect whether the EL2, or EL2&E0, translation regime is enabled or not.

If FEAT_PAuth is implemented and TCR_EL2.TBID1 is 1, then this field only applies to Data accesses.

If the value of TBI1 is 1 and bit [55] of the target address to be stored to the PC is 1, then bits[63:56] of that target address are also set to 1 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.

**TBI0, bit [37]**

Top Byte Ignored. Indicates whether the top byte of an address is used for address match for the TTBR0_EL2 region, or ignored and used for tagged addresses.

For more information, see *Address tagging in AArch64 state on page D5-2528.*

- 0b0: Top Byte used in the address calculation.
- 0b1: Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL2 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL2. It has an effect whether the EL2, or EL2&E0, translation regime is enabled or not.

If FEAT_PAuth is implemented and TCR_EL2.TBID0 is 1, then this field only applies to Data accesses.

If the value of TBI0 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.
AS, bit [36]

ASID Size.

- **0b0** 8 bit - the upper 8 bits of TTBR0_EL2 and TTBR1_EL2 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.

- **0b1** 16 bit - the upper 16 bits of TTBR0_EL2 and TTBR1_EL2 are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

This field resets to an architecturally UNKNOWN value.

Bit [35]

Reserved, RES0.

IPS, bits [34:32]

Intermediate Physical Address Size.

- **0b000** 32 bits, 4GB.
- **0b001** 36 bits, 64GB.
- **0b010** 40 bits, 1TB.
- **0b011** 42 bits, 4TB.
- **0b100** 44 bits, 16TB.
- **0b101** 48 bits, 256TB.
- **0b110** **When FEAT_LPA is implemented** 52 bits, 4PB.

All other values are reserved.

The reserved values behave in the same way as the 0b101 or 0b110 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

If the translation granule is not 64KB, the value 0b110 is treated as reserved.

It is IMPLEMENTATION DEFINED whether an implementation that does not implement FEAT_LPA supports setting the value of 0b110 for the 64KB translation granule size or whether setting this value behaves as the 0b101 encoding.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL2 are 0b0000.

This field resets to an architecturally UNKNOWN value.

TG1, bits [31:30]

Granule size for the TTBR1_EL2.

- **0b01** 16KB.
- **0b10** 4KB.
- **0b11** 64KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.
SH1, bits [29:28]
Shareability attribute for memory associated with translation table walks using TTBR1_EL2.

- 0b00: Non-shareable.
- 0b10: Outer Shareable.
- 0b11: Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.
This field resets to an architecturally UNKNOWN value.

ORGN1, bits [27:26]
Outer cacheability attribute for memory associated with translation table walks using TTBR1_EL2.

- 0b00: Normal memory, Outer Non-cacheable.
- 0b01: Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN1, bits [25:24]
Inner cacheability attribute for memory associated with translation table walks using TTBR1_EL2.

- 0b00: Normal memory, Inner Non-cacheable.
- 0b01: Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

EPD1, bit [23]
Translation table walk disable for translations using TTBR1_EL2. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1_EL2. The encoding of this bit is:

- 0b0: Perform translation table walks using TTBR1_EL2.
- 0b1: A TLB miss on an address that is translated using TTBR1_EL2 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

A1, bit [22]
Selects whether TTBR0_EL2 or TTBR1_EL2 defines the ASID. The encoding of this bit is:

- 0b0: TTBR0_EL2.ASID defines the ASID.
- 0b1: TTBR1_EL2.ASID defines the ASID.

This field resets to an architecturally UNKNOWN value.

T1SZ, bits [21:16]
The size offset of the memory region addressed by TTBR1_EL2. The region size is 2^{64-T1SZ} bytes. The maximum and minimum possible values for T1SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.
This field resets to an architecturally UNKNOWN value.

TG0, bits [15:14]
Granule size for the TTBR0_EL2.

- 0b00: 4KB.
0b01  64KB.
0b10  16KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

SH0, bits [13:12]
Shareability attribute for memory associated with translation table walks using TTBR0_EL2.
0b00  Non-shareable.
0b10  Outer Shareable.
0b11  Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

This field resets to an architecturally UNKNOWN value.

ORGN0, bits [11:10]
Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL2.
0b00  Normal memory, Outer Non-cacheable.
0b01  Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10  Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11  Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN0, bits [9:8]
Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL2.
0b00  Normal memory, Inner Non-cacheable.
0b01  Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
0b10  Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11  Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

EPD0, bit [7]
Translation table walk disable for translations using TTBR0_EL2. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0_EL2. The encoding of this bit is:
0b0  Perform translation table walks using TTBR0_EL2.
0b1  A TLB miss on an address that is translated using TTBR0_EL2 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Bit [6]
Reserved, RES0.

T0SZ, bits [5:0]
The size offset of the memory region addressed by TTBR0_EL2. The region size is 2^(64-T0SZ) bytes.
The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

Accessing the TCR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TCR_EL2 or TCR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, TCR_EL2**

```
<table>
<thead>

D13.2.122   TCR_EL3, Translation Control Register (EL3)

The TCR_EL3 characteristics are:

**Purpose**

The control register for stage 1 of the EL3 translation regime.

**Configurations**

This register is present only when EL3 is implemented. Otherwise, direct accesses to TCR_EL3 are UNDEFINED.

**Attributes**

TCR_EL3 is a 64-bit register.

**Field descriptions**

The TCR_EL3 bit assignments are:

Any of the bits in TCR_EL3 are permitted to be cached in a TLB.

**Bits [63:32]**

Reserved, RES0.

**Bit [31]**

Reserved, RES1.

**TCMA, bit [30]**

When **FEAT_MTE** is implemented:

Controls the generation of Unchecked accesses at EL3 when address [59:56] = 0b0000.

- 0b0 This control has no effect on the generation of Unchecked accesses.
- 0b1 All accesses are Unchecked.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
TBID, bit [29]

When FEAT_PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>TCR_EL3.TBI applies to Instruction and Data accesses.</td>
</tr>
<tr>
<td>0b1</td>
<td>TCR_EL3.TBI applies to Data accesses only.</td>
</tr>
</tbody>
</table>

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL3.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU62, bit [28]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
<tr>
<td>0b1</td>
<td>Bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.</td>
</tr>
</tbody>
</table>

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU61, bit [27]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
<tr>
<td>0b1</td>
<td>Bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.</td>
</tr>
</tbody>
</table>

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU60, bit [26]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
<tr>
<td>0b1</td>
<td>Bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.</td>
</tr>
</tbody>
</table>

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

HWU59, bit [25]

When FEAT_HPDS2 is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry.

0b0 Bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 Bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HPD, bit [24]

When FEAT_HPDS is implemented:
Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL3.

0b0 Hierarchical permissions are enabled.

0b1 Hierarchical permissions are disabled.

Note
In this case bit[61] (APTable[0]) and bit[59] (PXNTable) of the next level descriptor attributes are required to be ignored by the PE, and are no longer reserved, allowing them to be used by software.

When disabled, the permissions are treated as if the bits are zero.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bit [23]
Reserved, RES1.

HD, bit [22]

When FEAT_HAFDBS is implemented:
Hardware management of dirty state in stage 1 translations from EL3.

0b0 Stage 1 hardware management of dirty state disabled.

0b1 Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HA, bit [21]

When FEAT_HAFDBS is implemented:
Hardware Access flag update in stage 1 translations from EL3.

0b0 Stage 1 Access flag update disabled.

0b1 Stage 1 Access flag update enabled.
This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**TBI, bit [20]**

Top Byte Ignored. Indicates whether the top byte of an address is used for address match for the TTBR0_EL3 region, or ignored and used for tagged addresses.

- 0b0: Top Byte used in the address calculation.
- 0b1: Top Byte ignored in the address calculation.

This affects addresses generated in EL3 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL3. It has an effect whether the EL3 translation regime is enabled or not.

If FEAT_PAuth is implemented and TCR_EL3.TBID is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI is 1, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL3.
- A exception taken to EL3.
- An exception return to EL3.

For more information, see *Address tagging in AArch64 state on page D5-2528.*

**Note**

This control determines the scope of address tagging. It never causes an exception to be generated.

This field resets to an architecturally UNKNOWN value.

**Bit [19]**

Reserved, RES0.

**PS, bits [18:16]**

Physical Address Size.

- 0b000: 32 bits, 4GB.
- 0b001: 36 bits, 64GB.
- 0b010: 40 bits, 1TB.
- 0b011: 42 bits, 4TB.
- 0b100: 44 bits, 16TB.
- 0b101: 48 bits, 256TB.
- 0b110: 52 bits, 4PB.

All other values are reserved.

The reserved values behave in the same way as the 0b101 or 0b110 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

If the translation granule is not 64KB, the value 0b110 is treated as reserved.

It is IMPLEMENTATION DEFINED whether an implementation that does not implement FEAT_LPA supports setting the value of 0b110 for the 64KB translation granule size or whether setting this value behaves as the 0b101 encoding.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL3 are 0b0000.

This field resets to an architecturally UNKNOWN value.
TG0, bits [15:14]
Granule size for the TTBR0_EL3.

0b00  4KB.
0b01  64KB.
0b10  16KB.

Other values are reserved.
If the value is programmed to either a reserved value, or a size that has not been implemented, then
the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED
choice of the sizes that has been implemented for all purposes other than the value read back from
this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value
that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

SH0, bits [13:12]
Shareability attribute for memory associated with translation table walks using TTBR0_EL3.

0b00  Non-shareable.
0b10  Outer Shareable.
0b11  Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior
is CONSTRAINED UNPREDICTABLE.

This field resets to an architecturally UNKNOWN value.

ORGN0, bits [11:10]
Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL3.

0b00  Normal memory, Outer Non-cacheable.
0b01  Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10  Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11  Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN0, bits [9:8]
Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL3.

0b00  Normal memory, Inner Non-cacheable.
0b01  Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
0b10  Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11  Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

Bits [7:6]
Reserved, RES0.

T0SZ, bits [5:0]
The size offset of the memory region addressed by TTBR0_EL3. The region size is 2^{(64-T0SZ)} bytes.
The maximum and minimum possible values for T0SZ depend on the level of translation table and
the memory translation granule size, as described in the AArch64 Virtual Memory System
Architecture chapter.

This field resets to an architecturally UNKNOWN value.
### Accessing the TCR_EL3

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, TCR_EL3**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b110</td>
<td>0b0010</td>
<td>0b0000</td>
<td>0b010</td>
</tr>
</tbody>
</table>

```plaintext
if PSTATE_EL == EL0 then
  UNDEFINED;
elif PSTATE_EL == EL1 then
  UNDEFINED;
elif PSTATE_EL == EL2 then
  UNDEFINED;
elif PSTATE_EL == EL3 then
  return TCR_EL3;
```

**MSR TCR_EL3, <Xt>**

<table>
<thead>
<tr>

  UNDEFINED;
elif PSTATE_EL == EL2 then
  UNDEFINED;
elif PSTATE_EL == EL3 then
  TCR_EL3 = X[t];
```
D13.2.123 TFSRE0_EL1, Tag Fault Status Register (EL0).

The TFSRE0_EL1 characteristics are:

**Purpose**

Holds accumulated Tag Check Faults occurring in EL0 that are not taken precisely.

**Configurations**

This register is present only when FEAT_MTE is implemented and ID_AA64PFR1_EL1.MTE != 0b0001. Otherwise, direct accesses to TFSRE0_EL1 are UNDEFINED.

**Attributes**

TFSRE0_EL1 is a 64-bit register.

**Field descriptions**

The TFSRE0_EL1 bit assignments are:

- **Bits [63:2]**
  - Reserved, RES0.

- **TF1, bit [1]**
  - Tag Check Fault. Asynchronously set to 1 when a Tag Check Fault using a virtual address with bit[55] == 0b1 occurs.
  - This field resets to an architecturally UNKNOWN value.

- **TF0, bit [0]**
  - Tag Check Fault. Asynchronously set to 1 when a Tag Check Fault using a virtual address with bit[55] == 0b0 occurs.
  - This field resets to an architecturally UNKNOWN value.

**Accessing the TFSRE0_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.124 TFSR_EL1, Tag Fault Status Register (EL1)

The TFSR_EL1 characteristics are:

**Purpose**

Holds accumulated Tag Check Faults occurring in EL1 that are not taken precisely.

**Configurations**

This register is present only when FEAT_MTE is implemented and ID_AA64PFR1_EL1.MTE != 0b0001. Otherwise, direct accesses to TFSR_EL1 are UNDEFINED.

**Attributes**

TFSR_EL1 is a 64-bit register.

**Field descriptions**

The TFSR_EL1 bit assignments are:

```
   63  2  1  0
   ________
  | RES0 |
  +-------+
  | TF1   |
  | TF0   |
```

**Bits [63:2]**

Reserved, RES0.

**TF1, bit [1]**

Tag Check Fault. Asynchronously set to 1 when a Tag Check Fault using a virtual address with bit[55] == 0b1 occurs.

This field resets to an architecturally UNKNOWN value.

**TF0, bit [0]**

Tag Check Fault. Asynchronously set to 1 when a Tag Check Fault using a virtual address with bit[55] == 0b0 occurs.

This field resets to an architecturally UNKNOWN value.

D13.2.125 TFSR_EL2, Tag Fault Status Register (EL2)

The TFSR_EL2 characteristics are:

**Purpose**

Holds accumulated Tag Check Faults occurring in EL2 that are not taken precisely.

**Configurations**

This register is present only when FEAT_MTE is implemented and ID_AA64PFR1_EL1.MTE != 0b0001. Otherwise, direct accesses to TFSR_EL2 are UNDEFINED.

**Attributes**

TFSR_EL2 is a 64-bit register.

**Field descriptions**

The TFSR_EL2 bit assignments are:

![Field Diagram]

**Bits [63:2]**

Reserved, RES0.

**TF1, bit [1]**

Tag Check Fault. Asynchronously set to 1 when a Tag Check Fault using a virtual address with bit[55] == 0b1 occurs.

When HCR_EL2.E2H==0b0, this field is RES0.

This field resets to an architecturally UNKNOWN value.

**TF0, bit [0]**

Tag Check Fault. Asynchronously set to 1 when a Tag Check Fault using a virtual address with bit[55] == 0b0 occurs.

This field resets to an architecturally UNKNOWN value.

**Accessing the TFSR_EL2**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TFSR_EL2 or TFSR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, TFSR_EL2**

### D13.2.131 TPIDRRO_EL0, EL0 Read-Only Software Thread ID Register

The TPIDRRO_EL0 characteristics are:

**Purpose**

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

The PE makes no use of this register.

**Configurations**

AArch64 System register TPIDRRO_EL0[31:0] is architecturally mapped to AArch32 System register TPIDRRO[31:0].

**Attributes**

TPIDRRO_EL0 is a 64-bit register.

**Field descriptions**

The TPIDRRO_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Thread ID. Thread identifying information stored by software running at this Exception level.</th>
</tr>
</thead>

D13.2.132 TTBR0_EL1, Translation Table Base Register 0 (EL1)

The TTBR0_EL1 characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the EL1&0 translation regime, and other information for this translation regime.

**Configurations**

AArch64 System register TTBR0_EL1[63:0] is architecturally mapped to AArch32 System register TTBR0[63:0].

**Attributes**

TTBR0_EL1 is a 64-bit register.

**Field descriptions**

The TTBR0_EL1 bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>BADDR</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**ASID, bits [63:48]**

An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

This field resets to an architecturally UNKNOWN value.

**BADDR, bits [47:1]**

Translation table base address, A[47:x] or A[51:x], bits[47:1].

--- **Note** ---

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes FEAT_LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes FEAT_LPA, if the value of TCR_EL1.IPS is 0b110, then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
• Bits[5:2] of the stage 1 translation table base address are zero.

• In an implementation that includes FEAT_TTCNP bit[0] of the stage 1 translation table base address is zero.

--- Note

• In an implementation that includes FEAT_LPA a TCR_EL1.IPS value of 0b110, that selects an IPA size of 52 bits, is permitted only when using the 64KB translation granule.

• When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the Effective value of TCR_EL1.IPS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL1.IPS is not 0b110 then:

• Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.

• Register bits[(x-1):1] are RES0.

• If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

--- Note

This definition applies:

• To an implementation that includes FEAT_LPA and is using a translation granule smaller than 64KB.

• To any implementation that does not include FEAT_LPA.

If any TTBR0_EL1[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR0_EL1, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

• Bits[(x-1):0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.

• The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL1.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When FEAT_TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TTBR0_EL1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0_EL1.CnP is 1.

0b0 The translation table entries pointed to by TTBR0_EL1, for the current translation regime and ASID, are permitted to differ from corresponding entries for TTBR0_EL1 for other PEs in the Inner Shareable domain. This is not affected by:

• The value of TTBR0_EL1.CnP on those other PEs.

• The value of the current ASID.

• If EL2 is implemented and enabled in the current Security state, the value of the current VMID.

0b1 The translation table entries pointed to by TTBR0_EL1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL1.CnP is 1 and all of the following apply:

• The translation table entries are pointed to by TTBR0_EL1.
• The translation tables relate to the same translation regime.
• The ASID is the same as the current ASID.
• If EL2 is implemented and enabled in the current Security state, the value of the current VMID.

This field is permitted to be cached in a TLB.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

--- Note ---

If the value of the TTBR0_EL1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0_EL1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7966.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the TTBR0_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic TTBR0_EL1 or TTBR0_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.133 TTBR0_EL2, Translation Table Base Register 0 (EL2)

The TTBR0_EL2 characteristics are:

**Purpose**

When HCR_EL2.E2H is 0, holds the base address of the translation table for the initial lookup for stage 1 of an address translation in the EL2 translation regime, and other information for this translation regime.

When HCR_EL2.E2H is 1, holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the EL2&0 translation regime, and other information for this translation regime.

**Configurations**

AArch64 System register TTBR0_EL2[47:1] is architecturally mapped to AArch32 System register HTTBR[47:1].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

TTBR0_EL2 is a 64-bit register.

**Field descriptions**

The TTBR0_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>BADDR</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

*When FEAT_VHE is implemented:*

When HCR_EL2.E2H is 0, this field is RES0.

When HCR_EL2.E2H is 1, it holds an ASID for the translation table base address. The TCR_EL2.A1 field selects either TTBR0_EL2.ASID or TTBR1_EL2.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**BADDR, bits [47:1]**

Translation table base address, A[47:x] or A[51:x], bits[47:1].

--- Note ---

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes FEAT_LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.
In an implementation that includes FEAT_LPA, if the value of TCR_EL2.{I}PS is 0b110, then:
- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes FEAT_TTCNP bit[0] of the stage 1 translation table base address is zero.

--- Note ---

In an implementation that includes FEAT_LPA:
- A TCR_EL2.{I}PS value of 0b110, that selects an OA size of 52 bits, is permitted only when using the 64KB translation granule.
- The OA size is specified by:
  - The value of TCR_EL2.PS when the value of HCR_EL2.E2H is 0.
  - The value of TCR_EL2.IPS when the value of HCR_EL2.E2H is 1.

When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the Effective value of TCR_EL2.{I}PS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

--- Note ---

This definition applies:
- To an implementation that includes FEAT_LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include FEAT_LPA.

---

If any TTBR0_EL2[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR0_EL2, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:
- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL2.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.
CnP, bit [0]

When FEAT_TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TTBR0_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0_EL2.CnP is 1.

0b0  The translation table entries pointed to by TTBR0_EL2 for the current translation regime, and ASID if applicable, are permitted to differ from corresponding entries for TTBR0_EL2 for other PEs in the Inner Shareable domain. This is not affected by:
  • The value of TTBR0_EL2.CnP on those other PEs.
  • When the current translation regime is the EL2&0 regime, the value of the current ASID.

0b1  The translation table entries pointed to by TTBR0_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL2.CnP is 1 and all of the following apply:
  • The translation table entries are pointed to by TTBR0_EL2.
  • The translation tables relate to the same translation regime.
  • If that translation regime is the EL2&0 regime, the ASID is the same as the current ASID.

This field is permitted to be cached in a TLB.

Note

If the value of the TTBR0_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0_EL2s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7966.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the TTBR0_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TTBR0_EL2 or TTBR0_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

   TTBR0_EL1 = X[t];
elsif PSTATE.EL == EL2 then
   if HCR_EL2.E2H == '1' then
      TTBR0_EL2 = X[t];
   else
      TTBR0_EL1 = X[t];
elsif PSTATE.EL == EL3 then
   TTBR0_EL1 = X[t];
D13.2.134 TTBR0_EL3, Translation Table Base Register 0 (EL3)

The TTBR0_EL3 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of an address translation in the EL3 translation regime, and other information for this translation regime.

Configurations

This register is present only when EL3 is implemented. Otherwise, direct accesses to TTBR0_EL3 are UNDEFINED.

Attributes

TTBR0_EL3 is a 64-bit register.

Field descriptions

The TTBR0_EL3 bit assignments are:

63 48 47 1 0
RES0 BADDR

Bits [63:48]

Reserved, RES0.

BADDR, bits [47:1]

Translation table base address, A[47:x] or A[51:x].

--- Note ---

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes FEAT_LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes FEAT_LPA, if the value of TCR_EL3.PS is 0b110 then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes FEAT_TTCNP bit[0] of the stage 1 translation table base address is zero.
In an implementation that includes FEAT_LPA a TCR_EL3.PS value of 0b110, that selects a PA size of 52 bits, is permitted only when using the 64KB translation granule.

When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the Effective value of TCR_EL3.PS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL3.PS is not 0b110 then:
- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

This definition applies:
- To an implementation that includes FEAT_LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include FEAT_LPA.

If any TTBR0_EL3[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR0_EL3, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:
- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL3.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When FEAT_TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TTBR0_EL3 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0_EL3.CnP is 1.

0b0 The translation table entries pointed to by TTBR0_EL3, for the current translation regime, are permitted to differ from corresponding entries for TTBR0_EL3 for other PEs in the Inner Shareable domain. This is not affected by the value of TTBR0_EL3.CnP on those other PEs.

0b1 The translation table entries pointed to by TTBR0_EL3 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL3.CnP is 1 and the translation table entries are pointed to by TTBR0_EL3.

This field is permitted to be cached in a TLB.

If the value of the TTBR0_EL3.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0_EL3s do not point to the same translation table entries the results of translations using TTBR0_EL3 are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7966.

This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

Accessing the TTBR0_EL3

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, TTBR0_EL3**

```plaintext
<table>
<thead>

elsif PSTATE.EL == EL2 then
  UNDEFINED;
elsif PSTATE.EL == EL3 then
  TTBR0_EL3 = X[t];
```
D13.2.135 TTBR1_EL1, Translation Table Base Register 1 (EL1)

The TTBR1_EL1 characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the EL1&0 stage 1 translation regime, and other information for this translation regime.

**Configurations**

AArch64 System register TTBR1_EL1[63:0] is architecturally mapped to AArch32 System register TTBR1[63:0].

**Attributes**

TTBR1_EL1 is a 64-bit register.

**Field descriptions**

The TTBR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-48</td>
<td>ASID</td>
</tr>
<tr>
<td>47-1</td>
<td>BADDR</td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0. This field resets to an architecturally UNKNOWN value.

**BADDR, bits [47:1]**

Translation table base address, A[47:x] or A[51:x], bits[47:1].

--- Note ---

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes FEAT_LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes FEAT_LPA, if the value of TCR_EL1.IPS is 0b110, then:

- Register bits[47:z] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
• Bits[5:2] of the stage 1 translation table base address are zero.
• In an implementation that includes FEAT_TTCNP bit[0] of the stage 1 translation table base address is zero.

Note

• In an implementation that includes FEAT_LPA a TCR_EL1.IPS value of 0b110, that selects an IPA size of 52 bits, is permitted only when using the 64KB translation granule.
• When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the Effective value of TCR_EL1.IPS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL1.IPS is not 0b110 then:
• Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
• Register bits[(x-1):1] are RES0.
• If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

Note
This definition applies:
• To an implementation that includes FEAT_LPA and is using a translation granule smaller than 64KB.
• To any implementation that does not include FEAT_LPA.

If any TTBR1_EL1[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR1_EL1, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:
• Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
• The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL1.T1SZ, the stage of translation, and the translation granule size.
This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When FEAT_TTCNP is implemented:
Common not Private. This bit indicates whether each entry that is pointed to by TTBR1_EL1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR1_EL1.CnP is 1.
0b0 The translation table entries pointed to by TTBR1_EL1, for the current translation regime and ASID, are permitted to differ from corresponding entries for TTBR1_EL1 for other PEs in the Inner Shareable domain. This is not affected by:
• The value of TTBR1_EL1.CnP on those other PEs.
• The value of the current ASID.
• If EL2 is implemented and enabled in the current Security state, the value of the current VMID.
0b1 The translation table entries pointed to by TTBR1_EL1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR1_EL1.CnP is 1 and all of the following apply:
• The translation table entries are pointed to by TTBR1_EL1.
The translation tables relate to the same translation regime.

The ASID is the same as the current ASID.

If EL2 is implemented and enabled in the current Security state, the value of the current VMID.

This field is permitted to be cached in a TLB.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note

If the value of the TTBR1_EL1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR1_EL1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7966.

This field resets to an architecturally UNKNOWN value.

Reserved: RES0.

Accessing the TTBR1_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic TTBR1_EL1 or TTBR1_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, TTBR1_EL1**

<table>
<thead>

D13.2.136 TTBR1_EL2, Translation Table Base Register 1 (EL2)

The TTBR1_EL2 characteristics are:

**Purpose**

When HCR_EL2.E2H is 1, holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the EL2&0 translation regime, and other information for this translation regime.

--- Note ---

When HCR_EL2.E2H is 0, the contents of this register are ignored by the PE, except for a direct read or write of the register.

**Configurations**

This register is present only when FEAT_VHE is implemented. Otherwise, direct accesses to TTBR1_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

TTBR1_EL2 is a 64-bit register.

**Field descriptions**

The TTBR1_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td></td>
<td>BADDR</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

An ASID for the translation table base address. The TCR_EL2.A1 field selects either TTBR0_EL2.ASID or TTBR1_EL2.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

This field resets to an architecturally UNKNOWN value.

**BADDR, bits [47:1]**

Translation table base address, A[47:x] or A[51:x], bits[47:1].

--- Note ---

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes FEAT_LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes FEAT_LPA, if the value of TCR_EL2.{I}PS is 0b110, then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
— Otherwise, z=6.

• Register bits[5:2] hold bits[51:48] of the stage 1 translation table base address.
• When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base
  address are zero.
• When x>6 register bits[(x-1):6] are RES0.
• Register bit[1] is RES0.
• Bits[5:2] of the stage 1 translation table base address are zero.
• In an implementation that includes FEAT_TTCNP bit[0] of the stage 1 translation table base
  address is zero.

Note

• In an implementation that includes FEAT_LPA a TCR_EL2.{I}PS value of 0b110, that selects
  an OA size of 52 bits, is permitted only when using the 64KB translation granule.
• When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does
  not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB
  translation granule when the Effective value of TCR_EL2.{I}PS is 0b110 and the value of
  register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL2.{I}PS is not 0b110 then:

• Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
• Register bits[(x-1):1] are RES0.
• If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table
  base addresses used in this stage of translation are 0b0000.

Note

This definition applies:

• To an implementation that includes FEAT_LPA and is using a translation granule smaller
  than 64KB.
• To any implementation that does not include FEAT_LPA.

If any TTBR1_EL2[47:0] bit that is defined as RES0 has the value 1 when a translation table walk
is performed using TTBR1_EL2, then the translation table base address might be misaligned, with
effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

• Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value
  read back from the corresponding register bits is either the value written to the register or
  zero.

• The result of the calculation of an address for a translation table walk using this register can
  be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on
the value of TCR_EL2.T1SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When FEAT_TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TBR1_EL2 is a
member of a common set that can be used by every PE in the Inner Shareable domain for which the
value of TTBR1_EL2.CnP is 1.

0b0 The translation table entries pointed to by TTBR1_EL2 for the current ASID are
permitted to differ from corresponding entries for TTBR1_EL2 for other PEs in the
Inner Shareable domain. This is not affected by:

• The value of TTBR1_EL2.CnP on those other PEs.
• The value of the current ASID.
The translation table entries pointed to by TTBR1_EL2 are the same as the translation
table entries for every other PE in the Inner Shareable domain for which the value of
TTBR1_EL2.CnP is 1 and all of the following apply:

- The translation table entries are pointed to by TTBR1_EL2.
- The ASID is the same as the current ASID.

This field is permitted to be cached in a TLB.

--- Note ---

- TTBR1_EL2 is accessible only when the value of HCR_EL2.E2H is 1, meaning the current
  translation regime is the EL2&0 regime.
- If the value of the TTBR1_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable
  domain and those TTBR1_EL2s do not point to the same translation table entries when the
  other conditions specified for the case when the value of CnP is 1 apply, then the results
  of translations are CONSTRAINED UNPREDICTABLE, see CONSTRUANED UNPREDICTABLE
  behaviors due to caching of control or data values on page K1-7966.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

### Accessing the TTBR1_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TTBR1_EL2
or TTBR1_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.137  VBAR_EL1, Vector Base Address Register (EL1)

The VBAR_EL1 characteristics are:

**Purpose**
Holds the vector base address for any exception that is taken to EL1.

**Configurations**
AArch64 System register VBAR_EL1[31:0] is architecturally mapped to AArch32 System register VBAR[31:0].

**Attributes**
VBAR_EL1 is a 64-bit register.

**Field descriptions**
The VBAR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
</table>

**Note**
If the implementation does not support FEAT_LVA, then:
- If tagged addresses are being used, bits [55:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

If the implementation supports FEAT_LVA, then:
- If tagged addresses are being used, bits [55:52] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:52] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

This field resets to an architecturally UNKNOWN value.

**Bits [10:0]**
Reserved, RES0.

**Accessing the VBAR_EL1**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic VBAR_EL1 or VBAR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.138 VBAR_EL2, Vector Base Address Register (EL2)

The VBAR_EL2 characteristics are:

**Purpose**

Holds the vector base address for any exception that is taken to EL2.

**Configurations**

AArch64 System register VBAR_EL2[31:0] is architecturally mapped to AArch32 System register HVBAR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

VBAR_EL2 is a 64-bit register.

**Field descriptions**

The VBAR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:11]</th>
<th>Vector Base Address</th>
<th>RES0</th>
</tr>
</thead>
</table>

--- **Note** ---

If FEAT_LVA is implemented:

- If HCR_EL2.E2H == 0b1:
  - If tagged addresses are being used, bits [55:52] of VBAR_EL2 must be the same or else the use of the vector address will result in a recursive exception.
  - If tagged addresses are not being used, bits [63:52] of VBAR_EL2 must be the same or else the use of the vector address will result in a recursive exception.

- If HCR_EL2.E2H == 0b0:
  - If tagged addresses are being used, bits [55:48] of VBAR_EL2 must be 0 or else the use of the vector address will result in a recursive exception.
  - If tagged addresses are not being used, bits [63:48] of VBAR_EL2 must be 0 or else the use of the vector address will result in a recursive exception.

If FEAT_LVA is not implemented:

- If HCR_EL2.E2H == 0b1:
  - If tagged addresses are being used, bits [55:48] of VBAR_EL2 must be the same or else the use of the vector address will result in a recursive exception.
  - If tagged addresses are not being used, bits [63:48] of VBAR_EL2 must be the same or else the use of the vector address will result in a recursive exception.

- If HCR_EL2.E2H == 0b0:
  - If tagged addresses are being used, bits [55:48] of VBAR_EL2 must be 0 or else the use of the vector address will result in a recursive exception.
  - If tagged addresses are not being used, bits [63:48] of VBAR_EL2 must be 0 or else the use of the vector address will result in a recursive exception.
This field resets to an architecturally UNKNOWN value.

Bits [10:0]
Reserved, RES0.

**Accessing the VBAR_EL2**

elsif PSTATE.EL == EL3 then
    VBAR_EL3 = X[t];
```
D13.2.140 VMPIDR_EL2, Virtualization Multiprocessor ID Register

The VMPIDR_EL2 characteristics are:

Purpose
Holds the value of the Virtualization Multiprocessor ID. This is the value returned by EL1 reads of MPIDR_EL1.

Configurations
AArch64 System register VMPIDR_EL2[31:0] is architecturally mapped to AArch32 System register VMPIDR[31:0].

If EL2 is not implemented, reads of this register return the value of the MPIDR_EL1 and writes to the register are ignored.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes
VMPIDR_EL2 is a 64-bit register.

Field descriptions
The VMPIDR_EL2 bit assignments are:

![Bit assignments diagram]

Bits [63:40]
Reserved, RES0.

Aff3, bits [39:32]
Affinity level 3. See the description of VMPIDR_EL2.Aff0 for more information.
Aff3 is not supported in AArch32 state.
This field resets to an architecturally UNKNOWN value.

Bit [31]
Reserved, RES1.

U, bit [30]
Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

| 0b0 | Processor is part of a multiprocessor system. |
| 0b1 | Processor is part of a uniprocessor system. |

This field resets to an architecturally UNKNOWN value.

Bits [29:25]
Reserved, RES0.

MT, bit [24]
Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of VMPIDR_EL2.Aff0 for more information about affinity levels.

| 0b0 | Performance of PEs at the lowest affinity level is largely independent. |
| 0b1 | Performance of PEs at the lowest affinity level is largely dependent. |
Performance of PEs at the lowest affinity level is very interdependent.
This field resets to an architecturally UNKNOWN value.

**Aff2, bits [23:16]**
Affinity level 2. See the description of VMPIDR_EL2.Aff0 for more information.
This field resets to an architecturally UNKNOWN value.

**Aff1, bits [15:8]**
Affinity level 1. See the description of VMPIDR_EL2.Aff0 for more information.
This field resets to an architecturally UNKNOWN value.

**Aff0, bits [7:0]**
Affinity level 0. This is the **affinity** level that is most significant for determining PE behavior. Higher affinity levels are increasingly less significant in determining PE behavior. The assigned value of the MPIDR, {Aff2, Aff1, Aff0} or MPIDR_EL1, {Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.
This field resets to an architecturally UNKNOWN value.

**Accessing the VMPIDR_EL2**
Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.141 VNCR_EL2, Virtual Nested Control Register

The VNCR_EL2 characteristics are:

**Purpose**

When FEAT_NV2 is implemented, holds the base address that is used to define the memory location that is accessed by transformed reads and writes of System registers.

**Configurations**

This register is present only when FEAT_NV2 is implemented. Otherwise, direct accesses to VNCR_EL2 are UNDEFINED.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

VNCR_EL2 is a 64-bit register.

**Field descriptions**

The VNCR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, Sign extended.</td>
</tr>
<tr>
<td>53</td>
<td>Reserved</td>
</tr>

<td>52</td>
<td>Base Address</td>
</tr>
<tr>
<td>12</td>
<td>Reserved</td>
</tr>
<tr>
<td>11</td>
<td>Reserved</td>
</tr>
<tr>
<td>0</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**RESS, bits [63:53]**

Reserved, Sign extended. If the bits marked as RESS do not all have the same value, then there is a CONstrained UNPREDICTABLE choice between:

- Generating an EL2 translation regime Translation abort on use of the VNCR_EL2 register.
- Bits[63:49] of VNCR_EL2 are treated as the same value as bit[48] for all purposes other than reading back the register.
- Bits[63:49] of VNCR_EL2 are treated as the same value as bit[48] for all purposes.
- If the virtual address space for EL2 supports more than 48 bits, bits[63:53] of VNCR_EL2 are treated as the same value as bit[52] for all purposes other than reading back the register.
- If the virtual address space for EL2 supports more than 48 bits, bits[63:53] of VNCR_EL2 are treated as the same value as bit[52].

Where the EL2 translation regime has upper and lower address ranges, bit[52] is used to select between those address ranges to determine if the address space supports more than 48 bits.

**BADDR, bits [52:12]**

Base Address. If the virtual address space for EL2 does not support more than 48 bits, then bits [52:49] are RESS.

When a register read/write is transformed to be a Load or Store, the address of the load/store is to SignOffset(VNCR_EL2.BADDR:Offset<11:0>, 64).

This field resets to an architecturally UNKNOWN value.

**Bits [11:0]**

Reserved, res0.

Accessing the VNCR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:
MRS \( <Xt> \), VNCR_EL2

\[
\begin{array}{|c|c|c|c|c|}
\hline
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
\hline
0b11 & 0b100 & 0b0010 & 0b0010 & 0b000 \\
\hline
\end{array}
\]

if \( \text{PSTATE.EL} = \text{EL0} \) then

D13.2.142 VPIDR_EL2, Virtualization Processor ID Register

The VPIDR_EL2 characteristics are:

**Purpose**

Holds the value of the Virtualization Processor ID. This is the value returned by EL1 reads of MIDR_EL1.

**Configurations**

AArch64 System register VPIDR_EL2[31:0] is architecturally mapped to AArch32 System register VPIDR[31:0].

If EL2 is not implemented, reads of this register return the value of the MIDR_EL1 and writes to the register are ignored.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

VPIDR_EL2 is a 64-bit register.

**Field descriptions**

The VPIDR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Implementer, bits [31:24]**

The Implementer code. This field must hold an implementer code that has been assigned by Arm. Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>ASCII representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x41</td>
<td>A</td>
<td>Arm Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>B</td>
<td>Broadcom Corporation</td>
</tr>
<tr>
<td>0x43</td>
<td>C</td>
<td>Cavium Inc.</td>
</tr>
<tr>
<td>0x44</td>
<td>D</td>
<td>Digital Equipment Corporation</td>
</tr>
<tr>
<td>0x49</td>
<td>I</td>
<td>Infineon Technologies AG</td>
</tr>
<tr>
<td>0x4D</td>
<td>M</td>
<td>Motorola or Freescale Semiconductor Inc.</td>
</tr>
<tr>
<td>0x4E</td>
<td>N</td>
<td>NVIDIA Corporation</td>
</tr>
<tr>
<td>0x50</td>
<td>P</td>
<td>Applied Micro Circuits Corporation</td>
</tr>
<tr>
<td>0x51</td>
<td>Q</td>
<td>Qualcomm Inc.</td>
</tr>
<tr>
<td>0x56</td>
<td>V</td>
<td>Marvell International Ltd.</td>
</tr>
<tr>
<td>0x69</td>
<td>i</td>
<td>Intel Corporation</td>
</tr>
</tbody>
</table>
Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

This field resets to an architecturally UNKNOWN value.

**Variant, bits [23:20]**

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

This field resets to an architecturally UNKNOWN value.

**Architecture, bits [19:16]**

Architecture version. Defined values are:

- 0b0001 Armv4.
- 0b0010 Armv4T.
- 0b0011 Armv5 (obsolete).
- 0b0100 Armv5T.
- 0b0101 Armv5TE.
- 0b0110 Armv5TEJ.
- 0b0111 Armv6.
- 0b1111 Architectural features are individually identified in the ID_* registers, see ID registers on page K15-8205.

All other values are reserved.

This field resets to an architecturally UNKNOWN value.

**PartNum, bits [15:4]**

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

This field resets to an architecturally UNKNOWN value.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the device.

This field resets to an architecturally UNKNOWN value.

### Accessing the VPIDR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.143 VSTCR_EL2, Virtualization Secure Translation Control Register

The VSTCR_EL2 characteristics are:

**Purpose**

The control register for stage 2 of the Secure EL1&0 translation regime.

**Configurations**

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to VSTCR_EL2 are UNDEFINED.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

VSTCR_EL2 is a 64-bit register.

**Field descriptions**

The VSTCR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>31</td>
<td>Reserved, RES1.</td>
</tr>
<tr>
<td>30</td>
<td>Secure stage 2 translation output address space.</td>
</tr>
<tr>
<td>30</td>
<td>0b0: All stage 2 translations for the Secure IPA space access the Secure PA space.</td>
</tr>
<tr>
<td>30</td>
<td>0b1: All stage 2 translations for the Secure IPA space access the Non-secure PA space.</td>
</tr>
<tr>
<td>29</td>
<td>Secure stage 2 translation address space.</td>
</tr>
<tr>
<td>29</td>
<td>0b0: All stage 2 translation table walks for the Secure IPA space are to the Secure PA space.</td>
</tr>
<tr>
<td>29</td>
<td>0b1: All stage 2 translation table walks for the Secure IPA space are to the Non-secure PA space.</td>
</tr>
<tr>
<td>28:16</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
TG0, bits [15:14]

Secure stage 2 granule size for VSTTBR_EL2.

<table>
<thead>
<tr>
<th>TG0</th>
<th>Granule Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>4KB.</td>
</tr>
<tr>
<td>0b01</td>
<td>64KB.</td>
</tr>
<tr>
<td>0b10</td>
<td>16KB.</td>
</tr>
</tbody>
</table>

Other values are reserved.

If FEAT_GTG is implemented, ID_AA64MMFR0_EL1.{TGran4_2, TGran16_2, TGran64_2} indicate which granule sizes are supported for Level 2 translation.

If FEAT_GTG is not implemented, ID_AA64MMFR0_EL1.{TGran4, TGran16, TGran64} indicate which granule sizes are supported.

If the value is programmed to either a reserved value, or a size that has not been implemented, then for all purposes other than read back from this register, the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

Bits [13:8]

Reserved, RES0.

SL0, bits [7:6]

When FEAT_TTST is implemented:

Starting level of the Secure stage 2 translation lookup, controlled by VSTCR_EL2. The meaning of this field depends on the value of VSTCR_EL2.TG0.

<table>
<thead>
<tr>
<th>TG0</th>
<th>SL0</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>0b00</td>
<td>Start at level 2. If VSTCR_EL2.TG0 is 0b00 (4KB granule) or 0b10 (16KB granule) or 0b01 (64KB granule), start at level 3.</td>
</tr>
<tr>
<td>0b00</td>
<td>0b01</td>
<td>If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 1. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 2.</td>
</tr>
<tr>
<td>0b10</td>
<td>0b10</td>
<td>If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 0. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 1.</td>
</tr>
<tr>
<td>0b11</td>
<td>0b11</td>
<td>If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 3.</td>
</tr>
</tbody>
</table>

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VSTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Starting level of the Secure stage 2 translation lookup, controlled by VSTCR_EL2. The meaning of this field depends on the value of VSTCR_EL2.TG0.

<table>
<thead>
<tr>
<th>TG0</th>
<th>SL0</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>0b00</td>
<td>If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 2. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 3.</td>
</tr>
<tr>
<td>0b00</td>
<td>0b01</td>
<td>If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 1. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 2.</td>
</tr>
<tr>
<td>0b10</td>
<td>0b10</td>
<td>If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 0. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 1.</td>
</tr>
</tbody>
</table>

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VSTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.
T0SZ, bits [5:0]

The size offset of the memory region addressed by VSTTBR_EL2. The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for this field depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

If this field is programmed to a value that is not consistent with the programming of SL0, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

### Accessing the VSTCR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

    else
        VSTCR_EL2 = X[t];
D13.2.144 VSTTBR_EL2, Virtualization Secure Translation Table Base Register

The VSTTBR_EL2 characteristics are:

**Purpose**

The base register for stage 2 of the Secure EL1&0 translation regime. Holds the base address of the translation table for the initial lookup for stage 2 of an address translation in the Secure EL1&0 translation regime, and other information for this translation stage.

**Configurations**

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to VSTTBR_EL2 are **UNDEFINED**.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

VSTTBR_EL2 is a 64-bit register.

**Field descriptions**

The VSTTBR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>RES0</td>
</tr>
<tr>
<td>48</td>
<td>47</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>5:2</td>
<td>BADDR</td>
</tr>
</tbody>
</table>

Any of the bits in VSTTBR_EL2 are permitted to be cached in a TLB.

**Bits [63:48]**

Reserved, RES0.

**BADDR, bits [47:1]**

Translation table base address, A[47:x] or A[51:x].

**Note**

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes FEAT_LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

If the value of VTCR_EL2.PS is 0b1110, then:

- Register bits[47:z] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
Note

When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the Effective value of VTCR_EL2.PS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of VTCR_EL2.PS is not 0b110 then:

• Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
• Register bits[(x-1):1] are RES0.
• If the implementation supports 52-bit PAs and IPAs then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

If any VSTTBR_EL2[47:1] bit that is defined as RES0 has the value 1 when a translation table walk is performed using VSTTBR_EL2, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

• Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
• The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of VSTCR_EL2.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

Common not Private, for stage 2 of the Secure EL1&0 translation regime. In an implementation that includes FEAT_TTCNP, indicates whether each entry that is pointed to by VSTTBR_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VSTTBR_EL2.CnP is 1.

0b0 The translation table entries pointed to by VSTTBR_EL2 are permitted to differ from the entries for VSTTBR_EL2 for other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.

0b1 The translation table entries pointed to by VSTTBR_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of VSTTBR_EL2.CnP is 1 and the VMID is the same as the current VMID.

Note

If the value of VSTTBR_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those VSTTBR_EL2s do not point to the same translation table entries when using the current VMID, then the results of translations using VSTTBR_EL2 are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7966.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to an architecturally UNKNOWN value.

Accessing the VSTTBR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

    elsif EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
    elsif PSTATE.EL == EL2 then
        if HaveEL(EL3) && SCR_EL3.NS == '1' then
            UNDEFINED;
        else
            VSTTBR_EL2 = X[t];
    elsif PSTATE.EL == EL3 then
        if SCR_EL3.EEL2 == '0' then
            UNDEFINED;
        else
            VSTTBR_EL2 = X[t];
D13.2.145 VTCR_EL2, Virtualization Translation Control Register

The VTCR_EL2 characteristics are:

**Purpose**

The control register for stage 2 of the EL1&0 translation regime.

**Configurations**

AArch64 System register VTCR_EL2[31:0] is architecturally mapped to AArch32 System register VTCR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

VTCR_EL2 is a 64-bit register.

**Field descriptions**

The VTCR_EL2 bit assignments are:

Any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

**Bits [63:32]**

Reserved, RES0.

**Bit [31]**

Reserved, RES1.

**NSA, bit [30]**

*When FEAT_SEL2 is implemented:*

Non-secure stage 2 translation output address space.

0b0 All stage 2 translations for the Non-secure IPA space of the Secure EL1&0 translation regime access the Secure PA space.

0b1 All stage 2 translations for the Non-secure IPA space of the Secure EL1&0 translation regime access the Non-secure PA space.

This bit behaves as 1 for all purposes other than reading back the value of the bit when one of the following is true:

- The PE is executing in Non-secure state.
- The value of VTCR_EL2.NSW is 1.
The value of VSTCR_EL2.SA is 1.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

NSW, bit [29]
When FEAT_SEL2 is implemented:
Non-secure stage 2 translation table address space.
0b0 All stage 2 translation table walks for the Non-secure IPA space of the Secure EL1&0 translation regime are to the Secure PA space.
0b1 All stage 2 translation table walks for the Non-secure IPA space of the Secure EL1&0 translation regime are to the Non-secure PA space.

When the PE is executing in Non-secure state, this bit behaves as 1 for all purposes other than reading back the value of the bit.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU62, bit [28]
When FEAT_HPDS2 is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 2 translation table Block or Page entry.
0b0 Bit[62] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1 Bit[62] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU61, bit [27]
When FEAT_HPDS2 is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 2 translation table Block or Page entry.
0b0 Bit[61] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1 Bit[61] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU60, bit [26]
When FEAT_HPDS2 is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 2 translation table Block or Page entry.
0b0 Bit[60] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1 Bit[60] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.
This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**HWU59, bit [25]**

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 2 translation table Block or Page entry.

- **0b0**: Bit[59] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1**: Bit[59] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**Bits [24:23]**

Reserved, RES0.

**HD, bit [22]**

*When FEAT_HAFDBS is implemented:*

Hardware management of dirty state in stage 2 translations when EL2 is enabled in the current Security state.

- **0b0**: Stage 2 hardware management of dirty state disabled.
- **0b1**: Stage 2 hardware management of dirty state enabled, only if the VTCR_EL2.HA bit is also set to 1.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**HA, bit [21]**

*When FEAT_HAFDBS is implemented:*

Hardware Access flag update in Non-secure and Secure stage 2 translations when EL2 is enabled in the current Security state.

- **0b0**: Stage 2 Access flag update disabled.
- **0b1**: Stage 2 Access flag update enabled.

**Otherwise:**
Reserved, RES0.

**Bit [20]**

Reserved, RES0.

**VS, bit [19]**

*When FEAT_VMID16 is implemented:*

VMID Size.

- **0b0**: 8 bit - the upper 8 bits of VTTBR_EL2 and VSTTBR_EL2 are ignored by the hardware, and treated as if they are all zeros, for every purpose except when reading back the register.
- **0b1**: 16 bit - the upper 8 bits of VTTBR_EL2 and VSTTBR_EL2 are used for allocation and matching in the TLB.

If the implementation only supports an 8-bit VMID, this field is RES0.
This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**PS, bits [18:16]**

Physical address Size for the Second Stage of translation.

- **0b000**: 32 bits, 4GB.
- **0b001**: 36 bits, 64GB.
- **0b010**: 40 bits, 1TB.
- **0b011**: 42 bits, 4TB.
- **0b100**: 44 bits, 16TB.
- **0b101**: 48 bits, 256TB.
- **0b110**: 52 bits, 4PB.

All other values are reserved.

The reserved values behave in the same way as the **0b101** or **0b110** encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

If the translation granule is not 64KB, the value **0b110** is treated as reserved.

It is IMPLEMENTATION DEFINED whether an implementation that does not implement FEAT_LPA supports setting the value of **0b110** for the 64KB translation granule size or whether setting this value behaves as the **0b101** encoding.

In an implementation that supports 52-bit PAs, if the value of this field is not **0b110** or a value treated as **0b110**, then bits[51:48] of every translation table base address for the stage of translation controlled by VTCR_EL2 are **0b000**.

This field resets to an architecturally UNKNOWN value.

**TG0, bits [15:14]**

Granule size for the VTTBR_EL2.

- **0b0**: 4KB.
- **0b1**: 64KB.
- **0b10**: 16KB.

Other values are reserved.

If FEAT_GTG is implemented, ID_AA64MMFR0_EL1.{TGran4_2, TGran16_2, TGran64_2} indicate which granule sizes are supported for Level 2 translation.

If FEAT_GTG is not implemented, ID_AA64MMFR0_EL1.{TGran4, TGran16, TGran64} indicate which granule sizes are supported.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

**SH0, bits [13:12]**

Shareability attribute for memory associated with translation table walks using VTTBR_EL2 or VSTTBR_EL2.

- **0b0**: Non-shareable.
- **0b10**: Outer Shareable.
0b11  Inner Shareable.  
Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.  
This field resets to an architecturally UNKNOWN value.

**ORGN0, bits [11:10]**

Outer cacheability attribute for memory associated with translation table walks using VTTBR_EL2 or VSTTBR_EL2.

0b00  Normal memory, Outer Non-cacheable.
0b01  Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10  Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11  Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

**IRGN0, bits [9:8]**

Inner cacheability attribute for memory associated with translation table walks using VTTBR_EL2 or VSTTBR_EL2.

0b00  Normal memory, Inner Non-cacheable.
0b01  Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
0b10  Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11  Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

**SL0, bits [7:6]**

*When FEAT_TTST is implemented:*

Starting level of the Secure stage 2 translation lookup, controlled by VTCR_EL2. The meaning of this field depends on the value of VTCR_EL2.TG0.

0b00  If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 2. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 3.
0b01  If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 1. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 2.
0b10  If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 0. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 1.
0b11  If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 3.

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Starting level of the Secure stage 2 translation lookup, controlled by VTCR_EL2. The meaning of this field depends on the value of VTCR_EL2.TG0.

0b00  If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 2. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 3.
0b01  If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 1. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 2.
0b10  If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 0. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 1.

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.
This field resets to an architecturally UNKNOWN value.

T0SZ, bits [5:0]

The size offset of the memory region addressed by VTTBR_EL2. The region size is \(2^{64-\text{T0SZ}}\) bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

If this field is programmed to a value that is not consistent with the programming of SL0 then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

**Accessing the VTCR_EL2**

Any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, VTCR_EL2**

<table>
<thead>

    elsif EL2Enabled() & HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
    elsif PSTATE.EL == EL2 then
        VTCR_EL2 = X[t];
    elsif PSTATE.EL == EL3 then
        VTCR_EL2 = X[t];
D13.2.146  VTTBR_EL2, Virtualization Translation Table Base Register

The VTTBR_EL2 characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 2 of an address translation in the EL1&0 translation regime, and other information for this translation regime.

**Configurations**

AArch64 System register VTTBR_EL2[63:0] is architecturally mapped to AArch32 System register VTTBR[63:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

VTTBR_EL2 is a 64-bit register.

**Field descriptions**

The VTTBR_EL2 bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>56</th>
<th>55</th>
<th>48</th>
<th>47</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMID[15:8]</td>
<td>VMID[7:0]</td>
<td>BADDR</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**VMID[15:8], bits [63:56]**

*When FEAT_VMID16 is implemented and VTCR_EL2.VS == 1:*

Extension to VMID[7:0]. See VTTBR_EL2.VMID[7:0] for more details.

If EL2 is using AArch32, or if the implementation has an 8-bit VMID, this field is RES0.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**VMID[7:0], bits [55:48]**

The VMID for the translation table.

The VMID is 8 bits when any of the following are true:
- EL2 is using AArch32.
- The VTCR_EL2.VS is 0.
- FEAT_VMID16 is not implemented.

This field resets to an architecturally UNKNOWN value.

**BADDR, bits [47:1]**

Translation table base address, A[47:x] or A[51:x], bits[47:1].

--- **Note** ---

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes FEAT_LPA and is using the 64KB translation granule.
• A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes FEAT_LPA, if the value of VTCR_EL2.PS is 0b110, then:
• Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  — If x >= 6 then z=x.
  — Otherwise, z=6.
• Register bits[5:2] hold bits[51:48] of the stage 1 translation table base address.
• When z=x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
• When x>6 register bits[(x-1):6] are RES0.
• Register bit[1] is RES0.
• Bits[5:2] of the stage 1 translation table base address are zero.
• In an implementation that includes FEAT_TTCNP, bit[0] of the stage 1 translation table base address is zero.

—— Note ———
• In an implementation that includes FEAT_LPA a VTCR_EL2.PS value of 0b110, that selects a PA size of 52 bits, is permitted only when using the 64KB translation granule.
• When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the Effective value of VTCR_EL2.PS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of VTCR_EL2.PS is not 0b110 then:
• Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
• Register bits[(x-1):1] are RES0.
• If the implementation supports 52-bit PAs and IPAs then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

—— Note ———
This definition applies:
• To an implementation that includes FEAT_LPA and is using a translation granule smaller than 64KB.
• To any implementation that does not include FEAT_LPA.

If any VTTBR_EL2[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using VTTBR_EL2, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:
• Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
• The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of VTCR_EL2.T0SZ, the stage of translation, and the translation granule size.
This field resets to an architecturally UNKNOWN value.
CnP, bit [0]

When FEAT_TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by VTTBR_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VTTBR_EL2.CnP is 1.

0b0 The translation table entries pointed to by VTTBR_EL2 are permitted to differ from the entries for VTTBR_EL2 for other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.

0b1 The translation table entries pointed to by VTTBR_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of VTTBR_EL2.CnP is 1 and the VMID is the same as the current VMID.

This field is permitted to be cached in a TLB.

--- Note ---

If the value of VTTBR_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those VTTBR_EL2s do not point to the same translation table entries when using the current VMID then the results of translations using VTTBR_EL2 are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7966.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

This section lists the Debug System registers in AArch64 state, in alphabetic order:

- The principal encoding space for debug registers is \( \text{op0} = 0b10, \text{op1} = \{0, 3, 4\} \). *Instructions for accessing debug System registers on page D12-2845* summarizes the registers in this encoding space and lists them in order of their encodings.

- In addition, the following registers in the \( \text{op0} = 0b11 \) encoding space are classified as Debug registers:
  - DLR_EL0.
  - DSPSR_EL0.
  - MDCR_EL2.
  - MDCR_EL3.
  - SDER32_EL3.
D13.3.1 DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

**Purpose**

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

**Configurations**

AArch64 System register DBGAUTHSTATUS_EL1[31:0] is architecturally mapped to AArch32 System register DBGAUTHSTATUS[31:0].

AArch64 System register DBGAUTHSTATUS_EL1[31:0] is architecturally mapped to External register DBGAUTHSTATUS_EL1[31:0].

**Attributes**

DBGAUTHSTATUS_EL1 is a 64-bit register.

**Field descriptions**

The DBGAUTHSTATUS_EL1 bit assignments are:

```

D13.3.2  DBGCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGCR<n>_EL1 characteristics are:

**Purpose**
Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1.

**Configurations**
AArch64 System register DBGCR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGCR<n>[31:0].
AArch64 System register DBGCR<n>_EL1[31:0] is architecturally mapped to External register DBGCR<n>_EL1[31:0].
If breakpoint n is not implemented then accesses to this register are UNDEFINED.

**Attributes**
DBGCR<n>_EL1 is a 64-bit register.

**Field descriptions**
The DBGCR<n>_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Description</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 - 24</td>
<td>Reserved, RES0</td>

**Bits [63:24]**
Reserved, RES0.

**BT, bits [23:20]**
Breakpoint Type. Possible values are:

- 0b0000: Unlinked instruction address match. DBGBVR<n>_EL1 is the address of an instruction.
- 0b0001: As 0b0000, but linked to a Context matching breakpoint.
- 0b0010: Unlinked Context ID match. When FEAT_VHE is implemented, EL2 is using AArch64, and the Effective value of HCR_EL2.E2H is 1, if either the PE is executing at EL0 with HCR_EL2.TGE set to 1 or the PE is executing at EL2, then DBGBVR<n>_EL1.ContextID must match the CONTEXTIDR_EL2 value. Otherwise, DBGBVR<n>_EL1.ContextID must match the CONTEXTIDR_EL1 value.
- 0b0011: As 0b0010, with linking enabled.
- 0b0100: Unlinked CONTEXTIDR_EL1 match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1.
- 0b0111: As 0b0110, with linking enabled.
- 0b1000: Unlinked VMID match. DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.
- 0b1001: As 0b1000, with linking enabled.
- 0b1010: Unlinked VMID and Context ID match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.
0b1011  As 0b1010, with linking enabled.

0b1100  Unlinked CONTEXTIDR_EL2 match. DBGBVR<\textit{n}>_EL1.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.

0b1101  As 0b1100, with linking enabled.

0b1110  Unlinked Full Context ID match. DBGBVR<\textit{n}>_EL1.ContextID is compared against CONTEXTIDR_EL1, and DBGBVR<\textit{n}>_EL1.ContextID2 is compared against CONTEXTIDR_EL2.

0b1111  As 0b1110, with linking enabled.

All other values are reserved. Constraints on breakpoint programming mean other values are reserved under some conditions.

For more information on the operation of the SSC, HMC, and PMC fields, and on the effect of programming this field to a reserved value, see \textit{Execution conditions for which a breakpoint generates Breakpoint exceptions} on page D2-2442 and \textit{Reserved DBGBCR<\textit{n}>_EL1.BT values} on page D2-2447.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

\textbf{LBN, bits [19:16]}

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of DBGBCR<\textit{n}>_EL1.E is 0.
On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

\textbf{SSC, bits [15:14]}

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint \textit{n} is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the \{HMC, SSC, PMC\} fields.

For more information on the operation of the SSC, HMC, and PMC fields, and the effect of programming the fields to a reserved set of values, see \textit{Execution conditions for which a breakpoint generates Breakpoint exceptions} on page D2-2442 and \textit{Reserved DBGBCR<\textit{n}>_EL1.{SSC, HMC, PMC} values} on page D2-2448.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

\textbf{HMC, bit [13]}

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint \textit{n} is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the \{HMC, SSC, PMC\} fields. For more information see the SSC, bits [15:14] description.

For more information on the operation of the SSC, HMC, and PMC fields, see \textit{Execution conditions for which a breakpoint generates Breakpoint exceptions} on page D2-2442.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

\textbf{Bits [12:9]}

Reserved, \textit{RES0}.

Non-Confidential  ID072120
BAS, bits [8:5]

When AArch32 is supported at any Exception level:

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state.

The permitted values depend on the breakpoint type.

For Address match breakpoints, the permitted values are:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;n&gt;_EL1</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;n&gt;_EL1 + 2</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;n&gt;_EL1</td>
<td>Use for A64 and A32 instructions</td>
</tr>
</tbody>
</table>

All other values are reserved. For more information, see Reserved DBGBCR<n>_EL1.BAS values on page D2-2448.

For more information on using the BAS field in address match breakpoints, see Using the BAS field in Address Match breakpoints on page G2-5883.

For Context matching breakpoints, this field is RES1 and ignored.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

Otherwise:

Reserved, RES1.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>_EL1.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2442.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

E, bit [0]

Enable breakpoint DBGBVR<n>_EL1.

0b0 Breakpoint disabled.
0b1 Breakpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

### D13.3.3  DBGBVR<\(n\)>_EL1, Debug Breakpoint Value Registers, \(n = 0 - 15\)

The DBGBVR<\(n\)>_EL1 characteristics are:

#### Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint \(n\) together with control register DBGBCR<\(n\)>_EL1.

#### Configurations

AArch64 System register DBGBVR<\(n\)>_EL1[31:0] is architecturally mapped to AArch32 System register DBGBVR<\(n\)>[31:0].

- If the breakpoint is context-aware and EL2 is implemented, then AArch64 System register DBGBVR<\(n\)>_EL1[63:32] is architecturally mapped to AArch32 System register DBGBXVR<\(n\)>[31:0]. Otherwise, there is no System register access to DBGBVR<\(n\)>_EL1[63:32] from AArch32 state.
- AArch64 System register DBGBVR<\(n\)>_EL1[63:0] is architecturally mapped to External register DBGBVR<\(n\)>_EL1[63:0].
- If breakpoint \(n\) is not implemented then accesses to this register are UNDEFINED.

#### Attributes

How this register is interpreted depends on the value of DBGBCR<\(n\)>_EL1.BT.

- When DBGBCR<\(n\)>_EL1.BT is 0b000x, this register holds a virtual address.
- When DBGBCR<\(n\)>_EL1.BT is 0b001x, 0b011x, or 0b110x, this register holds a Context ID.
- When DBGBCR<\(n\)>_EL1.BT is 0b100x, this register holds a VMID.
- When DBGBCR<\(n\)>_EL1.BT is 0b101x, this register holds a VMID and a Context ID.
- When DBGBCR<\(n\)>_EL1.BT is 0b111x, this register holds two Context ID values.

For other values of DBGBCR<\(n\)>_EL1.BT, this register is RES0.

#### Field descriptions

The DBGBVR<\(n\)>_EL1 bit assignments are:

**When DBGBCR<\(n\)>_EL1.BT == 0b000x:**

- **RESS[14:4]**, bits [63:53]
  
  Reserved, Sign extended. Software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

  It is IMPLEMENTATION DEFINED whether:
  
  - Reads return the value of the most significant bit of the VA for every bit in this field.
  - Reads return the last value written.
  
  The PE ignores this field.

- **VA[52:49]**, bits [52:49]
  
  When FEAT_LVA is implemented:
  
On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

**Otherwise:**

**VA[48:2], bits [48:2]**
Bits[48:2] of the address value for comparison.
When FEAT_LVA is implemented, VA[52:49] forms the upper part of the address value. Otherwise, VA[52:49] are RESS.
On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

**Bits [1:0]**
Reserved, RES0.

*When DBGBCR<n>_EL1.BT == 0b001x:*

```
<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ContextID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:32]**
Reserved, RES0.

**ContextID, bits [31:0]**
Context ID value for comparison.
The value is compared against CONTEXTIDR_EL2 when FEAT_VHE is implemented, HCR_EL2.E2H is 1, and either:
- The PE is executing at EL2.
- HCR_EL2.TGE is 1, the PE is executing at EL0, and EL2 is enabled in the current Security state.
Otherwise, the value is compared against CONTEXTIDR_EL1.
On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

*When DBGBCR<n>_EL1.BT == 0b011x:*

```
<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ContextID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:32]**
Reserved, RES0.

**ContextID, bits [31:0]**
Context ID value for comparison against CONTEXTIDR_EL1.
On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.
When \( \text{DBGBCR}_n\_\text{EL1.BT} = 0b100x \) and \( \text{EL2} \) is implemented:

\[
\begin{array}{c|c|c|c|c}
   & 63 & 48 & 47 & 40 \ 39 & 32 & 31 & 0 \\
\hline
\text{RES0} & \text{VMID}[15:8] & \text{VMID}[7:0] & \text{RES0} \\
\end{array}
\]

Bits [63:48]

Reserved, RES0.

\text{VMID}[15:8], bits [47:40]

When \text{FEAT\_VMID16} is implemented, \( \text{VTCR\_EL2.VS} = 1 \) and \( \text{EL2} \) is using AArch64:

Extension to VMID[7:0]. See DBGBVR\( n \_\text{EL1.VMID}[7:0] \) for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

Otherwise:

Reserved, RES0.

\text{VMID}[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits when any of the following are true:

- \( \text{EL2} \) is using AArch32.
- \( \text{VTCR\_EL2.VS} \) is 0.
- \( \text{FEAT\_VMID16} \) is not implemented.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

Bits [31:0]

Reserved, RES0.

When \( \text{DBGBCR}_n\_\text{EL1.BT} = 0b101x \) and \( \text{EL2} \) is implemented:

\[
\begin{array}{c|c|c|c|c}
   & 63 & 48 & 47 & 40 \ 39 & 32 & 31 & 0 \\
\hline
\text{RES0} & \text{VMID}[15:8] & \text{VMID}[7:0] & \text{ContextID} \\
\end{array}
\]

Bits [63:48]

Reserved, RES0.

\text{VMID}[15:8], bits [47:40]

When \text{FEAT\_VMID16} is implemented, \( \text{VTCR\_EL2.VS} = 1 \) and \( \text{EL2} \) is using AArch64:

Extension to VMID[7:0]. See DBGBVR\( n \_\text{EL1.VMID}[7:0] \) for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

Otherwise:

Reserved, RES0.

\text{VMID}[7:0], bits [39:32]

VMID value for comparison.
The VMID is 8 bits when any of the following are true:

- EL2 is using AArch32.
- VTCR_EL2.VS is 0.
- FEAT_VMID16 is not implemented.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

**ContextID, bits [31:0]**

Context ID value for comparison against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

*When DBGBCR<El1.BT == 0b110x, EL2 is implemented and (FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented):*

**ContextID2, bits [63:32]**

Context ID value for comparison against CONTEXTIDR_EL2.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

**Bits [31:0]**

Reserved, RES0.

*When DBGBCR<El1.BT == 0b111x, EL2 is implemented and (FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented):*

**ContextID2, bits [63:32]**

Context ID value for comparison against CONTEXTIDR_EL2.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

**ContextID, bits [31:0]**

Context ID value for comparison against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

D13.3.4 DBGCLAIMCLR_EL1, Debug CLAIM Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

**Purpose**

Used by software to read the values of the CLAIM tag bits, and to clear CLAIM tag bits to 0. The architecture does not define any functionality for the CLAIM tag bits.

**Note**

CLAIM tags are typically used for communication between the debugger and target software. Used in conjunction with the DBGCLAIMSET_EL1 register.

**Configurations**

AArch64 System register DBGCLAIMCLR_EL1[31:0] is architecturally mapped to AArch32 System register DBGCLAIMCLR[31:0].

AArch64 System register DBGCLAIMCLR_EL1[31:0] is architecturally mapped to External register DBGCLAIMCLR_EL1[31:0].

An implementation must include eight CLAIM tag bits.

**Attributes**

DBGCLAIMCLR_EL1 is a 64-bit register.

**Field descriptions**

The DBGCLAIMCLR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>32-31</td>
<td>Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.</td>
</tr>
<tr>
<td>8-0</td>
<td>CLAIM, bits [7:0]. Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits. Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0. Writing 0 to one of these bits has no effect. On a Cold reset, this field resets to 0. On a Warm reset, the value of this field is unchanged.</td>
</tr>
</tbody>
</table>

D13.3.6  DBGDTR_EL0, Debug Data Transfer Register, half-duplex

The DBGDTR_EL0 characteristics are:

**Purpose**

Transfers 64 bits of data between the PE and an external debugger. Can transfer both ways using only a single register.

**Configurations**

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to AArch32 System register DBGDTRRXint[31:0] when written.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to External register DBGDTRRX_EL0[31:0] when written.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0] when written.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRTXint[31:0] when written.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to External register DBGDTRTX_EL0[31:0] when written.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRTXint[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to External register DBGDTRTX_EL0[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRTXint[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to External register DBGDTRTX_EL0[31:0] when read.

**Attributes**

DBGDTR_EL0 is a 64-bit register.

**Field descriptions**

The DBGDTR_EL0 bit assignments are:

63 32 31 0

| HighWord | LowWord |

**HighWord, bits [63:32]**

Writes to this register set DTRRX to the value in this field and do not change RXfull.

Reads of this register:

- If RXfull is set to 1, return the last value written to DTRTX.
- If RXfull is set to 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.
**LowWord, bits [31:0]**

Writes to this register set DTRTX to the value in this field and set TXfull to 1.

Reads of this register:
- If RXfull is set to 1, return the last value written to DTRRX.
- If RXfull is set to 0, return an **UNKNOWN** value.

After the read, RXfull is cleared to 0.

**Accessing the DBGDTR_EL0**

Accesses to this register use the following encodings in the System instruction encoding space:

```plaintext
MRS <Xt>, DBGDTR_EL0
```

D13.3.7 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

**Purpose**

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See **DBGDTR_EL0** for additional architectural mappings. It is a component of the Debug Communications Channel.

**Configurations**

AArch64 System register DBGDTRRX_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRRXint[31:0].

AArch64 System register DBGDTRRX_EL0[31:0] is architecturally mapped to External register DBGDTRRX_EL0[31:0].

**Attributes**

DBGDTRRX_EL0 is a 64-bit register.

**Field descriptions**

The DBGDTRRX_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>Update DTRRX</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved, RES0.</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Update DTRRX.

Reads of this register:

- If RXfull is set to 1, return the last value written to DTRRX.
- If RXfull is set to 0, return an **UNKNOWN** value.

After the read, RXfull is cleared to 0.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

On a Cold reset, this field resets to an architecturally **UNKNOWN** value.

On a Warm reset, the value of this field is unchanged.

**Accessing the DBGDTRRX_EL0**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, DBGDTRRX_EL0**

<table>

D13.3.8  DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communication Channel.

Configurations

AArch64 System register DBGDTRTX_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRTXint[31:0].
AArch64 System register DBGDTRTX_EL0[31:0] is architecturally mapped to External register DBGDTRTX_EL0[31:0].

Attributes

DBGDTRTX_EL0 is a 64-bit register.

Field descriptions

The DBGDTRTX_EL0 bit assignments are:

Bits [63:32]  
Reserved, RES0.

Bits [31:0]  
Return DTRTX.

Writes to this register:
- If TXfull is set to 1, set DTRRX and DTRTX to UNKNOWN.
- If TXfull is set to 0, update the value in DTRTX.

After the write, TXfull is set to 1.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

Accessing the DBGDTRTX_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

**MSR DBGDTRTX_EL0, <Xt>**

<table>
<thead>
<tr>
<th>op0</th>

endif
D13.3.9 DBGPRCR_EL1, Debug Power Control Register

The DBGPRCR_EL1 characteristics are:

**Purpose**

Controls behavior of the PE on powerdown request.

**Configurations**

AArch64 System register DBGPRCR_EL1[31:0] is architecturally mapped to AArch32 System register DBGPRCR[31:0].

Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register.

The other bits in these registers are not mapped to each other.

**Attributes**

DBGPRCR_EL1 is a 64-bit register.

**Field descriptions**

The DBGPRCR_EL1 bit assignments are:

![Diagram of DBGPRCR_EL1 bit assignments]

**Bits [63:1]**

Reserved, RES0.

**CORENPDRQ, bit [0]**

*When FEAT_DoPD is implemented:*

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

- **0b0** If the system responds to a powerdown request, it powers down Core power domain.
- **0b1** If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to its Cold reset value on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see [Core power domain power states on page H6-7118](#).

**Note**

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

On a Cold reset, if the powerup request is implemented and the powerup request has been asserted, this field is set to an IMPLEMENTATION DEFINED choice of 0 or 1. If the powerup request is not asserted, this field is set to 0.
On a Warm reset, the value of this field is unchanged.

**Otherwise:**

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

| 0b0 | If the system responds to a powerdown request, it powers down Core power domain. |
| 0b1 | If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain. |

In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see [Core power domain power states on page H6-7118](#).

**Note**

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

On a Cold reset, this field resets to the value in EDPRCR.COREPURQ.

On a Warm reset, the value of this field is unchanged.

### Accessing the DBGPRCR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\begin{array}{c|c|c|c|c}

**D13.3.10 DBGVCR32_EL2, Debug Vector Catch Register**

The DBGVCR32_EL2 characteristics are:

**Purpose**

Allows access to the AArch32 register DBGVCR from AArch64 state only. Its value has no effect on execution in AArch64 state.

**Configurations**

AArch64 System register DBGVCR32_EL2[31:0] is architecturally mapped to AArch32 System register DBGVCR[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGVCR32_EL2 are UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

**Attributes**

DBGVCR32_EL2 is a 64-bit register.

**Field descriptions**

The DBGVCR32_EL2 bit assignments are:

*When EL3 is implemented:*

Prefetch Abort vector catch enable in Secure state.
The exception vector offset is 0x0C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**SS, bit [2]**
Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is 0x08.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**SU, bit [1]**
Undefined Instruction vector catch enable in Secure state.
The exception vector offset is 0x04.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [0]**
Reserved, RES0.

*When EL3 is not implemented:*

![Diagram showing bit locations]

**Bits [63:8]**
Reserved, RES0.

**F, bit [7]**
FIQ vector catch enable.
The exception vector offset is 0x1C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**I, bit [6]**
IRQ vector catch enable.
The exception vector offset is 0x18.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [5]**
Reserved, RES0.

**D, bit [4]**
Data Abort vector catch enable.
The exception vector offset is 0x10.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**P, bit [3]**
Prefetch Abort vector catch enable.
The exception vector offset 0x0C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**S, bit [2]**
Supervisor Call (SVC) vector catch enable.
The exception vector offset 0x08.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**U, bit [1]**
Undefined Instruction vector catch enable.
The exception vector offset 0x04.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [0]**
Reserved, RES0.
Accessing the DBGVCR32_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

```
D13.3.11 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

**Purpose**
Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1.

**Configurations**
AArch64 System register DBGWCR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWCR<n>[31:0].
AArch64 System register DBGWCR<n>_EL1[31:0] is architecturally mapped to External register DBGWCR<n>_EL1[31:0].
If watchpoint n is not implemented then accesses to this register are UNDEFINED.

**Attributes**
DBGWCR<n>_EL1 is a 64-bit register.

**Field descriptions**
The DBGWCR<n>_EL1 bit assignments are:

![Diagram of DBGWCR bit assignments]  

**Bits [63:29]**
Reserved, RES0.

**MASK, bits [28:24]**
Address mask. Only objects up to 2GB can be watched using a single mask.
0b00000  No mask.
0b00001  Reserved.
0b00010  Reserved.
If programmed with a reserved value, a watchpoint must behave as if either:
- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.
Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.
Other values mask the corresponding number of address bits, from 0b000011 masking 3 address bits (0x00000007 mask for address) to 0b111111 masking 31 address bits (0x7FFFFFFF mask for address).
On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

**Bits [23:21]**
Reserved, RES0.
WT, bit [20]

Watchpoint type. Possible values are:

0b0 Unlinked data address match.
0b1 Linked data address match.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.
On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.
For more information, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2442, and Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-2448.
On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.
For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-2453.
On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n>_EL1 is being watched.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxxx11x</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1 + 1</td>
</tr>
<tr>
<td>xxxx1xx</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1 + 2</td>
</tr>
<tr>
<td>xxxx1xxx</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1 + 3</td>
</tr>
</tbody>
</table>

In cases where DBGWVR<n>_EL1 addresses a double-word:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description, if DBGWVR&lt;n&gt;_EL1[2] == 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxx1xxx</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1 + 4</td>
</tr>
</tbody>
</table>

The valid values for BAS are non-zero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See Reserved DBGWCR<n>_EL1.BAS values on page D2-2462.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

LSC, bits [4:3]
Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:
- 0b01 Match instructions that load from a watchpointed address.
- 0b10 Match instructions that store to a watchpointed address.
- 0b11 Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

PAC, bits [2:1]
Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-2453.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

E, bit [0]
Enable watchpoint n. Possible values are:
- 0b0 Watchpoint disabled.
- 0b1 Watchpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

D13.3.12 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n>_EL1 characteristics are:

**Purpose**

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>_EL1.

**Configurations**

AArch64 System register DBGWVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWVR<n>[31:0].

AArch64 System register DBGWVR<n>_EL1[63:0] is architecturally mapped to External register DBGWVR<n>_EL1[63:0].

If watchpoint n is not implemented then accesses to this register are UNDEFINED.

**Attributes**

DBGWVR<n>_EL1 is a 64-bit register.

**Field descriptions**

The DBGWVR<n>_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>53 52</th>
<th>49 48</th>
<th>2 1 0</th>
</tr>
</thead>
</table>

**RESS[14:4], bits [63:53]**

Reserved, Sign extended. Hardware and software must treat this field as RES0 if the most significant bit of VA is 0 or RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

**VA[52:49], bits [52:49]**

*When FEAT_LVA is implemented:*

On a Cold reset, this field resets to an architecturally UNKNOWN value.

On a Warm reset, the value of this field is unchanged.

*Otherwise:*

**VA[48:2], bits [48:2]**

Bits[48:2] of the address value for comparison.

When FEAT_LVA is implemented, VA[52:49] forms the upper part of the address value. Otherwise, VA[52:49] are RESS.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
On a Warm reset, the value of this field is unchanged.

**Bits [1:0]**

Reserved, RES0.

**Accessing the DBGWVR<\text{n}>_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, DBGWVR<\text{n}>_EL1**

```
D13.3.14  DSPSR_EL0, Debug Saved Program Status Register

The DSPSR_EL0 characteristics are:

Purpose

Holds the saved process state for Debug state. On entering Debug state, PSTATE information is written to this register. On exiting Debug state, values are copied from this register to PSTATE.

Configurations

AArch64 System register DSPSR_EL0[31:0] is architecturally mapped to AArch32 System register DSPSR[31:0].

Attributes

DSPSR_EL0 is a 64-bit register.

Field descriptions

The DSPSR_EL0 bit assignments are:

When AArch32 is supported at any Exception level and exiting Debug state to AArch32 state:

IT[1:0], bits [26:25]

If-Then. Copied to PSTATE.IT[1:0] on exiting Debug state.
On exiting Debug state DSPSR_EL0.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

DIT, bit [24]

When FEAT_DIT is implemented:
Data Independent Timing. Copied to PSTATE.DIT on exiting Debug state.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SSBS, bit [23]

When FEAT_SSBS is implemented:
Speculative Store Bypass. Copied to PSTATE.SSBS on exiting Debug state.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:
Privileged Access Never. Copied to PSTATE.PAN on exiting Debug state.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SS, bit [21]

Software Step. Copied to PSTATE.SS on exiting Debug state.
This field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Copied to PSTATE.IL on exiting Debug state.
This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Copied to PSTATE.GE on exiting Debug state.
This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]

If-Then. Copied to PSTATE.IT[7:2] on exiting Debug state.
DSPSR_EL0.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Copied to PSTATE.E on exiting Debug state.
If the implementation does not support big-endian operation, DSPSR_EL0.E is RES0. If the implementation does not support little-endian operation, DSPSR_EL0.E is RES1. On exiting Debug state, if the implementation does not support big-endian operation at the Exception level being returned to, DSPSR_EL0.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, DSPSR_EL0.E is RES1.
This field resets to an architecturally **UNKNOWN** value.

**A**, bit [8]

SError interrupt mask. Copied to PSTATE.A on exiting Debug state.
This field resets to an architecturally **UNKNOWN** value.

**I**, bit [7]

IRQ interrupt mask. Copied to PSTATE.I on exiting Debug state.
This field resets to an architecturally **UNKNOWN** value.

**F**, bit [6]

FIQ interrupt mask. Copied to PSTATE.F on exiting Debug state.
This field resets to an architecturally **UNKNOWN** value.

**T**, bit [5]

T32 Instruction set state. Copied to PSTATE.T on exiting Debug state.
This field resets to an architecturally **UNKNOWN** value.

**M[4]**, bit [4]

Execution state. Copied to PSTATE.nRW on exiting Debug state.

- **0b1** AArch32 execution state.

This field resets to an architecturally **UNKNOWN** value.

**M[3:0]**, bits [3:0]

AArch32 Mode. Copied to PSTATE.M[3:0] on exiting Debug state.

- **0b0000** User.
- **0b0001** FIQ.
- **0b0010** IRQ.
- **0b0011** Supervisor.
- **0b0100** Monitor.
- **0b0110** Abort.
- **0b1000** Hyp.
- **0b1011** Undefined.
- **0b1111** System.

Other values are reserved. If DSPSR_EL0.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, exiting Debug state is an illegal return event, as described in *Illegal return events from AArch64 state* on page D1-2345.

This field resets to an architecturally **UNKNOWN** value.
When AArch64 is supported at any Exception level and entering or exiting Debug state from or to AArch64 state:

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on entering Debug state, and copied to PSTATE.N on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on entering Debug state, and copied to PSTATE.Z on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on entering Debug state, and copied to PSTATE.C on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on entering Debug state, and copied to PSTATE.V on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Bits [27:26]

Reserved, RES0.

TCO, bit [25]

When FEAT_MTE is implemented:

Tag Check Override. Set to the value of PSTATE.TCO on entering Debug state, and copied to PSTATE.TCO on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [24]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on entering Debug state, and copied to PSTATE.DIT on exiting Debug state.

This field resets to an architecturally UNKNOWN value.
**D13.3 Debug registers**

**Otherwise:**
Reserved, RES0.

**UAO, bit [23]**

*When FEAT_UAO is implemented:*
User Access Override. Set to the value of PSTATE.UAO on entering Debug state, and copied to PSTATE.UAO on exiting Debug state.
This field resets to an architecturally **UNKNOWN** value.

**Otherwise:**
Reserved, RES0.

**PAN, bit [22]**

*When FEAT_PAN is implemented:*
Privileged Access Never. Set to the value of PSTATE.PAN on entering Debug state, and copied to PSTATE.PAN on exiting Debug state.
This field resets to an architecturally **UNKNOWN** value.

**Otherwise:**
Reserved, RES0.

**SS, bit [21]**
Software Step. Set to the value of PSTATE.SS on entering Debug state, and conditionally copied to PSTATE.SS on exiting Debug state.
This field resets to an architecturally **UNKNOWN** value.

**IL, bit [20]**
Illegal Execution state. Set to the value of PSTATE.IL on entering Debug state, and copied to PSTATE.IL on exiting Debug state.
This field resets to an architecturally **UNKNOWN** value.

**Bits [19:13]**
Reserved, RES0.

**SSBS, bit [12]**

*When FEAT_SSBS is implemented:*
Speculative Store Bypass. Set to the value of PSTATE.SSBS on entering Debug state, and copied to PSTATE.SSBS on exiting Debug state.
This field resets to an architecturally **UNKNOWN** value.

**Otherwise:**
Reserved, RES0.

**BTYPE, bits [11:10]**

*When FEAT_BTI is implemented:*
Branch Type Indicator. Set to the value of PSTATE.BTYPE on entering Debug state, and copied to PSTATE.BTYPE on exiting Debug state.
This field resets to an architecturally **UNKNOWN** value.

**Otherwise:**
Reserved, RES0.

**D, bit [9]**
Debug exception mask. Set to the value of PSTATE.D on entering Debug state, and copied to PSTATE.D on exiting Debug state.
This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on entering Debug state, and copied to PSTATE.A on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on entering Debug state, and copied to PSTATE.I on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on entering Debug state, and copied to PSTATE.F on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to 0b0, the value of PSTATE.nRW, on entering Debug state from AArch64 state, and copied to PSTATE.nRW on exiting Debug state.

0b0 AArch64 execution state.

This field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

0b0000 EL0t.
0b0100 EL1t.
0b0101 EL1h.
0b1000 EL2t.
0b1001 EL2h.
0b1100 EL3t.
0b1101 EL3h.

Other values are reserved. If DSPSR_EL0.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, exiting Debug state is an illegal return event, as described in Illegal return events from AArch64 state on page D1-2345.

The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on entering Debug state and copied to PSTATE.EL on exiting Debug state.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on entering Debug state and copied to PSTATE.SP on exiting Debug state

This field resets to an architecturally UNKNOWN value.

Accessing the DSPSR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:
### MRS <Xt>, DSPSR_EL0

```plaintext
if !Halted() then
    UNDEFINED;
else
    return DSPSR_EL0;
```

### MSR DSPSR_EL0, <Xt>

```plaintext
if !Halted() then
    UNDEFINED;
else
    DSPSR_EL0 = X[t];
```

D13.3.16 MDCCSR_EL0, Monitor DCC Status Register

The MDCCSR_EL0 characteristics are:

**Purpose**

Read-only register containing control status flags for the DCC.

**Configurations**

AArch64 System register MDCCSR_EL0[30:29] is architecturally mapped to External register EDSCR[30:29].

AArch64 System register MDCCSR_EL0[30:29] is architecturally mapped to AArch32 System register DBGDSCRint[30:29].

**Attributes**

MDCCSR_EL0 is a 64-bit register.

**Field descriptions**

The MDCCSR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

D13.3.17 MDCR_EL2, Monitor Debug Configuration Register (EL2)

The MDCR_EL2 characteristics are:

**Purpose**

Provides EL2 configuration options for self-hosted debug and the Performance Monitors Extension.

**Configurations**

AArch64 System register MDCR_EL2[31:0] is architecturally mapped to AArch32 System register HDCR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

MDCR_EL2 is a 64-bit register.

**Field descriptions**

The MDCR_EL2 bit assignments are:

<table>
<thead>
<tr>

</tbody>
</table>

**Bits [63:29]**

Reserved, RES0.

**MTPME, bit [28]**

*When FEAT_MTPMU is implemented and EL3 is not implemented:*

Multi-threaded PMU Enable. Enables use of the PMEVTYPER<n>_EL0.MT bits.

- **0b0** FEAT_MTPMU is disabled. The Effective value of PMEVTYPER<n>_EL0.MT is zero.
- **0b1** PMEVTYPER<n>_EL0.MT bits not affected by this bit.

If FEAT_MTPMU is disabled for any other PE in the system that has the same level 1 Affinity as the PE, it is IMPLEMENTATION DEFINED whether the PE behaves as if this bit is 0.

On a Cold reset, this field resets to 1.

*Otherwise:*

Reserved, RES0.
TDCC, bit [27]

*When FEAT_FGT is implemented:*

Traps DCC. Traps use of the Debug Comms Channel at EL1 and EL0 to EL2.

\[\begin{align*}
0b0 & \text{ This control does not cause any register accesses to be trapped.} \\
0b1 & \text{ If EL2 is implemented and enabled in the current Security state, accesses to the DCC} \\
& \text{ registers at EL1 and EL0 generate a Trap exception to EL2, unless the access also} \\
& \text{ generates a higher priority exception. Traps on the DCC data transfer registers are} \\
& \text{ ignored when the PE is in Debug state. }
\end{align*}\]

The DCC registers trapped by this control are:

AArch64: OSDTRRX_EL1, OSDTRTX_EL1, MDCCSR_EL0, MDCCINT_EL1, and, when the PE is in Non-debug state, DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0.

AArch32: DBGDTRRXext, DBGDTRTXext, DBGDSCRint, DBGDCCINT, and, when the PE is in Non-debug state, DBGDTRRXint and DBGDTRTXint.

The traps are reported with EC syndrome value:

\[\begin{align*}
0x05 & \text{ for trapped AArch32 MRC and MCR accesses with coproc == 0b1110.} \\
0x06 & \text{ for trapped AArch32 LDC to DBGDTRRXint and STC from DBGDTRRXint.} \\
0x18 & \text{ for trapped AArch64 MSR accesses.}
\end{align*}\]

When the PE is in Debug state, MDCR_EL2.TDCC does not trap any accesses to:

AArch64: DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0.

AArch32: DBGDTRRXint and DBGDTRTXint.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

HLP, bit [26]

*When FEAT_PMu3p5 is implemented:*

Hypervisor Long event counter enable. Determines when unsigned overflow is recorded by a counter overflow bit.

\[\begin{align*}
0b0 & \text{ Event counter overflow on increment that causes unsigned overflow of} \\
& \text{ PMEVCNTR<\text{n}>_EL0[31:0].} \\
0b1 & \text{ Event counter overflow on increment that causes unsigned overflow of} \\
& \text{ PMEVCNTR<\text{n}>_EL0[63:0].}
\end{align*}\]

If MDCR_EL2.HPMN is less than PMCR_EL0.N or PMCR.N, this bit affects the operation of event counters in the range [MDCR_EL2.HPMN..(PMCR_EL0.N-1)] or [MDCR_EL2.HPMN..(PMCR.N-1)]. Otherwise this bit has no effect on the operation of the event counters.

\[\text{Note}\]

The effect of MDCR_EL2.HPMN on the operation of this bit always applies if EL2 is implemented, at all Exception levels including EL2 and EL3, and regardless of whether EL2 is enabled in the current Security state.

For more information see the description of the MDCR_EL2.HPMN field.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

Bits [25:24]

Reserved, RES0.
HCCD, bit [23]

When FEAT_PMUv3p5 is implemented:
Hypervisor Cycle Counter Disable. Prohibits PMCCNTR_EL0 from counting at EL2.

0b0  Cycle counting by PMCCNTR_EL0 is not affected by this bit.
0b1  Cycle counting by PMCCNTR_EL0 is prohibited at EL2.

This bit does not affect the CPU_CYCLES event or any other event that counts cycles.

On a Warm reset, this field resets to 0.

Otherwise:
Reserved, RES0.

Bits [22:20]
Reserved, RES0.

TTRF, bit [19]

When FEAT_TRF is implemented:
Traps use of the Trace Filter Control registers at EL1 to EL2, as follows:
- Access to TRFCR_EL1 is trapped to EL2, reported using EC syndrome value 0x18.
- Access to TRFCR is trapped to EL2, reported using EC syndrome value 0x3.

0b0  Accesses to TRFCR_EL1 and TRFCR at EL1 are not affected by this control.
0b1  Accesses to TRFCR_EL1 and TRFCR at EL1 generate a trap exception to EL2 when EL2 is enabled in the current Security state.

Otherwise:
Reserved, RES0.

Bit [18]
Reserved, RES0.

HPMD, bit [17]

When FEAT_PMUv3p1 is implemented:
Guest Performance Monitors Disable. This control prohibits event counting at EL2.

0b0  Event counting allowed at EL2.
0b1  Event counting prohibited at EL2.

If FEAT_Debugv8p2 is not implemented, event counting is prohibited unless enabled by the IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled().

This control applies only to:
- The event counters in the range [0..(MDCR_EL2.HPMN-1)].
- If PMCR_EL0.DP is set to 1, PMCCNTR_EL0.

The other event counters are unaffected, and when PMCR_EL0.DP is set to 0, PMCCNTR_EL0 is unaffected.

On a Warm reset, this field resets to 0.

Otherwise:
Reserved, RES0.

Bits [16:15]
Reserved, RES0.
TPMS, bit [14]

When FEAT_SPE is implemented:

Trap Performance Monitor Sampling. When EL2 is enabled in the current Security state, this field controls access to Statistical Profiling control registers from EL1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Do not trap Statistical Profiling controls to EL2.</td>
</tr>
<tr>
<td>0b1</td>
<td>Accesses to Statistical Profiling controls at EL1 generate a Trap exception to EL2 when EL2 is enabled in the current Security state.</td>
</tr>
</tbody>
</table>

The Statistical Profiling control registers trapped by this control are: PMSCR_EL1, PMSEVFR_EL1, PMSFCR_EL1, PMSICR_EL1, PMSIDR_EL1, PMSIRR_EL1, and PMSLATFR_EL1.

Otherwise:

Reserved, RES0.

E2PB, bits [13:12]

When FEAT_SPE is implemented:

EL2 Profiling Buffer. If EL2 is implemented and enabled in the Profiling Buffer owning Security state, this field controls the owning translation regime. If EL2 is implemented and enabled in the current Security state, this field controls access to Profiling Buffer control registers from EL1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>If EL2 is implemented and enabled in the Profiling Buffer owning Security state, the Profiling Buffer uses the EL2 or EL2&amp;0 stage 1 translation regime. Otherwise the Profiling Buffer uses the EL1&amp;0 stage 1 translation regime. If EL2 is implemented and enabled in the current Security state, accesses to Profiling Buffer control registers at EL1 generate a Trap exception to EL2.</td>
</tr>
<tr>
<td>0b10</td>
<td>Profiling Buffer uses the EL1&amp;0 stage 1 translation regime. If EL2 is implemented and enabled in the current Security state, accesses to Profiling Buffer control registers at EL1 generate a Trap exception to EL2.</td>
</tr>
<tr>
<td>0b11</td>
<td>Profiling Buffer uses the EL1&amp;0 stage 1 translation regime. Accesses to Profiling Buffer control registers at EL1 are not trapped to EL2.</td>
</tr>
</tbody>
</table>

All other values are reserved.

The Profiling Buffer control registers trapped by this control are: PMLIMITR_EL1, PMBPTR_EL1, and PMBSR_EL1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TDRA, bit [11]

Trap Debug ROM Address register access. Traps System register accesses to the Debug ROM registers to EL2 when EL2 is enabled in the current Security state as follows:

- If EL1 is using AArch64 state, accesses to MDRAR_EL1 are trapped to EL2, reported using EC syndrome value 0x18.
- If EL0 or EL1 is using AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x05 and MRRC or MCRR accesses are trapped to EL2, reported using EC syndrome value 0x0C:
  - DBGDRAR, DBGDSAR.

0b0 This control does not cause any instructions to be trapped.

0b1 EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2 when EL2 is enabled in the current Security state, unless it is trapped by DBGDSCRext.UDCDis or MDSCR_EL1.TDCC.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- MDCR_EL2.TDE == 1.
• HCR_EL2.TGE == 1.

--- Note ---

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2. On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDOSA, bit [10]

When FEAT_DoubleLock is implemented:

Trap debug OS-related register access. Traps EL1 System register accesses to the powerdown debug registers to EL2, from both Execution states as follows:

• In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x18:
  — OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, and DBGPRCR_EL1.
  — Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

• In AArch32 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x05:
  — DBGOSLSR, DBGOSLAR, DBGOSDLR, and DBGPRCR.
  — Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 System register accesses to the powerdown debug registers are trapped to EL2 when EL2 is enabled in the current Security state.

--- Note ---

These registers are not accessible at EL0.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

• MDCR_EL2.TDE == 1.

• HCR_EL2.TGE == 1.

System register accesses to the debug registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2. On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Trap debug OS-related register access. Traps EL1 System register accesses to the powerdown debug registers to EL2, from both Execution states as follows:

• In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x18:
  — OSLAR_EL1, OSLSR_EL1, and DBGPRCR_EL1.
  — Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

• In AArch32 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x05:
  — DBGOSLSR, DBGOSLAR, and DBGPRCR.
  — Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.
It is IMPLEMENTATION DEFINED whether accesses to `OSDLR_EL1` are trapped.

It is IMPLEMENTATION DEFINED whether accesses to `DBGOSDLR` are trapped.

0b0   This control does not cause any instructions to be trapped.

0b1   EL1 System register accesses to the powerdown debug registers are trapped to EL2 when EL2 is enabled in the current Security state.

Note

These registers are not accessible at EL0.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- `MDCR_EL2.TDE` == 1.
- `HCR_EL2.TGE` == 1.

Note

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDA, bit [9]

Trap Debug Access. Traps EL0 and EL1 System register accesses to debug System registers that are not trapped by MDCR_EL2.TDRA or MDCR_EL2.TDOSA, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2 reported using EC syndrome value 0x18:
  - `MDCCSR_EL0`, `MDCCINT_EL1`, `OSDTRRX_EL1`, `MDSCR_EL1`,
    `OSDTRTX_EL1`, `OSECCR_EL1`, `DBGVR<n>_EL1`, `DBGCR<n>_EL1`,
    `DBGWVR<n>_EL1`, `DBGWCR<n>_EL1`, `DBGCLAIMSET_EL1`,
    `DBGCLAIMCLR_EL1`, `DBGAUTHSTATUS_EL1`.
  - When not in Debug state, `DBGDTR_EL0`, `DBGDTRRX_EL0`, `DBGDTRTX_EL0`.
- In AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x95.
  - `DBGIDR`, `DBGIDCINT`, `DBGIDCXINT`, `DBGFR`, `DBGIDCR`,
    `DBGIDCRX`, `DBGIDCRXX`, `DBGVR<n>`, `DBGCR<n>`,
    `DBGXVR<n>`, `DBGXCR<n>`, `DBGXVR<n>`,
    `DBGCLAIMSET`, `DBGCLAIMCLR`,
    `DBGAUTHSTATUS`, `DBGDEVID`, `DBGDEVID1`, `DBGDEVID2`,
    `DBGSECCR`.
  - When not in Debug state, `DBGDTRRXint` and `DBGDTRXXint`.
- In AArch32 state, STC accesses to `DBGDTRRXint` and LDC accesses to `DBGDTRXXint` are trapped to EL2, reported using EC syndrome value 0x96.

0b0   This control does not cause any instructions to be trapped.

0b1   EL0 or EL1 System register accesses to the debug registers are trapped from both Execution states to EL2 when EL2 is enabled in the current Security state, unless the access generates a higher priority exception.

Traps of AArch32 accesses to `DBGDTRRXint` and `DBGDTRXXint` are ignored in Debug state.

Traps of AArch64 accesses to `DBGDTR_EL0`, `DBGDTRRX_EL0`, and `DBGDTRTX_EL0` are ignored in Debug state.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- `MDCR_EL2.TDE` == 1
- `HCR_EL2.TGE` == 1
On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**TDE, bit [8]**

Trap Debug Exceptions. Controls routing of Debug exceptions, and defines the debug target Exception level, EL_D.

- **0b0**: The debug target Exception level is EL1.
- **0b1**: If EL2 is enabled for the current Effective value of SCR_EL3.NS, the debug target Exception level is EL2, otherwise the debug target Exception level is EL1.

The MDCR_EL2.{TDRA, TDOSA, TDA} fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

For more information, see *Routing debug exceptions* on page D2-2423.

This field is treated as being 1 for all purposes other than a direct read when HCR_EL2.TGE == 1.

On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**HPME, bit [7]**

*When FEAT_PMUv3 is implemented:*

[MDCR_EL2.HPMN..(N-1)] event counters enable.

- **0b0**: Event counters in the range [MDCR_EL2.HPMN..(PMCR_EL0.N-1)] are disabled.
- **0b1**: Event counters in the range [MDCR_EL2.HPMN..(PMCR_EL0.N-1)] are enabled by PMCNTENSET_EL0.

If MDCR_EL2.HPMN is less than PMCR_EL0.N or PMCR.N, the event counters in the range [MDCR_EL2.HPMN..(PMCR_EL0.N-1)] or [HDCR.HPMN..(PMCR.N-1)], are enabled and disabled by this bit. Otherwise this bit has no effect on the operation of the event counters.

--- **Note**

The effect of MDCR_EL2.HPMN on the operation of this bit applies regardless of whether EL2 is enabled in the current Security state.

---

For more information see the description of the HPMN field.

On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**TPM, bit [6]**

*When FEAT_PMUv3 is implemented:*

Trap Performance Monitors accesses. Traps EL0 and EL1 accesses to all Performance Monitor registers to EL2 when EL2 is enabled in the current Security state, from both Execution states, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x18:
  - PMCR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMOVSCLR_EL0, PMSWINC_EL0, PMSERL_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMXEVTPER_EL0, PMXEVCTR_EL0, PMUSERENR_EL0, PMINTENSET_EL1, PMINTENCLR_EL1, PMOVSET_EL0, PMEVCNTR<sp><sp>N_EL0, PMEVTYPER<sp><sp>N_EL0, PMCCFILTR_EL0.
  - If FEAT_PMUv3p4 is implemented, PMMIR_EL1
In AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2 and reported using EC syndrome value 0x03, MRRC or MCRR accesses are trapped to EL2 and reported using EC syndrome value 0x04:

- PMCR, PMCNTENSET, PMCNTENCLR, PMOVSR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTPER, PMXEVCNTR, PMUSERENR, PMINTENSET, PMINTENCLR, PMOVSS, PMEVCNTR<n>, PMEVTYPER<\n>, PMCCFILTER.

- If FEAT_PMUv3p4 is implemented, PMMIR.
- If FEAT_PMUv3p1 is implemented, PMCEID2, and PMCEID3.

0b0 This control does not cause any instructions to be trapped.

0b1 EL0 and EL1 accesses to all Performance Monitor registers are trapped to EL2 when EL2 is enabled in the current Security state.

--- Note ---

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**TPMCR, bit [5]**

*When FEAT_PMUv3 is implemented:*

Trap PMCR_EL0 or PMCR accesses. Traps EL0 and EL1 accesses to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to PMCR_EL0 are trapped to EL2, reported using EC syndrome value 0x18.
- In AArch32 state, accesses to PMCR are trapped to EL2, reported using EC syndrome value 0x03.

0b0 This control does not cause any instructions to be trapped.

0b1 EL0 and EL1 accesses to the PMCR_EL0 or PMCR are trapped to EL2 when EL2 is enabled in the current Security state, unless it is trapped by PMUSERENR.EN or PMUSERENR_EL0.EN.

--- Note ---

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HPMN, bits [4:0]**

*When FEAT_PMUv3 is implemented:*

Defines the number of event counters that are accessible from EL3, EL2, EL1, and from EL0 if permitted.

If HPMN is less than PMCR_EL0.N, HPMN divides the Performance Monitors into two ranges: [0..(HPMN-1)] and [HPMN..(PMCR_EL0.N-1)].

For an event counter in the range [0..(HPMN-1)]:

- The counter is accessible from EL3, EL2, and EL1, and from EL0 if permitted by PMUSERENR_EL0 or PMUSERENR.
If FEAT_PMUv3p5 is implemented, PMCR_EL0.LP or PMCR.LP determines whether the counter overflow flag is set on unsigned overflow of PMEVCNTR\(_n\)_EL0[31:0] or PMEVCNTR\(_n\)_EL0[63:0].

The counter is enabled by PMCR_EL0.E or PMCR.E and bit \(<n>\) of PMCNTENSET_EL0.

--- Note ---

If HPMN is equal to PMCR_EL0.N, this applies to all event counters.

If HPMN is less than PMCR_EL0.N, for an event counter in the range \([HPMN..(PMCR_EL0.N-1)]\):

- The counter is accessible from EL2 and EL3.
- If FEAT_SEL2 is disabled or is not implemented, the counter is also accessible from Secure EL1, and from Secure EL0 if permitted by PMUSERENR_EL0.
- If FEAT_PMUv3p5 is implemented, MDCR_EL2.HLP or HDCR.HLP determines whether the counter overflow flag is set on unsigned overflow of PMEVCNTR\(_n\)_EL0[31:0] or PMEVCNTR\(_n\)_EL0[63:0].
- The counter is enabled by MDCR_EL2.HPME or HDCR.HPME and bit \(<n>\) of PMCNTENSET_EL0.

If this field is set to 0, or to a value larger than PMCR_EL0.N, then the following constrained unpredictable behaviors apply:

- The value returned by a direct read of MDCR_EL2.HPMN is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 and EL3 use. That is, the PE behaves as if MDCR_EL2.HPMN is set to an UNKNOWN non-zero value less than or equal to PMCR_EL0.N.
  - All counters are reserved for EL2 and EL3 use, meaning no counters are accessible from EL1 and EL0.

On a Warm reset, this field resets to the value in PMCR_EL0.N.

**Otherwise:**

Reserved, RES0.

## Accessing the MDCR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.18 MDCR_EL3, Monitor Debug Configuration Register (EL3)

The MDCR_EL3 characteristics are:

**Purpose**

Provides EL3 configuration options for self-hosted debug and the Performance Monitors Extension.

**Configurations**

AArch64 System register MDCR_EL3[31:0] can be mapped to AArch32 System register SDCR[31:0], but this is not architecturally mandated.

This register is present only when EL3 is implemented. Otherwise, direct accesses to MDCR_EL3 are UNDEFINED.

**Attributes**

MDCR_EL3 is a 64-bit register.

**Field descriptions**

The MDCR_EL3 bit assignments are:

```
<table>

**Bits [63:29]**

Reserved, RES0.

**MTPME, bit [28]**

*When FEAT_MTPMU is implemented:*

When FEAT_MTPMU is enabled. Enables use of the PMEVTYPE<\textit{n}>_EL0.MT bits.

- \texttt{0b0} FEAT_MTPMU is disabled. The Effective value of PMEVTYPE<\textit{n}>_EL0.MT is zero.
- \texttt{0b1} PMEVTYPE<\textit{n}>_EL0.MT bits not affected by this bit.

If FEAT_MTPMU is disabled for any other PE in the system that has the same level 1 Affinity as the PE, it is IMPLEMENTATION DEFINED whether the PE behaves as if this bit is 0.

On a Cold reset, this field resets to 1.

*Otherwise:*

Reserved, RES0.
TDCC, bit [27]

When FEAT_FGT is implemented:

- Trap DCC. Traps use of the Debug Comms Channel at EL2, EL1, and EL0 to EL3.
  - 0b0: This control does not cause any register accesses to be trapped.
  - 0b1: Accesses to the DCC registers at EL2, EL1, and EL0 generate a Trap exception to EL3, unless the access also generates a higher priority exception.

Traps on the DCC data transfer registers are ignored when the PE is in Debug state.

The DCC registers trapped by this control are:

AArch64: OSDTRRX_EL1, OSDTRTX_EL1, MDCCSR_EL0, MDCCINT_EL1, and, when the PE is in Non-debug state, DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0.

AArch32: DBGDTRRXext, DBGDTRTXext, DBGDSCRint, DBGDCINT, and, when the PE is in Non-debug state, DBGDTRRXint and DBGDTRTXint.

The traps are reported with EC syndrome value:

- 0x05 for trapped AArch32 MRC and MCR accesses with coproc == 0b1110.
- 0x06 for trapped AArch32 LDC to DBGDTRRXint and STC from DBGDTRRXint.
- 0x18 for trapped AArch64 MSR and MSR accesses.

When the PE is in Debug state, MDCR_EL3.TDCC does not trap any accesses to:

AArch64: DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0.

AArch32: DBGDTRRXint and DBGDTRTXint.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [26:24]

Reserved, RES0.

SCCD, bit [23]

When FEAT_PMUv3p5 is implemented:

Secure Cycle Counter Disable. Prohibits PMCCNTR_EL0 from counting in Secure state.

- 0b0: Cycle counting by PMCCNTR_EL0 is not affected by this bit.
- 0b1: Cycle counting by PMCCNTR_EL0 is prohibited in Secure state.

This bit does not affect the CPU_CYCLES event or any other event that counts cycles.

On a Warm reset, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [22]

Reserved, RES0.

EPMAD, bit [21]

When FEAT_Debugv8p4 is implemented and FEAT_PMUv3 is implemented:

External Performance Monitors Non-secure Access Disable. Controls Non-secure access to Performance Monitor registers by an external debugger.

- 0b0: Non-secure access to Performance Monitor registers from external debugger is permitted.
- 0b1: Non-secure access to Performance Monitor registers from external debugger is not permitted.

If the Performance Monitors Extension does not support external debug interface accesses this bit is RES0.
Otherwise, if EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this bit is 0b1.

On a Warm reset, this field resets to 0.

**When FEAT_PMUv3 is implemented:**
External Performance Monitors Access Disable. Controls access to Performance Monitor registers by an external debugger.

- **0b0**: Access to Performance Monitor registers from external debugger is permitted.
- **0b1**: Access to Performance Monitor registers from external debugger is not permitted, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If the Performance Monitors Extension does not support external debug interface accesses this bit is RES0.

Otherwise, if EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this bit is 0b1.

On a Warm reset, this field resets to 0.

**Otherwise:**
Reserved, RES0.

**EDAD, bit [20]**

**When FEAT_Debugv8p4 is implemented:**
External Debug Non-secure Access Disable. Controls Non-secure access to breakpoint, watchpoint, and OSLAR_EL1 registers by an external debugger.

- **0b0**: Non-secure access to debug registers from external debugger is permitted.
- **0b1**: Non-secure access to breakpoint and watchpoint registers, and OSLAR_EL1 from external debugger is not permitted.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this field is 0b1.

On a Warm reset, this field resets to 0.

**When FEAT_Debugv8p2 is implemented:**
External Debug Access Disable. Controls access to breakpoint, watchpoint, and OSLAR_EL1 registers by an external debugger.

- **0b0**: Access to debug registers, and to OSLAR_EL1 from external debugger is permitted.
- **0b1**: Access to breakpoint and watchpoint registers, and to OSLAR_EL1 from external debugger is not permitted, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this field is 0b1.

On a Warm reset, this field resets to 0.

**Otherwise:**
External Debug Access disable. Controls access to breakpoint, watchpoint, and optionally OSLAR_EL1 registers by an external debugger.

- **0b0**: Access to debug registers from external debugger is permitted.
- **0b1**: Access to breakpoint and watchpoint registers from an external debugger is not permitted, unless overridden by the IMPLEMENTATION DEFINED authentication interface. It is IMPLEMENTATION DEFINED whether access to the OSLAR_EL1 register from an external debugger is permitted or not permitted.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this field is 0b1.

On a Warm reset, this field resets to 0.
TTRF, bit [19]

*When FEAT_TRF is implemented:*

Trap Trace Filter controls. Traps use of the Trace Filter control registers at EL2 and EL1 to EL3.
The Trace Filter registers trapped by this control are:

- **TRFCR_EL2, TRFCR_EL12, TRFCR_EL1**, reported using EC syndrome value 0x18.
- **HTRFCR and TRFCR**, reported using EC syndrome value 0x03.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Accesses to Trace Filter registers at EL2 and EL1 are not affected by this bit.</td>
</tr>
<tr>
<td>0b1</td>
<td>Accesses to Trace Filter registers at EL2 and EL1 generate a Trap exception to EL3, unless the access generates a higher priority exception.</td>
</tr>
</tbody>
</table>

*Otherwise:*

Reserved, RES0.

STE, bit [18]

*When FEAT_TRF is implemented:*

Secure Trace enable. Enables tracing in Secure state.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Trace prohibited in Secure state unless overridden by the IMPLEMENTATION DEFINED authentication interface.</td>
</tr>
<tr>
<td>0b1</td>
<td>Trace in Secure state is not affected by this bit.</td>
</tr>
</tbody>
</table>

This bit also controls the level of authentication required by an external debugger to enable external tracing. See [Register controls to enable self-hosted trace](#) on page G3-5920.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this bit is 0b1.

On a Warm reset, this field resets to 0.

*Otherwise:*

Reserved, RES0.

SPME, bit [17]

*When FEAT_PMUv3 is implemented and FEAT_Debugv8p2 is implemented:*

Secure Performance Monitors Enable. Controls event counting in Secure state.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Event counting prohibited in Secure state.</td>
</tr>
<tr>
<td>0b1</td>
<td>Event counting in Secure state not affected by this bit.</td>
</tr>
</tbody>
</table>

If EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this bit is 0b1.

On a Warm reset, this field resets to 0.

*When FEAT_PMUv3 is implemented:*

Secure Performance Monitors Enable. Controls event counting in Secure state.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Event counting prohibited in Secure state, unless <code>ExternalSecureNoninvasiveDebugEnabled()</code> is TRUE.</td>
</tr>
<tr>
<td>0b1</td>
<td>Event counting in Secure state not affected by this bit.</td>
</tr>
</tbody>
</table>

If EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this bit is 0b1.

On a Warm reset, this field resets to 0.

*Otherwise:*

Reserved, RES0.
SDD, bit [16]

AArch64 Secure Self-hosted invasive debug disable. Disables Software debug exceptions in Secure state, other than Breakpoint Instruction exceptions.

0b0  Debug exceptions in Secure state are not affected by this bit.
0b1  Debug exceptions, other than Breakpoint Instruction exceptions, are disabled from all Exception levels in Secure state.

The SDD bit is ignored unless both of the following are true:
- The PE is in Secure state.
- The Effective value of SCR_EL3.RW is 0b1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SPD32, bits [15:14]

When EL1 is capable of using AArch32:

AArch32 Secure self-hosted privileged debug. Enables or disables debug exceptions from Secure EL1 using AArch32, other than Breakpoint Instruction exceptions.

0b00  Legacy mode. Debug exceptions from Secure EL1 are enabled by the IMPLEMENTATION DEFINED authentication interface.
0b10  Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.
0b11  Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved, and have the CONSTRAINED UNPREDICTABLE behavior that they must have the same behavior as 0b00. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

This field has no effect on Breakpoint Instruction exceptions. These are always enabled.

This field is ignored if the PE is either:
- In Non-secure state.
- In Secure state and Secure EL1 is using AArch64.

If Secure EL1 is using AArch32 then:
- If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.
- Otherwise, debug exceptions from Secure EL0 are enabled only if the value of SDER32_EL3.SUIDEN is 0b1.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this field is 0b11.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NSPB, bits [13:12]

When FEAT_SPE is implemented:

Non-secure Profiling Buffer. This field controls the owning translation regime and accesses to Statistical Profiling and Profiling Buffer control registers.

0b00  Profiling Buffer uses Secure Virtual Addresses. Statistical Profiling enabled in Secure state and disabled in Non-secure state. Accesses to Statistical Profiling and Profiling Buffer control registers at EL2 and EL1 in both security states generate Trap exceptions to EL3.
0b01  Profiling Buffer uses Secure Virtual Addresses. Statistical Profiling enabled in Secure state and disabled in Non-secure state. Accesses to Statistical Profiling and Profiling Buffer control registers at EL2 and EL1 in Non-secure state generate Trap exceptions to EL3.
0b10 Profiling Buffer uses Non-secure Virtual Addresses. Statistical Profiling enabled in Non-secure state and disabled in Secure state. Accesses to Statistical Profiling and Profiling Buffer control registers at EL2 and EL1 in both security states generate Trap exceptions to EL3.

0b11 Profiling Buffer uses Non-secure Virtual Addresses. Statistical Profiling enabled in Non-secure state and disabled in Secure state. Accesses to Statistical Profiling and Profiling Buffer control registers at EL2 and EL1 in Secure state generate Trap exceptions to EL3.

The Statistical Profiling and Profiling Buffer control registers trapped by this control are: PMBLIMITR_EL1, PMBPTR_EL1, PMBSR_EL1, PMSCR_EL1, PMSCR_EL2, PMSEVFR_EL1, PMSFCR_EL1, PMSICR_EL1, PMSIDR_EL1, PMSIRR_EL1, and PMSLATFR_EL1.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b1, the Effective value of this field is 0b11.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is 0b0, the Effective value of this field is 0b01.

On a Warm reset, this field resets to an UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bit [11]**

Reserved, RES0.

**TDOSA, bit [10]**

*When FEAT_DoubleLock is implemented:*

 Trap debug OS-related register access. Traps EL2 and EL1 System register accesses to the powerdown debug registers to EL3.

Accesses to the registers are trapped as follows:

- Accesses from AArch64 state, OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1 and any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit, are trapped to EL3 and reported using EC syndrome value 0x18.

- Accesses using MCR or MRC to DBGOSLAR, DBGOSLSR, DBGOSDLR, and DBGPRCR, are trapped to EL3 and reported using EC syndrome value 0x05.

- Accesses to any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

0b0 This control does not cause any instructions to be trapped.

0b1 EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3, unless it is trapped by HDCR.TDOSA or MDCR_EL2.TDOSA.

--- **Note** ---

The powerdown debug registers are not accessible at EL0.

---

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Trap debug OS-related register access. Traps EL2 and EL1 System register accesses to the powerdown debug registers to EL3.

The following registers are affected by this trap:

- AArch64: OSLAR_EL1, OSLSR_EL1, and DBGPRCR_EL1.
- AArch32: DBGOSLAR, DBGOSLSR, and DBGPRCR.
- AArch64 and AArch32: Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.
• It is IMPLEMENTATION DEFINED whether accesses to OSDLR_EL1 and DBGOSDLR are trapped.

0b0 This control does not cause any instructions to be trapped.
0b1 EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3, unless it is trapped by HDCR.TDOSA or MDCR_EL2.TDOSA.

--- Note ---
The powerdown debug registers are not accessible at EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**TDA, bit [9]**

Trap Debug Access. Traps EL2, EL1, and EL0 System register accesses to those debug System registers that cannot be trapped using the MDCR_EL3.TDOSA field.

Accesses to the debug registers are trapped as follows:

• In AArch64 state, the following registers are trapped to EL3 and reported using EC syndrome value 0x18:
  - DBGBVR<n>_EL1, DBGBCR<n>_EL1, DBGWVR<n>_EL1, DBGWCR<n>_EL1,
    DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, DBGAUTHSTATUS_EL1,
    DBGVCR32_EL2.
  - AArch64: MDCR_EL2, MDRAR_EL1, MDCCSR_EL0, MDCCINT_EL1,
    MDSCR_EL1, OSDTRRX_EL1, OSDTRTX_EL1, OSECCR_EL1.

• In AArch32 state, SDER is trapped to EL3 and reported using EC syndrome value 0x03.
• In AArch32 state, accesses using MCR or MRC to the following registers are reported using EC syndrome value 0x05, accesses using MCRR or MRRC are reported using EC syndrome value 0x0C:
  - HDCR, DBGDRAR, DBGDSAR, DBGDIR, DBGDCINT, DBGWFAR,
    DBGVC, DBGBVR<n>, DBGBCR<n>, DBGXVR<n>, DBGWCR<n>,
    DBGWVR<n>.
  - DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID,
    DBGDEVID1, DBGDEVID2, DBGOSECCR.

• In AArch32 state, STC accesses to DBGDTRRXint and LDC accesses to DBGDTRTXint are reported using EC syndrome value 0x06.
• When not in Debug state, the following registers are also trapped to EL3:
  - AArch64 accesses to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0, reported using EC syndrome value 0x18.
  - AArch32 accesses using MCR or MRC to DBGDTRRXint and DBGDTRXTint, reported using EC syndrome value 0x05.

0b0 This control does not cause any instructions to be trapped.
0b1 EL0, EL1, and EL2 accesses to the debug registers, other than the registers that can be trapped by MDCR_EL3.TDOSA, are trapped to EL3, from both Security states and both Execution states, unless it is trapped by DBGDSCExt.UDCCdis,
    MDSCR_EL1.TDCC, HDCR.TDA or MDCR_EL2.TDA.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [8:7]**

Reserved, RES0.
TPM, bit [6]

*When FEAT_PMUv3 is implemented:*

Trap Performance Monitor register accesses. Accesses to all Performance Monitor registers from EL0, EL1 and EL2 to EL3, from both Security states and both Execution states are trapped as follows:

- In AArch64 state, accesses to the following registers are trapped to EL3 and are reported using EC syndrome value 0x18:
  - PMCR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMOVSCl EL0, PMSWINC_EL0, PMSELr_EL0, PMCEID0_EL0, PMCEID1_EL0,
  - PMCSS0_EL0, PMXEVYPER_EL0, PXEVENTR_EL0, PMUSERENR_EL0, PMSWINC_EL0, PMINTENSET_EL0, PMINTENCLR_EL0,
  - PMOVSCLR_EL0, PMSELR_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMCCNTR_EL1, PMOEVCNTR<0>_EL0, PMOEVYPER<0>_EL0, PMCCFILTR_EL0.
  - If FEAT_PMUv3p4 is implemented, PMMIR_EL1

- In AArch32 state, accesses using MCR or MRC to the following registers are reported using EC syndrome value 0x03, accesses using MCRR or MRRC are reported using EC syndrome value 0x04:
  - PMCR, PMCNTENSET, PMCNTENCLR, PMOVSR, PMSWINC, PMSELr, PMCEID0, PMCEID1, PMCCNTR, PMXEVYPER, PXEVENTR,
  - PMUSERENR, PMINTENSET, PMINTENCLR, PMOVSSET, PMOEVCNTR<0>, PMOEVYPER<0>, PMCCFILTR.
  - If FEAT_PMUv3p1 is implemented, PMCEID2, and PMCEID3.
  - If FEAT_PMUv3p4 is implemented, PMMIR.

0b0 This control does not cause any instructions to be trapped.
0b1 EL2, EL1, and EL0 System register accesses to all Performance Monitor registers are trapped to EL3, unless it is trapped by HDCR.TPM or MDCR_EL2.TPM.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**Bits [5:0]**

Reserved, RES0.

**Accessing the MDCR_EL3**

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.19  MDRAR_EL1, Monitor Debug ROM Address Register

The MDRAR_EL1 characteristics are:

**Purpose**

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a
ROM table that locates and describes the memory-mapped debug components in the system. Armv8
deprecates any use of this register.

**Configurations**

AArch64 System register MDRAR_EL1[63:0] is architecturally mapped to AArch32 System
register DBGDRAR[63:0].

**Attributes**

MDRAR_EL1 is a 64-bit register.

**Field descriptions**

The MDRAR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>52</td>
<td>ROMADDR[51:48]</td>
</tr>
<tr>
<td>51</td>
<td>ROMADDR[47:12]</td>
</tr>
<tr>
<td>48</td>
<td>Bits [63:52]</td>
</tr>
<tr>
<td>47</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>12</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>11</td>
<td>Valid</td>
</tr>
<tr>
<td>2</td>
<td>ROMADDR[51:48], bits [51:48]</td>
</tr>
<tr>
<td>1</td>
<td>Bits [47:12]</td>
</tr>
<tr>
<td>0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Bits [63:52]**

Reserved, RES0.

**ROMADDR[51:48], bits [51:48]**

*When FEAT_LPA is implemented:*

If MDRAR_EL1.Valid == 0b00, then this field is UNKNOWN.

**Otherwise:**

Reserved, RES0.

**ROMADDR[47:12], bits [47:12]**

Bits[47:12] of the ROM table physical address.
When FEAT_LPA is implemented, ROMADDR[51:48] forms the upper part of the address value.
Otherwise, ROMADDR[51:48] is RES0.
If the physical address size in bits (PAsize) is less than 52, then the register bits corresponding to
ROMADDR [51:PAsize] are RES0.
Bits [11:0] of the ROM table physical address are zero.
Arm strongly recommends that bits ROMADDR[(PAsize-1):32] are zero in any system that
supports AArch32 at the highest implemented Exception level.
In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is
IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.
If MDRAR_EL1.Valid == 0b00, then this field is UNKNOWN.

**Bits [11:2]**

Reserved, RES0.
Valid, bits [1:0]

This field indicates whether the ROM Table address is valid.

0b00   ROM Table address is not valid. Software must ignore ROMADDR.
0b11   ROM Table address is valid.

Other values are reserved.

Accessing the MDRAR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, MDRAR_EL1**

<table>

D13.3.20 MDSCR_EL1, Monitor Debug System Control Register

The MDSCR_EL1 characteristics are:

Purpose

Main control register for the debug implementation.

Configurations

AArch64 System register MDSCR_EL1[31:0] is architecturally mapped to AArch32 System register DBGDSCRext[31:0].

Attributes

MDSCR_EL1 is a 64-bit register.

Field descriptions

The MDSCR_EL1 bit assignments are:

| Bits [63:32] | Reserved, RES0. |
| TFO          | ERR            |
| RXfull       | TDCC           |
| TXfull       | KDE            |
| RES0         | HDE            |
| RX0          | MDE            |
| TXU          | RAZ/WI         |
| RES0         | SC2            |

| TDA          | TDA            |

When FEAT_TRF is implemented:

Trace Filter override. Used for save/restore of EDSCHR.TFO.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCHR.TFO. Reads and writes of this bit are indirect accesses to EDSCHR.TFO.

Accessing this field has the following behavior:
• When OSLSR_EL1.OSLK == 1, access to this field is RW.
• When OSLSR_EL1.OSLK == 0, access to this field is RO.

Otherwise:

Reserved, RES0.

RXfull, bit [30]

Used for save/restore of EDSCHR.RXfull.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCHR.RXfull. Reads and writes of this bit are indirect accesses to EDSCHR.RXfull.

The architected behavior of this field determines the value it returns after a reset.
Accessing this field has the following behavior:
- When OSLR_EL1.OSLK == 1, access to this field is RW.
- When OSLR_EL1.OSLK == 0, access to this field is RO.

TXfull, bit [29]
Used for save/restore of EDSCR.TXfull.
When OSLR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.
When OSLR_EL1.OSLK == 1, this bit holds the value of EDSCR.TXfull. Reads and writes of this bit are indirect accesses to EDSCR.TXfull.
The architected behavior of this field determines the value it returns after a reset.
Accessing this field has the following behavior:
- When OSLR_EL1.OSLK == 1, access to this field is RW.
- When OSLR_EL1.OSLK == 0, access to this field is RO.

Bit [28]
Reserved, RES0.

RXO, bit [27]
Used for save/restore of EDSCR.RXO.
When OSLR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.
When OSLR_EL1.OSLK == 1, this bit holds the value of EDSCR.RXO. Reads and writes of this bit are indirect accesses to EDSCR.RXO.
The architected behavior of this field determines the value it returns after a reset.
Accessing this field has the following behavior:
- When OSLR_EL1.OSLK == 1, access to this field is RW.
- When OSLR_EL1.OSLK == 0, access to this field is RO.

TXU, bit [26]
Used for save/restore of EDSCR.TXU.
When OSLR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.
When OSLR_EL1.OSLK == 1, this bit holds the value of EDSCR.TXU. Reads and writes of this bit are indirect accesses to EDSCR.TXU.
The architected behavior of this field determines the value it returns after a reset.
Accessing this field has the following behavior:
- When OSLR_EL1.OSLK == 1, access to this field is RW.
- When OSLR_EL1.OSLK == 0, access to this field is RO.

Bits [25:24]
Reserved, RES0.

INTdis, bits [23:22]
Used for save/restore of EDSCR.INTdis.
When OSLR_EL1.OSLK == 0, and software must treat this bit as UNK/SBZP.
When OSLR_EL1.OSLK == 1, this field holds the value of EDSCR.INTdis. Reads and writes of this field are indirect accesses to EDSCR.INTdis.
The architected behavior of this field determines the value it returns after a reset.
Accessing this field has the following behavior:
- When OSLR_EL1.OSLK == 1, access to this field is RW.
- When OSLR_EL1.OSLK == 0, access to this field is RO.
TDA, bit [21]

Used for save/restore of EDSCR.TDA.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.
When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.TDA. Reads and writes of this bit are indirect accesses to EDSCR.TDA.

The architected behavior of this field determines the value it returns after a reset.

Accessing this field has the following behavior:
• When OSLSR_EL1.OSLK == 1, access to this field is RW.
• When OSLSR_EL1.OSLK == 0, access to this field is RO.

Bit [20]

Reserved, RES0.

SC2, bit [19]

When FEAT_PCSRv8 is implemented, FEAT_VHE is implemented and FEAT_PCSRv8p2 is not implemented:

Used for save/restore of EDSCR.SC2.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.
When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.SC2. Reads and writes of this bit are indirect accesses to EDSCR.SC2.

Accessing this field has the following behavior:
• When OSLSR_EL1.OSLK == 1, access to this field is RW.
• When OSLSR_EL1.OSLK == 0, access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [18:16]

Reserved, RAZ/WI.

Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to write to the register.

MDE, bit [15]

Monitor debug events. Enable Breakpoint, Watchpoint, and Vector Catch exceptions.

0b0  Breakpoint, Watchpoint, and Vector Catch exceptions disabled.
0b1  Breakpoint, Watchpoint, and Vector Catch exceptions enabled.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

HDE, bit [14]

Used for save/restore of EDSCR.HDE.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.
When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.HDE. Reads and writes of this bit are indirect accesses to EDSCR.HDE.

The architected behavior of this field determines the value it returns after a reset.

Accessing this field has the following behavior:
• When OSLSR_EL1.OSLK == 1, access to this field is RW.
• When OSLSR_EL1.OSLK == 0, access to this field is RO.
KDE, bit [13]

Local (kernel) debug enable. If EL_D is using AArch64, enable debug exceptions within EL_D.
Permitted values are:

- 0b0: Debug exceptions, other than Breakpoint Instruction exceptions, disabled within EL_D.
- 0b1: All debug exceptions enabled within EL_D.
- RES0 if EL_D is using AArch32.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDCC, bit [12]

Traps EL0 accesses to the Debug Communication Channel (DCC) registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from both Execution states, as follows:

- In AArch64 state, MRS or MSR accesses to the following DCC registers are trapped, reported using EC syndrome value 0x18:
  - MDCCSR_EL0.
  - If not in Debug state, DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0.
- In AArch32 state, MRC or MCR accesses to the following registers are trapped, reported using EC syndrome value 0x05.
  - DBGDSCRInt, DBGDIDR, DBGDSAR, DBGDRAR.
  - If not in Debug state, DBGDTRRXint, and DBGDTRTXint.
- In AArch32 state, LDC access to DBGDTRXint and STC access to DBGDTRTXint are trapped, reported using EC syndrome value 0x06.
- In AArch32 state, MRRC accesses to DBGDSAR and DBGDRAR are trapped, reported using EC syndrome value 0x0C.

- 0b0: This control does not cause any instructions to be trapped.
- 0b1: EL0 using AArch64: EL0 accesses to the AArch64 DCC registers are trapped.
  EL0 using AArch32: EL0 accesses to the AArch32 DCC registers are trapped.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of EDSCR.ERR.
When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.
When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.ERR. Reads and writes of this bit are indirect accesses to EDSCR.ERR.

The architected behavior of this field determines the value it returns after a reset.
Accessing this field has the following behavior:

- When OSLSR_EL1.OSLK == 1, access to this field is RW.
- When OSLSR_EL1.OSLK == 0, access to this field is RO.

Bits [5:1]

Reserved, RES0.

SS, bit [0]

Software step control bit. If EL_D is using AArch64, enable Software step. Permitted values are:

- 0b0: Software step disabled
- 0b1: Software step enabled.
- RES0 if EL_D is using AArch32.
On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

### Accessing the MDSCR_EL1

Individual fields within this register might have restricted accessibility when OSLSR_EL1.OSLK == 0 (the OS lock is unlocked). See the field descriptions for more detail.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, MDSCR_EL1**

D13.3.21 OSDLR_EL1, OS Double Lock Register

The OSDLR_EL1 characteristics are:

**Purpose**

Used to control the OS Double Lock.

**Configurations**

AArch64 System register OSDLR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSDLR[31:0].

**Attributes**

OSDLR_EL1 is a 64-bit register.

**Field descriptions**

The OSDLR_EL1 bit assignments are:

![Diagram of OSDLR_EL1 register]

**Bits [63:1]**

Reserved, RES0.

**DLK, bit [0]**

*When FEAT_DoubleLock is implemented:*

- **0b0** OS Double Lock unlocked.
- **0b1** OS Double Lock locked, if DBGPRCR_EL1.CORENPDRQ (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state.

On a Warm reset, this field resets to 0.

*Otherwise:*

Reserved, RAZ/WI.

**Accessing the OSDLR_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.22  OSDTRRX_EL1, OS Lock Data Transfer Register, Receive

The OSDTRRX_EL1 characteristics are:

**Purpose**

Used for save/restore of DBGDTRRX_EL0. It is a component of the Debug Communications Channel.

**Configurations**

AArch64 System register OSDTRRX_EL1[31:0] is architecturally mapped to AArch32 System register DBGDTRRXext[31:0].

**Attributes**

OSDTRRX_EL1 is a 64-bit register.

**Field descriptions**

The OSDTRRX_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:32]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>[31:0]</td>
<td>Update DTRRX without side-effect.</td>
</tr>
</tbody>
</table>

Writes to this register update the value in DTRRX and do not change RXfull.
Reads of this register return the last value written to DTRRX and do not change RXfull.
For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

**Accessing the OSDTRRX_EL1**

Arm deprecates reads and writes of OSDTRRX_EL1 when the OS Lock is unlocked.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.24 OSECCR_EL1, OS Lock Exception Catch Control Register

The OSECCR_EL1 characteristics are:

**Purpose**

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

**Configurations**

AArch64 System register OSECCR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSECCR[31:0].

AArch64 System register OSECCR_EL1[31:0] is architecturally mapped to External register EDECCR[31:0].

If OSLSR_EL1.OSLK == 0, then OSECCR_EL1 returns an UNKNOWN value on reads and ignores writes.

**Attributes**

OSECCR_EL1 is a 64-bit register.

**Field descriptions**

The OSECCR_EL1 bit assignments are:

When OSLSR_EL1.OSLK == 1:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:32]</td>

**Bits [63:4]**

Reserved, RES0.

**OSLM[1], bit [3]**

This field is bit[1] of OSLM[1:0].

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented.

- **0b00**: OS Lock not implemented.
- **0b10**: OS Lock implemented.

All other values are reserved. In an Armv8 implementation the value **0b00** is not permitted.

The OSLM field is split as follows:

- OSLM[1] is OSLSR_EL1[3].
- OSLM[0] is OSLSR_EL1[0].

**nTT, bit [2]**

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

**OSLK, bit [1]**

OS Lock Status.

- **0b0**: OS Lock unlocked.
- **0b1**: OS Lock locked.

The OS Lock is locked and unlocked by writing to the OS Lock Access Register.

On a Cold reset, this field resets to 1.

On a Warm reset, the value of this field is unchanged.
OSLM[0], bit [0]

This field is bit[0] of OSLM[1:0].

See OSLM[1] for the field description.

Accessing the OSLSR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRS } <Xt>, \text{ OSLSR_EL1}
\]

\[
\begin{array}{cccccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
0b10 & 0b000 & 0b0001 & 0b0001 & 0b100 \\
\end{array}
\]

D13.3.27 SDER32_EL2, AArch32 Secure Debug Enable Register

The SDER32_EL2 characteristics are:

**Purpose**

Allows access to the AArch32 register SDER from Secure EL2 and EL3 only.

**Configurations**

This register is present only when EL2 is implemented, AArch32 is supported at any Exception level, FEAT_SEL2 is implemented and EL1 supports AArch32. Otherwise, direct accesses to SDER32_EL2 are **UNDEFINED**.

This register is ignored by the PE when one or more of the following are true:
- The PE is in Non-secure state.
- EL1 is using AArch64.

**Attributes**

SDER32_EL2 is a 64-bit register.

**Field descriptions**

The SDER32_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:2</td>
<td>Reserved, RES0.</td>

D13.3.28 SDER32_EL3, AArch32 Secure Debug Enable Register

The SDER32_EL3 characteristics are:

Purpose

Allows access to the AArch32 register SDER from AArch64 state only. Its value has no effect on execution in AArch64 state.

Configurations

AArch64 System register SDER32_EL3[31:0] is architecturally mapped to AArch32 System register SDER[31:0].

This register is present only when EL3 is implemented, AArch32 is supported at any Exception level and EL1 supports AArch32. Otherwise, direct accesses to SDER32_EL3 are UNDEFINED.

This register is ignored by the PE when one or more of the following are true:

• The PE is in Non-secure state.
• EL1 is using AArch64.

Attributes

SDER32_EL3 is a 64-bit register.

Field descriptions

The SDER32_EL3 bit assignments are:

Bits [63:2]

Reserved, RES0.

SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable.

0b0 This bit does not affect Performance Monitors event counting at Secure EL0.
0b1 If EL1 is using AArch32, Performance Monitors event counting is allowed in Secure EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SUIDEN, bit [0]

Secure User Invasive Debug Enable.

0b0 This bit does not affect the generation of debug exceptions at Secure EL0.
0b1 If EL1 is using AArch32, debug exceptions from Secure EL0 are enabled.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the SDER32_EL3

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, SDER32_EL3

if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  UNDEFINED;
elsif PSTATE.EL == EL2 then
  UNDEFINED;
elsif PSTATE.EL == EL3 then
  return SDER32_EL3;

MRS SDER32_EL3, <Xt>

elsif PSTATE.EL == EL2 then
  UNDEFINED;
elsif PSTATE.EL == EL3 then
  SDER32_EL3 = X[t];
D13.3.29 TRFCR_EL1, Trace Filter Control Register (EL1)

The TRFCR_EL1 characteristics are:

**Purpose**

Provides EL1 controls for Trace.

**Configurations**

AArch64 System register TRFCR_EL1[31:0] is architecturally mapped to AArch32 System register TRFCR[31:0].

This register is present only when FEAT_TRF is implemented. Otherwise, direct accesses to TRFCR_EL1 are **UNDEFINED**.

**Attributes**

TRFCR_EL1 is a 64-bit register.

**Field descriptions**

The TRFCR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:7]</th>
<th>RES0</th>
<th>TS</th>
<th>RES0</th>
</tr>
</thead>
<tbody>
<tr>
<td>E0TRE</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>E1TRE</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:7]**

Reserved, RES0.

**TS, bits [6:5]**

Timestamp Control

- **0b01** Virtual timestamp. The traced timestamp is the physical counter value, minus the value of CNTVOFF_EL2.
- **0b10** When FEAT_ECV is implemented Guest Physical timestamp. The traced timestamp is the physical counter value, minus the value of CNTPOFF_EL2.
- **0b11** Physical timestamp. The traced timestamp is the physical counter value.

All other values are reserved

This field is ignored if any of the following are true:

- SelfHostedTraceEnabled() == FALSE.
- EL2 is implemented and TRFCR_EL2.TS != 0b0.

If FEAT_ECV is implemented, and EL2 is implemented and enabled in the current Security state, the physical counter uses a fixed physical offset of zero if any of the following are true:

- CNTHCTL_EL2.ECV is 0.
- SCR_EL3.ECVEn is 0.
- HCR_EL2.{E2H, TGE} is {1, 1}.

On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Bits [4:2]**

Reserved, RES0.
E1TRE, bit [1]

EL1 Trace Enable.
0b0 Trace is prohibited at EL1.
0b1 Trace is allowed at EL1.

This field is ignored if SelfHostedTraceEnabled() == FALSE.

On a Warm reset, this field resets to 0.

E0TRE, bit [0]

EL0 Trace Enable.
0b0 Trace is prohibited at EL0.
0b1 Trace is allowed at EL0.

This field is ignored if any of the following are true:
- SelfHostedTraceEnabled() == FALSE.
- EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE == 1.

On a Warm reset, this field resets to 0.

Accessing the TRFCR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.30 TRFCR_EL2, Trace Filter Control Register (EL2)

The TRFCR_EL2 characteristics are:

**Purpose**
Provides EL2 controls for Trace.

**Configurations**
AArch64 System register TRFCR_EL2[31:0] is architecturally mapped to AArch32 System register HTRFCR[31:0].

This register is present only when FEAT_TRF is implemented. Otherwise, direct accesses to TRFCR_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**
TRFCR_EL2 is a 64-bit register.

**Field descriptions**
The TRFCR_EL2 bit assignments are:

| Bits [63:7] | Reserved, RES0. |
| TS, bits [6:5] | Timestamp Control. Controls which timebase is used for trace timestamps. |
| 0b00 | Timestamp controlled by TRFCR_EL1.TS or TRFCR.TS. |
| 0b01 | Virtual timestamp. The traced timestamp is the physical counter value, minus the value of CNTVOFF_EL2. |
| 0b10 | When FEAT_ECV is implemented Guest Physical timestamp. The traced timestamp is the physical counter value, minus the value of CNTPOFF_EL2. |
| 0b11 | Physical timestamp. The traced timestamp is the physical counter value. |

All other values are reserved.

This field is ignored if SelfHostedTraceEnabled() == FALSE.

If FEAT_ECV is implemented, and EL2 is implemented and enabled in the current Security state, the physical counter uses a fixed physical offset of zero if any of the following are true:

- CNTHCTL_EL2.ECV is 0.
- SCR_EL3.ECVEn is 0.
- HCR_EL2.{E2H, TGE} is \{1, 1\}.

On a Warm reset, this field resets to 0.
Bit [4]

    Reserved, RES0.

CX, bit [3]

    CONTEXTIDR_EL2 and VMID trace enable.
    0b0    CONTEXTIDR_EL2 and VMID trace prohibited.
    0b1    CONTEXTIDR_EL2 and VMID trace allowed.

    This field is ignored if SelfHostedTraceEnabled() == FALSE.
    On a Warm reset, this field resets to 0.

Bit [2]

    Reserved, RES0.

E2TRE, bit [1]

    EL2 Trace Enable.
    0b0    Trace is prohibited at EL2.
    0b1    Trace is allowed at EL2.

    This field is ignored if SelfHostedTraceEnabled() == FALSE.
    On a Warm reset, this field resets to 0.

E0HTRE, bit [0]

    EL0 Trace Enable.
    0b0    Trace is prohibited at EL0 when HCR_EL2.TGE == 1.
    0b1    Trace is allowed at EL0 when HCR_EL2.TGE == 1.

    This field is ignored if any of the following are true:
    - SelfHostedTraceEnabled() == FALSE.
    - EL2 is disabled in the current security state.
    - HCR_EL2.TGE == 0.

    On a Warm reset, this field resets to 0.

D13.4 Performance Monitors registers

This section lists the Performance Monitoring registers in AArch64.
### D13.4.1 PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register

The PMCCFILTR_EL0 characteristics are:

**Purpose**

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

**Configurations**

AArch64 System register PMCCFILTR_EL0[31:0] is architecturally mapped to AArch32 System register PMCCFILTR[31:0].

AArch64 System register PMCCFILTR_EL0[31:0] is architecturally mapped to External register PMCCFILTR_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCCFILTR_EL0 are **UNDEFINED**.

**Attributes**

PMCCFILTR_EL0 is a 64-bit register.

**Field descriptions**

The PMCCFILTR_EL0 bit assignments are:

<table>

</tbody>
</table>
NSK, bit [29]

When EL3 is implemented:

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1.

If the value of this bit is equal to the value of the PMCCFILTR_EL0.P bit, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NSU, bit [28]

When EL3 is implemented:

Non-secure EL0 (Unprivileged) filtering bit. Controls counting in Non-secure EL0.

If the value of this bit is equal to the value of the PMCCFILTR_EL0.U bit, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NSH, bit [27]

When EL2 is implemented:

EL2 (Hypervisor) filtering bit. Controls counting in EL2.

If Secure EL2 is implemented, and EL3 is implemented, counting in Secure EL2 is further controlled by the PMCCFILTR_EL0.SH bit.

0b0 Do not count cycles in EL2.

0b1 Count cycles in EL2.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

M, bit [26]

When EL3 is implemented:

Secure EL3 filtering bit.

If the value of this bit is equal to the value of the PMCCFILTR_EL0.P bit, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to 0.

--- Note ---

This field is not visible in the AArch32 PMCCFILTR System register.

---

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [25]

Reserved, RES0.
SH, bit [24]

*When FEAT_SEL2 is implemented and EL3 is implemented:*

Secure EL2 filtering.

If the value of this bit is not equal to the value of the PMCCFILTR_EL0.NSH bit, cycles in Secure EL2 are counted.

Otherwise, cycles in Secure EL2 are not counted.

If Secure EL2 is not implemented or is disabled, this field is RES0.

--- Note ---

This field is not visible in the AArch32 PMCCFILTR System register.

---

On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**Bits [23:0]**

Reserved, RES0.

### Accessing the PMCCFILTR_EL0

PMCCFILTR_EL0 can also be accessed by using PMXEVTYPER_EL0 with PMSELR_EL0.SEL set to 0b11111.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, PMCCFILTR_EL0**

D13.4.2 PMCCNTR_EL0, Performance Monitors Cycle Count Register

The PMCCNTR_EL0 characteristics are:

**Purpose**

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter on page D7-2696* for more information. PMCCFILTR_EL0 determines the modes and states in which the PMCCNTR_EL0 can increment.

**Configurations**

AArch64 System register PMCCNTR_EL0[63:0] is architecturally mapped to AArch32 System register PMCCNTR[63:0].

AArch64 System register PMCCNTR_EL0[63:0] is architecturally mapped to External register PMCCNTR_EL0[63:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCCNTR_EL0 are UNDEFINED.

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR_EL0 continues to increment when clocks are stopped by WFI and WFE instructions.

**Attributes**

PMCCNTR_EL0 is a 64-bit register.

**Field descriptions**

The PMCCNTR_EL0 bit assignments are:

```
| 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 | 55 | 54 | 53 | 52 | 51 | 50 | 49 | 48 | 47 | 46 | 45 | 44 | 43 | 42 | 41 | 40 | 39 | 38 | 37 | 36 | 35 | 34 | 33 | 32 | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| CCNT | bits [63:0] | Cycle count. Depending on the values of PMCR_EL0.{LC,D}, this field increments in one of the following ways:
| • Every processor clock cycle.
| • Every 64th processor clock cycle.
| Writing 1 to PMCR_EL0.C sets this field to 0.
| On a Warm reset, this field resets to an architecturally UNKNOWN value.
```

**Accessing the PMCCNTR_EL0**

### D13.4.3 PMCEID0_EL0, Performance Monitors Common Event Identification register 0

The PMCEID0_EL0 characteristics are:

**Purpose**

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the ranges 0x0000 to 0x001F and 0x4000 to 0x401F.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

--- **Note** ---

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEID<n>_EL0 registers see *The PMU event number space and common events on page D7-2715.*

**Configurations**

AArch64 System register PMCEID0_EL0[31:0] is architecturally mapped to AArch32 System register PMCEID0[31:0].

AArch64 System register PMCEID0_EL0[63:32] is architecturally mapped to AArch32 System register PMCEID2[31:0].

AArch64 System register PMCEID0_EL0[31:0] is architecturally mapped to External register PMCEID0[31:0].

AArch64 System register PMCEID0_EL0[63:32] is architecturally mapped to External register PMCEID2[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCEID0_EL0 are UNDEFINED.

**Attributes**

PMCEID0_EL0 is a 64-bit register.

**Field descriptions**

The PMCEID0_EL0 bit assignments are:
IDhi<n>, bit [n+32], for n = 0 to 31

When FEAT_PMUv3p1 is implemented:
IDhi[n] corresponds to common event (0x4000 + n).

For each bit:
0b0  The common event is not implemented, or not counted.
0b1  The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

--- Note ---
Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Otherwise:
Reserved, RES0.

ID<n>, bit [n], for n = 0 to 31
ID[n] corresponds to common event n.

For each bit:
0b0  The common event is not implemented, or not counted.
0b1  The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

--- Note ---
Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Accessing the PMCEID0_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, PMCEID0_EL0**

D13.4.4  PMCEID1_EL0, Performance Monitors Common Event Identification register 1

The PMCEID1_EL0 characteristics are:

**Purpose**

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the ranges 0x0020 to 0x003F and 0x4020 to 0x403F. When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

**Note**

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEID<n>_EL0 registers see *The PMU event number space and common events* on page D7-2715.

**Configurations**

AArch64 System register PMCEID1_EL0[31:0] is architecturally mapped to AArch32 System register PMCEID1[31:0].

AArch64 System register PMCEID1_EL0[63:32] is architecturally mapped to AArch32 System register PMCEID3[31:0].

AArch64 System register PMCEID1_EL0[31:0] is architecturally mapped to External register PMCEID1[31:0].

AArch64 System register PMCEID1_EL0[63:32] is architecturally mapped to External register PMCEID3[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCEID1_EL0 are UNDEFINED.

**Attributes**

PMCEID1_EL0 is a 64-bit register.

**Field descriptions**

The PMCEID1_EL0 bit assignments are:
IDhi<\textit{n}>>, bit [\textit{n}+32], for \textit{n} = 0 to 31

\textbf{When FEAT\textunderscore PMUv3p1 is implemented:}

IDhi[n] corresponds to common event (0x4020 + \textit{n}).

For each bit:

- 0b0 The common event is not implemented, or not counted.
- 0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

\textbf{Note}

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID\textit{<n>\_EL0} registers of that earlier version of the PMU architecture.

\textbf{Otherwise:}

Reserved, RES0.

ID<\textit{n}>, bit [\textit{n}], for \textit{n} = 0 to 31

ID[n] corresponds to common event (0x0020 + \textit{n}).

For each bit:

- 0b0 The common event is not implemented, or not counted.
- 0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

\textbf{Note}

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID\textit{<n>\_EL0} registers of that earlier version of the PMU architecture.

\textbf{Accessing the PMCEID1\_EL0}

Accesses to this register use the following encodings in the System instruction encoding space:

\textbf{MRS <Xt>, PMCEID1\_EL0}

D13.4.5 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

**Purpose**

Disables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<->. Reading this register shows which counters are enabled.

**Configurations**

AArch64 System register PMCNTENCLR_EL0[31:0] is architecturally mapped to AArch32 System register PMCNTENCLR[31:0].

AArch64 System register PMCNTENCLR_EL0[31:0] is architecturally mapped to External register PMCNTENCLR_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCNTENCLR_EL0 are UNDEFINED.

**Attributes**

PMCNTENCLR_EL0 is a 64-bit register.

**Field descriptions**

The PMCNTENCLR_EL0 bit assignments are:

```
| 63  | 56  | 48  | 40  | 32  | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| RES0 |     | C   |     |     |     | P<->, bit [n] |
```

**Bits [63:32]**

Reserved, RES0.

**C, bit [31]**

PMCCNTR_EL0 disable bit. Disables the cycle counter register. Possible values are:

- **0b0** When read, means the cycle counter is disabled. When written, has no effect.
- **0b1** When read, means the cycle counter is enabled. When written, disables the cycle counter.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**P<->, bit [n], for n = 0 to 30**

Event counter disable bit for PMEVCNTR<->_EL0.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

- **0b0** When read, means that PMEVCNTR<->_EL0 is disabled. When written, has no effect.
- **0b1** When read, means that PMEVCNTR<->_EL0 is enabled. When written, disables PMEVCNTR<->_EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

D13.4.6 PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

Purpose

Enables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<\textit{n}>. Reading this register shows which counters are enabled.

Configurations

AArch64 System register PMCNTENSET_EL0[31:0] is architecturally mapped to AArch32 System register PMCNTENSET[31:0].

AArch64 System register PMCNTENSET_EL0[31:0] is architecturally mapped to External register PMCNTENSET_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCNTENSET_EL0 are UNDEFINED.

Attributes

PMCNTENSET_EL0 is a 64-bit register.

Field descriptions

The PMCNTENSET_EL0 bit assignments are:

![Bit assignments](image)

Bits [63:32]

Reserved, RES0.

C, bit [31]

PMCCNTR_EL0 enable bit. Enables the cycle counter register. Possible values are:

0b0 When read, means the cycle counter is disabled. When written, has no effect.

0b1 When read, means the cycle counter is enabled. When written, enables the cycle counter.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

P<\textit{n}>, bit [\textit{n}], for \textit{n} = 0 to 30

Event counter enable bit for PMEVCNTR<\textit{n}>_EL0.

If \textit{N} is less than 31, then bits [30:30] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, \textit{N} is the value in MDCR_EL2.HPMN. Otherwise, \textit{N} is the value in PMCR_EL0.N.

0b0 When read, means that PMEVCNTR<\textit{n}>_EL0 is disabled. When written, has no effect.

0b1 When read, means that PMEVCNTR<\textit{n}>_EL0 event counter is enabled. When written, enables PMEVCNTR<\textit{n}>_EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

D13.4.7 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

**Purpose**

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

**Configurations**

AArch64 System register PMCR_EL0[31:0] is architecturally mapped to AArch32 System register PMCR[31:0].

AArch64 System register PMCR_EL0[7:0] is architecturally mapped to External register PMCR_EL0[7:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCR_EL0 are UNDEFINED.

**Attributes**

PMCR_EL0 is a 64-bit register.

**Field descriptions**

The PMCR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-32</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>31-24</td>
<td>IMP, implementer code</td>
</tr>
<tr>
<td>23-16</td>
<td>IDCODE, identification code</td>
</tr>
<tr>
<td>15-8</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>7-0</td>
<td>LP</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**IMP, bits [31:24]**

Implementer code.

If this field is zero, then PMCR_EL0.IDCODE is RES0 and software must use MIDR_EL1 to identify the PE.

Otherwise, this field and PMCR_EL0.IDCODE identify the PMU implementation to software. The implementer codes are allocated by Arm. A non-zero value has the same interpretation as MIDR_EL1.Implementer.

Use of this field is deprecated.

This field reads as an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**IDCODE, bits [23:16]**

*When PMCR_EL0.IMP != 0x00:*

Identification code. Use of this field is deprecated. This field has an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that are specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

Access to this field is RO.

*Otherwise:*

Reserved, RES0.
N, bits [15:11]
Indicates the number of event counters implemented. This value is in the range of 0b00000-0b11111. If the value is 0b00000 then only PMCCNTR_EL0 is implemented. If the value is 0b11111 PMCCNTR_EL0 and 31 event counters are implemented.
When EL2 is implemented and enabled for the current Security state, reads of this field from EL1 and EL0 return the value of MDCR_EL2.HPMN.
Access to this field is RO.

Bits [10:8]
Reserved, RES0.

LP, bit [7]
When FEAT_PMUv3p5 is implemented:
Long event counter enable. Determines when unsigned overflow is recorded by a counter overflow bit.
0b0 Event counter overflow on increment that causes unsigned overflow of PMEVCTR<n>_EL0[31:0].
0b1 Event counter overflow on increment that causes unsigned overflow of PMEVCTR<n>_EL0[63:0].
If EL2 is implemented and MDCR_EL2.HPMN or HDCR.HPMN is less than PMCR_EL0.N, this bit does not affect the operation of event counters in the range [HDCR.HPMN..(PMCR_EL0.N-1)] or [MDCR_EL2.HPMN..(PMCR_EL0.N-1)].

Note
The effect of MDCR_EL2.HPMN or HDCR.HPMN on the operation of this bit always applies if EL2 is implemented, at all Exception levels including EL2 and EL3, and regardless of whether EL2 is enabled in the current Security state. For more information, see the description of MDCR_EL2.HPMN or HDCR.HPMN.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

LC, bit [6]
When AArch32 is supported at any Exception level:
Long cycle counter enable. Determines when unsigned overflow is recorded by the cycle counter overflow bit.
0b0 Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR_EL0[31:0].
0b1 Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR_EL0[63:0].
Arm deprecates use of PMCR_EL0.LC = 0.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES1.

DP, bit [5]
When EL3 is implemented or (FEAT_PMUv3p1 is implemented and EL2 is implemented):
Disable cycle counter when event counting is prohibited.
0b0 Cycle counting by PMCCNTR_EL0 is not affected by this bit.
0b1 When event counting for counters in the range [0..(MDCR_EL2.HPMN-1)] is prohibited, cycle counting by PMCCNTR_EL0 is disabled.
For more information see *Prohibiting event counting* on page D7-2703.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

X, bit [4]

*When the implementation includes a PMU event export bus:*

Enable export of events in an IMPLEMENTATION DEFINED PMU event export bus.

- **0b0** Do not export events.
- **0b1** Export events where not prohibited.

This field enables the exporting of events over an IMPLEMENTATION DEFINED PMU event export bus to another device, for example to an OPTIONAL PE trace unit.

No events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RAZ/WI.

D, bit [3]

*When AArch32 is supported at any Exception level:*

Clock divider.

- **0b0** When enabled, PMCCNTR_EL0 counts every clock cycle.
- **0b1** When enabled, PMCCNTR_EL0 counts once every 64 clock cycles.

If PMCR_EL0.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

Arm deprecates use of PMCR_EL0.D = 1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

C, bit [2]

Cycle counter reset. The effects of writing to this bit are:

- **0b0** No action.
- **0b1** Reset PMCCNTR_EL0 to zero.

This bit is always RAZ.

**Note**

Resetting PMCCNTR_EL0 does not change the cycle counter overflow bit.

The value of PMCR_EL0.LC is ignored, and bits [63:0] of all affected event counters are reset.

Access to this field is WO.

P, bit [1]

Event counter reset. The effects of writing to this bit are:

- **0b0** No action.
- **0b1** Reset all event counters accessible in the current Exception level, not including PMCCNTR_EL0, to zero.

This bit is always RAZ.
In EL0 and EL1:

- If EL2 is implemented and enabled in the current Security state, and \texttt{MDCR\_EL2.HPMN} is less than \texttt{PMCR\_EL0.N}, a write of 1 to this bit does not reset event counters in the range \([\texttt{MDCR\_EL2.HPMN..(PMCR\_EL0.N-1)}]\).
- If EL2 is not implemented, EL2 is disabled in the current Security state, or \texttt{MDCR\_EL2.HPMN} equals \texttt{PMCR\_EL0.N}, a write of 1 to this bit resets all the event counters.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

\textbf{Note}

Resetting the event counters does not change the event counter overflow bits.

If \texttt{FEAT\_PMUv3p5} is implemented, the values of \texttt{MDCR\_EL2.HLP} and \texttt{PMCR\_EL0.LP} are ignored, and bits [63:0] of all affected event counters are reset.

Access to this field is WO.

\textbf{E, bit [0]}

Enable.

0b0 All event counters in the range [0..(PMN-1)] and \texttt{PMCCNTR\_EL0}, are disabled.

0b1 All event counters in the range [0..(PMN-1)] and \texttt{PMCCNTR\_EL0}, are enabled by \texttt{PMCNTENSET\_EL0}.

If EL2 is implemented, then:

- If EL2 is using AArch32, PMN is \texttt{HDCR.HPMN}.
- If EL2 is using AArch64, PMN is \texttt{MDCR\_EL2.HPMN}.
- If PMN is less than \texttt{PMCR\_EL0.N}, this bit does not affect the operation of event counters in the range \([\texttt{PMN..(PMCR\_EL0.N-1)}]\).

If EL2 is not implemented, PMN is \texttt{PMCR\_EL0.N}.

\textbf{Note}

The effect of \texttt{MDCR\_EL2.HPMN} or \texttt{HDCR.HPMN} on the operation of this bit always applies if EL2 is implemented, at all Exception levels including EL2 and EL3, and regardless of whether EL2 is enabled in the current Security state. For more information, see the description of \texttt{MDCR\_EL2.HPMN} or \texttt{HDCR.HPMN}.

On a Warm reset, this field resets to 0.

\section*{Accessing the PMCR\_EL0}

Accesses to this register use the following encodings in the System instruction encoding space:

D13.4.8 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

**Purpose**
Holds event counter n, which counts events, where n is 0 to 30.

**Configurations**
AArch64 System register PMEVCNTR<n>_EL0[31:0] is architecturally mapped to AArch32 System register PMEVCNTR<n>[31:0].
AArch64 System register PMEVCNTR<n>_EL0[31:0] is architecturally mapped to External register PMEVCNTR<n>_EL0[31:0].
This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMEVCNTR<n>_EL0 are UNDEFINED.

**Attributes**
PMEVCNTR<n>_EL0 is a 64-bit register.

**Field descriptions**
The PMEVCNTR<n>_EL0 bit assignments are:

*When FEAT_PMUv3p5 is implemented:*

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 to 0</td>
<td>Event counter n</td>
</tr>
</tbody>
</table>

On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 to 32</td>
<td>RES0</td>
</tr>
<tr>
<td>31 to 0</td>
<td>Event counter n</td>
</tr>
</tbody>
</table>

Reserved, RES0.

*Bits [31:0]*
Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing the PMEVCNTR<n>_EL0**
PMEVCNTR<n>_EL0 can also be accessed by using PMXEVCNTR_EL0 with PMSELR_EL0.SEL set to the value of <n>.
If FEAT_FGT is implemented and <n> is greater than or equal to the number of accessible counters, then the
behavior of permitted reads and writes of PMEVCNTR<n>_EL0 is as follows:

- If <n> is an unimplemented event counter, the access is UNDEFINED.
- Otherwise, the access is trapped to EL2.

If FEAT_FGT is not implemented and <n> is greater than or equal to the number of accessible counters, then reads
and writes of PMEVCNTR<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are
permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- If EL2 is implemented and enabled in the current Security state, and <n> is less than the number of
implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

--- Note ---

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.<ER,EN>.

If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies
the number of accessible event counters. Otherwise, the number of accessible event counters is the number
of implemented event counters. See MDCR_EL2.HPMN for more details.

---

Accesses to this register use the following encodings in the System instruction encoding space:

<table>

D13.4.9 PMEVTYPER<\text{n}>_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<\text{n}>_EL0 characteristics are:

**Purpose**

Configures event counter n, where n is 0 to 30.

**Configurations**

AArch64 System register PMEVTYPER<\text{n}>_EL0[31:0] is architecturally mapped to AArch32 System register PMEVTYPER<\text{n}>[31:0].
AArch64 System register PMEVTYPER<\text{n}>_EL0[31:0] is architecturally mapped to External register PMEVTYPER<\text{n}>_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMEVTYPER<\text{n}>_EL0 are UNDEFINED.

**Attributes**

PMEVTYPER<\text{n}>_EL0 is a 64-bit register.

**Field descriptions**

The PMEVTYPER<\text{n}>_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>31</td>
<td>P, bit [31] Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the PMEVTYPER&lt;\text{n}&gt;_EL0.NSK bit. 0b0: Count events in EL1. 0b1: Do not count events in EL1. On a Warm reset, this field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>30</td>
<td>U, bit [30] User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the PMEVTYPER&lt;\text{n}&gt;_EL0.NSU bit. 0b0: Count events in EL0. 0b1: Do not count events in EL0. On a Warm reset, this field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>
NSK, bit [29]

When EL3 is implemented:

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1.
If the value of this bit is equal to the value of the PMEVTYPER<n>_EL0.P bit, events in Non-secure EL1 are counted.
Otherwise, events in Non-secure EL1 are not counted.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NSU, bit [28]

When EL3 is implemented:

Non-secure EL0 (Unprivileged) filtering bit. Controls counting in Non-secure EL0.
If the value of this bit is equal to the value of the PMEVTYPER<n>_EL0.U bit, events in Non-secure EL0 are counted.
Otherwise, events in Non-secure EL0 are not counted.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NSH, bit [27]

When EL2 is implemented:

EL2 (Hypervisor) filtering bit. Controls counting in EL2.
If Secure EL2 is implemented, and EL3 is implemented, counting in Secure EL2 is further controlled by the PMEVTYPER<n>_EL0.SH bit.

0b0      Do not count events in EL2.
0b1      Count events in EL2.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

M, bit [26]

When EL3 is implemented:

Secure EL3 filtering bit.
If the value of this bit is equal to the value of the PMEVTYPER<n>_EL0.P bit, events in Secure EL3 are counted.
Otherwise, events in Secure EL3 are not counted.
Most applications can ignore this field and set its value to 0b0.

Note

This field is not visible in the AArch32 PMEVTYPER<n> System register.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
MT, bit [25]

When (FEAT_MTPMU is implemented and enabled) or an IMPLEMENTATION DEFINED multi-threaded PMU Extension is implemented:

- Count events only on controlling PE.
- Count events from any PE with the same affinity at level 1 and above as this PE.

Note

- When the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach, an implementation is described as multi-threaded. That is, the performance of PEs at the lowest affinity level is highly interdependent.
- Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SH, bit [24]

When FEAT_SEL2 is implemented and EL3 is implemented:

Secure EL2 filtering.

If the value of this bit is not equal to the value of the PMEVTYPER<n>_EL0.NSH bit, events in Secure EL2 are counted.

Otherwise, events in Secure EL2 are not counted.

Note

This field is not visible in the AArch32 PMEVTYPER<n> System register.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [23:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

When FEAT_PMUv3p1 is implemented:

Extension to evtCount[9:0]. See evtCount[9:0] for more details.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>_EL0.

Software must program this field with an event that is supported by the PE being programmed.

The ranges of event numbers allocated to each type of event are shown in Table D7-7 on page D7-2715.
If `evtCount` is programmed to an event that is reserved or not supported by the PE, the behavior depends on the value written:

- For the range `0x0000` to `0x003F`, no events are counted, and the value returned by a direct or external read of the `evtCount` field is the value written to the field.
- If 16-bit `evtCount` is implemented, for the range `0x4000` to `0x403F`, no events are counted, and the value returned by a direct or external read of the `evtCount` field is the value written to the field.
- For IMPLEMENTATIONDEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the `evtCount` field is UNKNOWN.

--- Note

UNPREDICTABLE means the event must not expose privileged information.

---

Arm recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATIONDEFINED events, then no event is counted and the value read back on `evtCount` is the value written.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing the PMEVTYPER<n>_EL0**

PMEVTYPER<n>_EL0 can also be accessed by using PMXEVTPYPER_EL0 with PMSELR_EL0.SEL set to n.

If FEAT_FGT is implemented and `<n>` is greater than or equal to the number of accessible counters, then the behavior of permitted reads and writes of PMEVTYPER<n>_EL0 is as follows:

- If `<n>` is an unimplemented event counter, the access is UNDEFINED.
- Otherwise, the access is trapped to EL2.

If FEAT_FGT is not implemented and `<n>` is greater than or equal to the number of accessible counters, then reads and writes of PMEVTYPER<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- If EL2 is implemented and enabled in the current Security state, and `<n>` is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

--- Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.EN.

If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible event counters. Otherwise, the number of accessible event counters is the number of implemented event counters. See MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.4.10 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR_EL1 characteristics are:

**Purpose**

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

**Configurations**

AArch64 System register PMINTENCLR_EL1[31:0] is architecturally mapped to AArch32 System register PMINTENCLR[31:0].

AArch64 System register PMINTENCLR_EL1[31:0] is architecturally mapped to External register PMINTENCLR_EL1[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMINTENCLR_EL1 are UNDEFINED.

**Attributes**

PMINTENCLR_EL1 is a 64-bit register.

**Field descriptions**

The PMINTENCLR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
<tbody>
<tr>
<td>C, bit [31]</td>
<td>PMCCNTR_EL0 overflow interrupt request disable bit. Possible values are:</td>
</tr>
<tr>
<td>P&lt;n&gt;, bit [n], for n = 0 to 30</td>
<td>Event counter overflow interrupt request disable bit for PMEVCNTR&lt;n&gt;_EL0.</td>
</tr>
</tbody>
</table>

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

| 0b0 | When read, means the PMEVCNTR<n>_EL0 event counter interrupt request is disabled. When written, has no effect. |
| 0b1 | When read, means the PMEVCNTR<n>_EL0 event counter interrupt request is enabled. When written, disables the PMEVCNTR<n>_EL0 interrupt request. |

On a Warm reset, this field resets to an architecturally UNKNOWN value.

D13.4.11 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET_EL1 characteristics are:

**Purpose**

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

**Configurations**

AArch64 System register PMINTENSET_EL1[31:0] is architecturally mapped to AArch32 System register PMINTENSET[31:0].

AArch64 System register PMINTENSET_EL1[31:0] is architecturally mapped to External register PMINTENSET_EL1[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMINTENSET_EL1 are UNDEFINED.

**Attributes**

PMINTENSET_EL1 is a 64-bit register.

**Field descriptions**

The PMINTENSET_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:32]</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>[31]</td>
<td>CPMCCNTR_EL0 overflow interrupt request enable bit. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>0b0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.</td>
</tr>
<tr>

D13.4.12 PMMIR_EL1, Performance Monitors Machine Identification Register

The PMMIR_EL1 characteristics are:

**Purpose**

Describes Performance Monitors parameters specific to the implementation to software.

**Configurations**

This register is present only when FEAT_PMUv3p4 is implemented. Otherwise, direct accesses to PMMIR_EL1 are UNDEFINED.

**Attributes**

PMMIR_EL1 is a 64-bit register.

**Field descriptions**

The PMMIR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:8]</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>[7:0]</td>
<td>SLOTS</td>
</tr>
</tbody>
</table>

**Bits [63:8]**

Reserved, RES0.

**SLOTS, bits [7:0]**

Operation width. The largest value by which the STALL_SLOT event might increment by in a single cycle. If the STALL_SLOT event is not implemented, this field might read as zero.

**Accessing the PMMIR_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, PMMIR_EL1**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>

endif
D13.4.13 PMOVCSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register

The PMOVCSCLR_EL0 characteristics are:

**Purpose**

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<n>. Writing to this register clears these bits.

**Configurations**

AArch64 System register PMOVCSCLR_EL0[31:0] is architecturally mapped to AArch32 System register PMOVSR[31:0].

AArch64 System register PMOVCSCLR_EL0[31:0] is architecturally mapped to External register PMOVCSCLR_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMOVCSCLR_EL0 are UNDEFINED.

**Attributes**

PMOVCSCLR_EL0 is a 64-bit register.

**Field descriptions**

The PMOVCSCLR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>C</td>
<td>P&lt;n&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**C, bit [31]**

Cycle counter overflow clear bit.

0b0  When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.

0b1  When read, means the cycle counter has overflowed since this bit was last cleared. When written, clears the cycle counter overflow bit to 0.

PMCR_EL0.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR_EL0[31:0] or unsigned overflow of PMCCNTR_EL0[63:0].

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**P<n>, bit [n], for n = 0 to 30**

Event counter overflow clear bit for PMEVCNTR<n>_EL0.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

0b0  When read, means that PMEVCNTR<n>_EL0 has not overflowed since this bit was last cleared. When written, has no effect.

0b1  When read, means that PMEVCNTR<n>_EL0 has overflowed since this bit was last cleared. When written, clears the PMEVCNTR<n>_EL0 overflow bit to 0.

If FEAT_PMUv3p5 is implemented, MDCR_EL2.HLP and PMCR_EL0.LP control whether an overflow is detected from unsigned overflow of PMEVCNTR<n>_EL0[31:0] or unsigned overflow of PMEVCNTR<n>_EL0[63:0].

On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing the PMOVSLR_EL0

D13.4.15 PMSEL_EL0, Performance Monitors Event Counter Selection Register

The PMSEL_EL0 characteristics are:

Purpose

Selects the current event counter PMEVCNTR<\texttt{n}>_EL0 or the cycle counter, CCNT.

PMSEL_EL0 is used in conjunction with PMXEVTYPER_EL0 to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with PMXEVCTR_EL0, to determine the value of a selected event counter.

Configurations

AArch64 System register PMSEL_EL0[31:0] is architecturally mapped to AArch32 System register PMSEL[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMSEL_EL0 are UNDEFINED.

Attributes

PMSEL_EL0 is a 64-bit register.

Field descriptions

The PMSEL_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SEL</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:5]

Reserved, RES0.

SEL, bits [4:0]

Selects event counter, PMEVCNTR<\texttt{n}>_EL0, where \texttt{n} is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPER_EL0 or PMXEVCTR_EL0 occurs.

This field can take any value from 0 (\texttt{0b00000}) to (PMCR.N)-1, or 31 (\texttt{0b11111}).

When PMSEL_EL0.SEL is \texttt{0b11111}, it selects the cycle counter and:

- A read of the PMXEVTYPER_EL0 returns the value of PMCCFILTR_EL0.
- A write of the PMXEVTYPER_EL0 writes to PMCCFILTR_EL0.
- A read or write of PMXEVCNTR_EL0 has CONSTRAINED UNPREDICTABLE effects. See PMXEVCNTR_EL0 for more details.

For details of the results of accesses to the event counters, see PMXEVTYPER_EL0 and PMXEVCNTR_EL0.

For information about the number of counters accessible at each Exception level, see MDCR_EL2.HPMN.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the PMSEL_EL0

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, PMSEL_R_EL0

D13.4.16  PMSWINC_EL0, Performance Monitors Software Increment register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event 0x00. For more information, see SW_INCR.

Configurations

AArch64 System register PMSWINC_EL0[31:0] is architecturally mapped to AArch32 System register PMSWINC[31:0].
AArch64 System register PMSWINC_EL0[31:0] is architecturally mapped to External register PMSWINC_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMSWINC_EL0 are UNDEFINED.

Attributes

PMSWINC_EL0 is a 64-bit register.

Field descriptions

The PMSWINC_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:31]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
<tbody>
<tr>
<td>P&lt;n&gt;, bit [n], for n = 0 to 30</td>
<td>Event counter software increment bit for PMEVCNTR&lt;n&gt;_EL0.</td>
</tr>
</tbody>
</table>

If N is less than 31, then bits [30:N] are W1. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

0b0 No action. The write to this bit is ignored.
0b1 If PMEVCNTR<n>_EL0 is enabled and configured to count the software increment event, increments PMEVCNTR<n>_EL0 by 1. If PMEVCNTR<n>_EL0 is disabled, or not configured to count the software increment event, the write to this bit is ignored.

Accessing the PMSWINC_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

**MSR PMSWINC_EL0, <Xt>**

D13.4.17 PMUSERENR_EL0, Performance Monitors User Enable Register

The PMUSERENR_EL0 characteristics are:

**Purpose**

Enables or disables EL0 access to the Performance Monitors.

**Configurations**

AArch64 System register PMUSERENR_EL0[31:0] is architecturally mapped to AArch32 System register PMUSERENR[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMUSERENR_EL0 are UNDEFINED.

**Attributes**

PMUSERENR_EL0 is a 64-bit register.

**Field descriptions**

The PMUSERENR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:4]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>ER, bit [3]</th>
<th>Event counter Read. Traps EL0 access to event counters to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.</th>
</tr>
</thead>
</table>

In AArch64 state, trapped accesses are reported using EC syndrome value 0x18.

In AArch32 state, trapped accesses are reported using EC syndrome value 0x03.

<table>
<thead>
<tr>
<th>0b0</th>
<th>EL0 using AArch64: EL0 reads of the PMXEVCNTR_EL0 and PMEVCNTR&lt;n&gt;_EL0, and EL0 read/write accesses to the PMSELR_EL0, are trapped if PMUSERENR_EL0.EN is also 0. EL0 using AArch32: EL0 reads of the PMXEVCNTR and PMEVCNTR&lt;n&gt;, and EL0 read/write accesses to the PMSELR, are trapped if PMUSERENR_EL0.EN is also 0.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>0b1</th>
<th>Overrides PMUSERENR_EL0.EN and enables:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• RO access to PMXEVCNTR_EL0 and PMEVCNTR&lt;n&gt;_EL0 at EL0.</td>
</tr>
<tr>
<td></td>
<td>• RW access to PMSELR_EL0 at EL0.</td>
</tr>
<tr>
<td></td>
<td>• RW access to PMSELR at EL0.</td>
</tr>
</tbody>
</table>

On a Warm reset, this field resets to an architecturally UNKNOWN value.

<table>
<thead>
<tr>
<th>CR, bit [2]</th>
<th>Cycle counter Read. Traps EL0 access to cycle counter reads to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.</th>
</tr>
</thead>
</table>

In AArch64 state, trapped accesses are reported using EC syndrome value 0x18.
In AArch32 state, trapped MRC accesses are reported using EC syndrome value 0x03, trapped MRRC accesses are reported using EC syndrome value 0x04.

0b0
EL0 using AArch64: EL0 read accesses to the PMCCNTR_EL0 are trapped if PMUSERENR_EL0.EN is also 0.
EL0 using AArch32: EL0 read accesses to the PMCCNTR are trapped if PMUSERENR_EL0.EN is also 0.

0b1
Overrides PMUSERENR_EL0.EN and enables access to:
- PMCCNTR_EL0 at EL0.
- PMCCNTR at EL0.

SW, bit [1]
Traps Software Increment writes to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.

In AArch64 state, trapped accesses are reported using EC syndrome value 0x18.

In AArch32 state, trapped accesses are reported using EC syndrome value 0x03.

0b0
EL0 using AArch64: EL0 writes to the PMSWINC_EL0 are trapped if PMUSERENR_EL0.EN is also 0.
EL0 using AArch32: EL0 writes to the PMSWINC are trapped if PMUSERENR_EL0.EN is also 0.

0b1
Overrides PMUSERENR_EL0.EN and enables access to:
- PMSWINC_EL0 at EL0.
- PMSWINC at EL0.

On a Warm reset, this field reset to an architecturally UNKNOWN value.

EN, bit [0]
Traps EL0 accesses to the Performance Monitor registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from both Execution states as follows:

- In AArch64 state, MRS or MSR accesses to the following registers are reported using EC syndrome value 0x18:
  - PMCR_EL0, PMOVSCLR_EL0, PMSELR_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMXEVTPER_EL0, PMXEVNTR_EL0, PMCNTENSET_EL0, PMCNTENSET_EL0, PMOVSSET_EL0, PMEVCNTR<n>_EL0, PMEVTYPER<n>_EL0, PMCCFILTR_EL0.
  - PMSWINC_EL0, MSR accesses only.
  - If FEAT_PMUv3p4 is implemented, PMMIR_EL1.

- In AArch32 state, MRC or MCR accesses to the following registers are reported using EC syndrome value 0x03:
  - PMCR, PMOVSR, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTPER, PMXEVNTR, PMCNTENSET, PMCNTENCLR, PMOVSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR.
  - PMSWINC, MCR accesses only.
  - If FEAT_PMUv3p4 is implemented, PMMIR.
  - If FEAT_PMUv3p1 is implemented, in AArch32 state, PMCEID2, and PMCEID3.

- In AArch32 state, MRRC or MCRR accesses to PMCCNTR are reported using EC syndrome value 0x04.

0b0
While at EL0, accesses to the specified registers at EL0 are trapped, unless overridden by one of PMUSERENR_EL0.{ER, CR, SW}.

0b1
While at EL0, software can access all of the specified registers.

On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing to the PMUSERENR_EL0

D13.4.18 PMXEVCNTR_EL0, Performance Monitors Selected Event Count Register

The PMXEVCNTR_EL0 characteristics are:

### Purpose
Reads or writes the value of the selected event counter, PMEVCNTR\(n\)\_EL0. PMSELR\_EL0.SEL determines which event counter is selected.

### Configurations
AArch64 System register PMXEVCNTR\_EL0[31:0] is architecturally mapped to AArch32 System register PMXEVCNTR[31:0].

This register is present only when FEAT\_PMUv3 is implemented. Otherwise, direct accesses to PMXEVCNTR\_EL0 are UNDEFINED.

### Attributes
PMXEVCNTR\_EL0 is a 64-bit register.

### Field descriptions
The PMXEVCNTR\_EL0 bit assignments are:

#### When FEAT\_PMUv3p5 is implemented:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>PMEVCNTR(n)</td>
</tr>
<tr>
<td>32-31</td>
<td>RESERVED (RES0)</td>
</tr>
<tr>
<td>0</td>
<td>PMEVCNTR(n)</td>
</tr>
</tbody>
</table>

PMEVCNTR\(n\), bits [63:0]

Value of the selected event counter, PMEVCNTR\(n\)\_EL0, where n is the value stored in PMSELR\_EL0.SEL.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

#### Otherwise:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>PMEVCNTR(n)</td>
</tr>
<tr>
<td>32-31</td>
<td>RESERVED (RES0)</td>
</tr>
<tr>
<td>31-32</td>
<td>PMEVCNTR(n)</td>
</tr>
<tr>
<td>0</td>
<td>PMEVCNTR(n)</td>
</tr>
</tbody>
</table>

Bits [63:32]

Reserved, RES0.

PMEVCNTR\(n\), bits [31:0]

Value of the selected event counter, PMEVCNTR\(n\)\_EL0, where n is the value stored in PMSELR\_EL0.SEL.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

### Accessing the PMXEVCNTR\_EL0

If FEAT\_FGT is implemented and PMSELR\_EL0.SEL is greater than or equal to the number of accessible counters, then the behavior of permitted reads and writes of PMXEVCNTR\_EL0 is as follows:

- If PMSELR\_EL0.SEL selects an unimplemented event counter, the access is UNDEFINED.

---

D13-3738  Copyright © 2013-2020 Arm Limited or its affiliates. All rights reserved.
Non-Confidential
• Otherwise, the access is trapped to EL2.

If FEAT_FGT is not implemented and PMSELR_EL0.SEL is greater than or equal to the number of accessible counters, then reads and writes of PMXEVCNTR_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP
• Accesses to the register behave as if PMSELR_EL0.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
• If EL2 is implemented and enabled in the current Security state, and PMSELR_EL0.SEL is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.<ER,EN>.

If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible event counters. Otherwise, the number of accessible event counters is the number of implemented event counters. See MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

\[

D13.4.19 PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register

The PMXEVTYPER_EL0 characteristics are:

**Purpose**

When PMSELR_EL0.SEL selects an event counter, this accesses a PMEVTYPER<n>_EL0 register. When PMSELR_EL0.SEL selects the cycle counter, this accesses PMCCFILTR_EL0.

**Configurations**

AArch64 System register PMXEVTYPER_EL0[31:0] is architecturally mapped to AArch32 System register PMXEVTYPER[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMXEVTYPER_EL0 are UNDEFINED.

**Attributes**

PMXEVTYPER_EL0 is a 64-bit register.

**Field descriptions**

The PMXEVTYPER_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>Bits [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Event type register or PMCCFILTR_EL0</td>
</tr>
</tbody>
</table>

**Accessing the PMXEVTYPER_EL0**

If FEAT_FGT is implemented, and PMSELR_EL0.SEL is not 31 and is greater than or equal to the number of accessible counters, then the behavior of permitted reads and writes of PMXEVTYPER_EL0 is as follows:

- If PMSELR_EL0.SEL selects an unimplemented event counter, the access is UNDEFINED.
- Otherwise, the access is trapped to EL2.

If FEAT_FGT is not implemented, and PMSELR_EL0.SEL is not 31 and is greater than or equal to the number of accessible counters, then reads and writes of PMXEVTYPER_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP
- Accesses to the register behave as if PMSELR_EL0.SEL has an UNKNOWN value less than the number of event counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if PMSELR_EL0.SEL is 31.
• If EL2 is implemented and enabled in the current Security state, PMSELR_EL0 is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

**Note**

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.EN.

If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible event counters. Otherwise, the number of accessible event counters is the number of implemented event counters. See MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.5  Activity Monitors registers

This section lists the Activity Monitors registers in AArch64.
D13.5.1  AMCFGR_EL0, Activity Monitors Configuration Register

The AMCFGR_EL0 characteristics are:

**Purpose**

Global configuration register for the activity monitors.
Provides information on supported features, the number of counter groups implemented, the total number of activity monitor event counters implemented, and the size of the counters.
AMCFGR_EL0 is applicable to both the architected and the auxiliary counter groups.

**Configurations**

AArch64 System register AMCFGR_EL0[31:0] is architecturally mapped to AArch32 System register AMCFGR[31:0].
AArch64 System register AMCFGR_EL0[31:0] is architecturally mapped to External register AMCFGR[31:0].
This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCFGR_EL0 are UNDEFINED.

**Attributes**

AMCFGR_EL0 is a 64-bit register.

**Field descriptions**

The AMCFGR_EL0 bit assignments are:

```
  63  32  28  25  24  14  8  0
  RES0   NCG  RES0   RAZ   SIZE  N
                         HDBG

Bits [63:32]
Reserved, RES0.

NCG, bits [31:28]
Defines the number of counter groups.
The number of implemented counter groups is defined as [AMCFGR_EL0.NCG + 1].
If the number of implemented auxiliary activity monitor event counters is zero, this field has a value of 0b0000. Otherwise, this field has a value of 0b0001.

Bits [27:25]
Reserved, RES0.

HDBG, bit [24]
Halt-on-debug supported.
From Armv8, this feature must be supported, and so this bit is 0b1.

0b0    AMCR_EL0.HDBG is RES0.
0b1    AMCR_EL0.HDBG is read/write.

Bits [23:14]
Reserved, RAZ.
SIZE, bits [13:8]

Defines the size of activity monitor event counters.

The size of the activity monitor event counters implemented by the activity monitors Extension is defined as \([\text{AMCFGR\_EL0.SIZE} + 1]\).

From Armv8, the counters are 64-bit, and so this field is 0b111111.

--- Note ---

Software also uses this field to determine the spacing of counters in the memory-map. From Armv8, the counters are at doubleword-aligned addresses.

N, bits [7:0]

Defines the number of activity monitor event counters.

The total number of counters implemented in all groups by the Activity Monitors Extension is defined as \([\text{AMCFGR\_EL0.N} + 1]\).

Accessing the AMCFGR\_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

\( \text{MRS <Xt>, AMCFGR\_EL0} \)

\[
\begin{array}{cccccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\

D13.5.3 AMCGCR_EL0, Activity Monitors Counter Group Configuration Register

The AMCGCR_EL0 characteristics are:

Purpose

Provides information on the number of activity monitor event counters implemented within each counter group.

Configurations

AArch64 System register AMCGCR_EL0[31:0] is architecturally mapped to AArch32 System register AMCGCR[31:0].

AArch64 System register AMCGCR_EL0[31:0] is architecturally mapped to External register AMCGCR[31:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCGCR_EL0 are UNDEFINED.

Attributes

AMCGCR_EL0 is a 64-bit register.

Field descriptions

The AMCGCR_EL0 bit assignments are:

63 16 8 7 0

RES0 CG1NC CG0NC

Bits [63:16]

Reserved, RES0.

CG1NC, bits [15:8]

Counter Group 1 Number of Counters. The number of counters in the auxiliary counter group.

In an implementation that includes FEAT_AMUv1, the permitted range of values is 0x0 to 0x10.

CG0NC, bits [7:0]

Counter Group 0 Number of Counters. The number of counters in the architected counter group.

In an implementation that includes FEAT_AMUv1, the value of this field is 0x4.

Accessing the AMCGCR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, AMCGCR_EL0

D13.5.4 AMCNTENCLR0_EL0, Activity Monitors Count Enable Clear Register 0

The AMCNTENCLR0_EL0 characteristics are:

Purpose

Disable control bits for the architected activity monitors event counters, AMEVCNTR0<n>_EL0.

Configurations

AArch64 System register AMCNTENCLR0_EL0[31:0] is architecturally mapped to AArch32 System register AMCNTENCLR0[31:0].

AArch64 System register AMCNTENCLR0_EL0[31:0] is architecturally mapped to External register AMCNTENCLR0[31:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR0_EL0 are UNDEFINED.

Attributes

AMCNTENCLR0_EL0 is a 64-bit register.

Field descriptions

The AMCNTENCLR0_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:16]</th>
<th>(\text{RES0})</th>
</tr>
</thead>
<tbody>
<tr>
<td>P&lt;(n&gt;), bit [n], for n = 0 to 15</td>
<td>(\text{AMEVCNTR0}&lt;n&gt;_\text{EL0})</td>
</tr>
</tbody>
</table>

Activity monitor event counter disable bit for \(\text{AMEVCNTR0}<n>_\text{EL0}\).

Bits [31:16] are \(\text{RES0}\). Bits [15:N] are RAZ/WI. \(N\) is the value in AMCGCR_EL0.CG0NC.

Possible values of each bit are:

\(0b0\) When read, means that \(\text{AMEVCNTR0}<n>_\text{EL0}\) is disabled. When written, has no effect.

\(0b1\) When read, means that \(\text{AMEVCNTR0}<n>_\text{EL0}\) is enabled. When written, disables \(\text{AMEVCNTR0}<n>_\text{EL0}\).

On a Cold reset, this field resets to \(0\).

Accessing the AMCNTENCLR0_EL0

The AMCNTENSET1_EL0 characteristics are:

**Purpose**
Enable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>_EL0.

**Configurations**
- AArch64 System register AMCNTENSET1_EL0[31:0] is architecturally mapped to AArch32 System register AMCNTENSET1[31:0].
- AArch64 System register AMCNTENSET1_EL0[31:0] is architecturally mapped to External register AMCNTENSET1[31:0].
- This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCNTENSET1_EL0 are UNDEFINED.

**Attributes**
AMCNTENSET1_EL0 is a 64-bit register.

**Field descriptions**
The AMCNTENSET1_EL0 bit assignments are:

![Bit assignments diagram]

**Bits [63:16]**
Reserved, RES0.

**P<n>, bit [n], for n = 0 to 15**
Activity monitor event counter enable bit for AMEVCNTR1<n>_EL0.
Bits [31:16] are RES0. Bits [15:N] are RAZ/WI. N is the value in AMCGCR_EL0.CG1NC. Possible values of each bit are:
- 0b0 When read, means that AMEVCNTR1<n>_EL0 is disabled. When written, has no effect.
- 0b1 When read, means that AMEVCNTR1<n>_EL0 is enabled. When written, enables AMEVCNTR1<n>_EL0.

On a Cold reset, this field resets to 0.

**Accessing the AMCNTENSET1_EL0**
If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENSET1_EL0 are UNDEFINED.

--- Note ---
The number of auxiliary activity monitor counters implemented is zero when AMCFGR_EL0.NCG == 0b0000.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.5.8 AMCR_EL0, Activity Monitors Control Register

The AMCR_EL0 characteristics are:

**Purpose**

Global control register for the activity monitors implementation. AMCR_EL0 is applicable to both the architectured and the auxiliary counter groups.

**Configurations**

AArch64 System register AMCR_EL0[31:0] is architecturally mapped to AArch32 System register AMCR[31:0].

AArch64 System register AMCR_EL0[31:0] is architecturally mapped to External register AMCR[31:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCR_EL0 are UNDEFINED.

**Attributes**

AMCR_EL0 is a 64-bit register.

**Field descriptions**

The AMCR_EL0 bit assignments are:

![AMCR_EL0 Bit Assignments Diagram]

**Bits [63:18]**

Reserved, RES0.

**CG1RZ, bit [17]**

*When FEAT_AMUv1p1 is implemented:*

Counter Group 1 Read Zero.

0b0 System register reads of AMEVCTR1<n>_EL0 return the event count at all implemented and enabled Exception levels.

0b1 If the current Exception level is the highest implemented Exception level, system register reads of AMEVCTR1<n>_EL0 return the event count. Otherwise, reads of AMEVCTR1<n>_EL0 return a zero value.

**Note**

Reads from the memory-mapped view are unaffected by this field.

**Otherwise:**

Reserved, RES0.

**Bits [16:11]**

Reserved, RES0.

**HDBG, bit [10]**

This bit controls whether activity monitor counting is halted when the PE is halted in Debug state.

0b0 Activity monitors do not halt counting when the PE is halted in Debug state.
Activity monitors halt counting when the PE is halted in Debug state.

Bits [9:0]
Reserved, RES0.

Accessing the AMCR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

D13.5.9  AMEVCNTR0<n>_EL0, Activity Monitors Event Counter Registers 0, n = 0 - 15

The AMEVCNTR0<n>_EL0 characteristics are:

**Purpose**

Provides access to the architected activity monitor event counters.

**Configurations**

AArch64 System register AMEVCNTR0<n>_EL0[63:0] is architecturally mapped to AArch32 System register AMEVCNTR0<n>[63:0].

AArch64 System register AMEVCNTR0<n>_EL0[63:0] is architecturally mapped to External register AMEVCNTR0<n>[63:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMEVCNTR0<n>_EL0 are UNDEFINED.

**Attributes**

AMEVCNTR0<n>_EL0 is a 64-bit register.

**Field descriptions**

The AMEVCNTR0<n>_EL0 bit assignments are:

ACNT, bits [63:0]

Architected activity monitor event counter n.

Value of architected activity monitor event counter n, where n is the number of this register and is a number from 0 to 15.

If FEAT_AMUv1p1 is implemented, HCR_EL2.AMVOFFEN is 1, SCR_EL3.AMVOFFEN is 1, HCR_EL2.{E2H, TGE} is not {1,1}, and EL2 is implemented in the current Security state, access to these registers at EL0 or EL1 return (PCount<63:0> - AMEVCNTRVOFF0<n>_EL2<63:0>).

PCount is the physical count returned when AMEVCNTR0<n>_EL0 is read from EL2 or EL3.

If the counter is enabled, writes to this register have UNPREDICTABLE results.

On a Cold reset, this field resets to 0.

**Accessing the AMEVCNTR0<n>_EL0**

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n>_EL0 are UNDEFINED.

--- Note ---

AMECGCR_EL0.CG0NC identifies the number of architected activity monitor event counters.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.5.13 AMEVTYPER0<n>_EL0, Activity Monitors Event Type Registers 0, n = 0 - 15

The AMEVTYPER0<n>_EL0 characteristics are:

Purpose

Provides information on the events that an architected activity monitor event counter AMEVCNTR0<n>_EL0 counts.

Configurations

AArch64 System register AMEVTYPER0<n>_EL0[31:0] is architecturally mapped to AArch32 System register AMEVTYPER0<n>[31:0].

AArch64 System register AMEVTYPER0<n>_EL0[31:0] is architecturally mapped to External register AMEVTYPER0<n>[31:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMEVTYPER0<n>_EL0 are UNDEFINED.

Attributes

AMEVTYPER0<n>_EL0 is a 64-bit register.

Field descriptions

The AMEVTYPER0<n>_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:16]</th>
<th>RES0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [15:0]</td>
<td>evtCount</td>
</tr>
</tbody>
</table>

Bits [63:16]

Reserved, RES0.

evtCount, bits [15:0]

Event to count. The event number of the event that is counted by the architected activity monitor event counter AMEVCNTR0<n>_EL0. The value of this field is architecturally mandated for each architected counter.

The following table shows the mapping between required event numbers and the corresponding counters:

| 0x0011 When n == 0 | Processor frequency cycles |
| 0x4004 When n == 1 | Constant frequency cycles |
| 0x0008 When n == 2 | Instructions retired |
| 0x4005 When n == 3 | Memory stall cycles |

Accessing the AMEVTYPER0<n>_EL0

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVTYPER0<n>_EL0 are UNDEFINED.

--- Note ---

AMECGCR_EL0.CG0NC identifies the number of architected activity monitor event counters.

Accesses to this register use the following encodings in the System instruction encoding space:
### MRS `<Xt>`, AMEVTYPE0<`n>` _EL0_

D13.5.14  AMEVTPER1<\(n\)>_EL0, Activity Monitors Event Type Registers 1, \(n = 0 - 15\)

The AMEVTPER1<\(n\)>_EL0 characteristics are:

**Purpose**

Provides information on the events that an auxiliary activity monitor event counter AMEVCNTR1<\(n\)>_EL0 counts.

**Configurations**

AArch64 System register AMEVTPER1<\(n\)>_EL0[31:0] is architecturally mapped to AArch32 System register AMEVTPER1<\(n\)>[31:0].

AArch64 System register AMEVTPER1<\(n\)>_EL0[31:0] is architecturally mapped to External register AMEVTPER1<\(n\)>[31:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMEVTPER1<\(n\)>_EL0 are UNDEFINED.

**Attributes**

AMEVTPER1<\(n\)>_EL0 is a 64-bit register.

**Field descriptions**

The AMEVTPER1<\(n\)>_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>evtCount</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:16]**

Reserved, RES0.

**evtCount, bits [15:0]**

Event to count. The event number of the event that is counted by the auxiliary activity monitor event counter AMEVCNTR1<\(n\)>_EL0.

It is IMPLEMENTATION DEFINED what values are supported by each counter.

If software writes a value to this field which is not supported by the corresponding counter AMEVCNTR1<\(n\)>_EL0, then:

- It is UNPREDICTABLE which event will be counted.
- The value read back is UNKNOWN.

The event counted by AMEVCNTR1<\(n\)>_EL0 might be fixed at implementation. In this case, the field is read-only and writes are UNDEFINED.

If the corresponding counter AMEVCNTR1<\(n\)>_EL0 is enabled, writes to this register have UNPREDICTABLE results.

**Accessing the AMEVTPER1<\(n\)>_EL0**

If \(<n\>\) is greater than or equal to the number of auxiliary activity monitor event counters, reads and writes of AMEVTPER1<\(n\)>_EL0 are UNDEFINED.

--- **Note** ---

AMECGCR_EL0.CG1NC identifies the number of auxiliary activity monitor event counters.

Accesses to this register use the following encodings in the System instruction encoding space:
MRS \texttt{<Xt>}, AMEVTYPER1_\texttt{n}_EL0

D13.5.15 AMUSERENR_EL0, Activity Monitors User Enable Register

The AMUSERENR_EL0 characteristics are:

**Purpose**

Global user enable register for the activity monitors. Enables or disables EL0 access to the activity monitors. AMUSERENR_EL0 is applicable to both the architected and the auxiliary counter groups.

**Configurations**

AArch64 System register AMUSERENR_EL0[31:0] is architecturally mapped to AArch32 System register AMUSERENR[31:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMUSERENR_EL0 are UNDEFINED.

**Attributes**

AMUSERENR_EL0 is a 64-bit register.

**Field descriptions**

The AMUSERENR_EL0 bit assignments are:

```
63 62 61 60 59 58 57 56 55 54 53 52 51 50 49 48 47 46 45 44 43 42 41 40 39 38 37 36 35 34 33 32 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
RSZ 63 1
EN
```

**Bits [63:1]**

Reserved, RES0.

**EN, bit [0]**

Traps EL0 accesses to the activity monitors registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- **In AArch64 state, accesses to the following registers are trapped, reported using EC syndrome value 0x18:**
  - AMCFGR_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0, AMCNTENCLR1_EL0, AMCNTENSET0_EL0, AMCNTENSET1_EL0, AMCR_EL0, AMEVCTR0<n>_EL0, AMEVCTR1<n>_EL0, AMEVTPYR0<n>_EL0, and AMEVTPYR1<n>_EL0.
- **In AArch32 state, MRC and MCRR accesses to the following registers are trapped and reported using EC syndrome value 0x03, MRRC and MCRR accesses are trapped and reported using EC syndrome value 0x04:**
  - AMCFGR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVCTR0<n>, AMEVCTR1<n>, AMEVTPYR0<n>, and AMEVTPYR1<n>.

0b0 EL0 accesses to the activity monitors registers are trapped.

0b1 This control does not cause any instructions to be trapped. Software can access all activity monitor registers at EL0.

**Note**

- AMUSERENR_EL0 can always be read at EL0 and is not governed by this bit.

D13.6  Statistical Profiling Extension registers

This section lists the Statistical Profiling Extension registers in AArch64.
### D13.6.1 PMBIDR_EL1, Profiling Buffer ID Register

The PMBIDR_EL1 characteristics are:

**Purpose**

Provides information to software as to whether the buffer can be programmed at the current Exception level.

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMBIDR_EL1 are **UNDEFINED**.

**Attributes**

PMBIDR_EL1 is a 64-bit register.

**Field descriptions**

The PMBIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>6</td>
<td>F, bit [5]</td>
</tr>
<tr>
<td>5</td>
<td>Flags updates. Defines whether the address translation performed by the Profiling Buffer manages the Access Flag and dirty state.</td>
</tr>
<tr>
<td>4</td>
<td>P, bit [4]</td>
</tr>
<tr>
<td>3</td>
<td>Programming not allowed. The Profiling Buffer is owned by a higher Exception level or the other Security state.</td>
</tr>
</tbody>
</table>

#### Bits [63:6]

Reserved, RES0.

#### F, bit [5]

Flag updates. Defines whether the address translation performed by the Profiling Buffer manages the Access Flag and dirty state.

- **0b0**: Hardware management of the Access Flag and dirty state for accesses made by the Statistical Profiling Extension is always disabled for all translation stages.
- **0b1**: Hardware management for the Access Flag and dirty state for accesses made by the Statistical Profiling Extension is controlled in the same way as explicit memory accesses in the owning translation regime.

If hardware management of the Access Flag is disabled for a stage of translation, an access to Page or Block with the Access flag bit not set in the descriptor will generate an Access Flag fault.

If hardware management of the dirty state is disabled for a stage of translation, an access to a Page or Block will ignore the Dirty Bit Modifier in the descriptor might generate a Permission fault, depending on the values of the access permission bits in the descriptor.

#### P, bit [4]

Programming not allowed. The Profiling Buffer is owned by a higher Exception level or the other Security state.

- **0b0**: Profiling Buffer is owned by the current or a lower Exception level in the current Security state.
- **0b1**: Profiling Buffer is owned by a higher Exception level or the other Security state.

The value read from this field depends on the current Exception level and the Effective values of MDCR_EL3.NSPB and MDCR_EL2.E2PB:

- If EL3 is implemented, and either MDCR_EL3.NSPB == 0b00 or MDCR_EL3.NSPB == 0b01, this bit reads as one from:
  - Non-secure EL1.
  - Non-secure EL2.
— If Secure EL2 is implemented and enabled, and `MDCR_EL2.E2PB == 0b00`, Secure EL1.

- If EL3 is implemented, and either `MDCR_EL3.NSPB == 0b10` or `MDCR_EL3.NSPB == 0b11`, this bit reads as one from:
  — Secure EL1.
  — If Secure EL2 is implemented, Secure EL2.
  — If EL2 is implemented and `MDCR_EL2.E2PB == 0b00`, Non-secure EL1.

- If EL3 is not implemented, EL2 is implemented, and `MDCR_EL2.E2PB == 0b00`, this bit reads as one from EL1.
- Otherwise, this bit reads as zero.

Align, bits [3:0]
Defines the minimum alignment constraint for `PMBPTR_EL1`. If this field is non-zero, then the PE must pad every record up to a multiple of this size.

- `0b0000` Byte
- `0b0001` Halfword.
- `0b0010` Word.
- `0b0011` Doubleword.
- `0b0100` 16 Bytes.
- `0b0101` 32 Bytes.
- `0b0110` 64 Bytes.
- `0b0111` 128 Bytes.
- `0b1000` 256 Bytes.
- `0b1001` 512 Bytes.
- `0b1010` 1KB.
- `0b1011` 2KB.

For more information, see *Restrictions on the current write pointer* on page D9-2792.

Accessing the PMBIDR_EL1
Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRS <Xt>, PMBIDR_EL1 \]

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>

  return PMBIDR_EL1;
elif `PSTATE.EL == EL2` then
  return PMBIDR_EL1;
elif `PSTATE.EL == EL3` then
  return PMBIDR_EL1;
D13.6.2 PMBLIMITR_EL1, Profiling Buffer Limit Address Register

The PMBLIMITR_EL1 characteristics are:

Purpose

Defines the upper limit for the profiling buffer, and enables the profiling buffer

Configurations

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMBLIMITR_EL1 are UNDEFINED.

Attributes

PMBLIMITR_EL1 is a 64-bit register.

Field descriptions

The PMBLIMITR_EL1 bit assignments are:

LIMIT, bits [63:12]

Limit address. PMBLIMITR_EL1.LIMIT:Zeros(12) is the address of the first byte in memory after the last byte in the profiling buffer. If the smallest implemented translation granule is not 4KB, then bits[N-1:12] are RES0, where N is the IMPLEMENTATION DEFINED value, Log2(smallest implemented translation granule).

This field resets to an architecturally UNKNOWN value.

Bits [11:3]

Reserved, RES0.

FM, bits [2:1]

Fill mode.

0b00 Fill mode. Stop collection and raise maintenance interrupt on buffer fill.

All other values are reserved.

This field resets to an architecturally UNKNOWN value.

E, bit [0]

Profiling Buffer enable

0b0 All output is discarded.

0b1 Profiling buffer enabled.

On a Warm reset, this field resets to 0.

Accessing the PMBLIMITR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:
## MRS <Xt>, PMBLIMITR_EL1

### D13.6.3 PMBPTR_EL1, Profiling Buffer Write Pointer Register

The PMBPTR_EL1 characteristics are:

**Purpose**
Defines the current write pointer for the profiling buffer.

**Configurations**
This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMBPTR_EL1 are UNDEFINED.

**Attributes**
PMBPTR_EL1 is a 64-bit register.

**Field descriptions**
The PMBPTR_EL1 bit assignments are:

![Register Diagram]

**PTR, bits [63:0]**
Current write address. Defines the virtual address of the next entry to be written to the buffer.

The architecture places restrictions on the values software can write to the pointer. For more information see *Restrictions on the current write pointer on page D9-2792.*

**Note**
As a result, an implementation might treat some of bits[M:0], where M is defined by PMBIDR_EL1.Align, as RES0.

On a management interrupt, PMBPTR_EL1 is frozen.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

### D13.6.4 PMBSR_EL1, Profiling Buffer Status/syndrome Register

The PMBSR_EL1 characteristics are:

**Purpose**

Provides syndrome information to software when the buffer is disabled because the management interrupt has been raised.

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMBSR_EL1 are UNDEFINED.

**Attributes**

PMBSR_EL1 is a 64-bit register.

**Field descriptions**

The PMBSR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>RES0</strong></td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td><strong>EC</strong></td>
<td>Exception class</td>
</tr>
<tr>
<td><strong>RES0</strong></td>
<td>Top-level description of the cause of the buffer management event</td>
</tr>
<tr>
<td><strong>DL</strong></td>
<td>stage 1 Data Abort on write to Profiling Buffer.</td>
</tr>
<tr>
<td><strong>S</strong></td>
<td>See MSS encoding for stage 1 or stage 2 Data Abort on write to buffer.</td>
</tr>
<tr>
<td><strong>MSS</strong></td>
<td>See MSS encoding for buffer management event for an IMPLEMENTATION DEFINED reason.</td>
</tr>
<tr>
<td><strong>COLL</strong></td>
<td>Stage 2 Data Abort on write to Profiling Buffer.</td>
</tr>
<tr>
<td><strong>EA</strong></td>
<td>See MSS encoding for stage 1 or stage 2 Data Abort on write to buffer.</td>
</tr>
</tbody>
</table>

All other values are reserved. Reserved values might be defined in a future version of the architecture.

Writing a reserved value to this field will make the value of this field UNKNOWN. Values that are not supported act as reserved values when writing to this register.

On a Warm reset, this field resets to an architecturally UNKNOWN value.
Bits [25:20]

Reserved, RES0.

DL, bit [19]

Partial record lost.
Following a buffer management event other than an asynchronous External abort, indicates whether the last record written to the Profiling Buffer is complete.

0b0  PMBPTR_EL1 points to the first byte after the last complete record written to the Profiling Buffer.

0b1  Part of a record was lost because of a buffer management event or synchronous External abort. PMBPTR_EL1 might not point to the first byte after the last complete record written to the buffer, and so restarting collection might result in a data record stream that software cannot parse. All records prior to the last record have been written to the buffer.

When the buffer management event was because of an asynchronous external abort, this bit is set to 1 and software must not assume that any valid data has been written to the Profiling Buffer.

This bit is RES0 if the PE never sets this bit as a result of a buffer management event caused by an asynchronous External abort.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [18]

External abort.

0b0  An external abort has not been asserted.

0b1  An external abort has been asserted and detected by the Statistical Profiling Extension.

This bit is RES0 if the PE never sets this bit as the result of an External abort.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

S, bit [17]

Service

0b0  PMBIRQ is not asserted.

0b1  PMBIRQ is asserted. All profiling data has either been written to the buffer or discarded.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

COLL, bit [16]

Collision detected.

0b0  No collision events detected.

0b1  At least one collision event was recorded.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

MSS, bits [15:0]

Management Event Specific Syndrome.
Contains syndrome specific to the management event.
The syndrome contents for each management event are described in the following sections.
On a Warm reset, this field resets to an architecturally UNKNOWN value.
MSS encoding for stage 1 or stage 2 Data Aborts on write to buffer

Fault status code

- 0b000000  Address size fault, level 0 of translation or translation table base register.
- 0b000001  Address size fault, level 1.
- 0b000010  Address size fault, level 2.
- 0b000011  Address size fault, level 3.
- 0b000100  Translation fault, level 0.
- 0b000101  Translation fault, level 1.
- 0b000110  Translation fault, level 2.
- 0b000111  Translation fault, level 3.
- 0b001001  Access flag fault, level 1.
- 0b001010  Access flag fault, level 2.
- 0b001011  Access flag fault, level 3.
- 0b001101  Permission fault, level 1.
- 0b001110  Permission fault, level 2.
- 0b001111  Permission fault, level 3.
- 0b010000  Synchronous External abort, not on translation table walk or hardware update of translation table.
- 0b010001  Asynchronous External abort.
- 0b010100  Synchronous External abort on translation table walk or hardware update of translation table, level 0.
- 0b010101  Synchronous External abort on translation table walk or hardware update of translation table, level 1.
- 0b010110  Synchronous External abort on translation table walk or hardware update of translation table, level 2.
- 0b010111  Synchronous External abort on translation table walk or hardware update of translation table, level 3.
- 0b010001  Alignment fault.
- 0b110000  TLB conflict abort.
- 0b110001  When FEAT_HAFDBS is implemented Unsupported atomic hardware update fault.

All other values are reserved.

It is IMPLEMENTATION DEFINED whether each of the Access Flag fault, asynchronous External abort and synchronous External abort, Alignment fault, and TLB Conflict abort values can be generated by the PE. For more information see Faults and watchpoints on page D9-2797.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

D13.6.5 PMSCR_EL1, Statistical Profiling Control Register (EL1)

The PMSCR_EL1 characteristics are:

**Purpose**
Provides EL1 controls for Statistical Profiling

**Configurations**
This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSCR_EL1 are UNDEFINED.

**Attributes**
PMSCR_EL1 is a 64-bit register.

**Field descriptions**
The PMSCR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:8</td>
</tr>
<tr>
<td>8:7</td>
</tr>
<tr>
<td>7:6</td>
</tr>
<tr>
<td>6:5</td>
</tr>
<tr>
<td>5:4</td>
</tr>
<tr>
<td>4:3</td>
</tr>
<tr>
<td>3:2</td>
</tr>
<tr>
<td>2:1</td>
</tr>
<tr>
<td>1:0</td>
</tr>
</tbody>
</table>

**Bits [63:8]**
Reserved, RES0.

**PCT, bits [7:6]**

*When EL2 is implemented:*

Physical Timestamp. If timestamp sampling is enabled and the Profiling Buffer is owned by EL1, requests which timestamp counter value is collected.

If FEAT_ECV is implemented, this is a two bit field as shown. Otherwise, bit[7] is RES0.

- **0b00** Virtual counter, CNTVCT_EL0, is collected.
- **0b01** Physical counter, CNTPCT_EL0, is collected.
- **0b11 When FEAT_ECV is implemented** Physical counter, CNTPCT_EL0, minus CNTPOFF_EL2 is collected.

If the Profiling Buffer owning Exception level is EL2, this field is ignored.

If the Profiling Buffer owning Exception level is EL1, this field is combined with PMSCR_EL2.PCT to determine which timestamp counter value is collected. For more information, see *Controlling the data that is collected on page D9-2789*.

When EL2 is implemented and enabled in the current Security state, the physical counter uses a fixed physical offset of zero if either of the following are true:

- CNTHCTL_EL2.ECV is 0.
- SCR_EL3.ECVEn is 0.
- HCR_EL2.{E2H, TGE} is {1, 1}.

On a Warm reset, this field resets to an architecturally UNKNOWN value.
Otherwise:

Physical Timestamp. Reserved. This field reads as 0b01 and ignores writes. Software should treat this field as UNK/SBZP.

When EL2 is not implemented, the Effective values of CNTVOFF_EL2 and CNTPOFF_EL2 are zero, meaning the virtual counter and physical counter have the same value.

TS, bit [5]

Timestamp enable.
0b0 Timestamp sampling disabled.
0b1 Timestamp sampling enabled.

This bit is ignored by the PE if EL2 is implemented and the Profiling Buffer is owned by EL2. For more information, see Controlling the data that is collected on page D9-2789.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

PA, bit [4]

Physical Address sample enable.
0b0 Physical addresses are not collected.
0b1 Physical addresses are collected.

If EL2 is implemented:
• If the Profiling Buffer is owned by EL1, this bit is combined with PMSCR_EL2.PA to determine which address is collected. For more information, see Controlling the data that is collected on page D9-2789.
• If the Profiling Buffer is owned by EL2, this bit is ignored by the PE.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

CX, bit [3]

CONTEXTIDR_EL1 sample enable.
0b0 CONTEXTIDR_EL1 is not collected.
0b1 CONTEXTIDR_EL1 is collected.

If EL2 is implemented and enabled in the current Security state when an operation is sampled:
• If the PE is at EL2, this bit is ignored by the PE.
• If HCR_EL2.TGE == 1, this bit is ignored by the PE.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [2]

Reserved, RES0.

E1SPE, bit [1]

EL1 Statistical Profiling Enable.
0b0 Sampling disabled at EL1.
0b1 Sampling enabled at EL1.

If EL2 is implemented and enabled in the current Security state, this bit is ignored by the PE when HCR_EL2.TGE == 1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

E0SPE, bit [0]

EL0 Statistical Profiling Enable. Controls sampling at EL0 when HCR_EL2.TGE == 0 or if EL2 is disabled or not implemented.
0b0 Sampling disabled at EL0.
0b1 Sampling enabled at EL0.
If EL2 is implemented and enabled in the current Security state, this bit is ignored by the PE when HCR_EL2.TGE == 1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

D13.6.6 PMSCR_EL2, Statistical Profiling Control Register (EL2)

The PMSCR_EL2 characteristics are:

Purpose

Provides EL2 controls for Statistical Profiling

Configurations

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSCR_EL2 are UNDEFINED.

Attributes

PMSCR_EL2 is a 64-bit register.

Field descriptions

The PMSCR_EL2 bit assignments are:

Bits [63:8]

Reserved, RES0.

PCT, bits [7:6]

Physical Timestamp. If timestamp sampling is enabled, determines which counter is collected. The behavior depends on the Profiling Buffer owning Exception level.

If FEAT_ECV is implemented, this is a two bit field as shown. Otherwise, bit[7] is RES0.

0b00 Virtual counter, CNTVCT_EL0, is collected.
0b01 If the Profiling Buffer owning Exception level is EL2: Physical counter, CNTPCT_EL0, is collected.
If the Profiling Buffer owning Exception level is EL1: Timestamp value is selected by PMSCR_EL1.PCT.
0b11 When FEAT_ECV is implemented If the Profiling Buffer owning Exception level is EL2: Physical counter, CNTPCT_EL0, minus CNTPOFF_EL2 is collected.
If the Profiling Buffer owning Exception level is EL1: If PMSCR_EL1.PCT == 0b00, the virtual counter, CNTVCT_EL0 is collected. Otherwise, the physical counter, CNTPCT_EL0, minus CNTPOFF_EL2 is collected.

When EL2 is implemented and enabled in the current Security state, the physical counter uses a fixed physical offset of zero if either of the following are true:

• CNTHCTL_EL2.ECV is 0.
• SCR_EL3.ECVEn is 0.
• HCR_EL2.{E2H, TGE} is {1, 1}.

If EL2 is not implemented or EL2 is disabled in the current Security state, the PE behaves as if this field is set to 0b001, other than for a direct read of the register.

On a Warm reset, this field resets to an architecturally UNKNOWN value.
TS, bit [5]

Timestamp Enable.

0b0    Timestamp sampling disabled.
0b1    Timestamp sampling enabled.

This bit is ignored by the PE when any of the following are true:
• The Profiling Buffer owning Exception level is EL1.
• In Secure state, and either FEAT_SEL2 is not implemented or Secure EL2 is disabled.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

PA, bit [4]

Physical Address Sample Enable.

0b0    Physical addresses are not collected.
0b1    Physical addresses are collected.

If the Profiling Buffer owning Exception level is EL1, and EL2 is enabled in the current Security state, this bit is combined with PMSCR_EL1.PA to determine which address is collected.

If EL2 is not implemented or EL2 is disabled in the current Security state, the PE ignores the value of this bit and behaves as if this bit is set to 1, other than for a direct read of the register.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

CX, bit [3]

CONTEXTIDR_EL2 Sample Enable.

0b0    CONTEXTIDR_EL2 is not collected.
0b1    CONTEXTIDR_EL2 is collected.

If EL2 is not implemented or EL2 is disabled in the current Security state, the PE ignores the value of this bit.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [2]

Reserved, RES0.

E2SPE, bit [1]

EL2 Statistical Profiling Enable.

0b0    Sampling disabled at EL2.
0b1    Sampling enabled at EL2.

This bit is RES0 if MDCR_EL2.E2PB != 0b00.

If EL2 is disabled in the current Security state, this bit is ignored by the PE.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

E0HSPE, bit [0]

EL0 Statistical Profiling Enable.

0b0    Sampling disabled at EL0.
0b1    Sampling enabled at EL0.

If MDCR_EL2.E2PB != 0b00, this bit is RES0.

If EL2 is implemented and enabled in the current Security state, this bit is ignored by the PE when HCR_EL2.TGE == 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing the PMSCR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

D13.6.7  PMSEVFR_EL1, Sampling Event Filter Register

The PMSEVFR_EL1 characteristics are:

**Purpose**
Controls sample filtering by events. The overall filter is the logical AND of these filters. For example, if E[3] and E[5] are both set to 1, only samples that have both event 3 (Level 1 unified or data cache refill) and event 5 set (TLB walk) are recorded.

**Configurations**
This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSEVFR_EL1 are UNDEFINED.

**Attributes**
PMSEVFR_EL1 is a 64-bit register.

**Field descriptions**
The PMSEVFR_EL1 bit assignments are:

```
E[63], bit [63]
E[63] is the event filter for event 63. If event 63 is not implemented, or filtering on event 63 is not supported, the corresponding bit is RAZ/WI.
0b0  Event 63 is ignored.
0b1  Do not record samples that have event 63 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when PMSCCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.
```
E[62], bit [62]

E[62] is the event filter for event 62. If event 62 is not implemented, or filtering on event 62 is not supported, the corresponding bit is RAZ/WI.

- 0b0 Event 62 is ignored.
- 0b1 Do not record samples that have event 62 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event. This field is ignored by the PE when PMSFCR_EL1.FE == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[61], bit [61]

E[61] is the event filter for event 61. If event 61 is not implemented, or filtering on event 61 is not supported, the corresponding bit is RAZ/WI.

- 0b0 Event 61 is ignored.
- 0b1 Do not record samples that have event 61 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event. This field is ignored by the PE when PMSFCR_EL1.FE == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[60], bit [60]

E[60] is the event filter for event 60. If event 60 is not implemented, or filtering on event 60 is not supported, the corresponding bit is RAZ/WI.

- 0b0 Event 60 is ignored.
- 0b1 Do not record samples that have event 60 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event. This field is ignored by the PE when PMSFCR_EL1.FE == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[59], bit [59]

E[59] is the event filter for event 59. If event 59 is not implemented, or filtering on event 59 is not supported, the corresponding bit is RAZ/WI.

- 0b0 Event 59 is ignored.
- 0b1 Do not record samples that have event 59 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event. This field is ignored by the PE when PMSFCR_EL1.FE == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[58], bit [58]

E[58] is the event filter for event 58. If event 58 is not implemented, or filtering on event 58 is not supported, the corresponding bit is RAZ/WI.

- 0b0 Event 58 is ignored.
- 0b1 Do not record samples that have event 58 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event. This field is ignored by the PE when PMSFCR_EL1.FE == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.
E[57], bit [57]

E[57] is the event filter for event 57. If event 57 is not implemented, or filtering on event 57 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 57 is ignored.
0b1  Do not record samples that have event 57 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[56], bit [56]

E[56] is the event filter for event 56. If event 56 is not implemented, or filtering on event 56 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 56 is ignored.
0b1  Do not record samples that have event 56 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[55], bit [55]

E[55] is the event filter for event 55. If event 55 is not implemented, or filtering on event 55 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 55 is ignored.
0b1  Do not record samples that have event 55 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[54], bit [54]

E[54] is the event filter for event 54. If event 54 is not implemented, or filtering on event 54 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 54 is ignored.
0b1  Do not record samples that have event 54 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[53], bit [53]

E[53] is the event filter for event 53. If event 53 is not implemented, or filtering on event 53 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 53 is ignored.
0b1  Do not record samples that have event 53 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.
E[52], bit [52]

E[52] is the event filter for event 52. If event 52 is not implemented, or filtering on event 52 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 52 is ignored.
0b1  Do not record samples that have event 52 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[51], bit [51]

E[51] is the event filter for event 51. If event 51 is not implemented, or filtering on event 51 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 51 is ignored.
0b1  Do not record samples that have event 51 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[50], bit [50]

E[50] is the event filter for event 50. If event 50 is not implemented, or filtering on event 50 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 50 is ignored.
0b1  Do not record samples that have event 50 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[49], bit [49]

E[49] is the event filter for event 49. If event 49 is not implemented, or filtering on event 49 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 49 is ignored.
0b1  Do not record samples that have event 49 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[48], bit [48]

E[48] is the event filter for event 48. If event 48 is not implemented, or filtering on event 48 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 48 is ignored.
0b1  Do not record samples that have event 48 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.
Bits [47:32]

Reserved, RAZ/WI.

E[31], bit [31]

E[31] is the event filter for event 31. If event 31 is not implemented, or filtering on event 31 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 31 is ignored.
0b1  Do not record samples that have event 31 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event. This field is ignored by the PE when PMSFCR_EL1.FE == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[30], bit [30]

E[30] is the event filter for event 30. If event 30 is not implemented, or filtering on event 30 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 30 is ignored.
0b1  Do not record samples that have event 30 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event. This field is ignored by the PE when PMSFCR_EL1.FE == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[29], bit [29]

E[29] is the event filter for event 29. If event 29 is not implemented, or filtering on event 29 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 29 is ignored.
0b1  Do not record samples that have event 29 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event. This field is ignored by the PE when PMSFCR_EL1.FE == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[28], bit [28]

E[28] is the event filter for event 28. If event 28 is not implemented, or filtering on event 28 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 28 is ignored.
0b1  Do not record samples that have event 28 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event. This field is ignored by the PE when PMSFCR_EL1.FE == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[27], bit [27]

E[27] is the event filter for event 27. If event 27 is not implemented, or filtering on event 27 is not supported, the corresponding bit is RAZ/WI.

0b0  Event 27 is ignored.
0b1  Do not record samples that have event 27 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when \texttt{PMSFCR\_EL1.FE} == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**E[26], bit [26]**

\texttt{E[26]} is the event filter for event 26. If event 26 is not implemented, or filtering on event 26 is not supported, the corresponding bit is RAZ/WI.

0b0 Event 26 is ignored.
0b1 Do not record samples that have event 26 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of \texttt{PMSEVFR\_EL1} define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when \texttt{PMSFCR\_EL1.FE} == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**E[25], bit [25]**

\texttt{E[25]} is the event filter for event 25. If event 25 is not implemented, or filtering on event 25 is not supported, the corresponding bit is RAZ/WI.

0b0 Event 25 is ignored.
0b1 Do not record samples that have event 25 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of \texttt{PMSEVFR\_EL1} define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when \texttt{PMSFCR\_EL1.FE} == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**E[24], bit [24]**

\texttt{E[24]} is the event filter for event 24. If event 24 is not implemented, or filtering on event 24 is not supported, the corresponding bit is RAZ/WI.

0b0 Event 24 is ignored.
0b1 Do not record samples that have event 24 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of \texttt{PMSEVFR\_EL1} define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when \texttt{PMSFCR\_EL1.FE} == 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [23:19]**

Reserved, RAZ/WI.

**E[18], bit [18]**

\textit{When FEAT\_SPEv1p1 is implemented and FEAT\_SVE is implemented:}

Empty predicate.

0b0 Empty predicate event is ignored.
0b1 Do not record samples that have the Empty predicate event == 0.

This bit is ignored by the PE when \texttt{PMSFCR\_EL1.FE} == 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

\textit{Otherwise:}

Reserved, RAZ/WI.

**E[17], bit [17]**

\textit{When FEAT\_SPEv1p1 is implemented and FEAT\_SVE is implemented:}

Partial predicate.

0b0 Partial predicate event is ignored.
0b1 Do not record samples that have the Partial predicate event == 0.
This bit is ignored by the PE when PMSFCR_EL1.FE == 0.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RAZ/WI.

Bit [16]
Reserved, RAZ/WI.

E[15], bit [15]
E[15] is the event filter for event 15. If event 15 is not implemented, or filtering on event 15 is not supported, the corresponding bit is RAZ/WI.
0b0 Event 15 is ignored.
0b1 Do not record samples that have event 15 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[14], bit [14]
E[14] is the event filter for event 14. If event 14 is not implemented, or filtering on event 14 is not supported, the corresponding bit is RAZ/WI.
0b0 Event 14 is ignored.
0b1 Do not record samples that have event 14 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[13], bit [13]
E[13] is the event filter for event 13. If event 13 is not implemented, or filtering on event 13 is not supported, the corresponding bit is RAZ/WI.
0b0 Event 13 is ignored.
0b1 Do not record samples that have event 13 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[12], bit [12]
E[12] is the event filter for event 12. If event 12 is not implemented, or filtering on event 12 is not supported, the corresponding bit is RAZ/WI.
0b0 Event 12 is ignored.
0b1 Do not record samples that have event 12 == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.
This field is ignored by the PE when PMSFCR_EL1.FE == 0
On a Warm reset, this field resets to an architecturally UNKNOWN value.

*When FEAT_SPEv1p1 is implemented:*

Alignment.

0b0 Alignment event is ignored.
0b1 Do not record samples that have the Alignment event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RAZ/WI.

Bits [10:8]

Reserved, RAZ/WI.

E[7], bit [7]

Mispredicted.

0b0 Mispredicted event is ignored.
0b1 Do not record samples that have the Mispredicted event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RAZ/WI.

E[5], bit [5]

TLB walk.

0b0 TLB walk event is ignored.
0b1 Do not record samples that have the TLB walk event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [4]

Reserved, RAZ/WI.

E[3], bit [3]

Level 1 data or unified cache refill.

0b0 Level 1 data or unified cache refill event is ignored.
0b1 Do not record samples that have the Level 1 data or unified cache refill event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [2]

Reserved, RAZ/WI.

E[1], bit [1]

*When the PE supports sampling of speculative instructions:*

Architecturally retired.

When the PE supports sampling of speculative instructions:

0b0 Architecturally retired event is ignored.
0b1 Do not record samples that have the Architecturally retired event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.
If the PE does not support the sampling of speculative instructions, or always discards the sample record for speculative instructions, this bit reads as an UNKNOWN value and the PE ignores its value. On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, UNKNOWN.

**Bit [0]**

Reserved, RAZ/WI.

### Accessing the PMSEVFR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.6.8 PMSFCR_EL1, Sampling Filter Control Register

The PMSFCR_EL1 characteristics are:

Purpose

Controls sample filtering. The filter is the logical AND of the FL, FT and FE bits. For example, if FE == 1 and FT == 1 only samples including the selected operation types and the selected events will be recorded

Configurations

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSFCR_EL1 are UNDEFINED.

Attributes

PMSFCR_EL1 is a 64-bit register.

Field descriptions

The PMSFCR_EL1 bit assignments are:

<table>
<thead>
<tr>

<td>ST</td>
<td>LD</td>
<td>B</td>
<td>RES0</td>
<td>FL</td>
<td>FT</td>
<td>FE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:19]

Reserved, RES0.

ST, bit [18]

Store filter enable

0b0   Do not record store operations
0b1   Record all store operations, including vector stores and all atomic operations

This bit is ignored by the PE when PMSFCR_EL1.FT == 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

LD, bit [17]

Load filter enable

0b0   Do not record load operations
0b1   Record all load operations, including vector loads and atomic operations that return data

This bit is ignored by the PE when PMSFCR_EL1.FT == 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

B, bit [16]

Branch filter enable

0b0   Do not record branch and exception return operations
0b1   Record all branch and exception return operations

This bit is ignored by the PE when PMSFCR_EL1.FT == 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [15:3]

Reserved, RES0.
FL, bit [2]
Filter by latency
0b0  Latency filtering disabled
0b1  Latency filtering enabled. Samples with a total latency less than PMSLATFR_EL1.MINLAT will not be recorded

If this field is set to 1 and PMSLATFR_EL1.MINLAT is set to zero, it is CONSTRAINED UNPREDICTABLE whether no samples are recorded or the PE behaves as if PMSFCR_EL1.FL is set to 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

FT, bit [1]
Filter by operation type. The filter is the logical OR of the ST, LD and B bits. For example, if LD and ST are both set, both load and store operations are recorded
0b0  Type filtering disabled
0b1  Type filtering enabled. Samples not one of the selected operation types will not be recorded

If this field is set to 1 and the PMSFCR_EL1.{ST, LD, B} bits are all set to zero, it is CONSTRAINED UNPREDICTABLE whether no samples are recorded or the PE behaves as if PMSFCR_EL1.FT is set to 0

On a Warm reset, this field resets to an architecturally UNKNOWN value.

FE, bit [0]
Filter by event.
0b0  Event filtering disabled.
0b1  Event filtering enabled. Samples not including the events selected by PMSEVFR_EL1 will not be recorded.

If PMSFCR_EL1.FE == 0b1 and PMSEVFR_EL1 is zero, it is CONSTRAINED UNPREDICTABLE whether no samples are recorded or the PE behaves as if PMSFCR_EL1.FE == 0b0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the PMSFCR_EL1
Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRS \ } <Xt>, \ \text{PMSFCR\_EL1}
\]

D13.6.9 PMSICR_EL1, Sampling Interval Counter Register

The PMSICR_EL1 characteristics are:

**Purpose**
Software must write zero to PMSICR_EL1 before enabling sample profiling for a sampling session. Software must then treat PMSICR_EL1 as an opaque, 64-bit, read/write register used for context switches only.

**Configurations**
This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSICR_EL1 are UNDEFINED.

**Attributes**
The value of PMSICR_EL1 does not change whilst profiling is disabled.

**Field descriptions**
The PMSICR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>56</th>
<th>55</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECOUNT</td>
<td>RES0</td>
<td>COUNT</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ECOUNT, bits [63:56]**

*When PMSIDR_EL1.ERnd == 1:*
Secondary sample interval counter.
This field provides the secondary counter used after the primary counter reaches zero. Whilst the secondary counter is nonzero and profiling is enabled, the secondary counter decrements by 1 for each member of the sample population. The primary counter also continues to decrement since it is also nonzero. When the secondary counter reaches zero, a member of the sampling population is selected for sampling.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*
Reserved, RES0.

**Bits [55:32]**
Reserved, RES0.

**COUNT, bits [31:0]**
Primary sample interval counter
Provides the primary counter used for sampling.

The primary counter is reloaded when the value of this register is zero and the PE moves from a state or Exception level where profiling is disabled to a state or Exception level where profiling is enabled whilst the primary counter is nonzero and sampling is enabled, the primary counter decrements by 1 for each member of the sample population.

When the counter reaches zero, the behavior depends on the values of PMSIDR_EL1.ERnd and PMSIRR_EL1.RND

- If PMSIRR_EL1.RND == 0 or PMSIDR_EL1.ERnd == 0:
  - A member of the sampling population is selected for sampling
  - The primary counter is reloaded
• If \texttt{PMSIRR\_EL1.RND == 1} and \texttt{PMSIDR\_EL1.ERnd == 1}:  
  — The secondary counter is set to a random or pseudorandom value in the range 0x00 to 
    0xFF  
  — The primary counter is reloaded  

On a Warm reset, this field resets to an architecturally \textit{UNKNOWN} value.

**Accessing the PMSICR\_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

**\texttt{MRS <Xt>, PMSICR\_EL1}**

D13.6.10 PMSIDR_EL1, Sampling Profiling ID Register

The PMSIDR_EL1 characteristics are:

**Purpose**

Describes the Statistical Profiling implementation to software

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSIDR_EL1 are UNDEFINED.

**Attributes**

PMSIDR_EL1 is a 64-bit register.

**Field descriptions**

The PMSIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-20</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>19-16</td>
<td>CountSize</td>
<td>0b0010 12-bit saturating counters</td>
</tr>
<tr>
<td>15-12</td>
<td>MaxSize</td>
<td>0b0100 16 bytes</td>
</tr>
<tr>
<td>11-8</td>
<td>Interval</td>
<td></td>
</tr>
<tr>
<td>7-0</td>
<td>Flag</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:20]**

Reserved, RES0.

**CountSize, bits [19:16]**

Defines the size of the counters

0b0010 12-bit saturating counters

All other values are reserved. Reserved values might be defined in a future version of the architecture.

**MaxSize, bits [15:12]**

Defines the largest size for a single record, rounded up to a power-of-two. If this is the same as the minimum alignment (PMBIDR_EL1.Align), then each record is exactly this size

0b0010 16 bytes
0b0100 32 bytes
0b0110 64 bytes
0b0111 128 bytes
0b1000 256 bytes
0b1001 512 bytes
0b1010 1024 bytes
0b1011 2KB

All other values are reserved. Reserved values might be defined in a future version of the architecture.
Interval, bits [11:8]

Recommended minimum sampling interval. This provides guidance from the implementer to the smallest minimum sampling interval, N.

- 0b0000 256
- 0b0010 512
- 0b0011 768
- 0b0100 1,024
- 0b0101 1,536
- 0b0110 2,048
- 0b0111 3,072
- 0b1000 4,096

All other values are reserved. Reserved values might be defined in a future version of the architecture.

Bits [7:6]

Reserved, RES0.

ERnd, bit [5]

Defines how the random number generator is used in determining the interval between samples, when enabled by PMSIRR_EL1.RND.

- 0b0 The random number is added at the start of the interval, and the sample is taken and a new interval started when the combined interval expires.
- 0b1 The random number is added and the new interval started after the interval programmed in PMSIRR_EL1.INTERVAL expires, and the sample is taken when the random interval expires.

LDS, bit [4]

Data source indicator for sampled load instructions

- 0b0 Loaded data source not implemented
- 0b1 Loaded data source implemented

ArchInst, bit [3]

Architectural instruction profiling

- 0b0 Micro-op sampling implemented
- 0b1 Architecture instruction sampling implemented

FL, bit [2]

Filtering by latency. This bit is RAO.

FT, bit [1]

Filtering by operation type. This bit is RAO.

FE, bit [0]

Filtering by events. This bit is RAO.

Accessing the PMSIDR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, PMSIDR_EL1

D13.6.11   PMSIRR_EL1, Sampling Interval Reload Register

The PMSIRR_EL1 characteristics are:

Purpose
Defines the interval between samples

Configurations
This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSIRR_EL1 are UNDEFINED.

Attributes
PMSIRR_EL1 is a 64-bit register.

Field descriptions
The PMSIRR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit position</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>32-31</td>
<td>INTERVAL, bits [31:8]</td>
<td></td>
</tr>
<tr>
<td>8-7</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>RND, bit [0]</td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:32] Reserved, RES0.

INTERVAL, bits [31:8]
Bits [31:8] of the PMSICR_EL1 interval counter reload value. Software must set this to a non-zero value. If software sets this to zero, an UNKNOWN sampling interval is used. Software should set this to a value greater than the minimum indicated by PMSIDR_EL1.Interval.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [7:1] Reserved, RES0.

RND, bit [0]
Controls randomization of the sampling interval
0b0 Disable randomization of sampling interval
0b1 Add (pseudo-)random jitter to sampling interval
The random number generator is not architected.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

D13.6.12  PMSLATFR_EL1, Sampling Latency Filter Register

The PMSLATFR_EL1 characteristics are:

**Purpose**
Controls sample filtering by latency

**Configurations**
This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSLATFR_EL1 are UNDEFINED.

**Attributes**
PMSLATFR_EL1 is a 64-bit register.

**Field descriptions**
The PMSLATFR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:12]</th>
<th>RES0</th>
</tr>
</thead>
<tbody>
<tr>
<td>MINLAT, bits [11:0]</td>
<td></td>
</tr>
</tbody>
</table>

Minimum latency. When PMSFCR_EL1.FL == 1, defines the minimum total latency for filtered operations. Samples with a total latency less than MINLAT will not be recorded

This field is ignored by the PE when PMSFCR_EL1.FL == 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing the PMSLATFR_EL1**
Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, PMSLATFR_EL1**

<table>
<thead>

D13.7  RAS registers

This section lists The Reliability, Availability, and Serviceability Extension registers in AArch64.
D13.7.1 DISR_EL1, Deferred Interrupt Status Register

The DISR_EL1 characteristics are:

Purpose

Records that an SError interrupt has been consumed by an ESB instruction.

Configurations

AArch64 System register DISR_EL1[31:0] is architecturally mapped to AArch32 System register DISR[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to DISR_EL1 are UNDEFINED.

Attributes

DISR_EL1 is a 64-bit register.

Field descriptions

The DISR_EL1 bit assignments are:

When DISR_EL1.IDS == 0:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>30</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>13</th>
<th>12</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>A</td>
<td>RES0</td>
<td>RES0</td>
<td>AET</td>
<td>RES0</td>
<td>DFSC</td>
<td>EA</td>
<td>IDS</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers an asynchronous SError interrupt. If the implementation does not include any sources of SError interrupt that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

This field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

Indicates the deferred SError interrupt type.

0b0 Deferred error uses architecturally-defined format.

This field resets to an architecturally UNKNOWN value.

Bits [23:13]

Reserved, RES0.

AET, bits [12:10]

Asynchronous Error Type. See the description of ESR_ELx.AET for an SError interrupt.

This field resets to an architecturally UNKNOWN value.
EA, bit [9]

External abort Type. See the description of ESR_ELx.EA for an SError interrupt.
This field resets to an architecturally UNKNOWN value.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

Fault Status Code. See the description of ESR_ELx.DFSC for an SError interrupt.
This field resets to an architecturally UNKNOWN value.

When DISR_EL1.IDS == 1:

Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers an asynchronous SError interrupt. If the implementation does
not include any sources of SError interrupt that can be synchronized by an Error Synchronization
Barrier, then this bit is RES0.
This field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

Indicates the deferred SError interrupt type.
0b1 Deferred error uses IMPLEMENTATION DEFINED format.
This field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]

IMPLEMENTATION DEFINED syndrome. See the description of ESR_ELx[23:0] for an SError interrupt.
This field resets to an architecturally UNKNOWN value.
The following subsections describe each ISS format.

Accessing the DISR_EL1

An indirect write to DISR_EL1 made by an ESB instruction does not require an explicit synchronization operation
for the value that is written to be observed by a direct read of DISR_EL1 occurring in program order after the ESB
instruction.

DISR_EL1 is RAZ/WI if EL3 is implemented, the PE is in Non-debug state, SCR_EL3.EA == 1, and any of the
following apply:
• At EL2.
• At EL1 and ((SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0) || HCR_EL2.AMO == 0).
Accesses to this register use the following encodings in the System instruction encoding space:

### MRS <Xt>, DISR_EL1

![Instruction Encoding Table]

```
D13.7.2 ERRIDR_EL1, Error Record ID Register

The ERRIDR_EL1 characteristics are:

**Purpose**

Defines the highest numbered index of the error records that can be accessed through the Error Record System registers.

**Configurations**

AArch64 System register ERRIDR_EL1[31:0] is architecturally mapped to AArch32 System register ERRIDR[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERRIDR_EL1 are UNDEFINED.

**Attributes**

ERRIDR_EL1 is a 64-bit register.

**Field descriptions**

The ERRIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:16</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>15:0</td>
<td>NUM</td>
</tr>
</tbody>
</table>

**Bits [63:16]**

Reserved, RES0.

**NUM, bits [15:0]**

Highest numbered index of the records that can be accessed through the Error Record System registers plus one. Zero indicates no records can be accessed through the Error Record System registers.

Each implemented record is owned by a node. A node might own multiple records.

**Accessing the ERRIDR_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

*MRS <Xt>, ERRIDR_EL1*

```plaintext
<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b000</td>
<td>0b0101</td>
<td>0b0011</td>
<td>0b000</td>
</tr>
</tbody>
</table>
```
UNDEFINED;
else
    AArch64.SystemAccessTrap(EL3, 0x18);
else
    return ERRIDR_EL1;
elsif PSTATE.EL == EL2 then
    if Halted() && HaveEL(EL3) && EDSCR.SDD == '1' && boolean IMPLEMENTATION_DEFINED "EL3 trap priority when SDD == '1'" && SCR_EL3.TERR == '1' then
        UNDEFINED;
    elsif HaveEL(EL3) && SCR_EL3.TERR == '1' then
        if Halted() && EDSCR.SDD == '1' then
            UNDEFINED;
        else
            AArch64.SystemAccessTrap(EL3, 0x18);
        end
    else
        return ERRIDR_EL1;
    end
elsif PSTATE.EL == EL3 then
    return ERRIDR_EL1;
D13.7.3 ERRSELR_EL1, Error Record Select Register

The ERRSELR_EL1 characteristics are:

**Purpose**

Selects an error record to be accessed through the Error Record System registers.

**Configurations**

AArch64 System register ERRSELR_EL1[31:0] is architecturally mapped to AArch32 System register ERRSELR[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERRSELR_EL1 are UNDEFINED.

If ERRIDR_EL1 indicates that zero error records are implemented, then it is IMPLEMENTATION DEFINED whether ERRSELR_EL1 is UNDEFINED or RES0.

**Attributes**

ERRSELR_EL1 is a 64-bit register.

**Field descriptions**

The ERRSELR_EL1 bit assignments are:

```
63  16  15  0
    RES0   SEL
```

**Bits [63:16]**

Reserved, RES0.

**SEL, bits [15:0]**

Selects the error record accessed through the ERX registers.

For example, if ERRSELR_EL1.SEL is set to 0x0004, then direct reads and writes of ERRXSTATUS_EL1 access ERR4STATUS.

If ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then all of the following apply:

- The value read back from ERRSELR_EL1.SEL is UNKNOWN.
- One of the following occurs:
  - An UNKNOWN error record is selected.
  - The ERX* EL1 registers are RAZ/WI.
  - ERX* EL1 register reads and writes are NOPs.
  - ERX* EL1 register reads and writes are UNDEFINED.

This field resets to an architecturally UNKNOWN value.

**Accessing the ERRSELR_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, ERRSELR_EL1

D13.7.4 ERXADDR_EL1, Selected Error Record Address Register

The ERXADDR_EL1 characteristics are:

Purpose

Accesses \texttt{ERR}<n>ADDR for the error record \texttt{<n>} selected by \texttt{ERRSELR_EL1.SEL}.

For details of this, see the \textit{Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8}, for the Armv8-A architecture profile.

Configurations

AArch64 System register ERXADDR_EL1[31:0] is architecturally mapped to AArch32 System register ERXADDR[31:0].

AArch64 System register ERXADDR_EL1[63:32] is architecturally mapped to AArch32 System register ERXADDR2[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXADDR_EL1 are \texttt{UNDEFINED}.

Attributes

ERXADDR_EL1 is a 64-bit register.

Field descriptions

The ERXADDR_EL1 bit assignments are:

```
63 0
  ERR<n>ADDR
```

Bits [63:0]

ERXADDR_EL1 accesses ERR\texttt{<n>}ADDR, where \texttt{<n>} is the value in ERRSELR_EL1.SEL.

Accessing the ERXADDR_EL1

If ERRIDR_EL1.NUM \texttt{== 0x0000} or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An \texttt{UNKNOWN} error record is selected.
- ERXADDR_EL1 is RAZ/WI.
- Direct reads and writes of ERXADDR_EL1 are NOPs.
- Direct reads and writes of ERXADDR_EL1 are \texttt{UNDEFINED}.

ERR\texttt{<n>}ADDR describes additional constraints that also apply when ERR\texttt{<n>}ADDR is accessed through ERXADDR_EL1.

Accesses to this register use the following encodings in the System instruction encoding space:
### MRS <Xt>, ERXADDR_EL1

D13.7.5 ERXCTLR_EL1, Selected Error Record Control Register

The ERXCTLR_EL1 characteristics are:

**Purpose**

Accesses ERR<n>CTLR for the error record <n> selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch64 System register ERXCTLR_EL1[31:0] is architecturally mapped to AArch32 System register ERXCTLR[31:0].

AArch64 System register ERXCTLR_EL1[63:32] is architecturally mapped to AArch32 System register ERXCTLR2[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXCTLR_EL1 are UNDEFINED.

**Attributes**

ERXCTLR_EL1 is a 64-bit register.

**Field descriptions**

The ERXCTLR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit position</th>
<th>Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-0</td>
<td>ERR&lt;n&gt;CTLR</td>
</tr>
</tbody>
</table>

ERXCTLR_EL1 accesses ERR<n>CTLR, where <n> is the value in ERRSELR_EL1.SEL.

**Accessing the ERXCTLR_EL1**

If ERRIDR_EL1.NUM == 0x0000 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An **UNKNOWN** error record is selected.
- ERXCTLR_EL1 is RAZ/WI.
- Direct reads and writes of ERXCTLR_EL1 are NOPs.
- Direct reads and writes of ERXCTLR_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then ERR<n>CTLR is not present, meaning reads and writes of ERXCTLR_EL1 are RES0.

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, ERXCTLR_EL1

D13.7.6 ERXFR_EL1, Selected Error Record Feature Register

The ERXFR_EL1 characteristics are:

Purpose

Accesses ERR<n>FR for the error record <n> selected by ERRSEL_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

Configurations

AArch64 System register ERXFR_EL1[31:0] is architecturally mapped to AArch32 System register ERXFR[31:0].

AArch64 System register ERXFR_EL1[63:32] is architecturally mapped to AArch32 System register ERXFR2[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXFR_EL1 are UNDEFINED.

Attributes

ERXFR_EL1 is a 64-bit register.

Field descriptions

The ERXFR_EL1 bit assignments are:

ERXFR_EL1 accesses ERR<n>FR, where <n> is the value in ERRSEL_EL1.SEL.

Accessing the ERXFR_EL1

If ERRIDR_EL1.NUM == 0x0000 or ERRSEL_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

• An UNKNOWN error record is selected.
• ERXFR_EL1 is RAZ.
• Direct reads of ERXFR_EL1 are NOPs.
• Direct reads of ERXFR_EL1 are UNDEFINED.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\begin{array}{cccccc}

D13.7.8 ERXMISC1_EL1, Selected Error Record Miscellaneous Register 1

The ERXMISC1_EL1 characteristics are:

**Purpose**

Accesses ERR<n>MISC1 for the error record <n> selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch64 System register ERXMISC1_EL1[31:0] is architecturally mapped to AArch32 System register ERXMISC2[31:0].

AArch64 System register ERXMISC1_EL1[63:32] is architecturally mapped to AArch32 System register ERXMISC3[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXMISC1_EL1 are UNDEFINED.

**Attributes**

ERXMISC1_EL1 is a 64-bit register.

**Field descriptions**

The ERXMISC1_EL1 bit assignments are:

![Bit assignments](image)

**Accessing the ERXMISC1_EL1**

If ERRDR_EL1.NUM == 0x0000 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRDR_EL1.NUM, then one of the following occurs:

- An **UNKNOWN** error record is selected.
- ERXMISC1_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC1_EL1 are NOPs.
- Direct reads and writes of ERXMISC1_EL1 are UNDEFINED.

ERR<n>MISC1 describes additional constraints that also apply when ERR<n>MISC1 is accessed through ERXMISC1_EL1.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.7.9  ERXMISC2_EL1, Selected Error Record Miscellaneous Register 2

The ERXMISC2_EL1 characteristics are:

Purpose
Accesses ERR<n>MISC2 for the error record <n> selected by ERRSELR_EL1.SEL.
For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

Configurations
AArch64 System register ERXMISC2_EL1[31:0] is architecturally mapped to AArch32 System register ERXMISC4[31:0].
AArch64 System register ERXMISC2_EL1[63:32] is architecturally mapped to AArch32 System register ERXMISC5[31:0].
This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXMISC2_EL1 are UNDEFINED.

Attributes
ERXMISC2_EL1 is a 64-bit register.

Field descriptions
The ERXMISC2_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERR&lt;n&gt;MISC2</td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:0]
ERXMISC2_EL1 accesses ERR<n>MISC2, where <n> is the value in ERRSELR_EL1.SEL.

Accessing the ERXMISC2_EL1
If ERRDR_EL1.NUM == 0x0000 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXMISC2_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC2_EL1 are NOPs.
- Direct reads and writes of ERXMISC2_EL1 are UNDEFINED.

ERR<n>MISC2 describes additional constraints that also apply when ERR<n>MISC2 is accessed through ERXMISC2_EL1.

Accesses to this register use the following encodings in the System instruction encoding space:
**MRS <xt>, ERXMISC2_EL1**

D13.7.10 ERXMISC3_EL1, Selected Error Record Miscellaneous Register 3

The ERXMISC3_EL1 characteristics are:

**Purpose**

Accesses ERR<n>MISC3 for the error record <n> selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch64 System register ERXMISC3_EL1[31:0] is architecturally mapped to AArch32 System register ERXMISC6[31:0].

AArch64 System register ERXMISC3_EL1[63:32] is architecturally mapped to AArch32 System register ERXMISC7[31:0].

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXMISC3_EL1 are UNDEFINED.

**Attributes**

ERXMISC3_EL1 is a 64-bit register.

**Field descriptions**

The ERXMISC3_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-0</td>
<td>ERR&lt;n&gt;MISC3</td>
</tr>
</tbody>
</table>

**Accessing the ERXMISC3_EL1**

If ERRDR_EL1.NUM != 0x0000 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRDR_EL1.NUM, then one of the following occurs:

- An **UNKNOWN** error record is selected.
- ERXMISC3_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC3_EL1 are NOPs.
- Direct reads and writes of ERXMISC3_EL1 are UNDEFINED.

ERR<n>MISC3 describes additional constraints that also apply when ERR<n>MISC3 is accessed through ERXMISC3_EL1.

D13.7.11 ERXPFGCDN_EL1, Selected Pseudo-fault Generation Countdown register

The ERXPFGCDN_EL1 characteristics are:

**Purpose**

Accesses ERR<n>PFGCDN for the error record <n> selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFGCDN_EL1 are UNDEFINED.

**Attributes**

ERXPFGCDN_EL1 is a 64-bit register.

**Field descriptions**

The ERXPFGCDN_EL1 bit assignments are:

63 0

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERXPFGCDN_EL1 accesses ERR&lt;n&gt;PFGCDN, where &lt;n&gt; is the value in ERRSELR_EL1.SEL.</td>
</tr>
</tbody>
</table>

**Accessing the ERXPFGCDN_EL1**

If ERRIDR_EL1.NUM == 0x0000 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXPFGCDN_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCDN_EL1 are NOPs.
- Direct reads and writes of ERXPFGCDN_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL selects an error record owned by a node that does not implement the RAS Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGCDN_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCDN_EL1 are NOPs.
- Direct reads and writes of ERXPFGCDN_EL1 are UNDEFINED.

--- Note ---

A node does not implement the RAS Common Fault Injection Model Extension when ERR<n>FR.INJ == 0b00. <q> is the index of the first error record owned by the same node as error record <n>, where <n> is the value in ERRSELR_EL1.SEL. If the node owns a single record, then q = n.

--- Note ---

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then ERR<n>PFGCDN is not present, meaning reads and writes of ERXPFGCDN_EL1 are RES0.
ERR<\textless{}n\textgreater{}>PFGCDN describes additional constraints that also apply when ERR<\textless{}n\textgreater{}>PFGCDN is accessed through ERXPFGCDN_EL1.

Accesses to this register use the following encodings in the System instruction encoding space:

\textbf{MRS <Xt>, ERXPFGCDN_EL1}

D13.7.12 ERXPFGCTL_EL1, Selected Pseudo-fault Generation Control register

The ERXPFGCTL_EL1 characteristics are:

**Purpose**

Accesses ERR<\textit{n}>PFGCTL for the error record \textit{n} selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFGCTL_EL1 are UNDEFINED.

**Attributes**

ERXPFGCTL_EL1 is a 64-bit register.

**Field descriptions**

The ERXPFGCTL_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>ERR&lt;\textit{n}&gt;PFGCTL</td>
</tr>
</tbody>
</table>

**Accessing the ERXPFGCTL_EL1**

If ERRIDR_EL1.NUM == 0x0000 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXPFGCTL_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCTL_EL1 are NOPs.
- Direct reads and writes of ERXPFGCTL_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL selects an error record owned by a node that does not implement the RAS Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGCTL_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCTL_EL1 are NOPs.
- Direct reads and writes of ERXPFGCTL_EL1 are UNDEFINED.

**Note**

A node does not implement the RAS Common Fault Injection Model Extension when ERR<\textit{n}>FR.INJ == 0b00. \textit{q} is the index of the first error record owned by the same node as error record \textit{n}, where \textit{n} is the value in ERRSELR_EL1.SEL. If the node owns a single record, then \textit{q} = \textit{n}.

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then ERR<\textit{n}>PFGCTL is not present, meaning reads and writes of ERXPFGCTL_EL1 are RES0.
ERR<n>PFGCTL describes additional constraints that also apply when ERR<n>PFGCTL is accessed through ERXPFGCTL_EL1.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.7.13   ERXPFGF_EL1, Selected Pseudo-fault Generation Feature register

The ERXPFGF_EL1 characteristics are:

**Purpose**

Accesses \( \text{ERR}<n>\text{PFGF} \) for the error record \(<n>\) selected by \( \text{ERRSELR_EL1.SEL} \).

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFGF_EL1 are UNDEFINED.

**Attributes**

ERXPFGF_EL1 is a 64-bit register.

**Field descriptions**

The ERXPFGF_EL1 bit assignments are:

```
63 0
```

\( \text{ERR}<n>\text{PFGF} \)

Bits [63:0]

ERXPFGF_EL1 accesses \( \text{ERR}<n>\text{PFGF} \), where \(<n>\) is the value in \( \text{ERRSELR_EL1.SEL} \).

**Accessing the ERXPFGF_EL1**

If \( \text{ERRIDR_EL1.NUM} \) is set to a value greater than or equal to \( \text{ERRSELR_EL1.SEL} \), then one of the following occurs:

- An \text{UNKNOWN} error record is selected.
- ERXPFGF_EL1 is RAZ.
- Direct reads of ERXPFGF_EL1 are NOPs.
- Direct reads of ERXPFGF_EL1 are UNDEFINED.

If \( \text{ERRSELR_EL1.SEL} \) selects an error record owned by a node that does not implement the RAS Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGF_EL1 is RAZ.
- Direct reads of ERXPFGF_EL1 are NOPs.
- Direct reads of ERXPFGF_EL1 are UNDEFINED.

**Note**

A node does not implement the RAS Common Fault Injection Model Extension when \( \text{ERR}<n>\text{FR.INJ} \) is set to a value greater than \( \text{ERRSELR_EL1.SEL} \). If the node owns a single record, then \( q = n \).

If \( \text{ERRSELR_EL1.SEL} \) is not the index of the first error record owned by a node, then \( \text{ERR}<n>\text{PFGF} \) is not present, meaning reads of ERXPFGF_EL1 are \text{RES0}.

A node does not implement the RAS Common Fault Injection Model Extension when \( \text{ERR}<n>\text{FR.INJ} \) is set to a value greater than \( \text{ERRSELR_EL1.SEL} \). If the node owns a single record, then \( q = n \).
ERR<n>PFGF describes additional constraints that also apply when ERR<n>PFGF is accessed through ERXPFGF_EL1.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, ERXPFGF_EL1**

D13.7.14 ERXSTATUS_EL1, Selected Error Record Primary Status Register

The ERXSTATUS_EL1 characteristics are:

**Purpose**

Accesses ERR<n>STATUS for the error record <n> selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch64 System register ERXSTATUS_EL1[31:0] is architecturally mapped to AArch32 System register ERXSTATUS[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXSTATUS_EL1 are UNDEFINED.

**Attributes**

ERXSTATUS_EL1 is a 64-bit register.

**Field descriptions**

The ERXSTATUS_EL1 bit assignments are:

![ERXSTATUS_EL1 diagram]

**Accessing the ERXSTATUS_EL1**

If ERRIDR_EL1.NUM == 0x0000 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An **UNKNOWN** error record is selected.
- ERXSTATUS_EL1 is RAZ/WI.
- Direct reads and writes of ERXSTATUS_EL1 are NOPs.
- Direct reads and writes of ERXSTATUS_EL1 are UNDEFINED.

ERR<n>STATUS describes additional constraints that also apply when ERR<n>STATUS is accessed through ERXSTATUS_EL1.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.7.15 VDISR_EL2, Virtual Deferred Interrupt Status Register

The VDISR_EL2 characteristics are:

**Purpose**

Records that a virtual SError interrupt has been consumed by an ESB instruction executed at EL1.

An indirect write to VDISR_EL2 made by an ESB instruction does not require an explicit synchronization operation for the value written to be observed by a direct read of DISR_EL1 or DISR occurring in program order after the ESB instruction.

**Configurations**

AArch64 System register VDISR_EL2[31:0] is architecturally mapped to AArch32 System register VDISR[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to VDISR_EL2 are UNDEFINED.

If EL2 is not implemented, this register is res0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

VDISR_EL2 is a 64-bit register.

**Field descriptions**

The VDISR_EL2 bit assignments are:

*When EL1 is using AArch64:*

```
  63  |  32  |  31  |  30  |  25  |  24  |  23  |  0
  +(-----+-----+-----+-----+-----+-----+-----+-----+)
     |     |     |     |     |     |     |     |
     | RES0|     | A   | RES0|     | ISS |     |
     |     |     |     |     |     |     |     |
     | IDS |
```

**Bits [63:32]**

Reserved, res0.

**A, bit [31]**

Set to 1 when an ESB instruction defers a virtual SError interrupt.

This field resets to an architecturally UNKNOWN value.

**Bits [30:25]**

Reserved, res0.

**IDS, bit [24]**

The value copied from VSESR_EL2.IDS.

This field resets to an architecturally UNKNOWN value.

**ISS, bits [23:0]**

The value copied from VSESR_EL2.ISS.

This field resets to an architecturally UNKNOWN value.

The following subsections describe each ISS format.
When EL1 is using AArch32 and VDISR_EL2.LPAE == 0:

<table>

FS[3:0], bits [3:0]
This field is bits[3:0] of FS[4:0].

When EL1 is using AArch32 and VDISR_EL2.LPAE == 1:

Bits [63:32]
Reserved, RES0.

A, bit [31]
Set to 1 when an ESB instruction defers a virtual SError interrupt.
This field resets to an architecturally UNKNOWN value.

Bits [30:16]
Reserved, RES0.

AET, bits [15:14]
The value copied from VSESRL2.AET.
This field resets to an architecturally UNKNOWN value.

Bit [13]
Reserved, RES0.

ExT, bit [12]
The value copied from VSESRL2.ExT.
This field resets to an architecturally UNKNOWN value.

Bits [11:10]
Reserved, RES0.

LPAE, bit [9]
Format.
Set to TTBCR.EAE when an ESB instruction defers a virtual SError interrupt.
0b1 Using the Long-descriptor translation table format.
This field resets to an architecturally UNKNOWN value.

Bits [8:6]
Reserved, RES0.
STATUS, bits [5:0]

Fault status code. Set to 0b010001 when an ESB instruction defers a virtual SError interrupt.

0b010001  Asynchronous SError interrupt.

All other values are reserved.

This field resets to an architecturally UNKNOWN value.

Accessing the VDISR_EL2

An indirect write to VDISR_EL2 made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of DISR_EL1 or DISR occurring in program order after the ESB instruction.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.7.16 VSESR_EL2, Virtual SError Exception Syndrome Register

The VSESR_EL2 characteristics are:

**Purpose**

Provides the syndrome value reported to software on taking a virtual SError interrupt exception to EL1, or on executing an E58 instruction at EL1.

When the virtual SError interrupt is taken to EL1 using AArch64, then the syndrome value is reported in ESR_EL1.

When the virtual SError interrupt is taken to EL1 using AArch32, then the syndrome value is reported in DFSR.{AET, ExT} and the remainder of DFSR is set as defined by VMSAv8-32. For more information, see Chapter G5 The AArch32 Virtual Memory System Architecture.

When the virtual SError interrupt is deferred by an E58 instruction, then the syndrome value is written to VDISR_EL2.

**Configurations**

AArch64 System register VSESR_EL2[31:0] is architecturally mapped to AArch32 System register VDFSR[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to VSESR_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

VSESR_EL2 is a 64-bit register.

**Field descriptions**

The VSESR_EL2 bit assignments are:

*When EL1 is using AArch32:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>16-15</td>
<td>AET</td>
</tr>
<tr>
<td>13-11</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>0</td>
<td>ExT</td>
</tr>
</tbody>
</table>

**Bits [63:16]**

Reserved, RES0.

**AET, bits [15:14]**

When a virtual SError interrupt is taken to EL1 using AArch32, DFSR[15:4] is set to VSESR_EL2.AET.

When a virtual SError interrupt is deferred by an E58 instruction, VDISR_EL2[15:4] is set to VSESR_EL2.AET.

This field resets to an architecturally UNKNOWN value.

**Bit [13]**

Reserved, RES0.
ExT, bit [12]

When a virtual SError interrupt is taken to EL1 using AArch32, DFSR[12] is set to VSESR_EL2.ExT.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR_EL2[12] is set to VSESR_EL2.ExT.

This field resets to an architecturally UNKNOWN value.

Bits [11:0]

Reserved, RES0.

When EL1 is using AArch64:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits [63:25]

Reserved, RES0.

IDS, bit [24]

When a virtual SError interrupt is taken to EL1 using AArch64, ESR_EL1[24] is set to VSESR_EL2.IDS.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR_EL2[24] is set to VSESR_EL2.IDS.

This field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]

When a virtual SError interrupt is taken to EL1 using AArch64, ESR_EL1[23:0] is set to VSESR_EL2.ISS.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR_EL2[23:0] is set to VSESR_EL2.ISS.

This field resets to an architecturally UNKNOWN value.

The following subsections describe each ISS format.

Accessing the VSESR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRS <Xt>, VSESR_EL2}
\]

D13.8  Generic Timer registers

This section lists the Generic Timer registers in AArch64.
D13.8.1  CNTFRQ_EL0, Counter-timer Frequency register

The CNTFRQ_EL0 characteristics are:

**Purpose**

This register is provided so that software can discover the frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

**Configurations**

AArch64 System register CNTFRQ_EL0[31:0] is architecturally mapped to AArch32 System register CNTFRQ[31:0].

**Attributes**

CNTFRQ_EL0 is a 64-bit register.

**Field descriptions**

The CNTFRQ_EL0 bit assignments are:

| Bits [63:32] | Reserved, RES0. |
|---------------|----------------|---|
| Bits [31:0]   | Clock frequency | Clock frequency indicates the system counter clock frequency, in Hz. This field resets to an architecturally UNKNOWN value.

**Accessing the CNTFRQ_EL0**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, CNTFRQ_EL0**

```
if PSTATE.EL == EL0 then
  if !(EL2Enabled() & HCR_EL2.<E2H,TGE> == '1') & CNTKCTL_EL1.<EL0PCTEN,EL0VCTEN> == '00' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  else
    AArch64.SystemAccessTrap(EL1, 0x18);
  elsif EL2Enabled() & HCR_EL2.TGE == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  else
    if PSTATE.EL == EL1 then
      return CNTFRQ_EL0;
    elsif PSTATE.EL == EL2 then
      return CNTFRQ_EL0;
    endif
    return CNTFRQ_EL0;
endif
```
elsif PSTATE.EL == EL3 then
    return CNTFRQ_EL0;

    MSR CNTFRQ_EL0, <x[t]>

D13.8.2 CNTHCTL_EL2, Counter-timer Hypervisor Control register

The CNTHCTL_EL2 characteristics are:

**Purpose**

Controls the generation of an event stream from the physical counter, and access from EL1 to the physical counter and the EL1 physical timer.

**Configurations**

AArch64 System register CNTHCTL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHCTL[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

CNTHCTL_EL2 is a 64-bit register.

**Field descriptions**

The CNTHCTL_EL2 bit assignments are:

*When FEAT_VHE is implemented and HCR_EL2.E2H == 1:*

![Diagram of CNTHCTL_EL2 bit assignments](image)

**Bits [63:18]**

Reserved, RES0.

**EVNTIS, bit [17]**

*When FEAT_ECV is implemented:*

Controls the scale of the generation of the event stream.

0b0 The CNTHCTL_EL2.EVNTI field applies to CNTPCT_EL0[15:0].

0b1 The CNTHCTL_EL2.EVNTI field applies to CNTPCT_EL0[23:8].

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

EL1NVVCT, bit [16]

When FEAT_ECV is implemented:
Traps EL1 accesses to the specified EL1 virtual timer registers using the EL02 descriptors to EL2, when EL2 is enabled for the current Security state.

0b0 This control does not cause any instructions to be trapped.
0b1 If ((HCR_EL2.E2H==1 && HCR_EL2.TGE==1) || HCR_EL2.NV2==0 || HCR_EL2.NV1==1 || HCR_EL2.NV==0), this control does not cause any instructions to be trapped.
   If ((HCR_EL2.E2H==0 || HCR_EL2.TGE==0) && HCR_EL2.NV2==1 && HCR_EL2.NV1==0 && HCR_EL2.NV==1), then EL1 accesses to CNTV_CTL_EL02 and CNTV_CVAL_EL02 are trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.
This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

EL1NVPCT, bit [15]

When FEAT_ECV is implemented:
Traps EL1 accesses to the specified EL1 physical timer registers using the EL02 descriptors to EL2, when EL2 is enabled for the current Security state.

0b0 This control does not cause any instructions to be trapped.
0b1 If ((HCR_EL2.E2H==1 && HCR_EL2.TGE==1) || HCR_EL2.NV2==0 || HCR_EL2.NV1==1 || HCR_EL2.NV==0), this control does not cause any instructions to be trapped.
   If (HCR_EL2.E2H==0 || HCR_EL2.TGE==0) && HCR_EL2.NV2==1 && HCR_EL2.NV1==0 && HCR_EL2.NV==1, then EL1 accesses to CNTP_CTL_EL02 and CNTP_CVAL_EL02 are trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.
This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

EL1TVCT, bit [14]

When FEAT_ECV is implemented:
Traps EL0 and EL1 accesses to the EL1 virtual counter registers to EL2, when EL2 is enabled for the current Security state.

0b0 This control does not cause any instructions to be trapped.
0b1 If HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.
   If HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, then:
   • In AArch64 state, traps EL0 and EL1 accesses to CNTVCT_EL0 to EL2, unless they are trapped by CNTKCTL_EL1.EL0VCTEN.
   • In AArch32 state, traps EL0 and EL1 accesses to CNTVCT to EL2, unless they are trapped by CNTKCTL_EL1.EL0VCTEN or CNTKCTL.PL0VCTEN.
If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**EL1TVT, bit [13]**

**When FEAT_ECV is implemented:**

Traps EL0 and EL1 accesses to the EL1 virtual timer registers to EL2, when EL2 is enabled for the current Security state.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>This control does not cause any instructions to be trapped.</td>
</tr>
<tr>
<td>0b1</td>
<td>If HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped. If HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, then:</td>
</tr>
</tbody>
</table>

- In AArch64 state, traps EL0 and EL1 accesses to CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0 to EL2, unless they are trapped by CNTKCTL_EL1.ELOVTEN.
- In AArch32 state, traps EL0 and EL1 accesses to CNTV_CTL, CNTV_CVAL, and CNTV_TVAL to EL2, unless they are trapped by CNTKCTL_EL1.ELOVTEN or CNTKCTL.PL0VTEN.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**ECV, bit [12]**

**When FEAT_ECV is implemented:**

Enables the Enhanced Counter Virtualization functionality registers.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Enhanced Counter Virtualization functionality is disabled.</td>
</tr>
<tr>
<td>0b1</td>
<td>When HCR_EL2.{E2H, TGE} == {1, 1} or SCR_EL3.{NS, EEL2} == {0, 0}, then Enhanced Counter Virtualization functionality is disabled. When SCR_EL3.NS or SCR_EL3.EEL2 are 1, and HCR_EL2.E2H or HCR_EL2.TGE are 0, then Enhanced Counter Virtualization functionality is enabled when EL2 is enabled for the current Security state. This means that:</td>
</tr>
</tbody>
</table>

- An MRS to CNTPCT_EL0 from either EL0 or EL1 that is not trapped will return the value (PCount<63:0> - CNTPOFF_EL2<63:0>).
- The EL1 physical timer interrupt is triggered when ((PCount<63:0> - CNTPOFF_EL2<63:0>) - PCVal<63:0>) is greater than or equal to 0. PCount<63:0> is the physical count returned when CNTPCT_EL0 is read from EL2 or EL3. PCVal<63:0> is the EL1 physical timer compare value for this timer.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.
EL1PTEN, bit [11]

When HCR_EL2.TGE is 0, traps EL0 and EL1 accesses to the E1 physical timer registers to EL2 when EL2 is enabled in the current Security state.

- **0b0**: From AArch64 state: EL0 and EL1 accesses to the CNTP_CTL_EL0, CNTP_CV AL_EL0, and CNTP_TV AL_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PTEN.
  
  From AArch32 state: EL0 and EL1 accesses to the CNTP_CTL, CNTP_CV AL, and CNTP_TV AL are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PTEN or CNTKCTL.PL0PTEN.

- **0b1**: This control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EL1PCTEN, bit [10]

When HCR_EL2.TGE is 0, traps EL0 and EL1 accesses to the EL1 physical counter register to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to CNTPCT_EL0 are trapped to EL2, reported using EC syndrome value 0x18.

- In AArch32 state, MRRC or MCRR accesses to CNTPCT are trapped to EL2, reported using EC syndrome value 0x04.

- **0b0**: From AArch64 state: EL0 and EL1 accesses to the CNTPCT_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PCTEN.

  From AArch32 state: EL0 and EL1 accesses to the CNTPCT are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PCTEN or CNTKCTL.PL0PCTEN.

- **0b1**: This control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EL0PTEN, bit [9]

When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, traps EL0 accesses to the physical timer registers to EL2.

- **0b0**: EL0 using AArch64: EL0 accesses to the CNTP_CTL_EL0, CNTP_CV AL_EL0, and CNTP_TV AL_EL0 registers are trapped to EL2.

- **0b1**: This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EL0VTEN, bit [8]

When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, traps EL0 accesses to the virtual timer registers to EL2.

- **0b0**: EL0 using AArch64: EL0 accesses to the CNTV_CTL_EL0, CNTV_CV AL_EL0, and CNTV_TV AL_EL0 registers are trapped to EL2.

- **0b1**: This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.
EVNTI, bits [7:4]
Selects which bit of the counter register CNTPCT_EL0 is the trigger for the event stream generated from that counter, when that stream is enabled.

If FEAT_ECV is implemented, and CNTHCTL_EL2.EVNTIS is 1, this field selects a trigger bit in the range 8 to 23 of the counter register CNTPCT_EL0.
Otherwise, this field selects a trigger bit in the range 0 to 15 of the counter register.
This field resets to an architecturally UNKNOWN value.

EVNTDIR, bit [3]
Controls which transition of the counter register CNTPCT_EL0 trigger bit, defined by EVNTI, generates an event when the event stream is enabled.

0b0  A 0 to 1 transition of the trigger bit triggers an event.
0b1  A 1 to 0 transition of the trigger bit triggers an event.
This field resets to an architecturally UNKNOWN value.

EVNTEN, bit [2]
Enables the generation of an event stream from the counter register CNTPCT_EL0.

0b0  Disables the event stream.
0b1  Enables the event stream.
This field resets to an architecturally UNKNOWN value.

EL0VCTEN, bit [1]
When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.
When HCR_EL2.TGE is 1, traps EL0 accesses to the frequency register and virtual counter register to EL2.

0b0  EL0 using AArch64: EL0 accesses to the CNTVCT_EL0 are trapped to EL2.
     EL0 using AArch64: EL0 accesses to the CNTFRQ_EL0 register are trapped to EL2, if CNTHCTL_EL2.EL0PCTEN is also 0.
     EL0 using AArch32: EL0 accesses to the CNTVCT are trapped to EL2.
     EL0 using AArch32: EL0 accesses to the CNTFRQ register are trapped to EL2, if CNTHCTL_EL2.EL0VCTEN is also 0.
0b1  This control does not cause any instructions to be trapped.
This field resets to an architecturally UNKNOWN value.

EL0PCTEN, bit [0]
When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.
When HCR_EL2.TGE is 1, traps EL0 accesses to the frequency register and physical counter register to EL2.

0b0  EL0 using AArch64: EL0 accesses to the CNTPCT_EL0 are trapped to EL2.
     EL0 using AArch64: EL0 accesses to the CNTFRQ_EL0 register are trapped to EL2, if CNTHCTL_EL2.EL0VCTEN is also 0.
     EL0 using AArch32: EL0 accesses to the CNTPCt are trapped to EL2.
     EL0 using AArch32: EL0 accesses to the CNTFRQ and register are trapped to EL2, if CNTHCTL_EL2.EL0VCTEN is also 0.
0b1  This control does not cause any instructions to be trapped.
This field resets to an architecturally UNKNOWN value.
Otherwise:

This format applies in all Armv8.0 implementations, and it also contains a description of the behavior when EL3 is implemented and EL2 is not implemented.

Bits [63:18]

Reserved, RES0.

EVNTIS, bit [17]

Controls the scale of the generation of the event stream.

0b0 The CNTHCTL_EL2.EVNTI field applies to CNTPCT_EL0[15:0].

0b1 The CNTHCTL_EL2.EVNTI field applies to CNTPCT_EL0[23:8].

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

This field resets to an architecturally UNKNOWN value.

EL1NVVCT, bit [16]

Traps EL1 accesses to the specified EL1 virtual timer registers using the EL02 descriptors to EL2, when EL2 is enabled for the current Security state.

0b0 This control does not cause any instructions to be trapped.

0b1 If ((HCR_EL2.E2H==1 & HCR_EL2.TGE==1) || HCR_EL2.NV2==0 || HCR_EL2.NV1==1 || HCR_EL2.NV==0), this control does not cause any instructions to be trapped.

If ((HCR_EL2.E2H==0 || HCR_EL2.TGE==0) && HCR_EL2.NV2==1 && HCR_EL2.NV1==0 && HCR_EL2.NV==1), then EL1 accesses to CNTV_CTL_EL02 and CNTV_CVAL_EL02 are trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

This field resets to an architecturally UNKNOWN value.

EL1NVPCT, bit [15]

Traps EL1 accesses to the specified EL1 physical timer registers using the EL02 descriptors to EL2, when EL2 is enabled for the current Security state.

0b0 This control does not cause any instructions to be trapped.

0b1 If ((HCR_EL2.E2H==1 & HCR_EL2.TGE==1) || HCR_EL2.NV2==0 || HCR_EL2.NV1==1 || HCR_EL2.NV==0), this control does not cause any instructions to be trapped.
If (HCR_EL2.E2H==0 || HCR_EL2.TGE==0) && HCR_EL2.NV2==1 &&
HCR_EL2.NV1==0 && HCR_EL2.NV==1, then EL1 accesses to CNTP_CTL_EL02
and CNTP_CVAL_EL02, are trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the
purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

This field resets to an architecturally UNKNOWN value.

**EL1TVCT, bit [14]**

Traps EL0 and EL1 accesses to the EL1 virtual counter registers to EL2, when EL2 is enabled for
the current Security state.

0b0  This control does not cause any instructions to be trapped.

0b1  If HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be
trapped.

If HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, then:

In AArch64 state, traps EL0 and EL1 accesses to CNTVCTL_EL0 to EL2, unless they
are trapped by CNTKCTL_EL1.EL0VTEN. In AArch32 state, traps EL0 and EL1
accesses to CNTVCT to EL2, unless they are trapped by CNTKCTL_EL1.EL0VTEN
or CNTKCTL.PL0VTEN.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the
purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

This field resets to an architecturally UNKNOWN value.

**EL1TVM, bit [13]**

Traps EL0 and EL1 accesses to the EL1 virtual timer registers to EL2, when EL2 is enabled for the
current Security state.

0b0  This control does not cause any instructions to be trapped.

0b1  If HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be
trapped.

If HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, then:

- In AArch64 state, traps EL0 and EL1 accesses to CNTV_CTL_EL0,
  CNTV_CVAL_EL0, and CNTV_TVAL_EL0 to EL2, unless they are trapped by
  CNTKCTL_EL1.EL0VTEN.

- In AArch32 state, traps EL0 and EL1 accesses to CNTV_CTL, CNTV_CVAL,
  and CNTV_TVAL to EL2, unless they are trapped by
  CNTKCTL_EL1.EL0VTEN or CNTKCTL.PL0VTEN.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the
purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

This field resets to an architecturally UNKNOWN value.

**ECV, bit [12]**

Enables the Enhanced Counter Virtualization functionality registers.

0b0  Enhanced Counter Virtualization functionality is disabled.

0b1  When HCR_EL2.{E2H, TGE} == {1, 1} or SCR_EL3.{NS, EEL2} == {0, 0}, then
Enhanced Counter Virtualization functionality is disabled.

When SCR_EL3.NS or SCR_EL3.EEL2 are 1, and HCR_EL2.E2H or HCR_EL2.TGE
are 0, then Enhanced Counter Virtualization functionality is enabled when EL2 is
enabled for the current Security state. This means that:

- An MRS to CNTPCT_EL0 from either EL0 or EL1 that is not trapped will return
  the value (PCount<63:0> - CNTPOFF_EL2<63:0> ).
The EL1 physical timer interrupt is triggered when 
\((\text{PCount}_{63:0} - \text{CNTPOFF}_{EL2}_{63:0} - \text{PCVal}_{63:0})\) is greater than or equal to 0. PCount is the physical count returned when \(\text{CNTPCT}_{EL0}\) is read from EL2 or EL3. PCVal\(_{63:0}\) is the EL1 physical timer compare value for this timer.

This field resets to an architecturally UNKNOWN value.

**Bits [11:8]**

Reserved, RES0.

**EVNTI, bits [7:4]**

Selects which bit of the counter register \(\text{CNTPCT}_{EL0}\) is the trigger for the event stream generated from that counter, when that stream is enabled.

If \(\text{FEAT}_E\text{CV}\) is implemented, and \(\text{CNTHCTL}_{EL2}.\text{EVNTIS}\) is 1, this field selects a trigger bit in the range 8 to 23 of the counter register \(\text{CNTPCT}_{EL0}\).
Otherwise, this field selects a trigger bit in the range 0 to 15 of the counter register.

This field resets to an architecturally UNKNOWN value.

**EVNTDIR, bit [3]**

Controls which transition of the counter register \(\text{CNTPCT}_{EL0}\) trigger bit, defined by EVNTI, generates an event when the event stream is enabled.

0b0 A 0 to 1 transition of the trigger bit triggers an event.
0b1 A 1 to 0 transition of the trigger bit triggers an event.

This field resets to an architecturally UNKNOWN value.

**EVNTEN, bit [2]**

Enables the generation of an event stream from the counter register \(\text{CNTPCT}_{EL0}\).

0b0 Disables the event stream.
0b1 Enables the event stream.

This field resets to 0.

**EL1PCEN, bit [1]**

Traps EL0 and EL1 accesses to the EL1 physical timer registers to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to \(\text{CNTP_CTL}_{EL0}\), \(\text{CNTP_CVAL}_{EL0}\), \(\text{CNTP_TVAL}_{EL0}\) are trapped to EL2, reported using EC syndrome value 0x18.
- In AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2 reported using EC syndrome value 0x3 and MRRC and MCRR accesses are trapped to EL2, reported using EC syndrome value 0x04:
  - \(\text{CNTP_CTL}\), \(\text{CNTP_CVAL}\), \(\text{CNTP_TVAL}\).

0b0 From AArch64 state: EL0 and EL1 accesses to the \(\text{CNTP_CTL}_{EL0}\), \(\text{CNTP_CVAL}_{EL0}\), \(\text{CNTP_TVAL}_{EL0}\) are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by \(\text{CNTKCTL}_{EL1}.\text{EL0PTEN}\).

From AArch32 state: EL0 and EL1 accesses to the \(\text{CNTP_CTL}\), \(\text{CNTP_CVAL}\), \(\text{CNTP_TVAL}\) are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by \(\text{CNTKCTL}_{EL1}.\text{EL0PTEN}\) or \(\text{CNTKCTL}.\text{PL0PTEN}\).
0b1 This control does not cause any instructions to be trapped.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to an architecturally UNKNOWN value.
EL1PCTEN, bit [0]

Traps EL0 and EL1 accesses to the EL1 physical counter register to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to CNTPCT_EL0 are trapped to EL2, reported using EC syndrome value 0x18.
- In AArch32 state, MRRC or MCRR accesses to CNTPCT are trapped to EL2, reported using EC syndrome value 0x04.

0b0 From AArch64 state: EL0 and EL1 accesses to the CNTPCT_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PCTEN.

From AArch32 state: EL0 and EL1 accesses to the CNTPCT are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PCTEN or CNTKCTL.PL0PCTEN.

0b1 This control does not cause any instructions to be trapped.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHCTL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHCTL_EL2 or CNTKCTL_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRS \langle Xt \rangle, \text{CNTHCTL}_\text{EL2} \]

<table>
<thead>
<tr>

```
D13.8.3  **CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register**

The CNTHP_CTL_EL2 characteristics are:

**Purpose**

Control register for the EL2 physical timer.

**Configurations**

AArch64 System register CNTHP_CTL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHP_CTL[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHP_CTL_EL2 is a 64-bit register.

**Field descriptions**

The CNTHP_CTL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>62</td>
<td>ISTATUS, bit [2]</td>
</tr>
<tr>
<td>61</td>
<td>IMASK, bit [1]</td>
</tr>
<tr>
<td>60</td>
<td>ENABLE, bit [0]</td>
</tr>
</tbody>
</table>

**Bits [63:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

- 0b0: Timer condition is not met.
- 0b1: Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN. This bit is read-only.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

- 0b0: Timer interrupt is not masked by the IMASK bit.
- 0b1: Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit. This field resets to an architecturally UNKNOWN value.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

- 0b0: Timer disabled.
- 0b1: Timer enabled.
Setting this bit to 0 disables the timer output signal, but the timer value accessible from 
\texttt{CNTHP\_TV\_AL\_EL2} continues to count down.

\textbf{Note}

Disabling the output signal might be a power-saving option.

This field resets to an architecturally \texttt{UNKNOWN} value.

\textbf{Accessing the \texttt{CNTHP\_CTL\_EL2}}

When \texttt{HCR\_EL2.E2H} is 1, without explicit synchronization, access from EL2 using the mnemonic \texttt{CNTHP\_CTL\_EL2} or \texttt{CNTP\_CTL\_EL0} are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

\texttt{MRS <Xt>, CNTHP\_CTL\_EL2}

\begin{align*}
\text{op0} & \quad \text{op1} & \quad \text{CRn} & \quad \text{CRm} & \quad \text{op2} \\

D13.8.4  **CNTHP_CVAL_EL2, Counter-timer Physical Timer CompareValue register (EL2)**

The CNTHP_CVAL_EL2 characteristics are:

**Purpose**

Holds the compare value for the EL2 physical timer.

**Configurations**

AArch64 System register CNTHP_CVAL_EL2[63:0] is architecturally mapped to AArch32 System register CNTHP_CVAL[63:0].

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHP_CVAL_EL2 is a 64-bit register.

**Field descriptions**

The CNTHP_CVAL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Width</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-0</td>
<td>CompareValue</td>
</tr>
</tbody>
</table>

**CompareValue, bits [63:0]**

Holds the EL2 physical timer CompareValue.

When CNTHP_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- **CNTHP_CTL_EL2.ISTATUS** is set to 1.
- If CNTHP_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHP_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally **UNKNOWN** value.

**Accessing the CNTHP_CVAL_EL2**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHP_CVAL_EL2 or CNTP_CVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

### D13.8.5 CNTHP_TVAL_EL2, Counter-timer Physical Timer TimerValue register (EL2)

The CNTHP_TVAL_EL2 characteristics are:

#### Purpose

Holds the timer value for the EL2 physical timer.

#### Configurations

AArch64 System register CNTHP_TVAL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHP_TVAL[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

#### Attributes

CNTHP_TVAL_EL2 is a 64-bit register.

#### Field descriptions

The CNTHP_TVAL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>31:0</td>
<td>TimerValue</td>
</tr>
</tbody>
</table>

#### TimerValue, bits [31:0]

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If CNTHP_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHP_CTL_EL2.ENABLE is 1, the value returned is (CNTHP_CVAL_EL2 - CNTPCT_EL0).

On a write of this register, CNTHP_CVAL_EL2 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHP_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTHP_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHP_CTL_EL2.ISTATUS is set to 1.
- If CNTHP_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHP_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

#### Accessing the CNTHP_TVAL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHP_TVAL_EL2 or CNTP_TVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, CNTHP_TVAL_EL2

D13.8.6  **CNGTHS_CTL_EL2, Counter-timer Secure Physical Timer Control register (EL2)**

The CNGTHS_CTL_EL2 characteristics are:

**Purpose**

Control register for the Secure EL2 physical timer.

**Configurations**

AArch64 System register CNGTHS_CTL_EL2[31:0] is architecturally mapped to AArch32 System register CNGTHS_CTL[31:0].

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to CNGTHS_CTL_EL2 are UNDEFINED.

**Attributes**

CNGTHS_CTL_EL2 is a 64-bit register.

**Field descriptions**

The CNGTHS_CTL_EL2 bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>3</td>
<td>ISTATUS</td>
</tr>
<tr>
<td>2</td>
<td>IMASK</td>
</tr>
<tr>
<td>1</td>
<td>ENABLE</td>
</tr>
</tbody>
</table>
```

**Bits [63:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

- **0b0**: Timer condition is not met.
- **0b1**: Timer condition is met.

When the value of the CNGTHS_CTL_EL2.ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the CNGTHS_CTL_EL2.ENABLE bit is 0, the ISTATUS field is UNKNOWN.

This bit is read-only.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

- **0b0**: Timer interrupt is not masked by the IMASK bit.
- **0b1**: Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

- **0b0**: Timer disabled.
- **0b1**: Timer enabled.
Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHPS_TVAL_EL2 continues to count down.

--- Note ---
Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTHPS_CTL_EL2**

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.7  CNTHPS_CVAL_EL2, Counter-timer Secure Physical Timer CompareValue register (EL2)

The CNTHPS_CVAL_EL2 characteristics are:

**Purpose**

Holds the compare value for the Secure EL2 physical timer.

**Configurations**

AArch64 System register CNTHPS_CVAL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHPS_CVAL[31:0].

This register is present only when EL2 is implemented and FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_CVAL_EL2 are UNDEFINED.

**Attributes**

CNTHPS_CVAL_EL2 is a 64-bit register.

**Field descriptions**

The CNTHPS_CVAL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CompareValue, bits [63:0]</td>
<td>Holds the EL2 physical timer CompareValue. When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met: • CNTHPS_CTL_EL2.ISTATUS is set to 1. • If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated. When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count. If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0. The value of this field is treated as zero-extended in all counter calculations. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the CNTHPS_CVAL_EL2**

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.8 CNTHPS_TVAL_EL2, Counter-timer Secure Physical Timer TimerValue register (EL2)

The CNTHPS_TVAL_EL2 characteristics are:

**Purpose**

Holds the timer value for the Secure EL2 physical timer.

**Configurations**

AArch64 System register CNTHPS_TVAL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHPS_TVAL[31:0].

This register is present only when EL2 is implemented and FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_TVAL_EL2 are UNDEFINED.

**Attributes**

CNTHPS_TVAL_EL2 is a 64-bit register.

**Field descriptions**

The CNTHPS_TVAL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>32-0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>TimerValue</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If CNTHPS_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHPS_CTL_EL2.ENABLE is 1, the value returned is (CNTHPS_CVAL_EL2 - CNTPCT_EL0).

On a write of this register, CNTHPS_CVAL_EL2 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTHPS_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

D13.8.9  CNTHV_CTL_EL2, Counter-timer Virtual Timer Control register (EL2)

The CNTHV_CTL_EL2 characteristics are:

**Purpose**

Control register for the EL2 virtual timer.

**Configurations**

AArch64 System register CNTHV_CTL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHV_CTL[31:0].

This register is present only when FEAT_VHE is implemented. Otherwise, direct accesses to CNTHV_CTL_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHV_CTL_EL2 is a 64-bit register.

**Field descriptions**

The CNTHV_CTL_EL2 bit assignments are:

![Diagram of CNTHV_CTL_EL2]

**Bits [63:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Timer condition is not met.</td>
</tr>
<tr>
<td>1</td>
<td>Timer condition is met.</td>
</tr>
</tbody>
</table>

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is **UNKNOWN**. This bit is read-only.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Timer interrupt is not masked by the IMASK bit.</td>
</tr>
<tr>
<td>1</td>
<td>Timer interrupt is masked by the IMASK bit.</td>
</tr>
</tbody>
</table>

For more information, see the description of the ISTATUS bit. This field resets to an architecturally **UNKNOWN** value.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Timer disabled.</td>
</tr>
</tbody>
</table>

0b1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHV_TV_AL_EL2 continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHV_CTL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHV_CTL_EL2 or CNTV_CTL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRS } <Xt>, \text{ CNTHV_CTL_EL2}
\]

\[
\begin{array}{cccccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
0b11 & 0b100 & 0b1110 & 0b0011 & 0b001
\end{array}
\]

D13.8.10  CNTHV_CVAL_EL2, Counter-timer Virtual Timer CompareValue register (EL2)

The CNTHV_CVAL_EL2 characteristics are:

**Purpose**

Holds the compare value for the EL2 virtual timer.

**Configurations**

AArch64 System register CNTHV_CVAL_EL2[63:0] is architecturally mapped to AArch32 System register CNTHV_CVAL[63:0].

This register is present only when FEAT_VHE is implemented. Otherwise, direct accesses to CNTHV_CVAL_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHV_CVAL_EL2 is a 64-bit register.

**Field descriptions**

The CNTHV_CVAL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 to 0</td>
<td>CompareValue</td>
</tr>
</tbody>
</table>

**CompareValue, bits [63:0]**

Holds the EL2 virtual timer CompareValue.

When CNTHV_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHV_CTL_EL2.ISTATUS is set to 1.
- If CNTHV_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHV_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTHV_CVAL_EL2**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHV_CVAL_EL2 or CNTV_CVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.11   CNTHV_TVAL_EL2, Counter-timer Virtual Timer TimerValue Register (EL2)

The CNTHV_TVAL_EL2 characteristics are:

**Purpose**

Holds the timer value for the EL2 virtual timer.

**Configurations**

AArch64 System register CNTHV_TVAL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHV_TVAL[31:0].

This register is present only when FEAT_VHE is implemented. Otherwise, direct accesses to CNTHV_TVAL_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHV_TVAL_EL2 is a 64-bit register.

**Field descriptions**

The CNTHV_TVAL_EL2 bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>62</th>
<th>61</th>
<th>32</th>
<th>31</th>
<th>30</th>
<th>...</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td>TimerValue</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:32]**

Reserved, RES0.

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 virtual timer.

On a read of this register:
- If CNTHV_CTL_EL2.ENABLE is 0, the value returned is **UNKNOWN**.
- If CNTHV_CTL_EL2.ENABLE is 1, the value returned is (CNTHV_CVAL_EL2 - CNTVCT_EL0).

On a write of this register, CNTHV_CVAL_EL2 is set to (CNTVCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHV_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CNTHV_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:
- CNTHV_CTL_EL2.ISTATUS is set to 1.
- If CNTHV_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHV_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally **UNKNOWN** value.

**Accessing the CNTHV_TVAL_EL2**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHV_TVAL_EL2 or CNTV_TVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13-3927
D13.8.12  **CNTHVS_CTL_EL2, Counter-timer Secure Virtual Timer Control register (EL2)**

The CNTHVS_CTL_EL2 characteristics are:

**Purpose**

Control register for the Secure EL2 virtual timer.

**Configurations**

AArch64 System register CNTHVS_CTL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHVS_CTL[31:0].

This register is present only when EL2 is implemented and FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHVS_CTL_EL2 are UNDEFINED.

**Attributes**

CNTHVS_CTL_EL2 is a 64-bit register.

**Field descriptions**

The CNTHVS_CTL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>3</td>
<td>ISTATUS, bit [2]</td>
</tr>
<tr>
<td>2</td>
<td>IMASK, bit [1]</td>
</tr>
<tr>
<td>0</td>
<td>ENABLE, bit [0]</td>
</tr>
</tbody>
</table>

**Bits [63:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

- 0b0 Timer condition is not met.
- 0b1 Timer condition is met.

When the value of the CNTHVS_CTL_EL2.ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

This bit is read-only.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

- 0b0 Timer interrupt is not masked by the IMASK bit.
- 0b1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the CNTHVS_CTL_EL2.ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

- 0b0 Timer disabled.
- 0b1 Timer enabled.
Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHVS_TVAL_EL2 continues to count down.

**Note**

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

D13.8.13   CNTHVS_CVAL_EL2, Counter-timer Secure Virtual Timer CompareValue register (EL2)

The CNTHVS_CVAL_EL2 characteristics are:

**Purpose**

Holds the compare value for the Secure EL2 virtual timer.

**Configurations**

AArch64 System register CNTHVS_CVAL_EL2[63:0] is architecturally mapped to AArch32 System register CNTHVS_CVAL[63:0].

This register is present only when EL2 is implemented and FEB SEL2 is implemented. Otherwise, direct accesses to CNTHVS_CVAL_EL2 are UNDEFINED.

**Attributes**

CNTHVS_CVAL_EL2 is a 64-bit register.

**Field descriptions**

The CNTHVS_CVAL_EL2 bit assignments are:

```
63 62 61 60 59 58 57 56 55 54 53 52 51 50 49 48 47 46 45 44 43 42 41 40 39 38 37 36 35 34 33 32 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
   64-bit CompareValue
```

**CompareValue, bits [63:0]**

Holds the Secure EL2 virtual timer CompareValue.

When CNTHVS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHVS_CTL_EL2.ISTATUS is set to 1.
- If CNTHVS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHVS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTHVS_CVAL_EL2**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, CNTHVS_CVAL_EL2**

D13.8.14  CNTHVS_TVAL_EL2, Counter-timer Secure Virtual Timer TimerValue register (EL2)

The CNTHVS_TVAL_EL2 characteristics are:

Purpose
Holds the timer value for the Secure EL2 virtual timer.

Configurations
AArch64 System register CNTHVS_TVAL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHVS_TVAL[31:0].
This register is present only when EL2 is implemented and FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHVS_TVAL_EL2 are UNDEFINED.

Attributes
CNTHVS_TVAL_EL2 is a 64-bit register.

Field descriptions
The CNTHVS_TVAL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-32</td>
<td>RES0</td>
</tr>
<tr>
<td>31-0</td>
<td>TimerValue</td>
</tr>
</tbody>
</table>

Bits [63:32]
Reserved, RES0.

TimerValue, bits [31:0]
The TimerValue view of the EL2 virtual timer.
On a read of this register:
- If CNTHVS_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHVS_CTL_EL2.ENABLE is 1, the value returned is (CNTHVS_CVAL_EL2 - CNTVCT_EL0).

On a write of this register, CNTHVS_CVAL_EL2 is set to (CNTVCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.
When CNTHVS_CTL_EL2.ENABLE is 1, the timer condition is met when ((CNTVCT_EL0 - CNTHVS_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:
- CNTHVS_CTL_EL2.ISTATUS is set to 1.
- If CNTHVS_CTL_EL2.IMASK is 0, an interrupt is generated.
When CNTHVS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count, so the TimerValue view appears to continue to count down.
This field resets to an architecturally UNKNOWN value.

Accessing the CNTHVS_TVAL_EL2
Accesses to this register use the following encodings in the System instruction encoding space:
### MRS <Xt>, CNTHVS_TVAL_EL2

D13.8.15 CNTKCTL_EL1, Counter-timer Kernel Control register

The CNTKCTL_EL1 characteristics are:

**Purpose**

When FEAT_VHE is not implemented, or when HCR_EL2.{E2H, TGE} is not \{1, 1\}, this register controls the generation of an event stream from the virtual counter, and access from EL0 to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

When FEAT_VHE is implemented and HCR_EL2.{E2H, TGE} is \{1, 1\}, this register does not cause any event stream from the virtual counter to be generated, and does not control access to the counters and timers. The access to counters and timers at EL0 is controlled by CNTHCTL_EL2.

**Configurations**

AArch64 System register CNTKCTL_EL1[31:0] is architecturally mapped to AArch32 System register CNTKCTL[31:0].

**Attributes**

CNTKCTL_EL1 is a 64-bit register.

**Field descriptions**

The CNTKCTL_EL1 bit assignments are:

| Bits [63:18] | Reserved, RES0. |
| Bits [16:10] | Reserved, RES0. |
| EVNTIS, bit [17] | When FEAT_ECV is implemented: |
| | Controls the scale of the generation of the event stream. |
| | 0b0 The CNTKCTL_EL1.EVNTI field applies to CNTVCT_EL0[15:0]. |
| | 0b1 The CNTKCTL_EL1.EVNTI field applies to CNTVCT_EL0[23:8]. |
| | This control applies regardless of the value of the CNTHCTL_EL2.ECV bit. |
| | This field resets to an architecturally UNKNOWN value. |
| bits [16:10] | Reserved, RES0. |
**EL0PTEN, bit [9]**
Traps EL0 accesses to the physical timer registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, the following registers are trapped, reported using EC syndrome value 0x18:
  - CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0.
- In AArch32 state, MRC and MCR accesses to the following registers are trapped, reported using EC syndrome value 0x03, MRRC and MCRR accesses are trapped, reported using EC syndrome value 0x04:
  - CNTP_CTL, CNTP_CVAL, CNTP_TVAL.

<table>
<thead>
<tr>
<th>Bit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>EL0 accesses to the physical timer registers are trapped to EL1.</td>
</tr>
<tr>
<td>0b1</td>
<td>This control does not cause any instructions to be trapped.</td>
</tr>
</tbody>
</table>

When FEAT_VHE is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

This field resets to an architecturally **UNKNOWN** value.

**EL0VTEN, bit [8]**
Traps EL0 accesses to the virtual timer registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped, reported using EC syndrome value 0x18:
  - CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0.
- In AArch32 state, MRC and MCR accesses to the following registers are trapped and reported using EC syndrome value 0x03, MRRC and MCRR accesses are trapped using EC syndrome value 0x04:
  - CNTV_CTL, CNTV_CVAL, and CNTV_TVAL.

<table>
<thead>
<tr>
<th>Bit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>EL0 accesses to the virtual timer registers are trapped.</td>
</tr>
<tr>
<td>0b1</td>
<td>This control does not cause any instructions to be trapped.</td>
</tr>
</tbody>
</table>

When FEAT_VHE is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

This field resets to an architecturally **UNKNOWN** value.

**EVNTI, bits [7:4]**
Selects which bit of the counter register CNTVCT_EL0 is the trigger for the event stream generated from that counter, when that stream is enabled.

If FEAT_ECV is implemented, and CNTKCTL_EL1.EVNTIS is 1, this field selects a trigger bit in the range 8 to 23 of the counter register CNTVCT_EL0.

Otherwise, this field selects a trigger bit in the range 0 to 15 of the counter register.

This field resets to an architecturally **UNKNOWN** value.

**EVNTDIR, bit [3]**
Controls which transition of the counter register CNTVCT_EL0 trigger bit, defined by EVNTI, generates an event when the event stream is enabled.

<table>
<thead>
<tr>
<th>Bit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>A 0 to 1 transition of the trigger bit triggers an event.</td>
</tr>
<tr>
<td>0b1</td>
<td>A 1 to 0 transition of the trigger bit triggers an event.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally **UNKNOWN** value.
EVNTEN, bit [2]

When FEAT_VHE is not implemented, or when HCR_EL2.{E2H, TGE} is not \{1, 1\}, enables the
generation of an event stream from the counter register CNTVCT_EL0.

- **0b0**: Disables the event stream.
- **0b1**: Enables the event stream.

When FEAT_VHE is implemented and HCR_EL2.{E2H, TGE} is \{1, 1\}, this control does not
enable the event stream.

This field resets to **0**.

EL0VCTEN, bit [1]

Traps EL0 accesses to the frequency register and virtual counter register to EL1, or to EL2 when it
is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped and reported using EC
  syndrome value **0x18**:
  - CNTVCT_EL0 and if CNTKCTL_EL1.EL0PCTEN is 0, CNTFRQ_EL0.

- In AArch32 state, MRC and MCR accesses to the following registers are trapped and
  reported using EC syndrome value **0x03**, MRRC and MCRR accesses are trapped and
  reported using EC syndrome value **0x04**:
  - CNTVT and if CNTKCTL_EL1.EL0PCTEN is 0, CNTFRQ.

- **0b0**: EL0 accesses to the frequency register and virtual counter registers are trapped.
- **0b1**: This control does not cause any instructions to be trapped.

When FEAT_VHE is implemented and HCR_EL2.{E2H, TGE} is \{1, 1\}, this control does not
cause any instructions to be trapped.

This field resets to an architecturally **UNKNOWN** value.

EL0PCTEN, bit [0]

Traps EL0 accesses to the frequency register and physical counter register to EL1, or to EL2 when it
is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, the following registers are trapped, reported using EC syndrome value
  **0x18**:
  - CNTPTC_EL0 and if CNTKCTL_EL1.EL0PCTEN is 0, CNTFRQ_EL0.

- In AArch32 state, MCR or MRC accesses the following registers are trapped, reported using
  EC syndrome value **0x03**, MCRR or MRRC accesses are trapped and reported using EC
  syndrome value **0x04**:
  - CNTPTC and if CNTKCTL_EL1.EL0PCTEN is 0, CNTFRQ.

- **0b0**: EL0 accesses to the frequency register and physical counter register are trapped.
- **0b1**: This control does not cause any instructions to be trapped.

When FEAT_VHE is implemented and HCR_EL2.{E2H, TGE} is \{1, 1\}, this control does not
cause any instructions to be trapped.

This field resets to an architecturally **UNKNOWN** value.

**Accessing the CNTKCTL_EL1**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic
CNTKCTL_EL1 or CNTKCTL_EL12 are not guaranteed to be ordered with respect to accesses using the other
mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

**D13.8.16 CNTP_CTL_EL0, Counter-timer Physical Timer Control register**

The CNTP_CTL_EL0 characteristics are:

**Purpose**
Control register for the EL1 physical timer.

**Configurations**
AArch64 System register CNTP_CTL_EL0[31:0] is architecturally mapped to AArch32 System register CNTP_CTL[31:0].

**Attributes**
CNTP_CTL_EL0 is a 64-bit register.

**Field descriptions**
The CNTP_CTL_EL0 bit assignments are:

```
+-------------------+-------------------+
| Bits [63:3]       | 63  3  2  1  0    |
| Reserved, RES0    |                3 2 1 0 0 |
| ISTATUS, bit [2]  | ENABLE          |
| IMASK, bit [1]    | IMASK           |
| ENABLE, bit [0]   | ISTATUS         |
```

**Bits [63:3]**
Reserved, RES0.

**ISTATUS, bit [2]**
The status of the timer. This bit indicates whether the timer condition is met:
- 0b0  Timer condition is not met.
- 0b1  Timer condition is met.
When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.
When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.
This bit is read-only.

**IMASK, bit [1]**
Timer interrupt mask bit. Permitted values are:
- 0b0  Timer interrupt is not masked by the IMASK bit.
- 0b1  Timer interrupt is masked by the IMASK bit.
For more information, see the description of the ISTATUS bit.
This field resets to an architecturally UNKNOWN value.

**ENABLE, bit [0]**
Enables the timer. Permitted values are:
- 0b0  Timer disabled.
- 0b1  Timer enabled.
Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TVAL_EL0 continues to count down.
Note
Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTP_CTL_EL0

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTP_CTL_EL0 or CNTP_CTL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRS} \langle \text{Xt} \rangle, \text{CNTP_CTL_EL0} \]

D13.8.17  **CNTP_CVAL_EL0, Counter-timer Physical Timer CompareValue register**

The CNTP_CVAL_EL0 characteristics are:

**Purpose**

Holds the compare value for the EL1 physical timer.

**Configurations**

AArch64 System register CNTP_CVAL_EL0[63:0] is architecturally mapped to AArch32 System register CNTP_CVAL[63:0].

**Attributes**

CNTP_CVAL_EL0 is a 64-bit register.

**Field descriptions**

The CNTP_CVAL_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:0</td>
<td>CompareValue</td>
</tr>
</tbody>
</table>

- **CompareValue**
  - Holds the EL1 physical timer CompareValue.
  - When CNTP_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:
    - CNTP_CTL_EL0.ISTATUS is set to 1.
    - If CNTP_CTL_EL0.IMASK is 0, an interrupt is generated.
  - When CNTP_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.
  - If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.
  - The value of this field is treated as zero-extended in all counter calculations.
  - This field resets to an architecturally UNKNOWN value.

**Accessing the CNTP_CVAL_EL0**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTP_CVAL_EL0 or CNTP_CVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, CNTP_CVAL_EL0**

D13.8.18  **CNTP_TVAL_EL0, Counter-timer Physical Timer TimerValue register**

The CNTP_TVAL_EL0 characteristics are:

**Purpose**

Holds the timer value for the EL1 physical timer.

**Configurations**

AArch64 System register CNTP_TVAL_EL0[31:0] is architecturally mapped to AArch32 System register CNTP_TVAL[31:0].

**Attributes**

CNTP_TVAL_EL0 is a 64-bit register.

**Field descriptions**

The CNTP_TVAL_EL0 bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td>TimerValue</td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:32]**

Reserved, RES0.

**TimerValue, bits [31:0]**

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If CNTP_CTL_EL0.ENABLE is 0, the value returned is **UNKNOWN**.
- If CNTP_CTL_EL0.ENABLE is 1, the value returned is (CNTP_CVAL_EL0 - CNTPCT_EL0).

On a write of this register, CNTP_CVAL_EL0 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTP_CVAL_EL0) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTP_CTL_EL0.ISTATUS is set to 1.
- If CNTP_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTP_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTPC_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally **UNKNOWN** value.

**Accessing the CNTP_TVAL_EL0**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTP_TVAL_EL0 or CNTP_TVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, CNTP_TVAL_EL0

D13.8.19  CNTPCTSS_EL0, Counter-timer Self-Synchronized Physical Count register

The CNTPCTSS_EL0 characteristics are:

**Purpose**

Holds the self-synchronized view of the 64-bit physical count value.

**Configurations**

AArch64 System register CNTPCTSS_EL0[63:0] is architecturally mapped to AArch32 System register CNTPCTSS[63:0].

This register is present only when FEAT_ECV is implemented. Otherwise, direct accesses to CNTPCTSS_EL0 are **UNDEFINED**.

All reads to the CNTPCTSS_EL0 occur in program order relative to reads to CNTPCT_EL0 or CNTPCTSS_EL0.

This register is a self-synchronised view of the CNTPCT_EL0 counter, and cannot be read speculatively.

**Attributes**

CNTPCTSS_EL0 is a 64-bit register.

**Field descriptions**

The CNTPCTSS_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

D13.8.20 CNTPCT_EL0, Counter-timer Physical Count register

The CNTPCT_EL0 characteristics are:

**Purpose**

Holds the 64-bit physical count value.

**Configurations**

AArch64 System register CNTPCT_EL0[63:0] is architecturally mapped to AArch32 System register CNTPCT[63:0].

All reads to the CNTPCT_EL0 occur in program order relative to reads to CNTPCTSS_EL0 or CNTPCT_EL0.

**Attributes**

CNTPCT_EL0 is a 64-bit register.

**Field descriptions**

The CNTPCT_EL0 bit assignments are:

```
63 62 61 60 59 58 57 56 55 54 53 52 51 50 49 48 47 46 45 44 43 42 41 40 39 38 37 36 35 34 33 32 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
Physical count value
```

**Bits [63:0]**

Physical count value.

Reads of CNTPCT_EL0 from EL0 or EL1 return (PCount<63:0> - CNTPOFF_EL2<63:0>) if the access is not trapped, and all of the following are true:

- CNTHCTL_EL2.ECV is 1.
- HCR_EL2.{E2H, TGE} is not {1, 1}.

Where PCount<63:0> is the physical count returned when CNTPCT_EL0 is read from EL2 or EL3.

**Accessing the CNTPCT_EL0**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xi>, CNTPCT_EL0**

### D13.8.21 CNTPS_CTL_EL1, Counter-timer Physical Secure Timer Control register

The CNTPS_CTL_EL1 characteristics are:

**Purpose**

Control register for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

**Configurations**

There are no configuration notes.

**Attributes**

CNTPS_CTL_EL1 is a 64-bit register.

**Field descriptions**

The CNTPS_CTL_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>RES0</td>
</tr>
<tr>
<td>3</td>
<td>ISTATUS, bit [2]</td>
</tr>
<tr>
<td>2</td>
<td>IMASK, bit [1]</td>
</tr>
<tr>
<td>1</td>
<td>ENABLE, bit [0]</td>
</tr>
</tbody>
</table>

**Bits [63:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

- 0b0 Timer condition is not met.
- 0b1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is unknown.

This bit is read-only.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

- 0b0 Timer interrupt is not masked by the IMASK bit.
- 0b1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally unknown value.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

- 0b0 Timer disabled.
- 0b1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTPS_TVAL_EL1 continues to count down.
Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTPS_CTL_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, CNTPS_CTL_EL1**

<table>
<thead>

        CNTPS_CTL_EL1 = X[t];
```
D13.8.22  CNTPOFF_EL2, Counter-timer Physical Offset register

The CNTPOFF_EL2 characteristics are:

**Purpose**

Holds the 64-bit physical offset. This is the offset for the AArch64 physical timers and counters when Enhanced Counter Virtualization is enabled.

**Configurations**

This register is present only when FEAT_ECV is implemented. Otherwise, direct accesses to CNTPOFF_EL2 are UNDEFINED.

The offsetting of the timers and counters based on EL2 using AArch64 apply at:

- EL1 when EL1 is using AArch64 or AArch32.
- EL0 when EL0 is using AArch64 or AArch32.

When EL2 is implemented and enabled in the current Security state, the physical counter uses a fixed physical offset of zero if either of the following are true:

- CNTHCTL_EL2.ECV is 0.
- SCR_EL3.ECVEn is 0.
- HCR_EL2.{E2H, TGE} is {1, 1}.

**Attributes**

CNTPOFF_EL2 is a 64-bit register.

**Field descriptions**

The CNTPOFF_EL2 bit assignments are:

![Physical offset diagram]

Bits [63:0]

Physical offset.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTPOFF_EL2**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, CNTPOFF_EL2**

<table>
<thead>
<tr>

    CNTPOFF_EL2 = X[t];
D13.8.23  CNTPS_CVAL_EL1, Counter-timer Physical Secure Timer CompareValue register

The CNTPS_CVAL_EL1 characteristics are:

**Purpose**

Holds the compare value for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

**Configurations**

There are no configuration notes.

**Attributes**

CNTPS_CVAL_EL1 is a 64-bit register.

**Field descriptions**

The CNTPS_CVAL_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CompareValue</td>
<td></td>
</tr>
</tbody>
</table>

**CompareValue, bits [63:0]**

Holds the secure physical timer CompareValue.

When CNTPS_CTL_EL1.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTPS_CTL_EL1.ISTATUS is set to 1.
- If CNTPS_CTL_EL1.IMASK is 0, an interrupt is generated.

When CNTPS_CTL_EL1.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTPS_CVAL_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, CNTPS_CVAL_EL1**

<table>
<thead>
<tr>

D13.8.24  **CNTPS_TVAL_EL1, Counter-timer Physical Secure Timer TimerValue register**

The CNTPS_TVAL_EL1 characteristics are:

**Purpose**

Holds the timer value for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

**Configurations**

There are no configuration notes.

**Attributes**

CNTPS_TVAL_EL1 is a 64-bit register.

**Field descriptions**

The CNTPS_TVAL_EL1 bit assignments are:

```
   Bits [63:32]  32 31 0  
   RES0  TimerValue
```

**Bits [63:32]**

Reserved, RES0.

**TimerValue, bits [31:0]**

The TimerValue view of the secure physical timer.

On a read of this register:

- If CNTPS_CTL_EL1.ENABLE is 0, the value returned is UNKNOWN.
- If CNTPS_CTL_EL1.ENABLE is 1, the value returned is (CNTPS_CVAL_EL1 - CNTPCT_EL0).

On a write of this register, CNTPS_CVAL_EL1 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTPS_CTL_EL1.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTPS_CVAL_EL1) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTPS_CTL_EL1.ISTATUS is set to 1.
- If CNTPS_CTL_EL1.IMASK is 0, an interrupt is generated.

When CNTPS_CTL_EL1.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTPS_TVAL_EL1**

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, CNTPS_TVAL_EL1

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then

D13.8.25 CNTV_CTL_EL0, Counter-timer Virtual Timer Control register

The CNTV_CTL_EL0 characteristics are:

**Purpose**
Control register for the virtual timer.

**Configurations**
AArch64 System register CNTV_CTL_EL0[31:0] is architecturally mapped to AArch32 System register CNTV_CTL[31:0].

**Attributes**
CNTV_CTL_EL0 is a 64-bit register.

**Field descriptions**
The CNTV_CTL_EL0 bit assignments are:

![Bit assignments diagram]

**Bits [63:3]**
Reserved, RES0.

**ISTATUS, bit [2]**
The status of the timer. This bit indicates whether the timer condition is met:

- 0b0  Timer condition is not met.
- 0b1  Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is **UNKNOWN**.

This bit is read-only.

**IMASK, bit [1]**
Timer interrupt mask bit. Permitted values are:

- 0b0  Timer interrupt is not masked by the IMASK bit.
- 0b1  Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally **UNKNOWN** value.

**ENABLE, bit [0]**
Enables the timer. Permitted values are:

- 0b0  Timer disabled.
- 0b1  Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TVAL_EL0 continues to count down.
--- Note ---

Disabling the output signal might be a power-saving option.

---

This field resets to an architecturally UNKNOWN value.

### Accessing the CNTV_CTL_EL0

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTV_CTL_EL0 or CNTV_CTL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRS } \langle Xt \rangle, \text{ CNTV_CTL_EL0}
\]

D13.8.26  CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL_EL0 characteristics are:

**Purpose**

Holds the compare value for the virtual timer.

**Configurations**

AArch64 System register CNTV_CVAL_EL0[63:0] is architecturally mapped to AArch32 System register CNTV_CVAL[63:0].

**Attributes**

CNTV_CVAL_EL0 is a 64-bit register.

**Field descriptions**

The CNTV_CVAL_EL0 bit assignments are:

```
63 0

CompareValue
```

**CompareValue, bits [63:0]**

Holds the EL1 virtual timer CompareValue.

When CNTV_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTV_CTL_EL0.ISTATUS is set to 1.
- If CNTV_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTV_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTV_CVAL_EL0**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTV_CVAL_EL0 or CNTV_CVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRS <Xt>, CNTV_CVAL_EL0
```

```

D13.8.27 CNTV_TVAL_EL0, Counter-timer Virtual Timer TimerValue register

The CNTV_TVAL_EL0 characteristics are:

**Purpose**

Holds the timer value for the EL1 virtual timer.

**Configurations**

AArch64 System register CNTV_TVAL_EL0[31:0] is architecturally mapped to AArch32 System register CNTV_TVAL[31:0].

**Attributes**

CNTV_TVAL_EL0 is a 64-bit register.

**Field descriptions**

The CNTV_TVAL_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-32</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>31-0</td>
<td>TimerValue, bits [31:0]</td>
</tr>
</tbody>
</table>

**TimerValue, bits [31:0]**

The TimerValue view of the EL1 virtual timer.

On a read of this register:

- If CNTV_CTL_EL0.ENABLE is 0, the value returned is UNKNOWN.
- If CNTV_CTL_EL0.ENABLE is 1, the value returned is (CNTV_CVAL_EL0 - CNTVCT_EL0).

On a write of this register, CNTV_CVAL_EL0 is set to (CNTVCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTV_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CNTV_CVAL_EL0) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTV_CTL_EL0.ISTATUS is set to 1.
- If CNTV_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTV_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count, so the TimerValue view appears to continue to count down. This field resets to an architecturally UNKNOWN value.

**Accessing the CNTV_TVAL_EL0**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTV_TVAL_EL0 or CNTV_TVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.28 CNTVCTSS_EL0, Counter-timer Self-Synchronized Virtual Count register

The CNTVCTSS_EL0 characteristics are:

**Purpose**
Holds the 64-bit virtual count value. The virtual count value is equal to the physical count value visible in CNTPCT_EL0 minus the virtual offset visible in CNTVOFF_EL2.

**Configurations**
AArch64 System register CNTVCTSS_EL0[63:0] is architecturally mapped to AArch32 System register CNTVCTSS[63:0].

This register is present only when FEAT_ECV is implemented. Otherwise, direct accesses to CNTVCTSS_EL0 are **UNDEFINED**.

All reads to the CNTVCTSS_EL0 occur in program order relative to reads to CNTVCT_EL0 or CNTVCTSS_EL0.

This register is a self-synchronised view of the CNTVCT_EL0 counter, and cannot be read speculatively.

**Attributes**
CNTVCTSS_EL0 is a 64-bit register.

**Field descriptions**
The CNTVCTSS_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-0</td>
<td>Self-synchronized virtual count value</td>
</tr>
</tbody>
</table>

**Accessing the CNTVCTSS_EL0**
Accesses to this register use the following encodings in the System instruction encoding space:

  return CNTVCTSS_EL0;
elsif PSTATE_EL == EL3 then
  return CNTVCTSS_EL0;
D13.8.29 CNTVCT_EL0, Counter-timer Virtual Count register

The CNTVCT_EL0 characteristics are:

**Purpose**

Holds the 64-bit virtual count value. The virtual count value is equal to the physical count value minus the virtual offset visible in CNTVOFF_EL2.

**Configurations**

AArch64 System register CNTVCT_EL0[63:0] is architecturally mapped to AArch32 System register CNTVCT[63:0].

The value of this register is the same as the value of CNTPCT_EL0 in the following conditions:

- When EL2 is not implemented.
- When EL2 is implemented, HCR_EL2.E2H is 1, and this register is read from EL2.
- When EL2 is implemented and enabled in the current Security state, HCR_EL2.{E2H, TGE} is {1, 1}, and this register is read from EL0 or EL2.

All reads to the CNTVCT_EL0 occur in program order relative to reads to CNTVCTSS_EL0 or CNTVCT_EL0.

**Attributes**

CNTVCT_EL0 is a 64-bit register.

**Field descriptions**

The CNTVCT_EL0 bit assignments are:

- Bits [63:0] Virtual count value.

**Accessing the CNTVCT_EL0**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MRS \langle \text{Xi} \rangle, \text{CNTVCT_EL0}
\]

```plaintext
if PSTATE.EL == EL0 then
  if !(EL2Enabled() && HCR_EL2.<E2H,TGE> == '11') && CNTKCTL_EL1.EL0VCTEN == '0' then
    if EL2Enabled() && HCR_EL2.TGE == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    else
      AArch64.SystemAccessTrap(EL1, 0x18);
    elsif EL2Enabled() && HCR_EL2.<E2H,TGE> == '11' && CNTHCTL_EL2.EL0VCTEN == '0' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    else
      AArch64.SystemAccessTrap(EL2, 0x18);
  else
    return CNTVCT_EL0;
```
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && CNTHCTL_EL2.EL1TVCT == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        return CNTVCT_EL0;
    endif
elsif PSTATE.EL == EL2 then
    return CNTVCT_EL0;
elsif PSTATE.EL == EL3 then
    return CNTVCT_EL0;
D13.8.30  CNTVOFF_EL2, Counter-timer Virtual Offset register

The CNTVOFF_EL2 characteristics are:

**Purpose**

Holds the 64-bit virtual offset. This is the offset between the physical count value visible in CNTPCT_EL0 and the virtual count value visible in CNTVCT_EL0.

**Configurations**

AArch64 System register CNTVOFF_EL2[63:0] is architecturally mapped to AArch32 System register CNTVOFF[63:0].

If EL2 is not implemented, this register is RES0 from EL3 and the virtual counter uses a fixed virtual offset of zero.

--- Note ---

When EL2 is implemented and enabled in the current Security state, and is using AArch64, the virtual counter uses a fixed virtual offset of zero in the following situations:

- HCR_EL2.E2H is 1, and CNTVCT_EL0 is read from EL2.
- HCR_EL2.{E2H, TGE} is {1, 1}, and either:
  - CNTVCT_EL0 is read from EL0 or EL2.
  - CNTVCT is read from EL0.

**Attributes**

CNTVOFF_EL2 is a 64-bit register.

**Field descriptions**

The CNTVOFF_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Virtual offset

Bits [63:0]

Virtual offset.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTVOFF_EL2**

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, CNTVOFF_EL2

Part E

The AArch32 Application Level Architecture
Chapter E1
The AArch32 Application Level Programmers’ Model

This chapter gives an Application level description of the programmers’ model for software executing in AArch32 state. This means it describes execution in EL0 when EL0 is using AArch32. It contains the following sections:

• About the Application level programmers’ model on page E1-3988.
• The Application level programmers’ model in AArch32 state on page E1-3989.
• Advanced SIMD and floating-point instructions on page E1-4000.
• About the AArch32 System register interface on page E1-4011.
• Exceptions on page E1-4012.
E1.1  About the Application level programmers’ model

This chapter contains the programmers’ model information required for the development of applications that will execute in AArch32 state.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of that system information is needed to put the Application level programmers' model into context.

Depending on the implementation, the architecture supports multiple levels of execution privilege. These privilege levels are indicated by different Exception levels that number upwards from EL0, where EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers’ model is the programmers’ model for software executing at EL0. For more information see Armv8 architectural concepts on page A1-37.

System software determines the Exception level, and therefore the level of privilege, at which application software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged. This has the following effects:

- It means that the operating system can allocate system resources to an application in a unique or shared manner.
- It provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some System level understanding is helpful, and if appropriate it gives a reference to the System level description.

Application level software is generally unaware of its Security state, and of any virtualization. For more information, see The Armv8-A security model on page G1-5719 and The effect of implementing EL2 on the Exception model on page G1-5724.

______ Note ________

- When an implementation includes EL3, application and operating system software normally executes in Non-secure state.
- Older documentation, describing implementations or architecture versions that support only two privilege levels, often refers to execution at EL1 as privileged execution.
- In this manual, the terms CONSTRAINED UNPREDICTABLE, IMPLEMENTATION DEFINED, OPTIONAL, RES0, RES1, UNDEFINED, UNKNOWN, and UNPREDICTABLE have Arm-specific meanings, as defined in the Glossary. In body text, these terms are shown in SMALL CAPS, for example IMPLEMENTATION DEFINED.
E1.2 The Application level programmers' model in AArch32 state

The following sections give more information about the Application level programmers’ model in AArch32 state:

- Instruction sets, arithmetic operations, and register files.
- Core data types and arithmetic in AArch32 state.
- The general-purpose registers, and the PC, in AArch32 state on page E1-3991.
- Process state, PSTATE on page E1-3993.
- Jazelle support on page E1-3999.

E1.2.1 Instruction sets, arithmetic operations, and register files

The A32 and T32 instruction sets both provide a wide range of integer arithmetic and logical operations, that operate on a register file of sixteen 32-bit registers, that are comprised of the AArch32 general-purpose registers and the PC. As described in The general-purpose registers, and the PC, in AArch32 state on page E1-3991, these registers include the registers SP (R13) and LR (R14), which have specialized uses. Core data types and arithmetic in AArch32 state gives more information about these operations.

In addition, an implementation that implements the T32 and A32 instruction sets includes both:
- Scalar floating-point instructions.
- The Advanced SIMD vector instructions.

Floating-point and vector instructions operate on a separate common register file, described in The SIMD and floating-point register file on page E1-4000. Advanced SIMD and floating-point instructions on page E1-4000 gives more information about these instructions.

E1.2.2 Core data types and arithmetic in AArch32 state

When executing in AArch32 state, a PE supports the following data types in memory:

<table>
<thead>
<tr>
<th>Type</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte</td>
<td>8 bits.</td>
</tr>
<tr>
<td>Halfword</td>
<td>16 bits.</td>
</tr>
<tr>
<td>Word</td>
<td>32 bits.</td>
</tr>
<tr>
<td>Doubleword</td>
<td>64 bits.</td>
</tr>
</tbody>
</table>

PE registers are 32 bits in size. The instruction sets provide instructions that use the following data types for data held in registers:

- 32-bit pointers.
- Unsigned or signed 32-bit integers.
- Unsigned 16-bit or 8-bit integers, held in zero-extended form.
- Signed 16-bit or 8-bit integers, held in sign-extended form.
- Two 16-bit integers packed into a register.
- Four 8-bit integers packed into a register.
- Unsigned or signed 64-bit integers held in two registers.

Load and store operations can transfer bytes, halfwords, or words to and from memory. Loads of bytes or halfwords zero-extend or sign-extend the data as it is loaded, as specified in the appropriate load instruction.

The instruction sets include load and store operations that transfer two or more words to and from memory. Software can load and store doublewords using these instructions.

Note

For information about the atomicity of memory accesses see Atomicity in the Arm architecture on page E2-4016.

When any of the data types is described as unsigned, the N-bit data value represents a non-negative integer in the range 0 to $2^N-1$, using normal binary format.

When any of these types is described as signed, the N-bit data value represents an integer in the range $-2^{(N-1)}$ to $+2^{(N-1)}-1$, using two's complement format.
The instructions that operate on packed halfwords or bytes include some multiply instructions that use only one of
two halfwords, and SIMD instructions that perform parallel addition or subtraction on all of the halfwords or bytes.

--- Note ---
These SIMD instructions operate on values held in the general-purpose registers, and must not be confused with the
Advanced SIMD instructions that operate on a separate register file that provides registers of up to 128 bits.

Direct instruction support for 64-bit integers is limited, and most 64-bit operations require sequences of two or more
instructions to synthesize them.

Integer arithmetic

The instruction set provides a wide range of operations on the values in registers, including bitwise logical
operations, shifts, additions, subtractions, multiplications, and divisions. The pseudocode described in
Appendix K14 Arm Pseudocode Definition defines these operations, usually in one of three ways:

- By direct use of the pseudocode operators and built-in functions defined in Operators on page K14-8139.
- By use of pseudocode helper functions defined in the main text. See Appendix K12 Pseudocode Index.
- By a sequence of the form:
  1. Use of the $\text{SInt}()$, $\text{UInt}()$, and $\text{Int}()$ built-in functions defined in Converting bitstrings to integers on
     page K14-8151 to convert the bitstring contents of the instruction operands to the unbounded integers
     that they represent as two's complement or unsigned integers.
  2. Use of mathematical operators, built-in functions and helper functions on those unbounded integers to
calculate other such integers.
  3. Use of either the bitstring extraction operator defined in Bitstring concatenation and slicing on
     page K14-8140 or of the saturation helper functions described in Pseudocode description of saturation
     on page E1-3991 to convert an unbounded integer result into a bitstring result that can be written to a
     register.

Shift and rotate operations

The following types of shift and rotate operations are used in instructions:

Logical Shift Left

The $\text{LSL}()$ pseudocode function moves each bit of a bitstring left by a specified number of bits. Zeros
are shifted in at the right end of the bitstring. Bits that are shifted off the left end of the bitstring are
discarded, except that the last such bit can be produced as a carry output.

Logical Shift Right

The $\text{LSR}()$ pseudocode function moves each bit of a bitstring right by a specified number of bits.
Zeros are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the
bitstring are discarded, except that the last such bit can be produced as a carry output.

Arithmetic Shift Right

The $\text{ASR}()$ pseudocode function moves each bit of a bitstring right by a specified number of bits.
Copies of the leftmost bit are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the
bitstring are discarded, except that the last such bit can be produced as a carry output.

Rotate Right

The $\text{ROR}()$ pseudocode function moves each bit of a bitstring right by one bit. A carry input is shifted
in at the left end of the bitstring. The bit shifted off the right end of the bitstring can be produced as a
carry output.
Pseudocode description of addition and subtraction

In pseudocode, addition and subtraction can be performed on any combination of unbounded integers and bitstrings, provided that if they are performed on two bitstrings, the bitstrings must be identical in length. The result is another unbounded integer if both operands are unbounded integers, and a bitstring of the same length as the bitstring operand or operands otherwise. For the definition of these operations, see *Addition and subtraction on page K14-8141*.

The main addition and subtraction instructions can produce status information about both unsigned carry and signed overflow conditions. When necessary, multi-word additions and subtractions can be synthesized from this status information. In pseudocode the *AddWithCarry()* function provides an addition with a carry input and a set of output Condition flags including carry output and overflow:

An important property of the *AddWithCarry()* function is that if:

\[(\text{result, nzcv}) = \text{AddWithCarry}(x, \text{NOT}(y), \text{carry\_in})\]

Then:

- If \(\text{carry\_in} == '1'\), then \(\text{result} == x-y\) with:
  - \(\text{nzcv<0>} == '1'\) if signed overflow occurred during the subtraction.
  - \(\text{nzcv<1>} == '1'\) if unsigned borrow did not occur during the subtraction, that is, if \(x\leq y\).
- If \(\text{carry\_in} == '0'\), then \(\text{result} == x-y-1\) with:
  - \(\text{nzcv<0>} == '1'\) if signed overflow occurred during the subtraction.
  - \(\text{nzcv<1>} == '1'\) if unsigned borrow did not occur during the subtraction, that is, if \(x\leq y\).

Taken together, this means that the \(\text{carry\_in}\) and \(\text{nzcv<1>}\) output in *AddWithCarry()* calls can act as NOT borrow flags for subtractions as well as carry flags for additions.

Pseudocode description of saturation

Some instructions perform *saturating arithmetic*, that is, if the result of the arithmetic overflows the destination signed or unsigned N-bit integer range, the result produced is the largest or smallest value in that range, rather than wrapping around modulo \(2^N\). This is supported in pseudocode by:

- The *SignedSatQ()* and *UnsignedSatQ()* functions when an operation requires, in addition to the saturated result, a Boolean argument that indicates whether saturation occurred.
- The *SignedSat()* and *UnsignedSat()* functions when only the saturated result is required.

\[\text{SatQ}(i, N, \text{unsigned})\] returns either \(*\text{UnsignedSatQ}(i, N)\) or *SignedSatQ*(i, N) depending on the value of its third argument, and \[\text{Sat}(i, N, \text{unsigned})\] returns either \(*\text{UnsignedSat}(i, N)\) or *SignedSat*(i, N) depending on the value of its third argument.

E1.2.3 The general-purpose registers, and the PC, in AArch32 state

In the AArch32 Application level view, a PE has:

- Fifteen general-purpose 32-bit registers, R0 to R14, of which R13 and R14 have alternative names reflecting how they are, or can be, used:
  - R13 is usually identified as SP.
  - R14 is usually identified as LR.
- The PC (*program counter*), that can be described as R15.

The specialized uses of the SP (R13), LR (R14), and PC (R15) are:

**SP, the stack pointer**

The PE uses SP as a pointer to the active stack.

In the T32 instruction set, some instructions cannot access SP. Instructions that can access SP can use SP as a general-purpose register.
The A32 instruction set provides more general access to SP, and it can be used as a general-purpose register.

--- Note ---

Using SP for any purpose other than as a stack pointer might break the requirements of operating systems, debuggers, and other software systems, causing them to malfunction.

Software can refer to SP as R13.

**LR, the link register**

The link register can be used to hold return link information, and some cases described in this manual require this use of the LR. When software does not require the LR for linking, it can use it for other purposes. Software can refer to LR as R14.

**PC, the program counter**

- When executing an A32 instruction, PC reads as the address of the current instruction plus 8.
- When executing a T32 instruction, PC reads as the address of the current instruction plus 4.
- Writing an address to PC causes a branch to that address.

Most T32 instructions cannot access PC.

The A32 instruction set provides more general access to the PC, and many A32 instructions can use the PC as a general-purpose register. However, Arm deprecates the use of PC for any purpose other than as the program counter. See Writing to the PC for more information.

Software can refer to PC as R15.

See AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-5731 for the system level view of these registers.

--- Note ---

In general, Arm strongly recommends using the names SP, LR and PC instead of R13, R14 and R15. However, sometimes it is simpler to use the R13-R15 names when referring to a group of registers. For example, it is simpler to refer to registers R8 to R15, rather than to registers R8 to R12, the SP, LR and PC. These two descriptions of the group of registers have exactly the same meaning.

--- Writing to the PC ---

In the A32 and T32 instruction sets, many data-processing instructions can write to the PC. Writes to the PC are handled as follows:

- In T32 state, the following 16-bit T32 instruction encodings branch to the value written to the PC:
  - Encoding T2 of **ADD, ADDS (register)** on page F5-4294.
  - Encoding T1 of **MOV, MOVS (register)** on page F5-4555.

  The value written to the PC is forced to be halfword-aligned by ignoring its least significant bit, treating that bit as being 0.

- The 8, **BL, CBNZ, CBZ, CHKA, HB, HBL, HBLP, HBP, TBB, and TBH** instructions remain in the same instruction set state and branch to the value written to the PC.

  The definition of each of these instructions ensures that the value written to the PC is correctly aligned for the current instruction set state.

- The **BLX (immediate)** instruction switches between A32 and T32 states and branches to the value written to the PC. Its definition ensures that the value written to the PC is correctly aligned for the new instruction set state.

- The following instructions write a value to the PC, treating that value as an interworking address to branch to, with low-order bits that determine the new instruction set state:
  - **BLX (register), BX, and BXJ.**
The AArch32 Application Level Programmers’ Model

E1.2 The Application level programmers’ model in AArch32 state

— LDR instructions with <Rt> equal to the PC.
— POP and all forms of LDM except LDM (exception return), when the register list includes the PC.
— In A32 state only, ADD, ADDS, AND, ASR (immediate), BIC, EOR, LSL (immediate), LSR (immediate), MOV, MVN, ORR, ROR (immediate), RXR, RSB, SBC, and SUB instructions with <Rd> equal to the PC and without flag-setting specified.

For details of how an interworking address specifies the new instruction set state and instruction address, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC.

Note

The register-shifted register instructions, that are available only in the A32 instruction set and are summarized in Data-processing register (register shift) on page F4-4229, are CONSTRAINED UNPREDICTABLE if they attempt to write to the PC, see Using R15 on page K1-7941.

• Some instructions are treated as exception return instructions, and write both the PC and the CPSR. For more information, including which instructions are exception return instructions, see Exception return to an Exception level using AArch32 on page G1-5765.

• Some instructions cause an exception, and the exception handler address is written to the PC as part of the exception entry.

Pseudocode description of operations on the AArch32 general-purpose registers and the PC

In pseudocode, the uses of the R[] function, with an index parameter n, are:

• Reading or writing R0-R12, SP, and LR, using n = 0-12, 13, and 14 respectively.
• Reading the PC, using n = 15.

Pseudocode description of general-purpose register and PC operations on page G1-5733 describes accesses to these registers.

Descriptions of A32 store instructions that store the PC value use the PCStoreValue() pseudocode function to specify the PC value stored by the instruction.

Writing an address to the PC causes either a simple branch to that address or an interworking branch that also selects the instruction set to execute after the branch. A simple branch is performed by the BranchWritePC() function.

An interworking branch is performed by the BXWritePC() function.

The LoadWritePC() and ALUWritePC() functions are used for two cases where the behavior was systematically modified between architecture versions.

E1.2.4 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

Note

In this chapter, references to PSTATE link to the more appropriate of:

• The Application-level view of PSTATE given in this section.
• The System-level description in Process state, PSTATE on page G1-5735.
The following PSTATE information is accessible at EL0:

The Condition flags

Flag-setting instructions set these. They are:

N  Negative Condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:
  • 1 if the result is negative.
  • 0 if the result is positive or zero.

Z  Zero Condition flag. Set to:
  • 1 if the result of the instruction is zero.
  • 0 otherwise.

A result of zero often indicates an equal result from a comparison.

C  Carry Condition flag. Set to:
  • 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
  • 0 otherwise.

V  Overflow Condition flag. Set to:
  • 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.
  • 0 otherwise.

Conditional instructions test the N, Z, C, and V Condition flags, combining them with the Condition code for the instruction, to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see Conditional execution on page F2-4121.

The overflow or saturation flag

Q  Some instructions can set this. For those instructions that can, the PE:
  • Sets it to 1 if the instruction indicates overflow or saturation.
  • Leaves it unchanged otherwise.

For more information, see Pseudocode description of saturation on page E1-3991.

The greater than or equal flags

GE[3:0]  The instructions described in Parallel addition and subtraction instructions on page F1-4086 update these to indicate the results from individual bytes or halfwords of the operation. These flags can control a later SEL instruction. For more information, see SEL on page F5-4712.

PSTATE also contains PE state controls. There is no direct access to these from application level instructions, but they can be changed by side-effects of application level instructions. They are:

Instruction set state

J, T  The current instruction set state, as shown in Table E1-1. In Armv8, the J bit is RES0, see the Note in this section.

<table>
<thead>
<tr>
<th>J</th>
<th>T</th>
<th>Instruction set state</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>T32</td>
</tr>
</tbody>
</table>

A32  The PE is executing the A32 instruction set, summarized in Chapter F4 A32 Instruction Set Encoding.
The PE is executing the T32 instruction set, summarized in Chapter F3 T32 Instruction Set Encoding.

Note

Encoding with J==1 before Armv8, Jazelle and T32EE states

In previous versions of the Arm architecture, the encoding {1, 0} selected Jazelle state, and encoding {1, 1} selected T32EE state. Armv8 does not support either of these states, and these are encodings for unimplemented instruction set states, see Unimplemented instruction sets on page G1-5741. Armv8 AArch32 state requires a Trivial Jazelle implementation, see Trivial implementation of the Jazelle extension on page G1-5741.

The IT block state

IT[7:0]
The If-Then controls for the T32 IT instruction, that applies to the IT block of instructions that immediately follow the IT instruction. See IT on page F5-4416 for a description of the IT instruction and its associated IT block.

For more information about the use of PSTATE.IT see Use of PSTATE.IT on page E1-3997.

Endianness mapping

E
For data accesses, controls the endianness:

0 Little-endian.
1 Big-endian.

If an implementation does not provide:

• Big-endian support for data accesses, this bit is RES0.
• Little-endian support for data accesses, this bit is RES1.

Instruction fetches are always little-endian, and ignore PSTATE.E.

Timing control bits

DIT
Data Independent Timing (DIT) bit. For more information, see About the DIT bit on page E1-3999.

This bit is implemented only when FEAT_DIT is implemented.

On a reset to AArch32 state, this bit is set to 0.

Accessing PSTATE fields at EL0

The following sections describe which PSTATE fields can be directly accessed at EL0, and how they can be accessed:

• The Application Program Status Register, APSR.
• The SETEND instruction on page E1-3996.

The Application Program Status Register, APSR

At EL0, some PSTATE fields can be accessed using the Special-purpose Application Program Status Register (APSR). The APSR can be directly read using the MRS instruction, and directly written using the MSR (register) and MSR (immediate) instructions.
### APSR Bit Assignments

The APSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

</table>

#### Condition Flags [31:28]

- **N**, **Z**, **C**, **V**, **Q**
  - The PSTATE Condition flags.

#### Q, bit [27]

- **Q**
  - The PSTATE overflow or saturation flag.

#### Bits[26:24]

- **RES0**
  - Reserved, write zeros to these bits.

#### Bits[23:20, 15:0]

- **RES0**
  - Reserved bits.

#### GE[3:0], bits [19:16]

- **RES0**
  - Reserved bit.

### Notes

- These bits are **UNKNOWN** on a Read, and it is permitted that, on a read of APSR:
  - Bit[22] returns the value of PSTATE.PAN.
  - Bit[9] returns the value of PSTATE.E.
  - Bits[4:0] return the value of PSTATE.M[4:0]. Bit[4] is RES1 indicating that the PE is in AArch32 state.

### Note

This is an exception to the general rule that an **UNKNOWN** field must not return information that cannot be obtained, at the current Privilege level, by an architected mechanism.

### GE[3:0], bits [19:16]

- **RES0**
  - Reserved bit.

### SETEND Instruction

The A32 and T32 instruction sets both include an instruction to manipulate PSTATE.E:

- **SETEND BE**
  - Sets PSTATE.E to 1, for big-endian operation.
- **SETEND LE**
  - Sets PSTATE.E to 0, for little-endian operation.

The SETEND instruction is unconditional. For more information, see **SETEND** on page F5-4714. Arm deprecates use of the SETEND instruction.
Use of PSTATE.IT

PSTATE.IT provides the If-Then controls for the T32 IT instruction, that applies to the IT block of instructions that immediately follow the IT instruction.

PSTATE.IT divides into two subfields:

IT[7:5]  Holds the base condition for the current IT block. The base condition is the top three bits of the Condition code specified by the <firstcond> field of the IT instruction.

IT[4:0]  Encodes:

- Implicitly, the size of the IT block. This is the number of instructions that are to be conditionally executed. The size of the block is indicated by the position of the least significant 1 in this field, as shown in Table E1-2.
- For each instruction in the IT block, the least significant bit of the Condition code. This is encoded in the IT block entries that Table E1-2 shows as Nx.

Note

Changing the least significant bit of a Condition code from 0 to 1 has the effect of inverting the Condition code.

Both subfields are all zeros when no IT block is active.

When an IT instruction is executed, PSTATE.IT is set according to the <firstcond> field of the instruction and the Then and Else (T and E) parameters in the instruction, see IT on page F5-4416. This means that, on executing an IT instruction, the initial state of PSTATE.IT depends on the number of instructions in the IT block, as Table E1-2 shows:

<table>
<thead>
<tr>
<th>Number of instructions in IT block</th>
<th>PSTATE.IT bitsa</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>[7:5]</td>
<td>[4]</td>
</tr>
<tr>
<td>4</td>
<td>cond_base</td>
<td>N1</td>
</tr>
<tr>
<td>3</td>
<td>cond_base</td>
<td>N1</td>
</tr>
<tr>
<td>2</td>
<td>cond_base</td>
<td>N1</td>
</tr>
<tr>
<td>1</td>
<td>cond_base</td>
<td>N1</td>
</tr>
<tr>
<td>Not executing an IT instruction</td>
<td>000</td>
<td>0</td>
</tr>
</tbody>
</table>

In Table E1-2, N1 refers to the first instruction in the IT block, and N2, N3, and N4 refer to the second, third, and fourth instructions in the IT block if they are present.

When permitted, an instruction in an IT block is conditional, see Conditional instructions on page F1-4077 and Conditional execution on page F2-4121. The Condition code used is the current value of IT[7:4]. When an instruction in an IT block completes its execution normally, PSTATE.IT[4:0] is left-shifted by one bit, so that PSTATE[4] always relates to the next instruction to be executed. Table E1-3 on page E1-3998 shows how PSTATE.IT during the execution of an IT instruction with four instructions in the IT block.
A few instructions, for example BKPT, cannot be conditional and therefore are always executed ignoring the current value of PSTATE.IT.

For details of what happens if an instruction in an IT block takes an exception, see Overview of exception entry on page G1-5750.

An instruction that might complete its normal execution by branching is only permitted in an IT block as the last instruction in the block. This means that normal execution of the instruction always results in PSTATE.IT advancing to execution where no IT block is active.

For performance reasons, Armv8 deprecates the use of IT other than with a single 16-bit T32 instruction from a specified subset of the 16-bit T32 instructions, see Partial deprecation of IT on page F1-4094. In addition, implementations can provide a set of ITD control fields, SCTLR.ITD, SCTLR_EL1.ITD, and HSCTLR.ITD, to disable these deprecated uses, making them UNDEFINED. When an implementation includes ITD control fields, Changes to an ITD control by an instruction in an IT block describes the permitted CONSTRAINED UNPREDICTABLE behaviors if an instruction in an IT block changes the value of an ITD control to disable the use of the IT instruction.

On a branch or an exception return, if PSTATE.IT is set to a value that is not consistent with the instruction stream being branched to or returned to, then instruction execution is CONSTRAINED UNPREDICTABLE.

PSTATE.IT affects instruction execution only in T32 state. In A32 state, PSTATE.IT must be 0b00000000, otherwise the behavior is CONSTRAINED UNPREDICTABLE.

For more information see CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT on page K1-7942.

### Changes to an ITD control by an instruction in an IT block

In an implementation that includes SCTLR.ITD, SCTLR_EL1.ITD, and HSCTLR.ITD controls, if an instruction in an IT block changes an ITD control so that the IT instruction using the IT block would be disabled, then one of the following behaviors applies:

- The change to the ITD field, once synchronized, has no effect on the execution of instructions in the current IT block, but applies only to any subsequent execution of an IT instruction to which the control applies.
- Synchronizing the change to the ITD field guarantees that all bits of PSTATE.IT are cleared to 0.

In addition, after the change to the ITD field has been synchronized, any remaining instructions in the IT block that would be made UNDEFINED by the new value of ITD are either:

- Executed normally.
- Treated as UNDEFINED.

The choice between the options described in this section is determined by the implementation, and any choice can vary between different changes to an ITD control by an instruction in an IT block.

### Table E1-3 Updates to PSTATE.IT when executing an IT instruction with a four-instruction IT block

Pseudocode description of PSTATE PE state fields

The pseudocode function `CurrentInstrSet()` returns the current instruction set. The pseudocode function `SelectInstrSet()` selects a new instruction set.

The pseudocode function `PSTATE.IT` advances after normal execution of an IT block instruction. This is described by the `AArch32.ITAdvance()` pseudocode function.

The pseudocode function `InITBlock()` tests whether the current instruction is in an IT block. The pseudocode function `LastInITBlock()` tests whether the current instruction is the last instruction in an IT block.

The `BigEndian()` pseudocode function tests whether big-endian data memory accesses are currently selected.

E1.2.5 About the DIT bit

When the value of `CPSR.DIT` is 1:

- The instructions listed in `CPSR` are required to have:
  - Timing which is independent of the values of the data supplied in any of its registers, and the values of the NZCV flags.
  - Responses to asynchronous exceptions which do not vary based on the values supplied in any of their registers, or the values of the NZCV flags.
- All loads and stores have their timing insensitive to the value of the data being loaded or stored.

Note

When the value of `CPSR.DIT` is 0, the architecture makes no statement about the timing properties of any instructions.

A corresponding DIT bit is added to `PSTATE` in AArch64 state, and to `CPSR` in AArch32 state.

When an exception is taken from AArch32 state to AArch32 state, `CPSR.DIT` is copied to `SPSR.DIT`.

When an exception is taken from AArch32 state to AArch64 state, `CPSR.DIT` is copied to `SPSR_ELx.DIT`.

When an exception returns to AArch32 state from AArch32 state, `SPSR.DIT` is copied to `CPSR.DIT`.

When an exception returns to AArch32 state from AArch64 state, `SPSR_ELx.DIT` is copied to `CPSR.DIT`.

`CPSR.DIT` bit can be written using an `MSR` instruction at any exception level in AArch32 state, and read using an `MRS` instruction at any exception level.

E1.2.6 Jazelle support

Armv8 requires AArch32 state to include a trivial implementation of the Jazelle extension, as described in `Trivial implementation of the Jazelle extension` on page G1-5741.
E1.3 Advanced SIMD and floating-point instructions

In general, Armv8 requires implementation of Advanced SIMD and floating-point instructions in the T32 and A32 instruction sets, but see Implications of not including Advanced SIMD and floating-point support on page E1-4006.

The Advanced SIMD instructions perform packed Single Instruction Multiple Data (SIMD) operations, either integer or single-precision floating-point. The floating-point instructions perform single-precision or double-precision scalar floating-point operations. When FEAT_FP16 is implemented, half-precision floating-point can also be used for data processing.

These instructions permit floating-point exceptions, such as Overflow or Divide by Zero, to be handled without trapping. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. Armv8 also optionally supports the trapping of floating-point exceptions, see Floating-point exceptions and exception traps on page G1-5816. For more information about floating-point exceptions see Floating-point exceptions and exception traps on page E1-4003.

The Advanced SIMD and floating-point instructions also provide the following conversion functions:

- Between half-precision floating-point and single-precision floating point, in both directions.
- From double-precision, floating point to a signed single precision integer.
- When FEAT_AA32BF16 is implemented, between single-precision floating-point and BFloat16 floating-point.

Some Advanced SIMD instructions support polynomial arithmetic over \{0, 1\}, as described in Polynomial arithmetic over \{0, 1\} on page A1-50.

For system level information about the Advanced SIMD and Floating-point implementation see Advanced SIMD and floating-point support on page G1-5812.

The following sections give more information about the Advanced SIMD and floating-point instructions:

- Floating-point standards, and terminology on page A1-54.
- The SIMD and floating-point register file.
- Data types supported by the Advanced SIMD implementation on page E1-4002.
- Advanced SIMD and floating-point System registers on page E1-4002.
- Floating-point data types and arithmetic on page E1-4002.
- Floating-point exceptions and exception traps on page E1-4003.
- Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-4006.
- Implications of not including Advanced SIMD and floating-point support on page E1-4006.
- Pseudocode description of floating-point operations on page E1-4007.

E1.3.1 The SIMD and floating-point register file

The Advanced SIMD and floating-point instructions use the same register file, that comprises 32 registers. This is distinct from the register file that holds the general-purpose registers and the PC.

The Advanced SIMD and floating-point views of the register file are different. The following sections describe these different views. Figure E1-1 on page E1-4001 shows the views of the register file, and the way the word, doubleword, and quadword registers overlap.

Advanced SIMD views of the register file

Advanced SIMD can view this register file as:

- Sixteen 128-bit quadword registers, Q0-Q15.
- Thirty-two 64-bit doubleword registers, D0-D31.

These views can be used simultaneously. For example, a program might hold 64-bit vectors in D0 and D1 and a 128-bit vector in Q1.
Floating-point views of the register file

The Advanced SIMD and floating-point register file consists of thirty-two doubleword registers, that can be viewed as:

- Thirty-two 64-bit doubleword registers, D0-D31. This view is also available to Advanced SIMD instructions.
- Thirty-two 32-bit single word registers, S0-S31. Only half of the set is accessible in this view.

Note

In AArch32 state, half-precision floating point values are always represented using the bottom 16 bits of a single word register, S0-S31. When a half-precision value is written to a single word register, the top 16 bits of that register are set to 0.

The two views can be used simultaneously.

SIMD and Floating-point register file mapping onto registers

Figure E1-1 shows the different views of the SIMD and floating-point register file, and the relationship between them.

Figure E1-1 SIMD and floating-point register file, AArch32 operation

The mapping between the registers is as follows:

- \( S_{2n} \) maps to the least significant half of \( D_{2n} \).
- \( S_{2n+1} \) maps to the most significant half of \( D_{2n} \).
- \( D_{2n} \) maps to the least significant half of \( Q_{2n} \).
- \( D_{2n+1} \) maps to the most significant half of \( Q_{2n} \).
For example, software can access the least significant half of the elements of a vector in Q6 by referring to D12, and the most significant half of the elements by referring to D13.

**Pseudocode description of the SIMD and Floating-point register file**

The functions _Dclone[], S[], and D[] provide the S0-S31, D0-D31, and Q0-Q15 views of the Advanced SIMD and floating-point registers:

The D[n] function returns a Doubleword register from the _Dclone[] copy of the SIMD and Floating-point register file, and the Q[n] function returns a Quadword register from that register file.

--- Note ---

The CheckAdvSIMDEnabled() function copies the D[] register file to _Dclone[], see Pseudocode description of enabling SIMD and floating-point functionality on page G1-5851.

---

**E1.3.2 Data types supported by the Advanced SIMD implementation**

Advanced SIMD instructions can operate on integer and floating-point data, and the implementation defines a set of data types that support the required data formats. Vector formats in AArch32 state on page A1-42 describes these formats.

**Advanced SIMD vectors**

In an implementation that includes support for Advanced SIMD operation, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector. In Vector formats in AArch32 state on page A1-42, Figure A1-3 on page A1-44 shows the Advanced SIMD vector formats.

**Pseudocode description of Advanced SIMD vectors**

The pseudocode function Elen[] accesses the element of a specified index and size in a vector.

---

**E1.3.3 Advanced SIMD and floating-point System registers**

The Advanced SIMD and floating-point instructions have a shared register space for System registers. The only register in this space that is accessible at the Application level is the FPSCR.

Writes to the FPSCR can have side-effects on various aspects of PE operation. All of these side-effects are synchronous to the FPSCR write. This means they are guaranteed not to be visible to earlier instructions in the execution stream, and they are guaranteed to be visible to later instructions in the execution stream.

See Advanced SIMD and floating-point System registers on page G1-5814 for the system level view of the registers.

These registers can be described as the SIMD and floating-point System registers.

---

**E1.3.4 Floating-point data types and arithmetic**

The T32 and A32 floating-point instructions support single-precision (32-bit) and double-precision (64-bit) data types and arithmetic as defined by the IEEE 754 floating-point standard. They also support the half-precision (16-bit) floating-point data type for data storage, by supporting conversions between single-precision and half-precision data types. When FEAT_FP16 is implemented, it also supports the half-precision floating-point data type for data processing operations. When FEAT_AA32BF16 is implemented, it also supports the BFloat16 floating-point storage format.
Arm standard floating-point arithmetic means IEEE 754 floating-point arithmetic with the restrictions described in Advanced SIMD and floating-point support on page A1-52, including supporting only the input and output values described in Arm standard floating-point input and output values on page A1-54.

The AArch32 Advanced SIMD instructions support single-precision and, when FEAT_FP16 is implemented, half-precision Arm standard floating-point arithmetic.

The following sections describe the Advanced SIMD and floating-point formats:

- Half-precision floating-point formats on page A1-44.
- Double-precision floating-point format on page A1-47.

The following sections describe features of Advanced SIMD and floating-point processing:

- NaN handling and the Default NaN on page A1-56.

### E1.3.5 Floating-point exceptions and exception traps

Arm Advanced SIMD and floating-point instructions record the following floating-point exceptions in the FPSCR cumulative bits, unless the floating-point exception is trapped and generates an exception:

**FPSCR.IOC**  
Invalid Operation. The bit is set to 1 if the result of an operation has no mathematical value or cannot be represented. Cases include, for example:

- \((\text{infinity}) \times 0\).
- \((+\text{infinity}) + (\text{--infinity})\).

These tests are made after flush-to-zero processing. For example, if flush-to-zero mode is selected, multiplying a denormalized number and an infinity is treated as \((0 \times \text{infinity})\), and causes an Invalid Operation floating-point exception.

IOC is also set on any floating-point operation with one or more signaling NaNs as operands, except for negation and absolute value, as described in Floating-point negation and absolute value on page E1-4007.

**FPSCR.DZC**  
Divide by Zero. The bit is set to 1 if a divide operation has a zero divisor and a dividend that is not zero, an infinity or a NaN. These tests are made after flush-to-zero processing, so if flush-to-zero processing is selected, a denormalized dividend is treated as zero and prevents Divide by Zero from occurring, and a denormalized divisor is treated as zero and causes Divide by Zero to occur if the dividend is a normalized number.

For the reciprocal and reciprocal square root estimate functions the dividend is assumed to be +1.0. This means that a zero or denormalized operand to these functions sets the DZC bit.

**FPSCR.OFC**  
Overflow. The bit is set to 1 if the absolute value of the result of an operation, produced after rounding, is greater than the maximum positive normalized number for the destination precision.

**FPSCR.UFC**  
Underflow. The bit is set to 1 if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, and the rounded result is inexact.

The criteria for the Underflow floating-point exception to occur are different in Flush-to-zero mode. For details, see Flush-to-zero on page A1-55.

**FPSCR.IXC**  
Inexact. The bit is set to 1 if the result of an operation is not equivalent to the value that would be produced if the operation were performed with unbounded precision and exponent range.

The criteria for the Inexact floating-point exception to occur are different in Flush-to-zero mode. For details, see Flush-to-zero on page A1-55.

**FPSCR.IDC**  
Input Denormal. The bit is set to 1 if a denormalized input operand is replaced in the computation by a zero, as described in Flush-to-zero on page A1-55.
For Advanced SIMD instructions, and for floating-point instructions when floating-point exception trapping is not supported, these are non-trapping exceptions and the data-processing instructions do not generate any trapped exceptions.

For floating-point instructions when floating-point exception trapping is supported:

- The floating-point exceptions can be trapped, by setting trap enable bits in the FPSCR, see Floating-point exceptions and exception traps on page G1-5816, and:
  - When a trap is not enabled the corresponding floating-point exception updates the corresponding FPSCR cumulative bit does not generate an exception.
  - When a trap is enabled the corresponding floating-point exception does not update the FPSCR, but generates an exception. In this case, bits in the FPEXC indicate which floating-point exceptions have occurred.

- The definition of the Underflow floating-point exception is different in the trapped and cumulative exception cases. In the trapped case the definition is:
  - The trapped Underflow floating-point exception occurs if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, regardless of whether the rounded result is inexact.

- As with cumulative exceptions, higher priority trapped exceptions can prevent lower priority exceptions from occurring, as described in Combinations of floating-point exceptions on page E1-4005.

- For Invalid Operation floating-point exceptions, for details of which quiet NaN is produced as the default result see NaN handling and the Default NaN on page A1-56.

- For Overflow floating-point exceptions, the sign bit of the default result is determined normally for the overflowing operation.

- For Divide by Zero floating-point exceptions, the sign bit of the default result is determined normally for a division. This means it is the exclusive OR of the sign bits of the two operands.

Table E1-4 shows the results of untrapped floating-point exceptions. That table uses the following abbreviations:

MaxNorm  The maximum normalized number of the destination precision.
RM  Round towards Minus Infinity mode, as defined in the IEEE 754 standard.
RN  Round to Nearest mode, as defined in the IEEE 754 standard.
RP  Round towards Plus Infinity mode, as defined in the IEEE 754 standard.
RZ  Round towards Zero mode, as defined in the IEEE 754 standard.

For more information about the IEEE 754 descriptions of the rounding modes see Floating-point standards, and terminology on page A1-54.

Combinations of floating-point exceptions

Many pseudocode functions perform floating-point operations, including FixedToFP(), FPAdd(), FPCmpare(), FPCompareEQ(), FPCompareGE(), FPCompareGT(), FPDiv(), FPMax(), FPMin(), FPMul(), FPMulAdd(), FPRecipEstimate(), FPRecipStep(), FPRsqrtEstimate(), FPRsqrtStep(), FPSqrt(), FPSub(), and FPtoFixed(). All of these operations can generate floating-point exceptions.

Note

FPAbs() and FPNeg() are not classified as floating-point operations because:

- They cannot generate floating-point exceptions.
- The floating-point operation behavior described in the following sections does not apply to them:
  - NaN handling and the Default NaN on page A1-56.

More than one exception can occur on the same operation. The only combinations of floating-point exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other floating-point exceptions.

The priority order of these floating-point exceptions is that the Inexact exception is treated as lowest priority, and the Input Denormal exception is treated as highest priority.

When none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative bit in the FPSCR to be set.

When one or more floating-point exceptions caused by an operation is trapped, the behavior of the instruction depends on the priority of the exceptions:

- If the higher priority floating-point exception is trapped, its trap handler is called. It is IMPLEMENTATION DEFINED whether any information about the lower priority floating-point exception is provided.
  
  Note

  Information about the lower priority floating-point exception might be provided in:
  
  - The FPEXC, if the exception generated by the trap is taken to an Exception level that is using AArch32.
  - The ESR_ELx.ISS field, if the exception generated by the trap is taken to an Exception level that is using AArch64.
  
  However, information might be provided in another IMPLEMENTATION DEFINED way, for example using an IMPLEMENTATION DEFINED register.

  Apart from this, the lower priority floating-point exception is ignored in this case.

- If the higher priority floating-point exception is untrapped, its cumulative bit is set to 1 and its default result is evaluated. Then the lower priority floating-point exception is handled normally, using this default result.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, a floating-point exception on one operation is treated as higher priority than a floating-point exception on another operation if the occurrence of the second floating-point exception depends on the result of the first operation. Otherwise, it is CONSTRAINED UNPREDICTABLE which floating-point exception is treated as higher priority.

For example, a VMLA.F32 instruction specifies a floating-point multiplication followed by a floating-point addition. The addition can generate Overflow, Underflow and Inexact floating-point exceptions, all of which depend on both operands to the addition and so are treated as lower priority than any floating-point exception on the multiplication. The same applies to Invalid Operation floating-point exceptions on the addition caused by adding opposite-signed infinities. The addition can also generate an Input Denormal floating-point exception, caused by the addend being a denormalized number while in Flush-to-zero mode. It is CONSTRAINED UNPREDICTABLE which of an Input Denormal floating-point exception on the addition and a floating-point exception on the multiplication is treated as

...
higher priority, because the occurrence of the Input Denormal floating-point exception does not depend on the result of the multiplication. The same applies to an Invalid Operation floating-point exception on the addition caused by the addend being a signaling NaN.

Note

The \texttt{VFMA} instruction performs a vector addition and a vector multiplication as a single operation. The \texttt{VFMS} instruction performs a vector subtraction and a vector multiplication as a single operation.

E1.3.6 Controls of Advanced SIMD operation that do not apply to floating-point operation

Armv7 permitted implementation of either, both, or neither of the Advanced SIMD and floating-point additions to the base instruction set, and provided some controls that applied to the Advanced SIMD functionality but not to the floating-point functionality. In Armv8, Advanced SIMD functionality cannot be separated from floating-point functionality, but in AArch32 state these controls function as they did in Armv7. This means they apply only to the following instructions and instruction encodings:

- All instructions with encodings defined in:
  - \textit{Advanced SIMD data-processing} on page F3-4165, for the T32 instruction set.
  - \textit{Advanced SIMD data-processing} on page F4-4262, for the A32 instruction set.

- All instructions with encodings defined in:
  - \textit{Advanced SIMD element or structure load/store} on page F3-4198, for the T32 instruction set.
  - \textit{Advanced SIMD element or structure load/store} on page F4-4274, for the A32 instruction set.

- The form of the \texttt{VDUP} instruction described in \textit{VDUP (general-purpose register)} on page F6-5193.

- The byte and halfword forms of the \texttt{VMOV} instructions described in each of:
  - \textit{VMOV (general-purpose register to scalar)} on page F6-5369.
  - \textit{VMOV (scalar to general-purpose register)} on page F6-5373.

The controls of this functionality are:

- The \texttt{CPACR.ASEDIS} field.
- The \texttt{HCPTR.TASE} field.

In an implementation that supports Advanced SIMD functionality, support for each of these controls is optional:

- If the \texttt{CPACR.ASEDIS} control is not supported then the \texttt{CPACR.ASEDIS} field is RAZ/WI. This is equivalent to the control permitting the execution of Advanced SIMD instructions at EL1 and EL0.

- If the \texttt{HCPTR.TASE} control is not supported then the \texttt{HCPTR.TASE} field is RAZ/WI. This means the \texttt{HCPTR} does not provide a control that can trap Non-secure execution of Advanced SIMD instructions to Hyp mode.

E1.3.7 Implications of not including Advanced SIMD and floating-point support

In general, Armv8 requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementation targeting specialized markets, Arm might produce or license an Armv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- Each of the \texttt{CPACR.(cp10, cp11)} fields is RES0.
- The \texttt{CPACR.ASEDIS} bit is RES0.
- Each of the \texttt{HCPTR.(TASE, TCP10, TCP11)} fields is RES1.
- Each of the \texttt{NSACR.(NSASEDIS, cp10, cp11)} fields is RES0.
- The \texttt{FPEXC} register is UNDEFINED.
E1.3.8 Pseudocode description of floating-point operations

The following subsections contain pseudocode definitions of the floating-point functionality supported by the Armv8 architecture:

- Generation of specific floating-point values.
- Floating-point negation and absolute value.
- Floating-point value unpacking.
- Floating-point exception and NaN handling.
- Floating-point rounding on page E1-4008.
- Selection of Arm standard floating-point arithmetic on page E1-4008.
- Floating-point comparisons on page E1-4008.
- Floating-point maximum and minimum on page E1-4008.
- Floating-point addition and subtraction on page E1-4008.
- Floating-point multiplication and division on page E1-4008.
- Floating-point fused multiply-add on page E1-4008.
- Floating-point reciprocal estimate and step on page E1-4009.
- Floating-point square root on page E1-4009.
- Floating-point reciprocal square root estimate and step on page E1-4009.
- Floating-point conversions on page E1-4010.

Generation of specific floating-point values

The following pseudocode functions generate specific floating-point values. The sign argument is '0' for the positive version and '1' for the negative version:

- FPInfinity().
- FPMaxNormal().
- FPZero().
- FPTwo().
- FPThree().
- FPDefaultNaN().

Floating-point negation and absolute value

The floating-point negation and absolute value operations only affect the sign bit. They do not treat NaN operands specially, nor denormalized number operands when flush-to-zero is selected.

The floating-point negation operation is described by the pseudocode function FPNeg(). The floating-point absolute value operation is described by the pseudocode function FPAbs().

Floating-point value unpacking

The FPUnpack() function determines the type of a floating-point number, defined by FPType{}, and its numerical value. It also does flush-to-zero processing on input operands.

Floating-point exception and NaN handling

The FPProcessException() procedure checks whether a floating-point exception is trapped, and handles it accordingly. The floating-point exception types are defined by FPExc{}.

The FPProcessNaN() function processes a NaN operand, producing the correct result value and generating an Invalid Operation floating-point exception if necessary. The FPProcessNaNs() function performs the standard NaN processing for a two-operand operation. The FPProcessNaNs3() function performs the standard NaN processing for a three-operand operation.
Floating-point rounding

The \texttt{FPRound()} function rounds and encodes a floating-point result to a specified destination format. This includes processing Overflow, Underflow and Inexact floating-point exceptions and performing flush-to-zero processing on result values.

Selection of Arm standard floating-point arithmetic

The \texttt{StandardFPSCRValue()} function returns the \texttt{FPSCR} value that selects Arm standard floating-point arithmetic. Most of the arithmetic functions have a Boolean \texttt{fpscr\_controlled} argument that is \texttt{TRUE} for Floating-point operations and \texttt{FALSE} for Advanced SIMD operations, and that selects between using the real \texttt{FPSCR} value and this value.

Floating-point comparisons

The \texttt{FPCompare()} function compares two floating-point numbers, producing a \{N, Z, C, V\} Condition flags result as shown in Table E1-5:

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|c|}
\hline
\textbf{Comparison result} & \textbf{N} & \textbf{Z} & \textbf{C} & \textbf{V} \\
\hline
Equal & 0 & 1 & 1 & 0 \\
\hline
Less than & 1 & 0 & 0 & 0 \\
\hline
Greater than & 0 & 0 & 1 & 0 \\
\hline
Unordered & 0 & 0 & 1 & 1 \\
\hline
\end{tabular}
\caption{Effect of a Floating-point comparison on the Condition flags}
\end{table}

This result defines the operation of the \texttt{VCMP} floating-point instruction. The \texttt{VCMP} instruction writes these flag values in the \texttt{FPSCR}. After using a \texttt{VMRS} instruction to transfer them to the APSR, they can control conditional execution as shown in Table F2-1 on page F2-4121.

The \texttt{FPCompareEQ()}, \texttt{FPCompareGE()}, and \texttt{FPCompareGT()} functions describe the operation of Advanced SIMD instructions that perform floating-point comparisons.

Floating-point maximum and minimum

The \texttt{FPMax()} function returns the maximum of two floating-point numbers. The \texttt{FPMin()} function returns the minimum of two floating-point numbers.

Floating-point addition and subtraction

The \texttt{FPAdd()} function adds two floating-point numbers. The \texttt{FPSub()} function subtracts one floating-point number from another floating-point number.

Floating-point multiplication and division

The \texttt{FPMul()} function multiplies two floating-point numbers. The \texttt{FPDiv()} function divides one floating-point number by another floating-point number.

Floating-point fused multiply-add

The \texttt{FPMulAdd()} function performs a floating-point fused multiply-add.
Floating-point reciprocal estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of a number.

The VRECPE instruction produces the initial estimate of the reciprocal. It uses the pseudocode functions:
- FPRecipEstimate().
- UnsignedRecipEstimate().

Table E1-6 shows the results where input values are out of range.

<table>
<thead>
<tr>
<th>Number type</th>

</tbody>
</table>

a. FPSCR.DZC is set to 1

The Newton-Raphson iteration:

\[ x_{n+1} = x_n(2-dx_n) \]

converges to \(1/d\) if \(x_0\) is the result of VRECPE applied to \(d\).

The VRECPS instruction performs a \((2 - \text{op1} \times \text{op2})\) calculation and can be used with a multiplication to perform a step of this iteration. The functionality of this instruction is defined by the FPRecipStep() pseudocode function.

Table E1-7 shows the results where input values are out of range.

<table>
<thead>
<tr>
<th>Input Vn[i]</th>
<th>Input Vm[i]</th>
<th>Result Vd[i]</th>

<tr>
<td>±infinity</td>
<td>±0.0 or denormalized number</td>
<td>2.0</td>
</tr>
</tbody>
</table>

Floating-point square root

The FPSqrt() function returns the square root of a floating-point number.

Floating-point reciprocal square root estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of the square root of a number.

The VRSQRTE instruction produces the initial estimate of the reciprocal of the square root. It uses the pseudocode functions:
- FPFRSqrtEstimate().
- UnsignedRSqrtEstimate().
Table E1-8 shows the results where input values are out of range.

<table>
<thead>
<tr>
<th>Number type</th>
<th>Input Vm[i]</th>
<th>Result Vd[i]</th>
</tr>
</thead>
<tbody>
<tr>

<td>a. FPSCR.DZC is set to 1.</td>
<td></td>
</tr>
</tbody>
</table>

The Newton-Raphson iteration:
\[ x_{n+1} = x_n \frac{3 - dx_n^2}{2} \]
converges to \( \frac{1}{\sqrt{d}} \) if \( x_0 \) is the result of VRSQRTE applied to \( d \).

The VRSQRTS instruction performs a \((3 - \text{op1} \times \text{op2})/2\) calculation and can be used with two multiplications to perform a step of this iteration. The functionality of this instruction is defined by the FPRSqrtStep() pseudocode function.

Table E1-9 shows the results where input values are out of range.

<table>
<thead>
<tr>
<th>Input Vn[i]</th>

</tbody>
</table>

FPR$\text{SqrtStep}()$ calls the FPHalvedSub() pseudocode function.

**Floating-point conversions**

The FPC$\text{onvert}()$ pseudocode function performs conversions between half-precision, single-precision, and double-precision floating-point numbers.

The FPT$\text{o}F\text{ixed}()$ and FixedToF$\text{P}()$ functions perform conversions between floating-point numbers and integers or fixed-point numbers.
E1.4 About the AArch32 System register interface

AArch32 state provides a System register encoding space, that is indexed by the parameter set \{coproc, opc1, CRn, CRm, opc2\}, and a set of System register access instructions. This encoding space is used for:

- System registers.
- System instructions, for:
  - Cache and branch predictor maintenance.
  - Address translation.
  - TLB maintenance.

In Armv8, this encoding space uses only the coproc values 0b111x.

**Note**
The encoding space with coproc values 0b101x is redefined to provide Advanced SIMD and floating-point functionality.

In Armv8:

- The (coproc==0b1111) encodings provide system control functionality, by providing access to System registers and System instructions. This includes architecture and feature identification, as well as control, status information and configuration support.

  The following sections give a general description of these encodings:
  - **About the System registers for VMSAv8-32 on page G5-6092.**
  - **VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G7-6116.**
  - **Functional grouping of VMSAv8-32 System registers on page G5-6098.**

  These encodings also provide:
  - The Performance Monitor registers. For more information, see Chapter D7 The Performance Monitors Extension.
  - The Activity Monitor registers. For more information, see Chapter D8 The Activity Monitors Extension.

- The (coproc==0b1110) encodings provide access to additional registers, that support:
  - Debug, see Chapter G2 AArch32 Self-hosted Debug.
  - The Jazelle identification registers, see Jazelle support on page E1-3999.

**UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses on page G8-6135** gives information more information about permitted accesses to the System registers in AArch32 state.

Most functionality in the (coproc==0b111x) encoding space cannot be accessed by software executing at EL0. This manual clearly identifies those functions that can be accessed at EL0.

For more information:

- About this encoding space, including the naming of the parameters that index the space, see The AArch32 System register interface on page G1-5809.
- About the System interface access instructions, see System register access instructions on page F1-4097.
E1.5 Exceptions

The Arm architecture uses the following terms to describe various types of exceptional condition:

**Exceptions**

In the Arm architecture, an *exception* causes entry to EL1, EL2, or EL3. If the Exception level that is entered is using AArch32, it also causes entry to the PE mode in which the exception must be taken. A software handler for the exception is then executed.

**Note**

The term *floating-point exception* does not use this meaning of *exception*. This term is described later in this list.

Exceptions include:

- Reset.
- Interrupts.
- Memory system aborts.
- Undefined instructions.
- Supervisor calls (SVCs), Secure Monitor calls (SMCs), and hypervisor calls (HVCs).
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in *Handling exceptions that are taken to an Exception level using AArch32* on page G1-5743. In an Armv8 implementation that includes all the Exception levels, aspects that are visible to application level software are:

- The **SVC** instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a call to the operating system, or other system component that is accessible only at EL1.
- The **SMC** instruction causes a Secure Monitor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Secure Monitor Call exception by methods defined by the operating system, or by another component of the software system that executes at EL1 or higher.
- The **HVC** instruction causes a Hypervisor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Hypervisor Call exception by methods defined by the hypervisor, or by another component of the software system that executes at EL1 or higher.
- The **BKPT** instruction causes a Breakpoint Instruction exception, that is taken as a Prefetch Abort exception. This provides a mechanism for a debugger to insert breakpoints into unprivileged software, or for unprivileged software to make a call into a debugger that is accessible at EL1.
- The **WFI** (Wait for Interrupt) instruction provides a hint that nothing needs to be done until an interrupt or another WFI wake-up event occurs, see *Wait For Interrupt* on page G1-5807. This means the hardware might enter a low-power state until the wake-up event occurs.
- The **WFE** (Wait for Event) instruction provides a hint that nothing needs to be done until either an SEV instruction generates an event, or another WFE wake-up event occurs, see *Wait For Event and Send Event* on page G1-5804. This means the hardware might enter a low-power state until the wake-up event occurs.

**Floating-point exceptions**

These relate to exceptional conditions encountered during floating-point arithmetic, such as Divide by Zero or Overflow. For more information see:

- *Floating-point exceptions and exception traps* on page E1-4003.
- The FPEXC and FPSCR register descriptions.
Chapter E2
The AArch32 Application Level Memory Model

This chapter gives an application level description of the memory model for software executing in AArch32 state. This means it describes the memory model for execution in EL0 when EL0 is using AArch32 in the following sections:

- About the Arm memory model on page E2-4014.
- Atomicity in the Arm architecture on page E2-4016.
- Definition of the Armv8 memory model on page E2-4020.
- Ordering of translation table walks on page E2-4038.
- Caches and memory hierarchy on page E2-4039.
- Alignment support on page E2-4044.
- Endian support on page E2-4046.
- Memory types and attributes on page E2-4050.
- Mismatched memory attributes on page E2-4060.
- Synchronization and semaphores on page E2-4063

Note
In this chapter, System register names usually link to the description of the register in Chapter G8 AArch32 System Register Descriptions, for example SCTLR.
E2.1  About the Arm memory model

The Arm architecture is a weakly ordered memory architecture that permits the observation and completion of memory accesses in a different order from the program order. The following sections of this chapter provide the complete definition of the Armv8 memory model, this introduction is not intended to contradict the definition found in those sections. In general, the basic principles of the Armv8 memory model are:

- To provide a memory model that has similar weaknesses to those found in the memory models used by high-level programming languages such as C or Java. For example, by permitting independent memory accesses to be re-ordered as seen by other observers.
- To avoid the requirement for multi-copy atomicity in the majority of memory types.
- The provision of instructions and memory barriers to compensate for the lack of multi-copy atomicity in the cases where it would be needed.
- The use of address, data, and control dependencies in the creation of order so as to avoid having excessive numbers of barriers or other explicit instructions in common situations where some order is required by the programmer or the compiler.

This section contains:
- Address space.
- Memory type overview.

E2.1.1  Address space

Address calculations are performed using 32-bit registers. Supervisory software determines the valid address range. Attempting to access an address that is not valid generates an MMU fault.

Address calculations are performed modulo 2^32. The result of an address calculation isUNKNOWN if it overflows or underflows the 32-bit address range A[31:0].

Memory accesses use the MemA[], MemO[], MemU[], and MemU_unpriv[] pseudocode functions:
- The MemA[] function makes an aligned access of the required type.
- The MemO[] function makes an ordered access of the required type.
- The MemU[] function makes an unaligned access of the required type
- The MemU_unpriv[] function makes an unaligned, unprivileged access of the required type.

Each of these functions calls Mem_with_type[] function, that specifies the required access. This calls AArch32.MemSingle[], which performs an atomic, little-endian read of size bytes.

The AccType enumeration defines the different access types.

Note
- Chapter G4 The AArch32 System Level Memory Model and Chapter G5 The AArch32 Virtual Memory System Architecture include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also reference pseudocode descriptions of these operations.
- For references to the pseudocode that relates to memory accesses, see Basic memory access on page G4-5957, Unaligned memory access on page G4-5958, and Aligned memory access on page G4-5957.

E2.1.2  Memory type overview

Armv8 provides the following mutually-exclusive memory types:

Normal  This is generally used for bulk memory operations, both read-write and read-only operations.
**Device**

The Arm architecture forbids speculative reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive locations.

Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See *Gathering* on page E2-4056.
- They preserve the access order and synchronization requirements, both for accesses to a single peripheral and where there is a synchronization requirement on the observability of one or more memory write and read accesses. See *Reordering* on page E2-4057.
- They indicate whether a write can be acknowledged other than at the end point. See *Early Write Acknowledgement* on page E2-4058.

For more information on Normal memory and Device memory, see *Memory types and attributes* on page E2-4050.

---

**Note**

Earlier versions of the Arm architecture defined a single Device memory type and a Strongly-Ordered memory type. A Note in *Device memory* on page E2-4054 describes how these memory types map onto the Armv8 memory types.
E2.2 Atomicity in the Arm architecture

Atomicity is a feature of memory accesses, described as atomic accesses. The Arm architecture description refers to two types of atomicity, single-copy atomicity and multi-copy atomicity. In the Armv8 architecture, the atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information see:

- Requirements for single-copy atomicity.
- Properties of single-copy atomic accesses on page E2-4017.
- Multi-copy atomicity on page E2-4017.
- Requirements for multi-copy atomicity on page E2-4018.
- Concurrent modification and execution of instructions on page E2-4018.

For more information about the memory types, see Memory type overview on page E2-4014.

E2.2.1 Requirements for single-copy atomicity

In AArch32 state, the single-copy atomic PE accesses are:

- All byte accesses.
- All halfword accesses to halfword-aligned locations.
- All word accesses to word-aligned locations.
- Memory accesses caused by LDREXD and STREXD instructions to doubleword-aligned locations.

LDM, LDC, LDRD, STM, STC, STR, PUSH, POP, RFE, SRS, VLDM, VLD, VSTM, and VSTR instructions are executed as a sequence of word-aligned word accesses. Each 32-bit word access is guaranteed to be single-copy atomic. The architecture does not require subsequences of two or more word accesses from the sequence to be single-copy atomic.

LDRD and STRD accesses to 64-bit aligned locations are 64-bit single-copy atomic as seen by translation table walks and accesses to translation tables.

Note

This requirement has been added to avoid the need for complex measures to avoid atomicity issues when changing translation table entries, without creating a requirement that all locations in the memory system are 64-bit single-copy atomic. This addition means:

- The system designer must ensure that all writable memory locations that might be used to hold translations, such as bulk SDRAM, can be accessed with 64-bit single-copy atomicity.
- Software must ensure that translation tables are not held in memory locations that cannot meet this atomicity requirement, such as peripherals that are typically accessed using a narrow bus.

This requirement places no burden on read-only memory locations for which reads have no side effects, since it is impossible to detect the size of memory accesses to such locations.

Advanced SIMD element and structure loads and stores are executed as a sequence of accesses of the element or structure size. The architecture requires the element accesses to be single-copy atomic if and only if both:

- The element size is 32 bits, or smaller.
- The elements are naturally aligned.

Accesses to 64-bit elements or structures that are 32-bit aligned are executed as a sequence of 32-bit accesses, each of which is single-copy atomic. The architecture does not require subsequences of two or more 32-bit accesses from the sequence to be single-copy atomic.

When an access is not single-copy atomic by the rules described in this section, it is executed as a sequence of one or more accesses that aggregate to the size of the original access. Each of the accesses in this sequence is single-copy atomic, at least at the byte level.
--- Note ---
In this section, the terms before the write operation and after the write operation mean before or after the write operation has had its effect on the coherence order of the bytes of the memory location accessed by the write operation.

---

If, according to these rules, an instruction is executed as a sequence of accesses, a synchronous Data Abort exception or Debug state entry can be taken during that sequence. This causes execution of the instruction to be abandoned. See Data Abort exception on page G1-5789 and, when FEAT_LSMAOC is implemented, Taking an interrupt or other exception during a multiple-register load or store on page G1-5777.

If the synchronous Data Abort exception is returned from using the preferred return address, the instruction that generated the sequence of accesses is re-executed and so any access that was performed before the exception was taken is repeated. This also applies to an exit from Debug state.

--- Note ---
The exception behavior for these multiple access instructions means they are not suitable for use for writes to memory for the purpose of software synchronization.

---

For implicit accesses:

- Cache line fills and evictions have no effect on the single-copy atomicity of explicit transactions or instruction fetches.

- Instruction fetches are single-copy atomic:
  - At 32-bit granularity in A32 state.
  - At 16-bit granularity in T32 state.

Concurrent modification and execution of instructions on page E2-4018 describes additional constraints on the behavior of instruction fetches.

- Translation table walks are performed using accesses that are single-copy atomic:
  - At 32-bit granularity when using Short-descriptor format translation tables.
  - At 64-bit granularity when using Long-descriptor format translation tables.

--- E2.2.2 Properties of single-copy atomic accesses ---
A memory access instruction that is single-copy atomic has the following properties:

1. For a pair of overlapping single-copy atomic store instructions, all of the overlapping writes generated by one of the stores are Coherence-after the corresponding overlapping writes generated by the other store.

2. For a single-copy atomic load instruction L1 that overlaps a single-copy atomic store instruction S2, if one of the overlapping reads generated by L1 Reads-from one of the overlapping writes generated by S2, then none of the overlapping writes generated by S2 are Coherence-after the corresponding overlapping reads generated by L1.

For more information, see Definition of the Armv8 memory model on page E2-4020.

--- E2.2.3 Multi-copy atomicity ---
In a multiprocessing system, writes to a memory location are multi-copy atomic if the following conditions are both true:

- All writes to the same location are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
• A read of a location does not return the value of a write until all observers observe that write.

--- Note ---
Writs that are not coherent are not multi-copy atomic.

E2.2.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory, writes are not required to be multi-copy atomic.

The Armv8 memory model is Other-multi-copy atomic. For more information, see Ordering constraints on page E2-4024.

E2.2.5 Concurrent modification and execution of instructions

The Armv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where the instruction before modification and the instruction after modification are:

• When executing the A32 instruction set, a B, BKPT, BL, HVC, ISB, NOP, SMC, or SVC instruction.
• When executing the T32 instruction set, a 16-bit B, BKPT, BLX, BX, NOP, or SVC instruction.

In addition, for the 32-bit T32 instructions, for which Instruction encodings on page F2-4116 describes the meaning of \{hw1, hw2\}:

• hw1 of a 32-bit BL (immediate) instruction can be concurrently modified to hw1 of another BL (immediate) instruction:
  — This means that some of the most significant bits of the immediate value can be modified.

• hw1 of a 32-bit BLX (immediate) instruction can be concurrently modified to hw1 of another BLX immediate instruction:
  — This means that some of the most significant bits of the immediate value can be modified.

• hw1 of a 32-bit BL (immediate) or BLX (immediate) instruction can be concurrently modified to a T32 16-bit B, BX, BLX, BKPT, or SVC instruction. This modification also works in reverse.

• hw2 of a 32-bit BL (immediate) instruction can be concurrently modified to hw2 of another BL (immediate) instruction with a different immediate:
  — This means that some bits of the immediate value, including the least significant bits, can be modified.

• hw2 of a 32-bit BLX (immediate) instruction can be concurrently modified to hw2 of another BLX (immediate) instruction with a different immediate:
  — This means that some bits of the immediate value, including the least significant bits, can be modified.

• hw2 of a 32-bit B (immediate) instruction with a condition field can be concurrently modified to hw2 of another 32-bit B (immediate) instruction with a condition field with a different immediate:
  — This means that some bits of the immediate value, including the least significant bits, can be modified.

• hw2 of a 32-bit B (immediate) instruction without a condition field can be concurrently modified to hw2 of another 32-bit B (immediate) instruction without a condition field:
  — This means that some bits of the immediate value, including the least significant bits, can be modified.

--- Note ---
• In the T32 instruction set:
  — The only encodings of BKPT and SVC are 16-bit.
The only encoding of BL is 32-bit.

- The 15$^\text{th}$ instruction can be concurrently modified and executed in the A32 and A64 instruction sets, but not in the T32 instruction set.

For the instructions explicitly identified in this section, the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

The instructions to which this applies are the B, BL, NOP, BKPT, SVC, HVC, and SMC instructions.

For both instruction sets, if one thread of execution changes a conditional branch instruction to another conditional branch instruction, and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:

- The old condition being associated with the new target address.
- The new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the always condition.

For all other instructions, to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.

2. To ensure that the modified instructions are observable, a PE that is writing the instructions must issue the following sequence of instructions and operations:

   ; Coherency example for self-modifying code
   ; Enter this code with <Rt> containing a new 32-bit instruction,
   ; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first
   ; line instead of STR for a 16-bit instruction.
   STR <Rt>, [Rn]
   DCCMVAU Rn ; Clean data cache by MVA to point of unification (PoU)
   DSB ; Ensure visibility of the data stored
   ICIMVAU Rn ; Invalidate instruction cache by VA to PoU
   BPIMVA Rn ; Invalidate branch predictor by MVA to PoU
   DSB

   __________Note_________

   - The DCCMVAU operation is not required if the area of memory is either Non-cacheable or Write-Through Cacheable.
   - If the contents of physical memory differ between the mappings, changing the mapping of VAs to PAs can cause the instructions to be concurrently modified by one PE and executed by another PE. If the modifications affect instructions other than those listed as being acceptable for modification, synchronization must be used to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.

3. In a multiprocessor system, the ICIMVAU and BPIMVA are broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, once the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

    ISB ; Synchronize fetched instruction stream

For more information about the required synchronization operation, see Synchronization and coherency issues between data and instruction accesses on page E2-4041.

For information about memory accesses caused by instruction fetches, see Ordering constraints on page E2-4024.
E2.3 Definition of the Armv8 memory model

This section describes observation and ordering in the Armv8 memory model. It contains the following subsections:

- Basic definitions.
- Dependency definitions on page E2-4022.
- Ordering relations on page E2-4023.
- Ordering constraints on page E2-4024.
- Internal visibility requirement on page E2-4024.
- External ordering constraints on page E2-4025.
- Completion and endpoint ordering on page E2-4027.
- Ordering of instruction fetches on page E2-4028.
- Restrictions on the effects of speculation on page E2-4029.
- Memory barriers on page E2-4031.

For more information on endpoint ordering of memory accesses, see Reordering on page E2-4057.

In the Armv8 memory model, the Shareability memory attribute indicates the degree to which hardware must ensure memory coherency between a set of observers, see Memory types and attributes on page E2-4050.

The Armv8 architecture defines additional memory attributes and associated behaviors, which are defined in the system level section of this manual. See:

- Chapter G4 The AArch32 System Level Memory Model.
- Chapter G5 The AArch32 Virtual Memory System Architecture.

See also Mismatched memory attributes on page E2-4060.

E2.3.1 Basic definitions

The Armv8 memory model provides a set of definitions that are used to construct conditions on the permitted sequences of accesses to memory.

Observer

An Observer refers to a processing element or mechanism in the system, such as a peripheral device, that can generate reads from, or writes to, memory.

Common Shareability Domain

For the purpose of this section, all Observers are assumed to belong to a Common Shareability Domain. All read and write effects access only Normal memory locations in a Common Shareability Domain, and excludes the situations described in Mismatched memory attributes on page E2-4060.

Location

A Location refers to a single byte in memory.

Effects

The Effects of an instruction can be:

- Register effects.
- Memory effects.
- Barrier effects.
- Points of divergence.

The effects of an instruction I1 are said to appear in program order before the effects of an instruction I2 if and only if I1 occurs before I2 in the order specified by the program. Each effect generated by an instruction has a unique identifier, which characterizes it amongst the events generated by the same instruction.
Register effect

The Register effects of an instruction are register reads or register writes of that instruction. For an instruction that accesses registers, a register read effect is generated for each register read by the instruction and a register write effect is generated for each register written by the instruction. An instruction may generate both read and write register Register effects.

Memory effect

The Memory effects of an instruction are the read or write effects of that instruction. For an instruction that accesses memory, a read effect is generated for each Location read by the instruction and a write effect is generated for each Location written by the instruction. An instruction may generate both read and write Memory effects.

Point of divergence

The Points of divergence of an instruction are effects which correspond to a branching decision being taken. At each point of divergence, the program order is split into two distinct branches, called executed and speculated branch respectively. The minimal Points of divergence in a program execution are the Points of divergence which have no other Point of divergence before them in program order.

Intrinsic order

There is a per-instruction Intrinsic order relation that provides a partial order over the effects of that instruction, according to the operation of that instruction. The operation of an instruction is defined by the pseudocode in Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions.

Reads-from-register

The Reads-from-register relation couples reads and writes to the same register such that each register read is paired with exactly one register write in the execution of a program. A read $R_2$ Reads-from-register a write $W_1$ to the same register if and only if $R_2$ takes its data from $W_1$. By construction $W_1$ must be in program order before $R_2$ and there must be no intervening write to the same register in program order between $W_1$ and $R_2$.

Reads-from

The Reads-from relation couples reads and writes to the same Location such that each read is paired with exactly one write in the execution of a program. If a read $R_2$ from a Location Reads-from a write $W_1$ to the same Location if and only if $R_2$ takes its data from $W_1$.

Coherence order

There is a per-location Coherence order relation that provides a total order over all writes from all coherent Observers to that Location, starting with a notional write of the initial value. The Coherence order of a Location represents the order in which writes to the Location arrive at memory.

Local read successor

A read $R_2$ of a Location is the Local read successor of a write $W_1$ from the same Observer to the same Location if and only if $W_1$ appears in program order before $R_2$ and there is not a write $W_3$ from the same Observer to the same Location appearing in program order between $W_1$ and $R_2$.

Local write successor

A write $W_2$ of a Location is a Local write successor of a write $W_1$ from the same Observer to the same Location if and only if $W_1$ appears in program order before $W_2$.

Coherence-after

A write $W_2$ to a Location is Coherence-after another write $W_1$ to the same Location if and only if $W_2$ is sequenced after $W_1$ in the Coherence order of the Location. A write $W_2$ to a Location is Coherence-after a read $R_1$ of the same location if and only if $R_1$ Reads-from a write $W_3$ to the same Location and $W_2$ is Coherence-after $W_3$. 

---

The AArch32 Application Level Memory Model
E2.3 Definition of the Armv8 memory model
Observed-by

A read or a write RW₁ from an Observer is Observed-by a write W₂ from a different Observer if and only if W₂ is coherence-after RW₁.

A write W₁ from an Observer is Observed-by a read R₂ from a different Observer if and only if R₂ Reads-from W₁.

Note

The Observed-by relation only relates accesses generated by different Observers.

Overlapping accesses

Two Memory effects overlap if and only if they access the same Location. Two instructions overlap if and only if one or more of their generated Memory effects overlap.

Single-copy-atomic-ordered-before

A read R₁ is Single-copy-atomic-ordered-before another read R₂ if and only if all of the following statements are true:

* R₁ and R₂ are reads generated by the same instruction.
* R₁ is not a Local read successor of a write.
* R₂ is a Local read successor of a write.

DMB FULL

A DMB FULL is a DMB with neither the LD or the ST qualifier.

Where this section refers to DMB without any qualification, then it is referring to all types of DMB. Unless a specific shareability domain is defined, a DMB applies to the Common Shareability Domain.

All properties that apply to DMB also apply to the corresponding DSB.

Context synchronization instruction

A Context synchronization instruction is one of the following:

* An ISB instruction.
* An instruction that generates a synchronous exception.
* An exception return instruction.
* A DCPS or DRPS instruction.

E2.3.2 Dependency definitions

Dependency through registers

A Dependency through registers from a first effect E₁ to a second effect E₂ exists within a PE if and only if at least one of the following applies:

* E₁ is a register write W₁ which has not been generated by a Store Exclusive, E₂ is a register read R₂ and R₂ Reads-from-register W₁.
* E₁ and E₂ have been generated by the same instruction and E₁ is before E₂ in the Intrinsic order of that instruction.
* There is a Dependency through registers from E₁ to a third effect E₃, and there is a Dependency through registers from E₃ to E₂.

Address dependency

An Address dependency from a memory read R₁ to a Memory effect RW₂ exists if and only if there is a Dependency through registers from R₁ to a Register effect E₃ generated by RW₂, and E₃ affects the address part of RW₂, and either:

* RW₂ is a Memory write effect W₂.
* RW₂ is a Memory read effect R₂ and there is no Point of divergence D₄ such that there is a Dependency through registers from R₁ to D₄ and from D₄ to R₂.
Data dependency

A *Data dependency* from a memory read R₁ to a memory write W₂ exists if and only if there is a *Dependency through registers* from R₁ to a *Register effect* E₃ generated by W₂, and E₃ affects the data part of W₂.

Control dependency

A *Control dependency* from a memory read R₁ to a subsequent *Memory effect* RW₂ exists if and only if either:

* There is a *Dependency through registers* from R₁ to *Point of divergence* D₃ and RW₂ only occurs as a result of one of the two branches of that *Point of divergence*.
* There is a *Dependency through registers* from R₁ to the determination of a synchronous exception on an instruction generating an effect RW₃, and RW₂ appears in program order after RW₃.

E2.3.3 Ordering relations

Dependency-ordered-before

A dependency creates externally-visible order between a read and another *Memory effect* generated by the same *Observer*. A read R₁ is *Dependency-ordered-before* a read or write RW₂ from the same *Observer* if and only if R₁ appears in program order before RW₂ and any of the following cases apply:

* There is an *Address dependency* or a *Data dependency* from R₁ to RW₂.
* RW₂ is a write W₂ and there is a *Control dependency* from R₁ to W₂.
* RW₂ is a read R₂ generated by an instruction appearing in program order after an instruction that generates a *Context synchronization event* E₃, and there is a *Control dependency* from R₁ to E₃.
* RW₂ is a write W₂ appearing in program order after a read or a write RW₃ and there is an *Address dependency* from R₁ to RW₃.
* RW₂ is a *Local read successor* R₂ of a write W₃ and there is an *Address dependency* or a *Data dependency* from R₁ to W₃.

 Atomic-ordered-before

Load-Exclusive and Store-Exclusive instructions provide some ordering guarantees, even in the absence of dependencies. A read or a write RW₁ is *Atomic-ordered-before* a read or a write RW₂ from the same *Observer* if and only if RW₁ appears in program order before RW₂ and either of the following cases apply:

* RW₁ is a read R₁ and RW₂ is a write W₂ such that R₁ and W₂ are generated by an atomic instruction or a successful Load-Exclusive/Store-Exclusive instruction pair to the same *Location*.
* RW₁ is a write W₁ generated by an atomic instruction or a successful Store-Exclusive instruction and RW₂ is a read R₂ generated by an instruction with Acquire semantics such that R₂ is a *Local read successor* of W₁.

For more information, see *Synchronization and semaphores* on page E2-4063.

Barrier-ordered-before

Barrier instructions order prior *Memory effects* before subsequent *Memory effects* generated by the same *Observer*. A read or a write RW₁ is *Barrier-ordered-before* a read or a write RW₂ from the same *Observer* if and only if RW₁ appears in program order before RW₂ and any of the following cases apply:

* RW₁ appears in program order before a *DMB FULL* that appears in program order before RW₂.
* RW₁ appears in program order before an atomic instruction with both Acquire and Release semantics that appears in program order before RW₂.
• RW₁ is a write W₁ generated by an instruction with Release semantics and RW₂ is a read R₂ generated by an instruction with Acquire semantics.
• RW₁ is a read R₁ and appears in program order before a DMB LD that appears in program order before RW₂.
• RW₁ is a read R₁ and is generated by an instruction with Acquire or AcquirePC semantics.
• RW₁ is a write W₁ and RW₂ is a write W₂ appearing in program order before a DMB ST that appears in program order before W₂.
• RW₂ is a write W₂ and is generated by an instruction with Release semantics.

Locally-ordered-before

Dependencies, Local write successor, Load/Store-Exclusive, atomic and barrier instructions can be composed within an Observer to create externally-visible order. A read or write RW₁ is Locally-ordered-before a read or write RW₂ from the same Observer if and only if any of the following apply:
• RW₁ is a write W₁ and RW₂ is a write W₂ that is equal to or generated by the same instruction as a Local write successor of RW₁.
• RW₁ is Dependency-ordered-before RW₂.
• RW₁ is Atomic-ordered-before RW₂.
• RW₁ is Barrier-ordered-before RW₂.
• RW₁ is Locally-ordered-before a read or a write that is Locally-ordered-before RW₂.

E2.3.4 Ordering constraints

The Armv8 memory model is described as being Other-multi-copy atomic. The definition of Other-multi-copy atomic is as follows:

Other-multi-copy atomic

In an Other-multi-copy atomic system, it is required that a write from an Observer, if observed by a different Observer, is then observed by all other Observers that access the Location coherently. It is, however, permitted for an Observer to observe its own writes prior to making them visible to other observers in the system.

The Other-multi-copy atomic property of the Armv8 memory model is enforced by placing constraints on the possible executions of a program. Those executions that meet the constraints given by the ordering model are said to be Architecturally well-formed. An implementation that is executing a program is only permitted to exhibit behavior consistent with an Architecturally well-formed execution.

Architecturally well-formed

An Architecturally well-formed execution must satisfy both the Internal visibility requirement and any of the three alternative External ordering constraints.

E2.3.5 Internal visibility requirement

For a read or a write RW₁ that appears in program order before a read or a write RW₂ to the same Location, the Internal visibility requirement requires that exactly one of the following statements is true:
• RW₂ is a write W₂ that is Coherence-after RW₁.
• RW₁ is a write W₁, RW₂ is a read R₂ and either:
  — R₂ Reads-from W₁.
  — R₂ Reads-from a write that is Coherence-after W₁.
• RW₁ and RW₂ are both reads R₁, R₂, R₁ Reads-from a write W₃ and either:
  — R₂ Reads-from W₃.
  — R₂ Reads-from a write that is Coherence-after W₃.
Informally, if a Memory effect M₁ from an Observer appears in program order before a Memory effect M₂ from the same Observer, then M₁ will be seen to occur before M₂ by that Observer.

E2.3.6 External ordering constraints

The Armv8 memory model offers the following three alternative representations of the External ordering constraint:

• External visibility requirement.
• External completion requirement.
• External global completion requirement.

An Architecturally well-formed execution must satisfy both the Internal visibility requirement and one of the three alternative representations in the External ordering constraints.

External visibility requirement

Ordered-before

An arbitrary pair of Memory effects is ordered if it can be linked by a chain of ordered accesses consistent with external observation. A read or a write RW₁ is Ordered-before a read or a write RW₂ if and only if any of the following cases apply:

• RW₁ is Observed-by a read or write RW₃ that is generated by the same instruction as RW₂.
• RW₁ is Locally-ordered-before RW₂.
• RW₁ is Ordered-before a read or a write that is Ordered-before RW₂.

For a read or a write RW₁ from an Observer that is Ordered-before a read or a write RW₂ from a different Observer, the External visibility requirement requires that RW₂ is not Observed-by RW₁. This means that an Architecturally well-formed execution must not exhibit a cycle in the Ordered-before relation.

Informally, if a Memory effect M₁ from an Observer is Ordered-before another Memory effect M₂ from a different Observer, then M₁ will be seen to occur before M₂ by all Observers in the system.

Completes-before order

The Completes-before order is a total order that corresponds to the order in which Memory effects complete within the system. The following effects constitute a single entry in the Completes-before order:

• Writes from the same instruction.
• Reads from the same instruction which read from external writes.
• Reads from the same instruction which read from the same internal write.

All other reads constitute distinct entries in the Completes-before order.

Completes-before

A read or a write RW₁ Completes-before a read or a write RW₂ if and only if RW₁ appears in the Completes-before order before RW₂.

Deriving Reads-from and Coherence order from the Completes-before order

The Completes-before order can be used to resolve the Reads-from and Coherence order relations for every memory access in the system as follows:

• For a read R₁ of a memory location by an Observer, then:
  — If there is a write W₂ to the same Location from the same Observer and all of the following are true:
    — W₂ appears in program order before R₁.
    — R₁ Completes-before W₂.
— There are no writes to the Location appearing in program order between W2 and R1 then R1 Reads-from W2.
— Otherwise, R1 Reads-from its closest preceding write in the Completes-before order to the same Location. If no such write exists, then R1 Reads-from the initial value of the memory location.

- The Coherence order of writes to a memory location is the order in which those writes appear in the Completes-before order. The final value of each memory location is therefore determined by the final write to each Location in the Completes-before order. If no such write exists for a given Location, the final value is the initial value of that Location.

External completion requirement
A read or a write RW1 Globally-completes-before a read or a write RW2 if and only if any of the following statements are true:

- RW1 is Locally-ordered-before RW2.
- RW1 is a read R1 and RW2 is a read R2 and R1 is Single-copy-atomic-ordered-before R2.

Globally-completes-before order
The Globally-completes-before order is a total order that corresponds to the order in which Memory effects globally-complete within the system. The following effects constitute a single entry in the Globally-completes-before order:

- Writes from the same instruction.
- Reads from the same instruction which read from external writes.
- Reads from the same instruction which read from the same internal write.

All other reads constitute distinct entries in the Globally-completes-before order.

Globally-completes-before
A read or a write RW1 globally-completes-before a read or a write RW2 if and only if RW1 appears in the Globally-completes-before order before RW2.

Deriving Reads-from and Coherence order from the Globally-completes-before order
The Globally-completes-before order can be used to resolve the Reads-from and Coherence order relations for every memory access in the system as follows:

- A read R1 of a memory location by an Observer Reads-from its closest preceding write in the Globally-completes-before order to the same Location. If no such write exists, then R1 Reads-from the initial value of the memory location.
- The Coherence order of writes to a memory location is the order in which those writes appear in the Globally-completes-before order. The final value of each memory location is therefore determined by the final write to each Location in the Globally-completes-before order. If no such write exists for a given Location, the final value is the initial value of that Location.

External global completion requirement
The External global completion requirement requires that a read or a write RW1 Globally-completes-before a read or a write RW2 if and only if any of the following statements are true:

- RW1 is Locally-ordered-before RW2 and either:
  — RW1 is a write.
  — RW1 is a read R1 and either:
    — R1 is not a Local read successor of a write.
    — R1 is a Local read successor of a write that is Locally-ordered-before RW2.
- RW1 is a read R1 and RW2 is a read R2 and R1 is Single-copy-atomic-ordered-before R2.
E2.3.7 Completion and endpoint ordering

Interaction between Observers in a system is not restricted to communication via shared variables in coherent memory. For example, an Observer could configure an interrupt controller to raise an interrupt on another Observer as a form of message passing. These interactions typically involve an additional agent, which defines the instruction sequence that is required to establish communication links between different Observers. When these forms of interaction are used in conjunction with shared variables, a DSB instruction can be used to enforce ordering between them.

For all memory, the completion rules are defined as:

• A read $R_1$ to a Location is complete for a shareability domain when all of the following are true:
  — Any write to the same Location by an Observer within the shareability domain will be Coherence-after $R_1$.
  — Any translation table walks associated with $R_1$ are complete for that shareability domain.

• A write $W_1$ to a Location is complete for a shareability domain when all of the following are true:
  — Any write to the same Location by an Observer within the shareability domain will be Coherence-after $W_1$.
  — Any read to the same Location by an Observer within the shareability domain will either Reads-from $W_1$ or Reads-from a write that is Coherence-after $W_1$.
  — Any translation table walks associated with the write are complete for that shareability domain.

• A translation table walk is complete for a shareability domain when the memory accesses, including the updates to translation table entries, associated with the translation table walk are complete for that shareability domain, and the TLB is updated.

• A cache or branch predictor maintenance instruction is complete for a shareability domain when the memory effects of the instruction are complete for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.

• A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.

The completion of any cache, branch predictor, or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction.

—— Note ———
These completion rules mean that, for example, a cache maintenance instruction that operates by VA to the PoC completes only after memory at the PoC has been updated.

Additionally, for Device-nGnRnE memory, a read or write of a Location in a Memory-mapped peripheral that exhibits side-effects is complete only when the read or write both:
• Can begin to affect the state of the Memory-mapped peripheral.
• Can trigger all associated side-effects, whether they affect other peripheral devices, PEs, or memory.

—— Note ———
This requirement for Device-nGnRnE memory is consistent with the memory access having reached the peripheral endpoint.
Peripherals

This section defines a Memory-mapped peripheral and the total order of reads and writes to a peripheral which is defined as the Peripheral coherence order:

**Memory-mapped peripheral**

A Memory-mapped peripheral occupies a memory region of IMPLEMENTATION DEFINED size and can be accessed using load and store instructions. Memory effects to a Memory-mapped peripheral can have side-effects, such as causing the peripheral to perform an action. Values that are read from addresses within a Memory-mapped peripheral might not correspond to the last data value written to those addresses. As such, Memory effects to a Memory-mapped peripheral might not appear in the Reads-from or Coherence order relations.

**Peripheral coherence order**

The Peripheral coherence order of a Memory-mapped peripheral is a total order on all reads and writes to that peripheral.

--- Note ---

The Peripheral coherence order for a Memory-mapped peripheral signifies the order in which accesses arrive at the endpoint.

---

For a read or a write RW₁ and a read or a write RW₂ to the same peripheral, then RW₁ will appear in the Peripheral coherence order for the peripheral before RW₂ if either of the following cases apply:

- RW₁ and RW₂ are accesses using Non-cacheable or Device attributes and RW₁ is Ordered-before RW₂.
- RW₁ and RW₂ are accesses using Device-nGnRE or Device-nGnRnE attributes and RW₁ appears in program order before RW₂.

**Out-of-band-ordered-before**

A read or a write RW₁ is Out-of-band-ordered-before a read or a write RW₂ if and only if either of the following cases apply:

- RW₁ appears in program order before a DSB instruction that begins an IMPLEMENTATION DEFINED instruction sequence indirectly leading to the generation of RW₂.
- RW₁ is Ordered-before a read or a write RW₃ and RW₃ is Out-of-band-ordered-before RW₂.

If a Memory effect M₁ is Out-of-band-ordered-before a read or a write M₂, then M₁ is seen to occur before M₂ by all Observers.

### E2.3.8 Ordering of instruction fetches

For two memory locations A and B, if A has been written to and been made coherent with the instruction fetches of the shareability domain, before an update to B by an observer in the same shareability domain, then the instruction stream of each observer in the shareability domain will not see the updated value of B without also seeing the updated value of A.

A write has been made coherent with an instruction fetch of a shareability domain when:

**CTR.\{DIC, IDC\} == \{0, 0\}**

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

**CTR.\{DIC, IDC\} == \{1, 0\}**

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain.
**CTR.\{DIC, IDC\} == \{0, 1\}**

The write is complete for the shareability domain. Subsequently the location has been invalidated to the **Point of unification (PoU)** from the instruction cache, and that invalidation is complete for the shareability domain.

**CTR.\{DIC, IDC\} == \{1, 1\}**

The write is complete for the shareability domain.

--- **Note** ---

Microarchitecturally, this means that these situations cannot both be true in an implementation:

- After delays in fetching from memory, the instruction queue can have entries written into it out of order.
- For an implementation:
  - When CTR.DIC == 0, if there is an outstanding entry in the instruction queue, then later entries in the instruction queue are not impacted by the **ICIMVAU** instructions of a different core.
  - When CTR.DIC == 1, if there is a write to the location that is held in the queue when there is an outstanding entry in the instruction queue for an older entry, then the instruction queue does not have entries invalidated from it.

---

### E2.3.9 Restrictions on the effects of speculation

This section covers restrictions on speculation effects, including:

- **Restrictions on the effects of speculation.**
- **Speculative Store Bypass Safe (SSBS) on page E2-4030.**
- **Further restrictions on the effects of speculation from Armv8.5 on page E2-4030.**

**Restrictions on the effects of speculation**

The Arm architecture places certain restrictions on the effects of speculation. These are:

- Each load from a location using a particular VA after an exception return that is a **Context synchronization event** will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception exit.

- Each load from a location using a particular VA after an exception entry that is a **Context synchronization event** will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception entry.

- Any load from a location using a particular VA before an exception entry that is a **Context synchronization event** will not speculatively read data from a store to the same location using the same VA after the exception entry.

- Any load from a location using a particular VA before an exception return that is a **Context synchronization event** will not speculatively read data from a store to the same location using the same VA after the exception exit.

- When data is loaded under speculation with a translation fault, it cannot be used to form an address or generate condition codes to be used by instructions newer than the load in the speculative sequence.

- When data is loaded under speculation from a location without a translation for the translation regime being speculated in, the data cannot be used to form an address or generate condition codes to be used by instructions newer than the load in the speculative sequence.

- Changes to System registers must not occur speculatively in a way that can affect a speculative memory access that can cause a change to the micro-architectural state.
• Changes to Special-purpose registers can occur speculatively.

**Speculative Store Bypass Safe (SSBS)**

When `FEAT_SSBS` is implemented, `CPSR.SSBS` is a control that can be set by software to indicate whether hardware is permitted to load or store speculatively, in a manner that could be exploited to produce a cache timing side channel using an address derived from a register value that has been loaded from memory using a load instruction that speculatively read an entry for the location being loaded from, where the entry that is speculatively read is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

When the value of `CPSR.SSBS` is 0, hardware is not permitted to load or store speculatively in this way.

When the value of `CPSR.SSBS` is 1, hardware is permitted to load or store speculatively in this way.

---

**Note**

- If speculation is permitted, then cache timing side channels can lead to addresses being derived using reads of address values that have been speculatively loaded from memory to a register.

- Software written for architectures from Armv8.0 to Armv8.4 will set `SPSR.SSBS` to 0. This means that `CPSR.SSBS` will not set, so hardware will not be permitted to use speculative loads with outstanding memory disambiguation issues for any subsequent speculative memory accesses if there is any possibility of those subsequent memory accesses creating a cache timing side channel.

---

**Further restrictions on the effects of speculation from Armv8.5**

From Armv8.5, there are some further restrictions on the effects of speculation in addition to those in Armv8.0:

- Data loaded under speculation with a permission or domain fault cannot be used to form an address or to generate condition codes to be used by instructions newer than the load in the speculative sequence.

- Any System register read under speculation to a register that is not architecturally accessible from the current Exception level cannot be used to form an address or to generate condition codes to be used by instructions newer than the load in the speculative sequence.

---

**Note**

As the effects of speculation are not architecturally visible, this restriction level requires that the effect of any speculation cannot give rise to side channels that will leak the values of memory locations, System registers, or Special-purpose registers to a level of privilege that would otherwise not be able to determine those values.

---

- For all execution prediction resources that predict address or register values, speculative execution at one hardware defined context should be separated in a hard-to-determine manner from the predictions trained in a different hardware defined context. In the case of this definition, the hardware defined context is determined by:
  - The Exception level.
  - The Security state.
  - When executing at EL1 and when EL2 is enabled in the current Security state, the VMID.
  - When executing at EL0 and using the EL1&0 translation regime, the ASID and, when EL2 is enabled in the current Security state, the VMID.
  - When executing at EL0 and using the EL2&0 translation regime, the ASID.

---

**Note**

- The definition of “hard-to-determine manner” is left open to implementations. Examples could include the complete separation of prediction resources, or the isolation of the predictions using a cryptographic or pseudo-random mechanism to separate each context.
— The architecture does not require that prediction resources that simply predict the direction of a branch are separated in this way.

• Changes to System registers must not occur speculatively in a way that can affect a speculative memory access that can cause a change to the micro-architectural state.

• Changes to Special-purpose registers can occur speculatively.

### E2.3.10 Memory barriers

The Arm architecture is a weakly ordered memory architecture that supports out of order completion. *Memory barrier* is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring Load/Store instructions. The memory barriers defined by the Armv8 architecture provide a range of functionality, including:

• Ordering of Load/Store instructions.
• Completion of Load/Store instructions.
• Context synchronization.

The following subsections describe the Armv8 memory barrier instructions:

• *Instruction Synchronization Barrier (ISB)* on page E2-4032.
• *Data Memory Barrier (DMB)* on page E2-4032.
• *Data Synchronization Barrier (DSB)* on page E2-4032.
• *Speculation Barrier (SB)* on page E2-4033.
• *Consumption of Speculative Data Barrier (CSDB)* on page E2-4033.
• *Speculative Store Bypass Barrier (SSBB)* on page E2-4034.
• *Physical Speculative Store Bypass Barrier (PSSBB)* on page E2-4034.
• *Trace Synchronization Barrier (TSB CSYNC)* on page E2-4034.
• *Shareability and access limitations on the data barrier operations* on page E2-4035.
• *Load-Acquire, Store-Release* on page E2-4036.

**Note**

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are only available when software execution is at EL1 or higher.

The DMB and DSB memory barriers affect reads and writes to the memory system generated by Load/Store instructions and data or unified cache maintenance instructions being executed by the PE. Instruction fetches or accesses caused by a hardware translation table access are not explicit accesses.

AArch32 state also supports the legacy barrier instructions CP15DMB, CP15DSB, and CP15ISB. These instructions are executed as MCRs using the appropriate encoding, and are accessible from EL0. However, for performance reasons Arm deprecates any use of these operations, and strongly recommends that software uses the DMB, DSB, and ISB instructions described in this section instead. Optionally, an implementation can support a CP15BEN control that supervisory software can use to disable use of these instructions, meaning the corresponding MCR encodings are UNDEFINED. When the CP15BEN control is supported, setting one of the following CP15BEN fields to 0 makes execution of CP15DMB, CP15DSB, and CP15ISB UNDEFINED:

- SCTLR_EL1.CP15BEN, for execution of these instructions at EL0 using AArch32 when EL1 is using AArch64.
- SCTLR.CP15BEN, for execution of these instructions at EL0 or EL1 when EL1 is using AArch32.
- HSCTLR.CP15BEN, for execution of these instructions at EL2 when EL2 is using AArch32.
Instruction Synchronization Barrier (ISB)

An ISB instruction ensures that all instructions that come after the ISB instruction in program order are fetched from the cache or memory after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction. Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to System registers.

Any context-changing operations appearing in program order after the ISB instruction only take effect after the ISB has been executed.

The pseudocode function for the operation of an ISB is InstructionSynchronizationBarrier().

See also Memory barriers on page G4-5959.

Data Memory Barrier (DMB)

The DMB instruction is a memory barrier instruction that ensures the relative order of memory accesses before the barrier with memory accesses after the barrier. The DMB instruction does not ensure the completion of any of the memory accesses for which it ensures relative order.

The full definition of the DMB instruction is covered formally in the Definition of the Armv8 memory model on page E2-4020 and this introduction to the DMB instruction is not intended to contradict that section.

The basic principle of a DMB instruction is to introduce order between memory accesses that are specified to be affected by the DMB options supplied as arguments to the DMB instruction. The DMB instruction ensures that all affected memory accesses by the PE executing the DMB instruction that appear in program order before the DMB instruction and those which originate from a different PE, to the extent required by the DMB options, which have been Observed-by the PE before the DMB instruction is executed, are Observed-by each PE, to the extent required by the DMB options, before any affected memory accesses that appear in program order after the DMB instruction are Observed-by that PE.

The use of a DMB instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The pseudocode function for the operation of a DMB instruction is DataMemoryBarrier().

Data Synchronization Barrier (DSB)

A DSB instruction is a memory barrier that ensures that memory accesses that occur before the DSB instruction have completed before the completion of the DSB instruction. In doing this, it acts as a stronger barrier than a DMB and all ordering that is created by a DMB with specific options is also generated by a DSB with the same options.

Execution of a DSB at EL2 ensures that any memory accesses caused by speculative translation table walks from the Non-secure PL1&0 translation regime have been observed.

For more information, see Use of out-of-context translation regimes on page G5-5968.

A DSB executed by a PE, PEe, completes when all of the following apply:

- All explicit memory accesses of the required access types appearing in program order before the DSB are complete for the set of observers in the required shareability domain.
- If the required access types of the DSB is reads and writes, then all cache maintenance instructions, all TLB maintenance instructions, and all PSB CYNC instructions issued by PEe before the DSB are complete for the required shareability domain.

In addition, no instruction that appears in program order after the DSB instruction can alter any state of the system or perform any part of its functionality until the DSB completes, other than:

- Being fetched from memory and decoded.
• Reading the general-purpose, SIMD and floating-point, Special-purpose, or System registers that are directly or indirectly read without causing side-effects.

The pseudocode function for the operation of a DSB is `DataSynchronizationBarrier()`.

See also Memory barrier instructions on page G4-5956 and Memory barriers on page G4-5959.

Speculation Barrier (SB)

An SB is a memory barrier that prevents speculative execution of instructions until after the barrier has completed when those instructions could be observed through side-channels.

Until the barrier completes, the speculative execution of any instruction appearing later in the program order than the barrier:
• Cannot be performed to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
• Can be performed when predicting that an instruction that could generate an exception does not generate an exception.

Speculative execution of an SB instruction:
• Cannot be as a result of control flow speculation.
• Cannot be as a result of data value speculation.
• Can be as a result of predicting that an instruction that could generate an exception does not generate an exception.

An SB instruction can complete when:
• It is known that it is not speculative.
• All the predicted data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

Note

The SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched, so long as the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after an uncompleted SB instruction.

Consumption of Speculative Data Barrier (CSDB)

The CSDB instruction is a memory barrier instruction that controls speculative execution and data value prediction. This includes:
• Data value predictions of any instructions.
• PSTATE.\{N,Z,C,V\} predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
• Predictions of SVE prediction state for any SVE instructions.

For purposes of the definition of CSDB, PSTATE.\{N,Z,C,V\} is not considered a data value. This definition permits:
• Control flow speculation before and after the CSDB.
• Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.\{N,Z,C,V\} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.
Speculative Store Bypass Barrier (SSBB)

The SSBB instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the SSBB instruction.

- When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order after the SSBB instruction.

Physical Speculative Store Bypass Barrier (PSSBB)

The PSSBB instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB instruction.

- When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order after the PSSBB instruction.

--- Note ---

The effect of this barrier applies to accesses to the same location even if they are accessed with different virtual addresses and from different Exception levels.

---

Trace Synchronization Barrier (TSB CSYNC)

The TSB CSYNC is a memory barrier instruction that preserves the relative order of memory accesses to System registers due to trace operations and other memory accesses to the same registers.

A trace operation is an operation of the PE Trace Unit generating trace for an instruction when FEAT_TRF is implemented and enabled.

A TSB CSYNC is not required to execute in program order with respect to other instructions. This includes being reordered with respect to other trace instructions. One or more context synchronization events are required to ensure that TSB CSYNC is executed in the necessary order.

If trace is generated between a context synchronization event and a TSB CSYNC operation, these trace operations may be reordered with respect to the TSB CSYNC operation, and therefore may not be synchronized.
The following situations are synchronized using a TSB CSYNC:

- A direct write B to a System register is ordered after an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all of the following are true:
  - A is executed in program order before a context synchronization event C.
  - C is in program order before a TSB CSYNC operation T.
  - B is executed in program order after T.

- A direct read B of a System register is ordered after an indirect write to the same register by a trace operation of a traced instruction A if all the following are true:
  - A is executed in program order before a context synchronization event C1.
  - C1 is in program order before TSB CSYNC operation T.
  - T is executed in program order before a second context synchronization event C2.
  - B is executed in program order after C2.

A TSB CSYNC is not needed when a direct write B to a System register is ordered before an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all the following are true:

- A is executed in program order after a context synchronization event C.
- B is executed in program order before C.

The pseudocode function for the operation of a TSB CSYNC is `TraceSynchronizationBarrier()`.

**Shareability and access limitations on the data barrier operations**

The DMB and DSB instructions can each take an optional limitation argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
  - Full system.
  - Outer Shareable.
  - Inner Shareable.
  - Non-shareable.

  Full system applies to all the observers in the system and, as such, encompasses the Inner and Outer Shareable domains of the processor.

  ______ Note _______

  The distinction between Full system and Outer Shareable is only applicable for Normal Non-Cacheable memory accesses and Device memory accesses.

  ______ Note _______

  The accesses for which the instruction operates. This is one of:
  - Read and write accesses, both before and after the barrier instruction.
  - Write accesses only, before and after the barrier instruction.
  - Read accesses before the barrier instruction, and read and write accesses after the barrier instruction.

  ______ Note _______

  This form of a DMB or DSB instruction can be described as a Load-Load/Store barrier.

For more information on whether an access is before or after a barrier instruction, see `Data Memory Barrier (DMB)` on page E2-4032 or `Data Synchronization Barrier (DSB)` on page E2-4032.
Table E2-1 shows how these options are encoded in the <option> field of the instruction.

<table>
<thead>
<tr>
<th>Accesses</th>
<th>Shareability domain</th>
<th>Before the barrier</th>
<th>After the barrier</th>
<th>Full system</th>
<th>Outer Shareable</th>
<th>Inner Shareable</th>
<th>Non-shareable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reads and writes</td>
<td>SY</td>
<td>OSH</td>
<td>ISH</td>
<td>NSH</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Writes</td>
<td>ST</td>
<td>OSHST</td>
<td>ISHST</td>
<td>NSHST</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Reads</td>
<td>LD</td>
<td>OSHLD</td>
<td>ISHLD</td>
<td>NSHLD</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If no <option> is specified then the instruction operates for read and write accesses, over the full system, meaning the operation is the same as for the SY option. See the instruction descriptions for more information:
- DMB on page F5-4392.
- DSB on page F5-4395.

**Note**

ISB also supports an optional limitation argument that can only contain one value that corresponds to full system operation, see ISB on page F5-4415.

### Load-Acquire, Store-Release

Armv8 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores.

The full definition of the Load-Acquire instruction is covered formally in the Definition of the Armv8 memory model on page E2-4020 and this introduction to the Load-Acquire instruction is not intended to contradict that section.

The basic principle of a Load-Acquire instruction is to introduce order between the memory access generated by the Load-Acquire instruction and the memory accesses appearing in program order after the Load-Acquire instruction, such that the memory access generated by the Load-Acquire instruction is Observed-by each PE, to the extent that that PE is required to observe the access coherently, before any of the memory accesses appearing in program order after the Load-Acquire instruction are Observed-by that PE, to the extent that the PE is required to observe the accesses coherently.

The use of a Load-Acquire instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The full definition of the Store-Release instruction is covered formally in the Definition of the Armv8 memory model on page E2-4020 and this introduction to the Store-Release instruction is not intended to contradict that section.

The basic principle of a Store-Release instruction is to introduce order between the memory accesses generated by the PEe executing the Store-Release instruction, together with those which originate from a different PE, to the extent that the PEe is required to observe them coherently, Observed-by the PEe before executing the Store-release.

The use of a Store-Release instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

In addition, the use of a Load-Acquire or a Store-Release instruction on accesses to a Memory-mapped peripheral introduces order between the Memory effects of the instructions that access that peripheral, as described in the definition of Peripheral coherence order.

Load-Acquire and Store-Release, other than LDAEXD and STLEXD, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

LDAEXD and STLEXD access two data elements. The address supplied to the instructions must be doubleword aligned, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the release semantics if the store is successful.
Note

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
  - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
  - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.
- The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction.

Table E2-2 summarizes the Load-Acquire/Store-release instructions.

<table>

</tbody>
</table>
E2.4 Ordering of translation table walks

If FEAT_ETS is implemented, and a memory access RW₁ is Ordered-before a second memory access RW₂, then RW₁ is also Ordered-before any translation table walk generated by RW₂ that generates any of the following:

- A Translation fault.
- An Address size fault.
- An Access flag fault.
E2.5 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. Armv8 defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- Introduction to caches.
- Memory hierarchy.
- Implication of caches for the application programmer on page E2-4040.
- Preloading caches on page E2-4042.

E2.5.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a tag.
- The associated data.

Caches increase the average speed of a memory access and take account of two principles of locality:

**Spatial locality**

An access to one location is likely to be followed by accesses to adjacent locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

**Temporal locality**

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a cache line. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. Armv8 permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

E2.5.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an Armv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure E2-1 on page E2-4040 shows an example of such a system in an Armv8-A system that supports virtual addressing.
The AArch32 Application Level Memory Model

E2.5 Caches and memory hierarchy

Note
In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the PE, as shown in Figure E2-1.

Note
Armv8 FEAT_DPB adds architectural support for an additional conceptual point, Point of Persistence, but this support is provided only in AArch64 state. For more information see About cache maintenance in AArch64 state on page D4-2500.

The Cacheability and Shareability memory attributes

Cacheability and Shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

**Cacheability** This term defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.

**Shareability** This term defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about the Cacheability and Shareability attributes see Memory types and attributes on page E2-4050.

E2.5.3 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.
For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.

- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

**Data coherency issues**

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  - Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  - Not enabling caches in the system.

- By using system calls to functions using cache maintenance instructions that execute at a higher Exception level.

- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see Non-shareable Normal memory on page E2-4052 and Shareable, Inner Shareable, and Outer Shareable Normal memory on page E2-4051.

**Note**

The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

**Synchronization and coherency issues between data and instruction accesses**

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last Context synchronization event on that PE.

- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being re-fetched from memory.

The Arm architecture does not require the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory.

If software requires coherency between instruction execution and memory, it must manage this coherency using Context synchronization events and cache maintenance instructions. These can only be accessed from an Exception level that is higher than EL0, and therefore require a system call, see Exception-generating and exception-handling instructions on page F1-4095. The following code sequence can be used for this purpose:

```asm
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.
STR Rt, [Rn]
DCCMVAU Rn          ; Clean data cache by MVA to point of unification (PoU)
DSB                  ; Ensure visibility of the data cleaned from cache
ICIMVAU Rn           ; Invalidate instruction cache by MVA to PoU
BPIMVA  Rn           ; Invalidate branch predictor by MVA to PoU
DSB                  ; Ensure completion of the invalidations
ISB                  ; Synchronize the fetched instruction stream
```
A write has been made coherent with an instruction fetch of a shareability domain when:

CTR.{DIC, IDC} == \{0, 0\}

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR.{DIC, IDC} == \{1, 0\}

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain.

CTR.{DIC, IDC} == \{0, 1\}

The write is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR.{DIC, IDC} == \{1, 1\}

The write is complete for the shareability domain.

---

**Note**

- For accesses that are Non-cacheable or Write-Through, the clean data cache instruction is not required. For accesses that are Non-cacheable, the invalidate instruction cache is not required, because in AArch32 state these accesses are not permitted to be held in an instruction cache.

- This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The Armv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See *Concurrent modification and execution of instructions* on page E2-4018.

---

**E2.5.4 Preloading caches**

The Arm architecture provides the memory system hints PLD (Preload Data), PLDW (Preload Data With Intent To Write) and PLI (Preload Instruction) that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as NOPs without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous External abort, which is reported using an SError interrupt and taken using an asynchronous Data Abort exception. For more information, see *Data Abort exception* on page G1-5789.

A PLD, PLDW, or PLI instruction can only cause allocation to software-visible caching structures such caches or TLBs for memory locations that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

- Reads.
- Writes.
- Instruction fetches.

A PLD, PLDW, or PLI instruction can access any memory location in Normal memory that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

- Reads.
- Writes.
- Instruction fetches.
Note

In each case, the entire list applies to each of PLD, PLD\textsubscript{w}, and PLI.

A PLD, PLD\textsubscript{w}, or PLI instruction is guaranteed not to access any type of Device memory.

A PLI instruction must not perform any access that cannot be performed by a speculative instruction fetch by the processor. Therefore in a VMSA implementation, if all associated MMUs are disabled, a PLI instruction cannot access any memory location that cannot be accessed by instruction fetches.

The pseudocode enumeration \texttt{PrefetchHint} defines the prefetch hint types.

The \texttt{Hint_Prefetch()} pseudocode function signals to the memory system that memory accesses of the type hint to or from the specified address are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level target and non-temporal hint stream.

For more information on PLD, PLI, and PLD\textsubscript{w}, see:

- \texttt{PLD, PLDW (immediate)} on page F5-4612.
- \texttt{PLD (literal)} on page F5-4614.
- \texttt{PLD, PLDW (register)} on page F5-4616.
- \texttt{PLI (immediate, literal)} on page F5-4618.
- \texttt{PLI (register)} on page F5-4621.
E2.6 Alignment support

This section describes alignment support. It contains the following subsections:

- Instruction alignment.
- Unaligned data access.
- Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE on page E2-4045.
- Unaligned data access restrictions on page E2-4045.
- Generation of Alignment faults by Load/store multiple accesses to Device memory on page E2-4045.

For more information about Alignment faults see Alignment faults on page G5-6060.

E2.6.1 Instruction alignment

A32 instructions are word-aligned.

T32 instructions are halfword-aligned.

E2.6.2 Unaligned data access

An Armv8 implementation must support unaligned data accesses to Normal memory by some load and store instructions. As Table E2-3 shows, software can control whether a misaligned access to Normal memory by one of these instructions causes an Alignment fault Data Abort exception:

- By setting SCTLR.A, for unaligned accesses from any mode other than Hyp mode.
- By setting HSCTLR.A, for unaligned accesses from Hyp mode.

### Table E2-3 Alignment requirements of load/store instructions

<tr>
<td>VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with :align specified</td>
<td>As specified by :align</td>
<td>Alignment fault</td>
</tr>
</tbody>
</table>

a. Previous versions of this manual used @<align> to specify alignment. Both forms are supported, see Chapter F6 T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions for more information.
Note
Any unaligned access to any type of Device memory generates an Alignment fault, see Alignment faults on page G5-6060.

E2.6.3 Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE

Any load instruction that is not faulted by the alignment restrictions shown in Table E2-3 on page E2-4044 and that loads the PC has CONSTRAINED UNPREDICTABLE behavior if the address it loads from is not word-aligned, see Loads and Stores to unaligned locations on page K1-7942. This overrules any permitted Load/Store behavior shown in Table E2-3 on page E2-4044.

E2.6.4 Unaligned data access restrictions

The following points apply to unaligned data accesses in Armv8:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see Atomicity in the Arm architecture on page E2-4016.
- Unaligned accesses typically take a number of additional cycles to complete compared to a naturally-aligned access.
- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary.

E2.6.5 Generation of Alignment faults by Load/store multiple accesses to Device memory

When FEAT_LSMAOC is implemented and the value of the applicable nTLSMD field is 0, any memory access by an AArch32 Load Multiple or Store Multiple instruction to an address that the stage 1 translation assigns as Device-nGRE, Device-nGnRE, or Device-nGnRnE generates an Alignment fault.

The applicable nTLSMD field is the field in the SCTLR_EL1, SCTLR_EL2, HSCTLR, or SCTLR register that applies to the Exception level and Security state at which the LDM or STM instruction is executed.
E2.7 Endian support

General description of endianness in the Arm architecture describes the relationship between endianness and memory addressing in the Arm architecture.

The following subsections then describe the endianness schemes supported by the architecture:
- Instruction endianness.
- Data endianness on page E2-4047.
- Endianness of memory-mapped peripherals on page E2-4048.

E2.7.1 General description of endianness in the Arm architecture

This section only describes memory addressing and the effects of endianness for data elements up to doubleword of 64 bits. However, this description can be extended to apply to larger data elements.

For an address A, Figure E2-2 shows, for big-endian and little-endian memory systems, the relationship between:
- The doubleword at address A.
- The words at addresses A and A+4.
- The halfwords at addresses A, A+2, A+4, and A+6.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, and A+7.

The terms in Figure E2-2 have the following definitions:
- MSByte Most-significant byte.
- LSBYTE Least-significant byte.

![Diagram showing endianness relationships in AArch32 state](image)

In this figure, Byte, A+1 is an abbreviation for Byte at address A+1

E2.7.2 Instruction endianness

In Armv8-A, the mapping of instruction memory is always little-endian.
### E2.7.3 Data endianness

The size of the data value that is loaded or stored is the size that is used for the purpose of endian conversion for floating-point, Advanced SIMD, and general-purpose register loads and stores.

Table E2-4 shows the element sizes of all the load/store instructions, for all instruction sets.

<table>
<thead>
<tr>
<th>Instructions</th>
<th>Element size</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, TBB</td>
<td>Byte</td>
</tr>
<tr>
<td>LDRH, LDREXH, LDRHT, LDRSH, LDRSHT, STRH, STREXH, STRHT, TBH</td>
<td>Halfword</td>
</tr>
<tr>
<td>LDR, LDRT, LDREX, STR, STRT, STREX</td>
<td>Word</td>
</tr>
<tr>
<td>LDRD, LDREXD, STRD, STREXD</td>
<td>Word</td>
</tr>
<tr>
<td>All forms of LDM, PUSH, POP, RFE, SRS, all forms of STM,</td>
<td>Word</td>
</tr>
<tr>
<td>LDC, STC</td>
<td>Word</td>
</tr>
<tr>
<td>Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 32-bit Si registers</td>
<td>Word</td>
</tr>
<tr>
<td>Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 64-bit Di registers</td>
<td>Doubleword</td>
</tr>
<tr>
<td>VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4</td>
<td>Element size of the Advanced SIMD access</td>
</tr>
</tbody>
</table>

CPSR.E determines the data endianness.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for Advanced SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for Advanced SIMD element and data structure loads and stores. For more information see *Endianness in Advanced SIMD* on page E2-4048.

### Instructions to reverse bytes in registers

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table E2-5 shows the instructions that provide this functionality in the A32 and T32 instruction sets.

<table>
<thead>
<tr>
<th>Function</th>
<th>T32 / A32 instruction</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reverse bytes in whole register</td>
<td>REV</td>
<td>For use with general purpose registers.</td>
</tr>
<tr>

<td>REVSH</td>
<td>For use with general purpose registers.</td>
</tr>
</tbody>
</table>
Endianness in Advanced SIMD

Advanced SIMD element Load/Store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used by the PE to load and store data correctly in both big-endian and little-endian systems.

Consider, for example, the A32 or T32 instruction:

\[
\text{VLD1.16 \{D0\}, \[R1\]}
\]

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure E2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

### Table E2-5 Byte reversal instructions (continued)

#### Endianness in Advanced SIMD

For information about the alignment of Advanced SIMD instructions see Alignment support on page E2-4044.

The \texttt{BigEndian()} pseudocode function determines the current endianness of the data.

The \texttt{BigEndianReverse()} pseudocode function reverses the endianness of a bitstring.

The \texttt{BigEndian()} and \texttt{BigEndianReverse()} functions are defined in Chapter J1 Armv8 Pseudocode.

#### E2.7.4 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the Arm architecture must be little-endian.
Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a cross-trigger interface, see Chapter H8 About the External Debug Registers.
- The memory-mapped register interface to the system level implementation of the Generic Timer, see Chapter I2 System Level Implementation of the Generic Timer.
- A memory-mapped register interface to the Performance Monitors, see Chapter I3 Recommended External Interface to the Performance Monitors.
- A memory-mapped register interface to the Activity Monitors, see Chapter I4 Recommended External Interface to the Activity Monitors.
- Memory-mapped register interfaces to an Arm Generic Interface Controller, see the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0.
- The memory-mapped register interface to an Arm trace component. See, for example, the ARM® Embedded Trace Macrocell Architecture Specification, ETMv4.
E2.8 Memory types and attributes

In Armv8 the ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- Normal memory.
- Device memory on page E2-4054.
- Memory access restrictions on page E2-4059.

E2.8.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform Speculative data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time.
- Writes to a memory location with the Normal memory type that is either Non-cacheable or Write-through cacheable for both the Inner and Outer cacheability must reach the endpoint for that location in the memory system in finite time. Two writes to the same location, where at least one is using the Normal memory type, might be merged before they reach the endpoint unless there is an ordered-before relationship between the two writes.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See Multi-register loads and stores that access Normal memory on page E2-4054.

Note:
- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side-effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.
- Normal memory allows speculative reads and may be affected by intermediate buffering and forwarding of data. If non-idempotent memory locations are mapped as Normal memory, the following may occur:
  - Memory accesses return UNKNOWN values.
  - UNPREDICTABLE effects on memory-mapped peripherals.
- An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture on page E2-4016 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The following sections describe the other attributes for Normal memory:

- Shareable Normal memory on page E2-4051.
- Non-shareable Normal memory on page E2-4052.
- Cacheability attributes for Normal memory on page E2-4052.
See also:

- Multi-register loads and stores that access Normal memory on page E2-4054.
- Atomicity in the Arm architecture on page E2-4016.
- Memory barriers on page E2-4031. For accesses to Normal memory, a DMB instruction is required to ensure the required ordering.
- Concurrent modification and execution of instructions on page E2-4018.

Shareable Normal memory

A Normal memory location has a Shareability attribute that is defined as one of:

- Inner Shareable.
- Outer Shareable.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, that hardware must enforce. They do not affect the coherency requirements of instruction fetches, see Synchronization and coherency issues between data and instruction accesses on page E2-4041.

Note

- System designers can use the Shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the Shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different PEs.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

Shareable, Inner Shareable, and Outer Shareable Normal memory

The Arm architecture abstracts the system as a series of Inner and Outer Shareability domains. Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set. Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
- The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.
The details of the use of the Shareability attributes are system-specific. Example E2-1 shows how they might be used.

Example E2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.

- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different Shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same Shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable Shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable Shareability domain.

For Shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

Cacheability attributes for Normal memory

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Through Cacheable.
- Write-Back Cacheable.
- Non-cacheable.

Also, for Write-Through Cacheable and Write-Back Cacheable Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

For more information see Cacheability, cache allocation hints, and cache transient hints on page G4-5932.
A memory location can be marked as having different cacheability attributes, for example when using aliases in a VA to PA mapping:

- If the attributes differ only in the cache allocation hint this does not affect the behavior of accesses to that location.
- For other cases see Mismatched memory attributes on page E2-4060.

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the Shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

- A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.
- A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

--- Note ---
Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the Arm architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the inner and the outer cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.
- An implementation might not have any outer cache.

Example E2-2, Example E2-3 on page E2-4054, and Example E2-4 on page E2-4054 describe the possible ways of implementing a system with three levels of cache, level 1 (L1) to level 3 (L3).

--- Note ---
- L1 cache is the level closest to the PE, see Memory hierarchy on page E2-4039.
- When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the Shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example E2-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 and L2 cache.
- The Outer cacheability attribute applied to L3 cache.
Example E2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example E2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

• The Inner cacheability attribute applied to L1 cache.
• The Outer cacheability attribute applied to L2 and L3 cache.

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more registers from the SIMD and floating-point register file from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

E2.8.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for Armv8 Device memory are:

Gathering  Identified as G or nG, see Gathering on page E2-4056.
Reordering  Identified as R or nR, see Reordering on page E2-4057.
Early Write Acknowledgement  Identified as E or nE, see Early Write Acknowledgement on page E2-4058.

The Armv8 Device memory types are:

Device-nGnRnE  Device non-Gathering, non-Reordering, No Early write acknowledgement. Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.
Device-nGnRE  Device non-Gathering, non-Reordering, Early Write Acknowledgement. Equivalent to the Device memory type in earlier versions of the architecture.
Device-nGRE  Device non-Gathering, Reordering, Early Write Acknowledgement. Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory. The Device-nGRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.
Device-GRE  Device Gathering, Reordering, Early Write Acknowledgement.
Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that speculative accesses to Device-GRE memory is forbidden.

The Device-GRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format. Collectively these are referred to as any Device memory type. Going down the list, the memory types are described as getting weaker; conversely the going up the list the memory types are described as getting stronger.

--- Note ---

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.

- The architecture does not require an implementation to distinguish between each of these memory types and Arm recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.

- Earlier versions of the Arm architecture defined the following memory types:
  - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
  - Device memory. This is the equivalent of the Device-nGnRE memory type.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

An exception to this applies:
- Reads generated by the Advanced SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.

--- Note ---

- An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture on page E2-4016 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program only defines a single access. For this reason, Arm strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.

- Write speculation that is visible to other observers is prohibited for all memory types.

- A write to a memory location with any Device memory type completes in finite time.

- If a value that would be returned from a read of a memory location with the Device memory type changes without an explicit write by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.

- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.

- A memory location with any Device memory attribute cannot be allocated into a cache.

- Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Two writes of Device memory type to the same location might be merged before they reach the endpoint, unless both writes have the non-Gathering attribute or there is an ordered-before relationship between the two writes.
• All accesses to memory with any Device memory attribute must be aligned. Any unaligned access generates an Alignment fault at the first stage of translation that defined the location as being Device.

**Note**

In the Non-secure PL1&0 translation regime in systems where HCR.TGE==1 and HCR.DC==0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes the value of HSR.ISS.[24] to be 0.

• Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as Execute-never for all Exception levels.

**Note**

This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as Execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as Execute-never for all Exception levels is a programming error.

See also *Memory access restrictions* on page E2-4059.

The memory types for Translation table walks cannot be defined as any Device memory type within the TCR. For the Non-secure EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the HCR.PTW bit is 1, a stage 2 permission fault is generated if a first stage translation table walk is made to any Device memory type.

For instruction fetches, if branches cause the program counter to point to an area of memory with the Device attribute which is not marked as Execute-never for the current Exception level, an implementation can either:

• Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
• Take a Permission fault.

**Gathering**

In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

• Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.

• Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

• The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.

• All access occur at their programmed size, except that there is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See *Multi-register loads and stores that access Device memory* on page E2-4058.

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.
A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

--- Note ---

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  - The accesses are not separated by a DMB or DSB barrier that affects both of the accesses.
  - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
  - The accesses are not generated by a Store-Release instruction.

- The Arm architecture only defines programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the non-Gathering attribute.

An implementation is not permitted to perform an access with the non-Gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

**Reordering**

In the Device memory attribute:

| R  | Indicates that the location has the Reordering attribute. |
| nR | Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering. |

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

--- Note ---

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.

- The Arm architecture only defines programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.

An implementation is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.

An additional relaxation is that an implementation is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses to one physical address with the non-Reordering attribute and accesses to a different physical address with the Reordering attribute.
- Access to one physical address with the non-Reordering attribute and access to a different physical address to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.
Early Write Acknowledgement

In the Device memory attribute:

- Indicates that the location has the Early Write Acknowledgement attribute.
- Indicates that the location has the No Early Write Acknowledgement attribute.

For memory system endpoints where the system architecture in which the PE is operating requires that
acknowledgement of a write comes from the endpoint, assigning the No Early Write Acknowledgement attribute to
a Device memory location guarantees that:

- Only the endpoint of the write access returns a write acknowledgement of the access.
- No earlier point in the memory system returns a write acknowledgement.

This means that a DSB barrier instruction, executed by the PE that performed the write to the No Early Write
Acknowledgement Location, completes only after the write has reached its endpoint in the memory system.

Peripherals are an example of system endpoints that require that the acknowledgement of a write comes from the
endpoint.

Note

- The Early Write Acknowledgement attribute only affects where the endpoint acknowledgement is returned
  from, and does not affect the ordering of arrival at the endpoint between accesses, which is determined by
  either the Device Reordering attribute, or the use of barriers to create order.
- The areas of the physical memory map for which write acknowledgement from the endpoint is required is
  outside the scope of the Arm Architecture definition and must be defined as part of the system architecture
  in which the PE is operating. In particular, regions of memory handled as PCIe configuration writes are
  expected to support write acknowledgement from the endpoint.
- Arm recognizes that not all areas of a physical memory map will be capable of supporting write
  acknowledgement from the endpoint. In particular, Arm expects that regions of memory handled as posted
  writes under PCIe will not support write acknowledgement from the endpoint.
- For maximum software compatibility, Arm strongly recommends that all peripherals for which standard
  software drivers expect that the use of a DSB instruction will determine that a write has reached its endpoint
  are placed in areas of the physical memory map that support write acknowledgement from the endpoint.

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register there is no requirement for the memory
system beyond the PE to be able to identify the size of the elements accessed by these load and store instructions.

For all instructions that load or store one or more registers from the SIMD and floating-point register file there is
no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these
load and store instructions.

For an LDRD, STRD, or LDM instruction with a register list that includes the PC, or an STM instruction with a register list
that includes the PC, the order in which the registers are accessed is not defined by the architecture.

For a load or store of an Advanced SIMD element or structure, the order in which the registers are accessed is not
defined by the architecture.

For a VLDM and VSTM instruction with a register list that does not include the PC, all registers are accessed in ascending
address order for accesses to Device memory with the non-Reordering attribute.

For a LDM or STM instruction with a register list that does not include the PC:

- When FEAT_LSMAOC is not implemented, and when FEAT_LSMAOC is implemented and the value of
  the applicable LSMAOE field is 1, all registers are accessed in ascending address order for accesses to Device
  memory with the non-Reordering attribute.
- When FEAT_LSMAOC is implemented and the value of the applicable LSMAOE field is 0, no memory
  accesses are required to be ordered.
• When FEAT_LSMAOC is implemented and the value of the applicable nTLSMD field is 0, any memory access to an address that the stage 1 translation assigns as Device-nGRE, Device-nGnRE, or Device-nGnRnE generates an Alignment fault.

The applicable LSMAOE or nTLSMD field is the field in the SCTLR_EL1, SCTLR_EL2, HSCTLR, or SCTLR register that applies to the Exception level and Security state at which the LDM or STM instruction is executed.

Armv8.2 deprecates software relying on accesses to Device memory made by a single LDM or STM instruction not being reordered.

E2.8.3 Memory access restrictions

The following restrictions apply to memory accesses:

• For accesses to any two bytes, \( p \) and \( q \), that are generated by the same instruction:
  — The bytes \( p \) and \( q \) must have the same memory type and Shareability attributes. otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an LDC, LDM, LDRD STC, STM or STRD instruction, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
  — Except for possible differences in the cache allocation hints, Arm deprecates having different cacheability attributes for bytes \( p \) and \( q \).

For the permitted CONSTRAINED UNPREDICTABLE behavior, see Crossing a page boundary with different memory types or Shareability attributes on page K1-7951.

• If the accesses of an instruction that causes multiple accesses to any type of Device memory cross a 4KB address boundary then behavior is CONSTRAINED UNPREDICTABLE and Crossing a 4KB boundary with a Device access on page K1-7951 describes the permitted behaviors.

Note

— The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.
— This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses a 4KB address boundary.
— Arm expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.
E2.9 Mismatched memory attributes

In the Armv8 architecture mismatched memory attributes are controlled by privileged software. For more information, see Chapter G5 The AArch32 Virtual Memory System Architecture.

Physical memory Locations are accessed with mismatched attributes if all accesses to the Location do not use a common definition of all of the following attributes of that Location:

- Memory type: Device-nGnRnE, Device-nGnRE, Device-nGRE, Device-GRE or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

--- Note ---

In this document, the terms location and memory location refer to any byte within the current coherency granule and are used interchangeably.

---

When a memory Location is accessed with mismatched attributes the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory Location might be lost. This means:
  - A read of the memory Location by one agent might not return the value most recently written to that memory Location by the same agent.
  - Multiple writes to the memory Location by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory Location.
- There might be a loss of properties derived from the memory type, as described in later bullets in this section.
- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory Location do not use consistent memory attributes, the Exclusives monitor state becomes UNKNOWN.
- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of speculative read accesses.
- Prohibition on Gathering.
- Prohibition on Re-ordering.

For the following situations, when a physical memory Location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. Any agent that reads that memory Location using the same common definition of the Memory type, Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:
   - All writes are performed to an alias of the memory Location that uses the same definition of the Memory type, Shareability and Cacheability attributes.
   - Either:
     - In the Non-secure PL1&0 translation regime, HCR2.MIOCNCE has a value of 0.
     - All aliases with write permission have the Inner Cacheability attribute the same as the Outer Cacheability attribute.
   - Either:
     - All writes are performed to an alias of the memory Location that has Inner Cacheability and Outer Cacheability attributes both as Non-cacheable.
All aliases to a memory Location use a definition of the Shareability attributes that encompasses all the agents with permission to access the Location.

2. The possible software-visible effects caused by mismatched attributes for a memory Location are defined more precisely if all of the mismatched attributes define the memory Location as one of:
   • Any Device memory type.
   • Normal Inner Non-cacheable, Outer Non-cacheable memory.

In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:
   • Possible loss of properties derived from the memory type when multiple agents attempt to access the memory Location.
   • Possible reordering of memory transactions to the same memory Location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting DM_B barrier instructions between accesses to the same memory Location that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory Location all assign the same Shareability attribute to a Location that has a cacheable attribute, any loss of uniprocessor semantics, ordering, or coherency within a Shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable Locations between agents in different shareability domains. This means:
   • Before writing to a cacheable Location not using the Write-Back attribute, software must invalidate, or clean, a Location from the caches if any agent might have written to the Location with the Write-Back attribute. This avoids the possibility of overwriting the Location with stale data.
   • After writing to a cacheable Location with the Write-Back attribute, software must clean the Location from the caches, to make the write visible to external memory.
   • Before reading the Location with a cacheable attribute, software must invalidate, or clean and invalidate, the Location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.
   • Executing a DM_B barrier instruction, with scope that applies to the common Shareability of the accesses, between any accesses to the same cacheable Location that use different attributes.

Note

In AArch32 state, cache maintenance instructions can only be accessed from an Exception level that is higher than EL0, and therefore require a system call. For information on system calls, see Exception-generating and exception-handling instructions on page F1-4095. For information about the AArch32 cache maintenance instructions, see AArch32 cache and branch predictor support on page G4-5929.

In all cases:
   • Location refers to any byte within the current coherency granule.
   • A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
   • In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see Ordering of cache and branch predictor maintenance instructions on page G4-5947.

Note

With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same Location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.
2. If the mismatched attributes for a Location mean that multiple cacheable accesses to the Location might be made with different Shareability attributes, then ordering and coherency are guaranteed only if:

   - Software running on a PE cleans and invalidates a Location from cache before and after each read or write to that Location by that PE.
   - A DMB barrier with scope that covers the full Shareability of the accesses is placed between any accesses to the same memory Location that use different attributes.

   **Note**

   The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a Location, and the accesses from the different agents have different memory attributes associated with the Location, the Exclusives monitor state becomes UNKNOWN.

Arm strongly recommends that software does not use mismatched attributes for aliases of the same Location. An implementation might not optimize the performance of a system that uses mismatched aliases.
E2.10 Synchronization and semaphores

Armv8 provides non-blocking synchronization of shared memory, using synchronization primitives. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal and Device memory.

Note

Use of the Armv8 synchronization primitives scales for multiprocessing system designs.

Table E2-6 shows the synchronization primitives and the associated CLREX instruction.

**Table E2-6 Synchronization primitives and associated instruction, T32 and A32 instruction sets**

a. Instruction in the T32 and A32 instruction sets.

Except for the row showing the CLREX instruction, the two instructions in a single row are a Load-Exclusive/Store-Exclusive instruction pair. The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address $x$ is:

- The Load-Exclusive instruction reads a value from memory address $x$.
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address $x$ only if no other observer, process, or thread has performed a more recent store to address $x$. The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see Marking and the size of the marked memory block on page E2-4069. A Store-Exclusive instruction to any address in the marked block clears the marking.

Note

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- Exclusive access instructions and Non-shareable memory locations on page E2-4064.
- Exclusive access instructions and shareable memory locations on page E2-4065.
- Marking and the size of the marked memory block on page E2-4069.
- Context switch support on page E2-4069.
- Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-4069.
- Use of WFE and SEV instructions by spin-locks on page E2-4072.
E2.10.1 **Exclusive access instructions and Non-shareable memory locations**

For memory locations for which the Shareability attribute is Non-shareable, the exclusive access instructions rely on a *local Exclusives monitor*, or *local monitor*, that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

**If the local monitor is in the Exclusive Access state**

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs.
  
  Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.

- A status value is returned to a register:
  - If the store took place the status value is 0.
  - Otherwise, the status value is 1.

- The local monitor of the executing PE transitions to the Open Access state.

When an Exclusives monitor is in the Exclusive Access state the monitor is set.

**If the local monitor is in the Open Access state**

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

When an Exclusives monitor is in the Exclusive Access state the monitor is clear.

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a PA that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

- If the write is to a PA that is marked as Exclusive Access by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked PA causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the PA to be marked.

Figure E2-4 on page E2-4065 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.
For more information about marking see Marking and the size of the marked memory block on page E2-4069.

--- Note ---

For the local monitor state machine, as shown in Figure E2-4:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any PA, but instead treats any access as matching the address of the previous Load-Exclusive instruction.

- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.

- The architecture does not require a load instruction, by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.

- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the Store or StoreExcl is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure E2-4.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure E2-4.

- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure E2-4 must not indefinitely delay forward progress of execution.

E2.10.2 Exclusive access instructions and shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.
For shareable memory locations, exclusive access instructions rely on:

- A **local monitor** for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in Exclusive access instructions and Non-shareable memory locations on page E2-4064, except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  - Updating memory.
  - Returning a status value of 0.

The local monitor can ignore accesses from other PEs in the system.

- A **global monitor** that marks a PA as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the Shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  - Can hold at least one marked block.
  - Maintains a state machine for each marked block it can hold.

**Note**

For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is CONSTRAINED UNPREDICTABLE, see Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-4069.

**Note**

The global monitor can either reside in a block that is part of the hardware on which the PE executes or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

**Note**

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport’s Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global Exclusives monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hint and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hints and not transient.
If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an External abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Fault status code of:
  - DFSR.STATUS = 0b110101 when using the Long-descriptor translation table format. The fault can also be reported in the HSR.ISS[5:0] field for exceptions to Hyp mode.
  - DFSR.FS = 0b10101 when using the Short-descriptor translation table format.

If the IMPLEMENTATION DEFINED MMU fault is generated for the Non-secure PL1&0 translation regime then:

- If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.
- Otherwise, the fault is a second stage fault and the exception is taken to EL2.

The priority of this fault is IMPLEMENTATION DEFINED.

- The instruction is treated as a NOP.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by an Arm PE is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

**Operation of the global Exclusives monitor**

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the PA of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other PA that has been marked by the requesting PE.

---

**Note**

The global monitor only supports a single outstanding exclusive access to shareable memory for each PE.

---

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the PA accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.

- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.

- If a different PA is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means it responds to:

- Accesses generated by PE(n).
- Accesses generated by the other observers in the Shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

A global monitor:

- In the Exclusive Access state is set.
- In the Open Access state is clear.

**Clear global monitor event**

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see *Wait For Event and Send Event* on page G1-5804.

Figure E2-5 shows the state machine for PE(n) in a global monitor.

---

**Note**

For the global monitor state machine, as shown in Figure E2-5:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
• Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure E2-5 on page E2-4068 only shows how the operations by '(n) cause state transitions of the state machine for PE(n).

• A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.

• When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.

• It is IMPLEMENTATION DEFINED:
  — Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  — Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

E2.10.3  Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size $2^a$ bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the Exclusives reservation granule. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4 - 512 words.

——— Note ————
This definition means that the Exclusives reservation granule is:
• 4 words in an implementation where $a$ is 4.
• 512 words in an implementation where $a$ is 11.

For example, in an implementation where $a$ is 4, a successful LDREXB of address 0x341B4 defines a marked block using bits[47:4] of the address. This means that the four words of memory from 0x341B0 to 0x341BF are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see CTR. Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

E2.10.4  Context switch support

An exception return clears the local monitor. As a result, performing a CLREX instruction as part of a context switch is not required in most situations.

——— Note ————
Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

E2.10.5  Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDREX/STREX pair or a LDREXB/STREXB pair. To support different implementations of these functions, software must follow the notes and restrictions given in this subsection.
The following notes describe use of a Load-Exclusive/Store-Exclusive instruction pair, LoadExcl/StoreExcl, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table E2-6 on page E2-4063. In this context, a LoadExcl/StoreExcl pair comprises two instructions in the same thread of execution:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the IsExclusiveLocal() function. If the target VA of a StoreExcl is different from the VA of the preceding LoadExcl instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The StoreExcl either passes or fails, the status value returned by the StoreExcl is UNKNOWN, and the states of the local and global monitors for that PE are UNKNOWN.

  **Note**

  This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with mismatched addresses, and fail for other instances of a LoadExcl/StoreExcl pair with mismatched addresses.

  — The data at the address accessed by the LoadExcl, and at the address accessed by the StoreExcl, is UNKNOWN.

  This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if the LoadExcl and the StoreExcl are executed with the same VA.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a StoreExcl instruction is the same as the transaction size of the preceding LoadExcl instruction executed in that thread. If the transaction size of a StoreExcl instruction is different from the preceding LoadExcl instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The StoreExcl either passes or fails, and the status value returned by the StoreExcl is UNKNOWN.

  **Note**

  This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with mismatched transaction sizes, and fail for other instances of a LoadExcl/StoreExcl pair with mismatched transaction sizes.

  — The block of data of the size of the larger of the transaction sizes used by the LoadExcl/StoreExcl pair at the address accessed by the LoadExcl/StoreExcl pair, is UNKNOWN.

  This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if the LoadExcl and the StoreExcl have the same transaction size.

- LoadExcl/StoreExcl loops are guaranteed to make forward progress only if, for any LoadExcl/StoreExcl loop within a single thread of execution, the software meets all of the following conditions:

  1. Between the Load-Exclusive and the Store-Exclusive, there are no explicit memory accesses, preloads, direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.

  2. Between the Store-Exclusive returning a failing result and the retry of the corresponding Load-Exclusive:

     • There are no stores or PLDW instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive.

     • There are no loads or preloads to any address within the Exclusives reservation granule accessed by the Store-Exclusive that use a different VA alias to that address.

     • There are no direct or indirect System register writes, other than changes to the flag fields in the CPSR or FPSCR, caused by data processing or comparison instructions.

     • There are no direct or indirect address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.

     • All loads and stores are to a block of contiguous virtual memory of not more than 512 bytes in size.
The Exclusives monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the Exclusives monitor. However, it is permissible for the LoadExcl/StoreExcl loop not to make forward progress if a different thread is repeatedly doing any of the following in a tight loop:

- Performing stores to a PA covered by the Exclusives monitor.
- Prefetching with intent to write to a PA covered by the Exclusives monitor.
- Executing data cache clean, data cache invalidate, or data cache clean and invalidate instructions to a PA covered by the Exclusives monitor.
- Executing instruction cache invalidate all instructions.
- Executing instruction cache invalidate by VA instructions to a PA covered by the Exclusives monitor.

• Implementations can benefit from keeping the LoadExcl and StoreExcl operations close together in a single thread of execution. This minimizes the likelihood of the Exclusives monitor state being cleared between the LoadExcl instruction and the StoreExcl instruction. Therefore, for best performance, Arm strongly recommends a limit of 128 bytes between LoadExcl and StoreExcl instructions in a single thread of execution.

• The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, Arm recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusives reservation granule. This is a performance guideline rather than a functional requirement.

• After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN.

• For the memory location accessed by a LoadExcl/StoreExcl pair, if the memory attributes for a StoreExcl instruction are different from the memory attributes for the preceding LoadExcl instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. Where this occurs because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction, the CONSTRAINED UNPREDICTABLE behavior is as follows:

  - The StoreExcl either passes or fails, and the status value returned by the StoreExcl is UNKNOWN.

  ___ Note ___

  This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with changed memory attributes, and fail for other instances of a LoadExcl/StoreExcl pair with changed memory attributes.

  ___ Note ___

  The data at the address accessed by the StoreExcl is UNKNOWN.

  Another bullet point in this list covers the case where the memory attributes of a LoadExcl/StoreExcl pair differ as a result of using different VAs with different attributes that point to the same PA.

  ___ Note ___

  The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same Shareability domain as the PE executing the cache maintenance instruction, as determined by the Shareability domain of the address being maintained.

  ___ Note ___

  Arm strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

  ___ Note ___

  If the mapping of the VA to PA is changed between the LoadExcl instruction and the StoreExcl instruction, and the change is performed using a break-before-make sequence as described in Using break-before-make when updating translation table entries on page G5-6036, if the StoreExcl is performed after another write
to the same PA as the StoreExcl, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the StoreExcl will not pass its monitor check.

--- Note ---

Arm expects that, in many implementations, either:

— The TLB invalidation will clear either the local or global monitor.
— The PA will be checked between the LoadExcl and StoreExcl.

---

- The Exclusive Access state for an address accessed by a PE can be lost as a result of a PLDW instruction to the same PA executed by another PE. This means that a very high rate of repeated PLDW accesses to a memory location might impede the forward progress of another PE.

--- Note ---

In the event of repeatedly-contending LoadExcl/StoreExcl instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

---

E2.10.6   Use of WFE and SEV instructions by spin-locks

Armv8 provides Wait For Event, Send Event, and Send Event Local instructions, WFE, SEV, SEVL, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in Wait For Event and Send Event on page G1-5804. However, in Armv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

--- Note ---

This is equivalent to issuing an SEVL instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an SEV instruction after clearing a spinlock.

---
Part F
The AArch32 Instruction Sets
Chapter F1
The AArch32 Instruction Sets Overview

This chapter describes the T32 and A32 instruction sets. It contains the following sections:

- Support for instructions in different versions of the Arm architecture on page F1-4076.
- Unified Assembler Language on page F1-4077.
- Branch instructions on page F1-4079.
- Data-processing instructions on page F1-4080.
- PSTATE and banked register access instructions on page F1-4088.
- Load/store instructions on page F1-4089.
- Load/store multiple instructions on page F1-4092.
- Miscellaneous instructions on page F1-4093.
- Exception-generating and exception-handling instructions on page F1-4095.
- System register access instructions on page F1-4097.
- Advanced SIMD and floating-point load/store instructions on page F1-4098.
- Advanced SIMD and floating-point register transfer instructions on page F1-4100.
- Advanced SIMD data-processing instructions on page F1-4101.
- Floating-point data-processing instructions on page F1-4112.
F1.1  Support for instructions in different versions of the Arm architecture

This manual describes the T32 and A32 instruction sets for the Armv8 architecture. Therefore, it indicates how any options or extensions in the Armv8 architecture affect the available instructions.
F1.2 Unified Assembler Language

This manual uses the Arm Unified Assembler Language (UAL). This assembly language syntax provides a canonical form for all T32 and A32 instructions.

UAL describes the syntax for the mnemonic and the operands of each instruction. In addition, it assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, nor what assembler directives and options are available. See your assembler documentation for these details.

Most earlier Arm assembly language mnemonics are still supported as synonyms, as described in the instruction details.

——— Note ————

Most earlier T32 assembly language mnemonics are not supported.

UAL includes instruction selection rules that specify which instruction encoding is selected when more than one can provide the required functionality. For example, both 16-bit and 32-bit encodings exist for an ADD R0, R1, R2 instruction. The most common instruction selection rule is that when both a 16-bit encoding and a 32-bit encoding are available, the 16-bit encoding is selected, to optimize code density.

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

F1.2.1 Conditional instructions

For maximum portability of UAL assembly language between the T32 and A32 instruction sets, Arm recommends that:

• IT instructions are written before conditional instructions in the correct way for the T32 instruction set.

• When assembling to the A32 instruction set, assemblers check that any IT instructions are correct, but do not generate any code for them.

Although other T32 instructions are unconditional, all instructions that are made conditional by an IT instruction must be written with a condition. These conditions must match the conditions imposed by the IT instruction. For example, an ITTEE EQ instruction imposes the EQ condition on the first two following instructions, and the NE condition on the next two. Those four instructions must be written with EQ, EQ, NE and NE conditions respectively.

Some instructions cannot be made conditional by an IT instruction. Some instructions can be conditional if they are the last instruction in the IT block, but not otherwise.

The branch instruction encodings that include a Condition code field cannot be made conditional by an IT instruction. If the assembler syntax indicates a conditional branch that correctly matches a preceding IT instruction, it is assembled using a branch instruction encoding that does not include a Condition code field.

——— Note ————

For performance reasons Armv8 deprecates many uses of IT, see Partial deprecation of IT on page F1-4094. As described in that section, an implementation can include ITD controls that disable those uses of IT, making them UNDEFINED.

F1.2.2 Use of labels in UAL instruction syntax

The UAL syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must:

1. Calculate the PC or Align(PC, 4) value of the instruction. The PC value of an instruction is its address plus 4 for a T32 instruction, or plus 8 for an A32 instruction. The Align(PC, 4) value of an instruction is its PC value ANDed with 0xFFFFFFFF to force it to be word-aligned. There is no difference between the PC and Align(PC, 4) values for an A32 instruction, but there can be for a T32 instruction.
2. Calculate the offset from the PC or Align(PC, 4) value of the instruction to the address of the labeled instruction or literal data item.

3. Assemble a PC-relative encoding of the instruction, that is, one that reads its PC or Align(PC, 4) value and adds the calculated offset to form the required address.

   **Note**
   For instructions that can encode a subtraction operation, if the instruction cannot encode the calculated offset but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.

The syntax of the following instructions includes a label:

- **B, BL, and BLX (immediate).** The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a sign-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch.

- **CBNZ and CBZ.** The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a zero-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch. They do not support backward branches.

- **LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLDW, PLI, and VLDR.** The normal assembler syntax of these load instructions can specify the label of a literal data item that is to be loaded. The encodings of these instructions specify a zero-extended immediate offset that is either added to or subtracted from the Align(PC, 4) value of the instruction to form the address of the data item. A few such encodings perform a fixed addition or a fixed subtraction and must only be used when that operation is required, but most contain a bit that specifies whether the offset is to be added or subtracted.

When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the Align(PC, 4) value of the instruction. Encodings that subtract 0 from the Align(PC, 4) value cannot be specified by the normal syntax.

There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by [PC, #+/-imm], where:

+/- Is + or omitted to specify that the immediate offset is to be added to the Align(PC, 4) value, or - if it is to be subtracted.

<imm> Is the immediate offset.

This alternative syntax makes it possible to assemble the encodings that subtract 0 from the Align(PC, 4) value, and to disassemble them to a syntax that can be re-assembled correctly.

- **ADR.** The normal assembler syntax for this instruction can specify the label of an instruction or literal data item whose address is to be calculated. Its encoding specifies a zero-extended immediate offset that is either added to or subtracted from the Align(PC, 4) value of the instruction to form the address of the data item, and some opcode bits that determine whether it is an addition or subtraction.

When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the Align(PC, 4) value of the instruction. The encoding that subtracts 0 from the Align(PC, 4) value cannot be specified by the normal syntax.

There is an alternative syntax for this instruction that specifies the addition or subtraction and the immediate value explicitly, by writing them as additions ADD <Rd>, PC, #<imm> or subtractions SUB <Rd>, PC, #<imm>. This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the Align(PC, 4) value, and to disassemble it to a syntax that can be re-assembled correctly.

   **Note**
   Arm recommends that where possible, software avoids using:

   - The alternative syntax for the ADR, LDC, LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLDW, PLI, and VLDR instructions.

   - The encodings of these instructions that subtract 0 from the Align(PC, 4) value.
F1.3 Branch instructions

Table F1-1 summarizes the branch instructions in the T32 and A32 instruction sets. In addition to providing for changes in the flow of execution, some branch instructions can change instruction set.

a. These instructions do not exist in the A32 instruction set.

Branches to loaded and calculated addresses can be performed by $LDR, LDM$ and data-processing instructions. For details see Load/store instructions on page F1-4089, Load/store multiple instructions on page F1-4092, Standard data-processing instructions on page F1-4080, and Shift instructions on page F1-4082.

In addition to the branch instructions shown in Table F1-1:

- In the A32 instruction set, a data-processing instruction that targets the PC behaves as a branch instruction. For more information, see Data-processing instructions on page F1-4080.
- In the T32 and A32 instruction sets, a load instruction that targets the PC behaves as a branch instruction. For more information, see Load/store instructions on page F1-4089.
F1.4 Data-processing instructions

Core data-processing instructions belong to one of the following groups:

- **Standard data-processing instructions.**
  These instructions perform basic data-processing operations, and share a common format with some variations.
- **Shift instructions on page F1-4082.**
- **Multiply instructions on page F1-4082.**
- **Saturating instructions on page F1-4084.**
- **Saturating addition and subtraction instructions on page F1-4084.**
- **Packing and unpacking instructions on page F1-4085.**
- **Parallel addition and subtraction instructions on page F1-4086.**
- **Divide instructions on page F1-4087.**
- **Miscellaneous data-processing instructions on page F1-4087.**

For related Advanced SIMD and floating-point instructions see *Advanced SIMD data-processing instructions on page F1-4101* and *Floating-point data-processing instructions on page F1-4112."

F1.4.1 Standard data-processing instructions

These instructions generally have a destination register Rd, a first operand register Rn, and a second operand. The second operand can be another register Rm, or an immediate constant.

If the second operand is an immediate constant, it can be:

- Encoded directly in the instruction.
- A modified immediate constant that uses 12 bits of the instruction to encode a range of constants. T32 and A32 instructions have slightly different ranges of modified immediate constants. For more information, see *Modified immediate constants in T32 instructions on page F2-4135* and *Modified immediate constants in A32 instructions on page F2-4136.*

If the second operand is another register, it can optionally be shifted in any of the following ways:

- **LSL** Logical Shift Left by 1-31 bits.
- **LSR** Logical Shift Right by 1-32 bits.
- **ASR** Arithmetic Shift Right by 1-32 bits.
- **ROR** Rotate Right by 1-31 bits.
- **RRX** Rotate Right with Extend. For details see *Shift and rotate operations on page E1-3990.*

In T32 code, the amount to shift by is always a constant encoded in the instruction. In A32 code, the amount to shift by is either a constant encoded in the instruction, or the value of a register, Rs.

For instructions other than CMN, CMP, TEQ, and TST, the result of the data-processing operation is placed in the destination register. In the A32 instruction set, the destination register can be the PC, causing the result to be treated as a branch address. In the T32 instruction set, this is only permitted for some 16-bit forms of the ADD and MOV instructions.

These instructions can optionally set the Condition flags, according to the result of the operation. If they do not set the flags, existing flag settings from a previous instruction are preserved.

Table F1-2 on page F1-4081 summarizes the main data-processing instructions in the T32 and A32 instruction sets. Generally, each of these instructions is described in three sections in *Chapter F2 About the T32 and A32 Instruction Descriptions*, one section for each of the following:

- **INSTRUCTION (immediate) where the second operand is a modified immediate constant.**
- **INSTRUCTION (register) where the second operand is a register, or a register shifted by a constant.**
- **INSTRUCTION (register-shifted register) where the second operand is a register shifted by a value obtained from another register. These are only available in the A32 instruction set.**

RXRS on page F5-4675 |

In the A32 instruction set only, the destination register of these instructions can be the PC, causing the result to be treated as an address to branch to.

### F1.4.3 Multiply instructions

These instructions can operate on signed or unsigned quantities. In some types of operation, the results are the same whether the operands are signed or unsigned.

- Table F1-4 summarizes the multiply instructions where there is no distinction between signed and unsigned quantities.
  
  The least significant 32 bits of the result are used. More significant bits are discarded.

- Table F1-5 on page F1-4083 summarizes the signed multiply instructions.

- Table F1-6 on page F1-4083 summarizes the unsigned multiply instructions.

F1.4.7 Parallel addition and subtraction instructions

These instructions perform additions and subtractions on the values of two registers and write the result to a destination register, treating the register values as sets of two halfwords or four bytes. That is, they perform SIMD additions or subtractions on the general-purpose registers.

These instructions consist of a prefix followed by a main instruction mnemonic. The prefixes are as follows:

- **S**: Signed arithmetic modulo $2^8$ or $2^{16}$.
- **Q**: Signed saturating arithmetic.
- **SH**: Signed arithmetic, halving the results.
- **U**: Unsigned arithmetic modulo $2^8$ or $2^{16}$.
- **UQ**: Unsigned saturating arithmetic.
- **UH**: Unsigned arithmetic, halving the results.

The main instruction mnemonics are as follows:

- **ADD16**: Adds the top halfwords of two operands to form the top halfword of the result, and the bottom halfwords of the same two operands to form the bottom halfword of the result.
- **ASX**: Exchanges halfwords of the second operand, and then adds top halfwords and subtracts bottom halfwords.
- **SAX**: Exchanges halfwords of the second operand, and then subtracts top halfwords and adds bottom halfwords.
- **SUB16**: Subtracts each halfword of the second operand from the corresponding halfword of the first operand to form the corresponding halfword of the result.
- **ADD8**: Adds each byte of the second operand to the corresponding byte of the first operand to form the corresponding byte of the result.
- **SUB8**: Subtracts each byte of the second operand from the corresponding byte of the first operand to form the corresponding byte of the result.

The instruction set permits all 36 combinations of prefix and main instruction operand, as Table F1-10 shows.

See also *Advanced SIMD parallel addition and subtraction* on page F1-4102.

F1.4.8 Divide instructions

In Armv8, signed and unsigned integer divide instructions are included in both the T32 instruction set and the A32 instruction set.

For descriptions of the instructions see:
• SDIV on page F5-4710.
• UDIV on page F5-4925.

For the SDIV and UDIV instructions, division by zero always returns a zero result.

The ID_ISAR0.Divide_instrs field indicates the level of support for these instructions. The field value of 0b0010 indicates they are implemented in both the T32 and A32 instruction sets.

F1.4.9 Miscellaneous data-processing instructions

Table F1-11 lists the miscellaneous data-processing instructions in the T32 and A32 instruction sets. Immediate values in these instructions are simple binary numbers.

</table>
F1.5  PSTATE and banked register access instructions

These instructions transfer PE state information to or from a general-purpose register.

F1.5.1  PSTATE access instructions

PSTATE holds process state information, see Process state, PSTATE on page E1-3993. In AArch32 state:

- At EL1 or higher, PSTATE is accessible using the Current Program Status Register (CPSR).
- At EL0, a subset of the CPSR is accessible as the Application Program Status Register (APSR).
- On taking an exception, the contents of the CPSR are copied to the Saved Program Status Register (SPSR) of the mode from which the exception is taken.

The MRS and MSR instructions move the contents of the CPSR, APSR, or the SPSR of the current mode to or from a general-purpose register, see:

- MRS on page F5-4570.
- MSR (immediate) on page F5-4580.
- MSR (register) on page F5-4582.

When executed at EL0, MRS and MSR instructions can only access the APSR.

The PSTATE Condition flags, PSTATE.\{N, Z, C, V\} are set by the execution of data-processing instructions, and can control the execution of conditional instructions. However, software can set the Condition flags explicitly using the MSR instruction, and can read the current state of the Condition flags explicitly using the MRS instruction.

In addition, at EL1 or higher, software can use the CPS instruction to change the PSTATE.M field and the PSTATE.\{A, I, F\} interrupt mask bits, see CPS, CPSID, CPSIE on page F5-4372.

F1.5.2  Banked register access instructions

At EL1 or higher, the MRS (banked register) and MSR (banked register) instructions move the contents of a banked general-purpose register, the SPSR, or the ELR_hyp, to or from a general-purpose register. See:

- MRS (Banked register) on page F5-4572.
- MSR (Banked register) on page F5-4576.
F1.6 Load/store instructions

Table F1-12 summarizes the general-purpose register load/store instructions in the T32 and A32 instruction sets. Some of these instructions can also operate on the PC. See also:

- *Load/store multiple instructions* on page F1-4092.
- *Synchronization and semaphores* on page E2-4063, for more information about the Load-Exclusive and Store-Exclusive instructions.
- *Advanced SIMD and floating-point load/store instructions* on page F1-4098.

Load/store instructions have several options for addressing memory. For more information, see *Addressing modes* on page F1-4090.

F1.6.1 Loads to the PC

The LDR instruction can load a value into the PC. The value loaded is treated as an interworking address, as described by the `LoadWritePC()` pseudocode function in *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3993.

F1.6.2 Halfword and byte loads and stores

Halfword and byte stores store the least significant halfword or byte from the register, to 16 or 8 bits of memory respectively. There is no distinction between signed and unsigned stores.

Halfword and byte loads load 16 or 8 bits from memory into the least significant halfword or byte of a register. Unsigned loads zero-extend the loaded value to 32 bits, and signed loads sign-extend the value to 32 bits.
F1.6.3 Load unprivileged and Store unprivileged

When executing at EL0, a Load unprivileged or Store unprivileged instruction operates in exactly the same way as the corresponding ordinary load or store instruction. For example, an LDRT instruction executes in exactly the same way as the equivalent LDR instruction. When executed at PL1, Load unprivileged and Store unprivileged instructions behave as they would if they were executed at EL0. For example, an LDRT instruction executes in exactly the way that the equivalent LDR instruction would execute at EL0. In particular, the instructions make unprivileged memory accesses.

--- Note ---
As described in Security state, Exception levels, and AArch32 execution privilege on page G1-5722, execution at PL1 describes all of the following:
- Execution at Non-secure EL1 using AArch32.
- Execution at Secure EL1 using AArch32 when EL3 is not implemented.
- Execution at Secure EL1 using AArch32 when EL3 is implemented and is using AArch64.
- Execution at Secure EL3 when EL3 is implemented and is using AArch32.

The Load unprivileged and Store unprivileged instructions are CONSTRAINED UNPREDICTABLE if executed at EL2, see Execution of Load/Store unprivileged instructions in Hyp mode on page K1-7961.

For more information about execution privilege, see About access permissions on page G5-6008.

F1.6.4 Load-Exclusive and Store-Exclusive

Load-Exclusive and Store-Exclusive instructions provide shared memory synchronization. For more information, see Synchronization and semaphores on page E2-4063.

F1.6.5 Load-Acquire and Store-Release

Load-Acquire and Store-Release instructions provide memory barriers. Load-Acquire Exclusive and Store-Release Exclusive instructions provide memory barriers with shared memory synchronization. For more information, see Load-Acquire, Store-Release on page E2-4036.

F1.6.6 Addressing modes

The address for a load or store is formed from two parts: a value from a base register, and an offset.

The base register can be any one of the general-purpose registers R0-R12, SP, or LR.

For loads, the base register can be the PC. This provides PC-relative addressing for position-independent code.

Instructions marked (literal) in their title in Chapter F2 About the T32 and A32 Instruction Descriptions are PC-relative loads.

The offset takes one of three formats:

Immediate
The offset is an unsigned number that can be added to or subtracted from the base register value. Immediate offset addressing is useful for accessing data elements that are a fixed distance from the start of the data object, such as structure fields, stack offsets, and input/output registers.

Register
The offset is a value from a general-purpose register. The value can be added to, or subtracted from, the base register value. Register offsets are useful for accessing arrays or blocks of data.

Scaled register
The offset is a general-purpose register, shifted by an immediate value, then added to or subtracted from the base register. This means an array index can be scaled by the size of each array element.
The offset and base register can be used in three different ways to form the memory address. The addressing modes are described as follows:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offset</td>
<td>The offset is added to or subtracted from the base register to form the memory address.</td>
</tr>
<tr>
<td>Pre-indexed</td>
<td>The offset is added to or subtracted from the base register to form the memory address. The base register is then updated with this new address, to permit automatic indexing through an array or memory block.</td>
</tr>
<tr>
<td>Post-indexed</td>
<td>The value of the base register alone is used as the memory address. The offset is then added to or subtracted from the base register. The result is stored back in the base register, to permit automatic indexing through an array or memory block.</td>
</tr>
</tbody>
</table>

--- Note ---

Not every variant is available for every instruction, and the range of permitted immediate values and the options for scaled registers vary from instruction to instruction. See Chapter F2 About the T32 and A32 Instruction Descriptions for full details for each instruction.
F1.7 Load/store multiple instructions

Load Multiple instructions load from memory a subset, or possibly all, of the general-purpose registers and the PC.
Store Multiple instructions store to memory a subset, or possibly all, of the general-purpose registers.

The memory locations are consecutive word-aligned words. The addresses used are obtained from a base register, and can be either above or below the value in the base register. The base register can optionally be updated by the total size of the data transferred.

Table F1-13 summarizes the load/store multiple instructions in the T32 and A32 instruction sets.

<table>

<td>\textit{STMIB, STMFA} on page F5-4814</td>
</tr>
</tbody>
</table>

\textsuperscript{a} Not available in the T32 instruction set.
\textsuperscript{b} This instruction is equivalent to an \textit{LDM} instruction with the SP as base register, and base register updating.
\textsuperscript{c} This instruction is equivalent to an \textit{STM} instruction with the SP as base register, and base register updating.

When executing at EL1, variants of the \textit{LDM} and \textit{STM} instructions load and store User mode registers. Another system level variant of the \textit{LDM} instruction performs an exception return.

F1.7.1 Loads to the PC

The \textit{LDM}, \textit{LDMDA}, \textit{LDMDB}, \textit{LDMIB}, and \textit{POP} instructions can load a value into the PC. The value loaded is treated as an interworking address, as described by the \texttt{LoadWritePC()} pseudocode function in \textit{Pseudocode description of operations on the AArch32 general-purpose registers and the PC} on page E1-3993.

\textsuperscript{a} For performance reasons, Arm deprecates many uses of the \texttt{IT} instruction, see \textit{Partial deprecation of IT} on page F1-4094.  
\textsuperscript{b} Arm deprecates any use of the \texttt{SETEND} instruction.  
\textsuperscript{c} See also \textit{The Yield instruction}.

---

\textbf{Note}

Previous versions of the architecture defined the \texttt{DBG} instruction, that could provide a hint to the debug system, in this group. In Armv8, this instruction executes as a \texttt{NOP}. Arm deprecates any use of the \texttt{DBG} instruction.

---

\textbf{F1.8.1 The Yield instruction}

In a \textit{Symmetric Multithreading} (SMT) design, a thread can use the \texttt{YIELD} instruction to give a hint to the PE that it is running on. The \texttt{YIELD} hint indicates that whatever the thread is currently doing is of low importance, and so could yield. For example, the thread might be sitting in a spin-lock. A similar use might be in modifying the arbitration priority of the snoop bus in a multiprocessor (MP) system. Defining such an instruction permits binary compatibility between SMT and SMP systems.
AArch32 state defines a \texttt{YIELD} instruction as a specific NOP (No Operation) hint instruction.

The \texttt{YIELD} instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use on migration to a multiprocessor or multithreading system. Operating systems can use \texttt{YIELD} in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.

### F1.8.2 Partial deprecation of IT

Armv8-A deprecates some uses of the T32 IT instruction, for performance reasons. All uses of IT that apply to instructions other than a single subsequent 16-bit instruction from a restricted set are deprecated, as are explicit references to the PC within that single 16-bit instruction. This permits the non-deprecated forms of IT and subsequent instructions to be treated as a single 32-bit conditional instruction. Table F1-15 shows the restricted set of 16-bit instructions that are not deprecated when used in conjunction with IT.

<table>
<thead>
<tr>

</tbody>
</table>

The full Armv7 IT instruction functionality remains available in order to execute legacy T32 code. It is \textsc{Implementation Defined} whether an Armv8 implementation provides an ITD control, that software can use to disable the deprecated uses of the IT instruction. In an implementation that included the ITD control, setting an ITD field to 1 disables the deprecated uses of the IT instruction, making those uses of the IT instruction \textsc{Undefined}. The ITD control fields are:

- **HSCTLR.ITD** When EL2 is using AArch32, makes execution of the deprecated uses of the IT \textsc{Undefined} at EL2.
- **SCTLR.ITD** When EL1 is using AArch32, makes execution of the deprecated uses of the IT \textsc{Undefined} at EL0 and EL1.
- **SCTLR_EL1.ITD** When EL1 is using AArch64, makes execution of the deprecated uses of the IT \textsc{Undefined} at EL0 when EL0 is using AArch32.
F1.9 Exception-generating and exception-handling instructions

The following instructions are intended specifically to cause a synchronous exception to occur:

- The `SVC` instruction generates a Supervisor Call exception. For more information, see `Supervisor Call (SVC) exception` on page `G1-5782`.
- The `BKPT` instruction provides software breakpoints. For more information, see `Breakpoint Instruction exceptions` on page `G2-5867`.
- In an implementation that includes EL3 the `SMC` instruction generates a Secure Monitor Call exception. For more information, see `Secure Monitor Call (SMC) exception` on page `G1-5783`.
- In an implementation that includes EL2 the `HVC` instruction generates a Hypervisor Call exception. For more information, see `Hypervisor Call (HVC) exception` on page `G1-5784`.

`Debug state` on page `F1-4096` summarizes the Debug state instructions.

For an exception taken to an EL1 mode:

- The system level variants of the `SUBS` and `LDM` instructions can perform a return from an exception.

  Note

  The variants of `SUBS` include `MOVS`. See the references to `Subtract (exception return)`, `Move (exception return)`, and `Load Multiple (exception return)` in Table `F1-16` for more information.

- The `SRS` instruction can be used near the start of the handler, to store return information. The `RFE` instruction can then perform a return from the exception using the stored return information.

In an implementation that includes EL2, the `ERET` instruction performs a return from an exception taken to Hyp mode.

For more information, see `Exception return to an Exception level using AArch32` on page `G1-5765`.

Table `F1-16` summarizes the instructions, in the T32 and A32 instruction sets, for generating or handling an exception. Except for `BKPT` and `SVC`, these are system level instructions.

Table F1-17 T32 Debug state instructions
F1.10 System register access instructions

The System register encoding space is indexed using the parameters \{coproc, opc1, CRn, CRm, opc2\}, see The AArch32 System register interface on page G1-5809. This encoding space provides System registers and System instructions. In Armv8, the only permitted values of coproc are 0b1110 and 0b1111, and the following instructions give access to this encoding space:

- Instructions that transfer data between general-purpose registers and System registers. See:
  - \textit{MCR} on page F5-4543.
  - \textit{MCRR} on page F5-4545.
  - \textit{MRC} on page F5-4566.
  - \textit{MRRC} on page F5-4568.

- Instructions that load or store from memory to a System register. See:
  - \textit{LDC} (immediate) on page F5-4432.
  - \textit{LDC} (literal) on page F5-4434.
  - \textit{STC} on page F5-4783.

\textbf{Note}

The System register encoding space with coproc==0b101x is redefined to provide some of the Advanced SIMD and floating-point functionality. That is, to:

- Initiate a floating-point data-processing operation, see Floating-point data-processing instructions on page F1-4112.
- Transfer data between general-purpose registers and the Advanced SIMD and floating-point registers, see Advanced SIMD and floating-point register transfer instructions on page F1-4100.
- Load or store data to the Advanced SIMD and floating-point registers, see Advanced SIMD and floating-point load/store instructions on page F1-4098.

System register access instructions are part of the instruction stream executed by the PE, and therefore any System register access instruction that cannot be executed by the implementation causes an Undefined Instruction exception. In Armv8-A and Armv8-R, the instruction encodings in the System register access instruction encoding space are unallocated, and generate Undefined Instruction exceptions, except for:

- The instructions summarized in this section that access the coproc==0b111x encoding space.
- The instructions in the coproc==0b101x encoding space that are redefined to provide Advanced SIMD and floating-point functionality, as summarized in the Note in this section.
F1.11 Advanced SIMD and floating-point load/store instructions

Table F1-18 summarizes the SIMD and floating-point register file load/store instructions in the Advanced SIMD and floating-point instruction sets.

Advanced SIMD also provides instructions for loading and storing multiple elements, or structures of elements, see Element and structure load/store instructions.

<table>

F1.11.1 Element and structure load/store instructions

Table F1-19 shows the element and structure load/store instructions available in the Advanced SIMD instruction set. Loading and storing structures of more than one element automatically de-interleaves or interleaves the elements, see Figure F1-1 on page F1-4099 for an example of de-interleaving. Interleaving is the inverse process.

Figure F1-1 shows the de-interleaving of a VLD3.16 (multiple 3-element structures) instruction:

![De-interleaving an array of 3-element structures](image)

A is a packed array of 3-element structures. Each element is a 16-bit halfword.

Figure F1-1 shows the VLD3.16 instruction operating to three 64-bit registers that comprise four 16-bit elements:

- Different instructions in this group would produce similar figures, but operate on different numbers of registers. For example, VLD4 and VST4 instructions operate on four registers.
- Different element sizes would produce similar figures but with 8-bit or 32-bit elements.
- These instructions operate only on doubleword (64-bit) registers.
### F1.12 Advanced SIMD and floating-point register transfer instructions

Table F1-20 summarizes the SIMD and floating-point register file transfer instructions in the Advanced SIMD and floating-point instruction sets. These instructions transfer data between the general-purpose registers and the registers in the SIMD and floating-point register file.

Advanced SIMD vectors, and single-precision and double-precision floating-point registers, are all views of the same register file. For details see The SIMD and floating-point register file on page E1-4000.

</table>
F1.13 Advanced SIMD data-processing instructions

Advanced SIMD data-processing instructions process registers containing vectors of elements of the same type packed together, enabling the same operation to be performed on multiple items in parallel.

Instructions operate on vectors held in 64-bit or 128-bit registers. Figure F1-2 shows an operation on two 64-bit operand vectors, generating a 64-bit vector result.

--- Note ---

Figure F1-2 and other similar figures show 64-bit vectors that consist of four 16-bit elements, and 128-bit vectors that consist of four 32-bit elements. Other element sizes produce similar figures, but with 1, 2, 8, or 16 operations performed in parallel instead of 4.

Figure F1-2 Advanced SIMD instruction operating on 64-bit registers

Many Advanced SIMD instructions have variants that produce vectors of elements double the size of the inputs. In this case, the number of elements in the result vector is the same as the number of elements in the operand vectors, but each element, and the whole vector, is double the size.

Figure F1-3 shows an example of an Advanced SIMD instruction operating on 64-bit registers, and generating a 128-bit result.

Figure F1-3 Advanced SIMD instruction producing wider result

There are also Advanced SIMD instructions that have variants that produce vectors containing elements half the size of the inputs. Figure F1-4 on page F1-4102 shows an example of an Advanced SIMD instruction operating on one 128-bit register, and generating a 64-bit result.
Some Advanced SIMD instructions do not conform to these standard patterns. Their operation patterns are described in the individual instruction descriptions.

Advanced SIMD instructions that perform floating-point arithmetic use the Arm standard floating-point arithmetic defined in *Advanced SIMD and floating-point support* on page A1-52.

The following sections summarize the Advanced SIMD data-processing instructions:

- Advanced SIMD parallel addition and subtraction.
- Bitwise Advanced SIMD data-processing instructions on page F1-4103.
- Advanced SIMD comparison instructions on page F1-4104.
- Advanced SIMD shift instructions on page F1-4105.

</table>

Advanced SIMD multiply instructions can operate on vectors of:

- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit polynomials over \{0, 1\}. VMUL and VMULL are the only instructions that operate on polynomials. VMULL produces a 16-bit polynomial over \{0, 1\}.
• Single-precision (32-bit) or half-precision (16-bit) floating-point numbers.

They can also act on one vector and one scalar.

Long instructions have doubleword (64-bit) operands, and produce quadword (128-bit) results. Other Advanced SIMD multiply instructions can have either doubleword or quadword operands, and produce results of the same size.

Floating-point multiply instructions can operate on:
• Half-precision (16-bit) floating-point numbers.
• Single-precision (32-bit) floating-point numbers.
• Double-precision (64-bit) floating-point numbers.

**F1.13.6 Advanced SIMD dot product instructions**

**FEAT_DotProd** provides SIMD instructions that perform the dot product of the four 8-bit subelements of the 32-bit elements of one vector with the four 8-bit subelements of a second vector. It provides two forms of the instructions, each with signed and unsigned versions:

**Vector form**

The dot product is calculated for each element of the first vector with the corresponding element of the second element.

**Indexed form**

The dot product is calculated for each element of the first vector with the element of the second vector that is indicated by the index argument to the instruction.

---

**Note**

That is, a single element from the second vector is used, and the dot product is calculated between each element of the first vector and this single element from the second vector.

**Table F1-26 Advanced SIMD dot product instructions**

<td>Mixed sign integer dot product by indexed quadruplet&lt;sup&gt;a&lt;/sup&gt;</td>
<td>VUSDOT (by element) on page F6-5694</td>
</tr>
</tbody>
</table>

<sup>a</sup> This instruction is only supported when FEAT_AA32I8MM is implemented.

**F1.13.7 Advanced SIMD complex number arithmetic instructions**

**FEAT_FCMA** provides AArch32 Advanced SIMD instructions that perform arithmetic on complex numbers held in element pairs in vector registers, where the less significant element of the pair contains the real component and the more significant element contains the imaginary component.

These instructions provide single-precision versions. If FEAT_FP16 is implemented they also provide half-precision versions, otherwise the half-precision encodings are UNDEFINED.
Table F1-27 shows the FEAT_FCMA AArch32 Advanced SIMD instructions.

<table>
<thead>
<tr>

</tr>
<tr>
<td>VOMLA</td>
<td>Floating-point complex multiply accumulate (indexed form)</td>
<td>VCMLA (by element) on page F6-5121</td>
</tr>
</tbody>
</table>

A pair of VOMLA instructions can be used to perform a complex number multiplication. In Complex multiplication on page K10-8068, this is demonstrated for the similar AArch64 instruction FCMLA. The usage of VOMLA in this manner is identical.

F1.13.8 Advanced SIMD BFloat16 instructions

When FEAT_AA32BF16 is implemented, BFloat16 instructions are available in AArch32 state.

Table F1-28 shows the Advanced SIMD BFloat16 instructions.

</tbody>
</table>

F1.13.9 Advanced SIMD matrix multiply instructions

When FEAT_AA32I8MM is implemented, these instructions are available in AArch32 state. They include integer and mixed sign dot product instructions.

The matrix multiply-accumulate instructions delimit source and destination vectors into segments. Within each segment:
• The first source vector matrix is organized in row-by-row order.
• The second source vector matrix elements are organized in a column-by-column order.
• The destination vector matrix is organized in row-by-row order.

One matrix multiplication is performed per segment.

Table F1-29 shows the Advanced SIMD matrix multiply instructions.

a. The Cryptographic Extension adds the variant of the instruction that operates on two 64-bit polynomials.
F1.14 Floating-point data-processing instructions

Table F1-32 summarizes the data-processing instructions in the floating-point instruction set. In this table, floating-point register means a register in the SIMD and floating-point register file. The BFloat16 floating-point instructions are provided by FEAT_AA32BF16.

For details of the floating-point arithmetic used by floating-point instructions, see Advanced SIMD and floating-point support on page A1-52.

Chapter F2
About the T32 and A32 Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- Format of instruction descriptions on page F2-4116.
- Standard assembler syntax fields on page F2-4120.
- Conditional execution on page F2-4121.
- Shifts applied to a register on page F2-4123.
- Memory accesses on page F2-4125.
- Encoding of lists of general-purpose registers and the PC on page F2-4126.
- General information about the T32 and A32 instruction descriptions on page F2-4127.
- Additional pseudocode support for instruction descriptions on page F2-4140.
- Additional information about Advanced SIMD and floating-point instructions on page F2-4141.
F2.1 Format of instruction descriptions

The instruction descriptions in Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions and Chapter F6 T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions normally use the following format:

- Instruction section title.
- Introduction to the instruction.
- A description of each encoding of the instruction.
- Assembler syntax.
- Pseudocode describing how the instruction operates.
- Notes, if applicable.

Each of these items is described in more detail in the following subsections.

F2.1.1 Instruction section title

The instruction section title gives the base mnemonic for the instruction or instructions described in the section. When one mnemonic has multiple forms described in separate instruction sections, this is followed by a short description of the form in parentheses. The most common use of this is to distinguish between forms of an instruction in which one of the operands is an immediate value and forms in which it is a register.

F2.1.2 Introduction to the instruction

The introduction to the instruction briefly describes the main features of the instruction. This description is not necessarily complete and is not definitive. If there is any conflict between it and the more detailed information that follows, the latter takes priority.

F2.1.3 Instruction encodings

This is a list of one or more instruction encodings. Each instruction encoding is labeled as:

- A1, A2, A3 … for the first, second, third, and any additional A32 encodings.
- T1, T2, T3 … for the first, second, third, and any additional T32 encodings.

Each instruction encoding description consists of:

- An assembly syntax that ensures that the assembler selects the encoding in preference to any other encoding. Sometimes, multiple syntax variants are given. These are written in a typewriter font using the conventions described in Assembler syntax prototype line conventions on page F2-4118. The correct one to use can be indicated by:
  - A subheading that identifies the encodings that correspond to the syntax. See, for example, the subheading Flag setting, rotate right with extend variant in the description of the A1 encoding of the ADC, ADCS (register) instructions in A1 on page F5-4284.
  - An annotation to the syntax, such as Inside IT block or Outside IT block. See, for example, the syntax descriptions of the T1 encoding of the ADC, ADCS (register) instructions in T1 on page F5-4285.
In other cases, the correct one to use can be determined by looking at the assembler syntax description and using it to determine which syntax corresponds to the instruction being disassembled.

There is usually more than one syntax variant that ensures re-assembly to any particular encoding, and the exact set of syntaxes that do so usually depends on the register numbers, immediate constants, and other operands to the instruction. For example, when assembling to the T32 instruction set, the syntax AND R0, R0, R8 ensures selection of a 32-bit encoding but AND R0, R0, R1 selects a 16-bit encoding.
For each instruction encoding belonging to a target instruction set, an assembler can use this information to
determine whether it can use that encoding to encode the instruction requested by the UAL source. If multiple
encodings can encode the instruction, then:

— If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecture prefers the
16-bit encoding. This means the assembler must use the 16-bit encoding rather than the 32-bit
encoding.

Software can use the .W and .N qualifiers to specify the required encoding width, see Standard
assembler syntax fields on page F2-4120.

— If multiple encodings of the same length can encode the instruction, the Assembler syntax subsection
says which encoding is preferred, and how software can, instead, select the other encodings.

Each encoding also documents UAL syntax that selects it in preference to any other encoding.

If no encodings of the target instruction set can encode the instruction requested by the UAL source, normally
the assembler generates an error saying that the instruction is not available in that instruction set.

Note
In some cases, an instruction is available in one instruction set but not in another. The Assembler syntax
subsection identifies many of these cases. For example, the A32 instructions with bits<31:28> == 0b1111
described in Branch, branch with link, and block data transfer on page F4-4244, System register access,
Advanced SIMD, floating-point, and Supervisor call on page F4-4246, and Unconditional instructions on
page F4-4261 cannot have a Condition code, but the equivalent T32 instructions often can, and this usually
appears in the Assembler syntax subsection as a statement that the A32 instruction cannot be conditional.

However, some such cases are too complex to describe in the available space, so the definitive test of whether
an instruction is available in a given instruction set is whether there is an available encoding for it in that
instruction set.

The assembly syntax given for an encoding is therefore a suitable one for a disassembler to disassemble that
encoding to. However, disassemblers might wish to use simpler syntaxes when they are suitable for the
operand combination, to produce more readable disassembled code.

• An encoding diagram, where:
  — For a 32-bit A32 encoding diagram, the bits are numbered from 31-0.
  — For a 16-bit T32 encoding diagram, the bits are numbered from 15-0.

This halfword can be described as hw1 of the instruction.

  — For a 32-bit T32 encoding diagram, the bits are numbered from 15-0 for each halfword, as a reminder
that a 32-bit T32 instruction consists of two consecutive halfwords rather than a word.

In this case, the left-hand halfword in the diagram is identified as hw1, and the right-hand halfword is
identified as hw2.

Where instructions are stored using the standard little-endian instruction endianness:

  — The encoding diagram for an A32 instruction at address A shows, from left to right, the bytes at
addresses A+3, A+2, A+1, A.

  — The encoding diagram for a 32-bit T32 instruction shows bytes in the order A+1, A for hw1, followed
by bytes A+3, A+2 for hw2.

• Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields
into inputs to the encoding-independent pseudocode in the Operation subsection, and that picks out any
special cases in the encoding. For a detailed description of the pseudocode used and of the relationship
between the encoding diagram, the encoding-specific pseudocode and the encoding-independent
pseudocode, see Appendix K14 Arm Pseudocode Definition.

F2.1.4 Assembler symbols

The Assembly symbols describe the standard UAL syntax for the instruction.

Each syntax description consists of the following elements:

• Descriptions of all variable or optional fields of the syntax.
Some syntax fields are standardized across all or most instructions. *Standard assembler syntax fields on page F2-4120* describes these fields.

By default, syntax fields that specify registers, such as `<Rd>`, `<Rn>`, or `<Rt>`, can be any of R0-R12 or LR in T32 instructions, and any of R0-R12, SP, or LR in A32 instructions. These require that the encoding-specific pseudocode set the corresponding integer variable (such as `d`, `n`, or `t`) to the corresponding register number, using 0-12 for R0-R12, 13 for SP, or 14 for LR:

- Normally, software can do this by setting the corresponding field in the instruction, typically named `Rd`, `Rn`, `Rt`, to the binary encoding of that number.
- In the case of 16-bit T32 encodings, the field is normally of length 3, and so the encoding is only available when the assembler syntax specifies one of R0-R7. Such encodings often use a register field name like `Rdn`. This indicates that the encoding is only available if `<Rd>` and `<Rn>` specify the same register, and that the register number of that register is encoded in the field if they do.

The description of a syntax field that specifies a register sometimes extends or restricts the permitted range of registers or documents other differences from the default rules for such fields. Examples of extensions are permitting the use of the SP in a T32 instruction, or permitting the use of the PC, identified using register number 15.

- Where appropriate, text that briefly describes changes from the pre-UAL assembler syntax. Where present, this usually consists of an alternative pre-UAL form of the assembler mnemonic. The pre-UAL assembler syntax does not conflict with UAL. Arm recommends that it is supported, as an optional extension to UAL, so that pre-UAL assembler source files can be assembled.

### Assembler syntax prototype line conventions

The following conventions are used in assembler syntax prototype lines and their subfields:

- **< >** Any item bracketed by `<` and `>` is a short description of a type of value to be supplied by the user in that position. A longer description of the item is normally supplied by subsequent text. Such items often correspond to a similarly named field in an encoding diagram for an instruction. When the correspondence only requires the binary encoding of an integer value or register number to be substituted into the instruction encoding, it is not described explicitly. For example, if the assembler syntax for an instruction contains an item `<Rn>` and the instruction encoding diagram contains a 4-bit field named `Rn`, the number of the register specified in the assembler syntax is encoded in binary in the instruction field.

  If the correspondence between the assembler syntax item and the instruction encoding is more complex than simple binary encoding of an integer or register number, the item description indicates how it is encoded. This is often done by specifying a required output from the encoding-specific pseudocode, such as `add = TRUE`. The assembler must only use encodings that produce that output.

- **{ }** Any item bracketed by `{` and `}` is optional. A description of the item and of how its presence or absence is encoded in the instruction is normally supplied by subsequent text.

  Many instructions have an optional destination register. Unless otherwise stated, if such a destination register is omitted, it is the same as the immediately following source register in the instruction syntax.

- **#** In the assembler syntax, numeric constants are normally preceded by a #. Some UAL instruction syntax descriptions explicitly show this # as optional. Any UAL assembler:

  - Must treat the # as optional where an instruction syntax description shows it as optional.
  - Can treat the # either as mandatory or as optional where an instruction syntax description does not show it as optional.

    ——— Note ———

    Arm recommends that UAL assemblers treat all uses of # shown in this manual as optional.

- **spaces** Single spaces are used for clarity, to separate items. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.
+/− This indicates an optional + or - sign. If neither is coded, + is assumed.

All other characters must be encoded precisely as they appear in the assembler syntax. Apart from { and }, the special characters described above do not appear in the basic forms of assembler instructions documented in this manual. In a few places, the { and } characters must be encoded as part of a variable item. When this happens, the long description of the variable item indicates how they must be used.

**F2.1.5 Pseudocode describing how the instruction operates**

The *Operation for all classes* subsection contains encoding-independent pseudocode that describes the main operation of the instruction. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see *Appendix K14 Arm Pseudocode Definition*. 
F2.2 Standard assembler syntax fields

The following assembler syntax fields are standard across all or most instructions:

\(<c>\)

Is an optional field. It specifies the condition under which the instruction is executed. See Conditional execution on page F2-4121 for the range of available conditions and their encoding. If \(<c>\) is omitted, it defaults to always (AL).

\(<q>\)

Specifies optional assembler qualifiers on the instruction. The following qualifiers are defined:

\(\cdot N\)

Meaning narrow, specifies that the assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.

\(\cdot W\)

Meaning wide, specifies that the assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither \(\cdot W\) nor \(\cdot N\) is specified, the assembler can select either 16-bit or 32-bit encodings. If both are available, it must select a 16-bit encoding. In a few cases, more than one encoding of the same length can be available for an instruction. The rules for selecting between such encodings are instruction-specific and are part of the instruction description. The assembler syntax includes a mandatory \(\cdot W\) qualifier, along with a note describing the cases in which it applies, where this qualifier is required to select a particular encoding for an instruction. Additional assembler syntax will describe the syntax when the conditions are not met.

Note

When assembling to the A32 instruction set, the \(\cdot N\) qualifier produces an assembler error and the \(\cdot W\) qualifier has no effect.
F2.3 Conditional execution

Most T32 and A32 instructions can be executed conditionally, based on the values of the APSR Condition flags. Table F2-1 lists the available conditions.

Table F2-1 Condition codes

<table>
<thead>
<tr>
<th>cond</th>
<th>Mnemonic extension</th>
<th>Meaning (integer)</th>
<th>Meaning (floating-point)</th>
<th>Condition flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>

<td>Z == 1 or N != V</td>
</tr>
<tr>
<td>1110</td>
<td>None (AL) d</td>
<td>Always (unconditional)</td>
<td>Always (unconditional)</td>
<td>Any</td>
</tr>
</tbody>
</table>

- a. Unordered means at least one NaN operand.
- b. HS (unsigned higher or same) is a synonym for CS.
- c. LO (unsigned lower) is a synonym for CC.
- d. AL is an optional mnemonic extension for always, except in IT instructions. For details, see IT on page F5-4416.

In T32 instructions, the condition, if it is not AL, is normally encoded in a preceding IT instruction. For more information, see Conditional instructions on page F1-4077 and IT on page F5-4416. Some conditional branch instructions do not require a preceding IT instruction, because they include a Condition code in their encoding.

For performance reasons, Armv8 deprecates the use of IT other than with a single 16-bit T32 instruction from a specified subset of the 16-bit T32 instructions, see Partial deprecation of IT on page F1-4094. In addition, implementations can provide a set of ITD control fields, SCTLR.ITD, SCTLR_EL1.ITD, and HSCTLR.ITD, to disable these deprecated uses, making them UNDEFINED. For more information, see:

- Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality on page G1-5821.
- Disabling or enabling EL2 use of AArch32 deprecated functionality on page G1-5830.

In A32 instructions, bits[31:28] of the instruction contain either:

- The Condition code, see The Condition code field in A32 instruction encodings on page F2-4122.
- 0b1111 for some A32 instructions that can only be executed unconditionally.
### F2.3.1 The Condition code field in A32 instruction encodings

Every conditional A32 instruction contains a 4-bit Condition code field, the \textit{cond} field, in bits 31-28:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

This field contains one of the values \texttt{0b0000-0b1110}, as shown in Table F2-1 on page F2-4121. Most instruction mnemonics can be extended with the letters defined in the \textit{Mnemonic extension} on page F2-4121 column of that table.

If the \textit{always} (AL) condition is specified, the instruction is executed irrespective of the value of the Condition flags. The absence of a Condition code on an instruction mnemonic implies the AL Condition code.

### F2.3.2 Pseudocode description of conditional execution

The \texttt{AArch32.CurrentCond()} function returns a 4-bit condition specifier as follows:

- For A32 instructions, it returns bits[31:28] of the instruction.
- For the T1 and T3 encodings of the Branch instruction (see \texttt{B} on page F5-4329), it returns the 4-bit \textit{cond} field of the encoding.
- For all other T32 instructions:
  - If \texttt{PSTATE.IT<3:0> != '0000'} it returns \texttt{PSTATE.IT<7:4>}
  - If \texttt{PSTATE.IT<7:0> == '00000000'} it returns \texttt{'1110'}
  - Otherwise, execution of the instruction is \texttt{CONSTRAINED UNPREDICTABLE}.

For more information, see \textit{Process state, PSTATE} on page E1-3993.

The \texttt{ConditionPassed()} function uses this condition specifier and the Condition flags to determine whether the instruction must be executed, by calling the \texttt{ConditionHolds()} function.

Chapter J1 \textit{Armv8 Pseudocode} includes the definitions of these functions.

\textit{Undefined Instruction exception} on page G1-5778 describes the handling of conditional instructions that are \texttt{UNDEFINED}, \texttt{UNPREDICTABLE}, or \texttt{CONSTRAINED UNPREDICTABLE}. The pseudocode in the manual, as a sequential description of the instructions, has limitations in this respect. For more information, see \textit{Limitations of the instruction pseudocode} on page K14-8132.
F2.4 Shifts applied to a register

A32 register offset load/store word and unsigned byte instructions can apply a wide range of different constant shifts to the offset register. Both T32 and A32 data-processing instructions can apply the same range of different constant shifts to the second operand register. For details, see Constant shifts.

A32 data-processing instructions can apply a register-controlled shift to the second operand register.

F2.4.1 Constant shifts

These are the same in T32 and A32 instructions, except that the input bits come from different positions.

<shift> is an optional shift to be applied to <Rm>. It can be any one of:

- (omitted) No shift.
- LSL #<n> Logical shift left <n> bits. 1 <= <n> <= 31.
- LSR #<n> Logical shift right <n> bits. 1 <= <n> <= 32.
- ASR #<n> Arithmetic shift right <n> bits. 1 <= <n> <= 32.
- ROR #<n> Rotate right <n> bits. 1 <= <n> <= 31.
- RRX Rotate right one bit, with extend. Bit[0] is written to shifter_carry_out, bits[31:1] are shifted right one bit, and the Carry flag is shifted into bit[31].

Note

Assemblers can permit the use of some or all of ASR #0, LSL #0, LSR #0, and ROR #0 to specify that no shift is to be performed. This is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must omit the shift specifier when the instruction specifies no shift.

Similarly, assemblers can permit the use of #0 in the immediate forms of ASR, LSL, LSR, and ROR instructions to specify that no shift is to be performed, that is, that a MOV (register) instruction is wanted. Again, this is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must use the MOV (register) syntax when the instruction specifies no shift.

Encoding

The assembler encodes <shift> into two type bits and five immediate bits, as follows:

- (omitted) type = 0b00, immediate = 0.
- LSL #<n> type = 0b00, immediate = <n>.
- LSR #<n> type = 0b01.
  - If <n> < 32, immediate = <n>.
  - If <n> == 32, immediate = 0.
- ASR #<n> type = 0b10.
  - If <n> < 32, immediate = <n>.
  - If <n> == 32, immediate = 0.
- ROR #<n> type = 0b11, immediate = <n>.
- RRX type = 0b11, immediate = 0.
F2.4.2 Register controlled shifts

These are only available in A32 instructions.

<type> is the type of shift to apply to the value read from <Rm>. It must be one of:
- **AR**  Arithmetic shift right, encoded as type = 0b10.
- **LSL** Logical shift left, encoded as type = 0b00.
- **LSR** Logical shift right, encoded as type = 0b01.
- **ROR** Rotate right, encoded as type = 0b11.

The bottom byte of <Rs> contains the shift amount.

F2.4.3 Pseudocode description of instruction-specified shifts and rotates

The pseudocode enumeration **SRTType{}** defines the shift types. Shift and rotate instruction decode is described by the pseudocode function:

- **DecodeImmShift()** for a constant shift.
- **DecodeRegShift()** for a register controlled shift.

Shift and rotate operations are made by the pseudocode function **Shift()**.
F2.5 Memory accesses

Commonly, the following addressing modes are permitted for memory access instructions:

Offset addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access. The value of the base register is unchanged.

The assembly language syntax for this mode is:

\[ [<Rn>, <offset>] \]

Pre-indexed addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access, and written back into the base register.

The assembly language syntax for this mode is:

\[ [<Rn>, <offset>!] \]

Post-indexed addressing

The address obtained from the base register is used, unchanged, as the address for the memory access. The offset value is applied to the address, and written back into the base register.

The assembly language syntax for this mode is:

\[ [<Rn>, <offset>] \]

In each case, \( <Rn> \) is the base register. \( <offset> \) can be:

- An immediate constant, such as \( <\text{imm8}> \) or \( <\text{imm12}> \).
- An index register, \( <Rm> \).
- A shifted index register, such as \( <Rm>, \text{LSL} \ #\text{shift}\).

For information about unaligned access, endianness, and exclusive access, see:

- *Alignment support on page E2-4044.*
- *Endian support on page E2-4046.*
- *Synchronization and semaphores on page E2-4063.*
F2.6 Encoding of lists of general-purpose registers and the PC

A number of instructions operate on lists of general-purpose registers. For some load instructions, the list of registers to be loaded can include the PC. For these instructions, the assembler syntax includes a <registers> field, that provides a list of the registers to be operated on, with list entries separated by commas.

The registers list is encoded in the instruction encoding. Most often, this is done using an 8-bit, 13-bit, or 16-bit register_list field. This section gives more information about these and other possible register list encodings.

In a register_list field, each bit corresponds to a single register, and if the <registers> field of the assembler instruction includes Rt then register_list<0> is set to 1, otherwise it is set to 0.

The full rules for the encoding of lists of general-purpose registers, and possibly the PC, are:

- Except for the cases listed here, 16-bit T32 encodings use an 8-bit register list, and can access only registers R0-R7.

  The exceptions to this rule are:
  - The T1 encoding of POP uses an 8-bit register list, and an additional bit, \( p \), that corresponds to the PC. This means it can access any of R0-R7 and the PC.
  - The T1 encoding of PUSH uses an 8-bit register list, and an additional bit, \( m \), that corresponds to the LR. This means it can access any of R0-R7 and the LR.

- 32-bit T32 encodings of load operations use a 13-bit register list, and two additional bits, \( m \) and \( p \), corresponding to the LR and the PC. This means these instructions can access any of R0-R12 and the LR and PC.

- 32-bit T32 encodings of store operations use a 13-bit register list, and one additional bit, \( m \), corresponding to the LR. This means these instructions can access any of R0-R12 and the LR.

- Except for the case listed here, A32 encodings use a 16-bit register list. This means these instructions can access any of R0-R12 and the SP, LR, and PC.

  The exception to this rule is:
  - The System instructions LDM (exception return) and LDM (User registers) use a 15-bit register list. This means these instructions can access any of R0-R12 and the SP and LR.

- The T3 and A2 encodings of POP, and the T3 and A2 encodings of PUSH, access a single register from the set of registers \{R0-R12, LR, PC\} and encode the register number in the \( Rt \) field.

--- Note ---

POP is a load operation, and PUSH is a store operation.

--- Note ---

Some Advanced SIMD and floating-point instructions operate on lists of SIMD and floating-point registers. The assembler syntax of these instructions includes a <list> field that specifies the registers to be operated on, and the description of the instruction in Alphabetical list of T32 and A32 base instruction set instructions on page F5-4280 defines the use and encoding of this field.
F2.7 General information about the T32 and A32 instruction descriptions

Chapter F3 T32 Instruction Set Encoding describes the T32 instruction encodings, and Chapter F4 A32 Instruction Set Encoding describes the A32 instruction encodings. The following subsections give more information about the descriptions of these instructions and their encodings:

- **Execution of instructions in debug state.**
- **Fixed values in AArch32 instruction and System register descriptions.**
- **UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space on page F2-4128.**
- **T32 and A32 Advanced SIMD and floating-point instruction encodings on page F2-4129.**
- **The PC and the use of 0b1111 as a register specifier in T32 and A32 instructions on page F2-4133.**
- **The SP and the use of 0b1101 as a register specifier in T32 and A32 instructions on page F2-4134.**
- **Modified immediate constants in T32 and A32 instructions on page F2-4134.**

F2.7.1 Execution of instructions in debug state

In general, except for the instructions described in Debug state on page F1-4096, the T32 instruction descriptions do not indicate any differences in the behavior of the instruction if it is executed in Debug state. For this information, see Executing instructions in Debug state on page H2-7025.

---

**Note**

- A32 instructions cannot be executed in Debug state.
- For many T32 instructions, execution is unchanged in Debug state. Executing instructions in Debug state on page H2-7025 identifies these instructions.

F2.7.2 Fixed values in AArch32 instruction and System register descriptions

This section summarizes the terms used to describe fixed values in AArch64 register and instruction descriptions. The Glossary gives full descriptions of these terms, and each entry in this section includes a link to the corresponding Glossary entry.

---

**Note**

In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the Glossary.

---

The following terms are used to describe bits or fields with fixed values:

- **RAZ** Read-As-Zero. See Read-As-Zero (RAZ).
- **(0), RES0** Reserved, Should-Be-Zero (SBZ) or RES0.

In diagrams, a RAZ bit can be shown as 0.

In instruction encoding diagrams, and sometimes in other descriptions, (0) indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 0.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (0)(0)(0) or as (000).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. For more information, see the Glossary definition of RES0.

---

**Note**

Some of the System instruction descriptions in this chapter are based on the field description of the input value for the instruction. These are register descriptions and therefore can include RES0 fields,
The (0) and RES0 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

**RAO**
Read-As-One. See Read-As-One (RAO).
In diagrams, a RAO bit can be shown as 1.

**(1), RES1**
Reserved, Should-Be-One (SBO) or RES1.
In instruction encoding diagrams, and sometimes in other descriptions, (1) indicates a SBO bit. If the bit is set to 0, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:
- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 1.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (1)(1)(1) or as (111).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. For more information, see the Glossary definition of RES1.

---

**Note**

Some of the System instruction descriptions in this chapter are based on the field description of the input value for the instruction. These are register descriptions and therefore can include RES1 fields, as shown above.

The (1) and RES1 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

---

**Note**

In register diagrams, (0) is a synonym for RES0, and (1) is a synonym for RES1, where RES0 and RES1 are defined in the Glossary. However, when used in an instruction encoding diagram, (0) and (1) have the narrower definition that behavior is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE if either:
- A bit marked as (0) has the value 1.
- A bit marked as (1) has the value 0.

---

**F2.7.3 UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space**

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE. Armv8-A greatly reduces the architecturally UNPREDICTABLE behavior in AArch32 state. Most cases that earlier versions of the architecture describe as UNPREDICTABLE become either:
  - CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.
  - Fully predictable.
  For more information, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in Chapter F3 T32 Instruction Set Encoding or Chapter F4 A32 Instruction Set Encoding.

An instruction is UNPREDICTABLE only if:

- It is declared as UNPREDICTABLE in an instruction description or in Chapter F3 or Chapter F4, and Appendix K1 does not redefine the behavior as CONSTRAINED UNPREDICTABLE.

- The pseudocode for that encoding does not indicate that a different special case applies, and a bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1 respectively. In most cases, Armv8 makes these cases CONSTRAINED UNPREDICTABLE, as described in SBZ or SBO fields T32 and A32 in instructions on page K1-7944.
Unless otherwise specified, T32 and A32 instructions provided as part of an architectural extension, or by an optional feature of the architecture, are UNDEFINED in an implementation that does not include that extension or feature.

--- Note ---
Examples of where this rule applies are:

- The instructions provided by the Cryptographic Extension.
- The System instructions that provide access to the System registers of the OPTIONAL Performance Monitors Extension.
- The Advanced SIMD and floating-point instructions.

---

For more information about UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction behavior, see *Undefined Instruction exception on page G1-5778.*

### F2.7.4 T32 and A32 Advanced SIMD and floating-point instruction encodings

The T32 and A32 encodings of Advanced SIMD and floating-point instructions that are described in Chapter F3 *T32 Instruction Set Encoding* and in Chapter F4 *A32 Instruction Set Encoding* are common to the T32 and A32 instruction sets. This means:

- The instruction groups, and the set of instructions in each group, are identical for T32 and A32.
- For each instruction:
  - Each T32 encoding is exactly equivalent to an A32 encoding.
  - There is no T32 encoding without an equivalent A32 encoding, and no A32 encoding without an equivalent T32 encoding.

--- Note ---
In the T32 instruction sets, the Advanced SIMD and floating-point instructions have 32-bit encodings.

---

32-bit T32 encodings are described as two contiguous halfwords, \{hw1:hw2\}, as described in *Instruction encodings on page F2-4116.* In general:

- hw1 of a T32 encoding maps onto bits[31:16] of an equivalent A32 encoding.
- hw2 of a T32 encoding maps onto bits[15:0] of an equivalent A32 encoding.

However, the different structures of the T32 instruction encoding space and the A32 instruction encoding space mean that:

- For a given Advanced SIMD and floating-point instruction group:
  - The positions of the fields that identify the instruction, or instruction encoding, within the instruction group might differ between the T32 encodings and the A32 encodings.
  - However, the field values that identify the instruction of instruction encoding are identical for the T32 encoding and the A32 encoding.

The remainder of this section describes the equivalence of the T32 and A32 encodings for each of the Advanced SIMD and floating-point instruction groups.

#### Advanced SIMD data-processing

The T32 encoding of the Advanced SIMD data-processing group is:
The A32 encoding of the Advanced SIMD data-processing group is:

```
| 31  | 25 24 23 22 | | | | | | | | 5 4 3 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1111001 | | | | | | | | | | | | |
```

The encodings in this group are identified by:

- \( \text{hw1}[15:13] \) of the T32 encoding is equivalent to bits[27:25] of the A32 encoding, and:
  - Has the value \( 0b111 \) in the T32 encoding.
  - Has the value \( 0b001 \) in the A32 encoding.

- \( \text{hw1}[11:8] \) of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and has the value \( 0b1111 \).

This table shows the equivalence of the fields that identify the instructions, or instruction encodings, within this group:

<table>
<thead>
<tr>
<th>T32 encoding</th>
<th>A32 encoding</th>
<th>Field size</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0:op1</td>
<td>op0</td>
<td>2 bits</td>
</tr>
<tr>
<td>op2</td>
<td>op1</td>
<td>15 bits</td>
</tr>
<tr>
<td>op3</td>
<td>op2</td>
<td>1 bit</td>
</tr>
<tr>
<td>op4</td>
<td>op3</td>
<td>1 bit</td>
</tr>
</tbody>
</table>

**Advanced SIMD element or structure load/store**

The T32 encoding of the Advanced SIMD element or structure load/store group is:

```
| 15  | 13 12|11  8 7 6 | 0 |15 | | 5 4 3 0 |
|---|---|---|---|---|---|---|---|
| 111 1111001 | | | | | | | |
```

The A32 encoding of the Advanced SIMD element or structure load/store group is:

```
| 31  | 24 23 22 21 20 |19 | | | | | | | | 12|11|10|9 | | | | 0 |
| 11110100 | | | | | | | | | | | | | | | | | | | | | | | | | | | |
```

The encodings in this group are identified by:

- \( \text{hw1}[15:12] \) of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and has the value \( 0b1111 \).
• hw1[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and:
  — Has the value 0b1001 in the T32 encoding.
  — Has the value 0b0100 in the A32 encoding.

• hw1[4] of the T32 encoding is equivalent to bit[20] of the A32 encoding, and has the value 0b0.

op0, op1, and op2 are the fields that identify the instructions, or instruction encodings, within this group, and they are in equivalent positions in the T32 and A32 encodings.

Floating-point and Advanced SIMD load/store and 64-bit register moves

The T32 encoding of the Floating-point and Advanced SIMD load/store and 64-bit register moves group is:

<table>
<thead>
<tr>
<th>15</th>
<th>8</th>
<th>5 4</th>
<th>0</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110110</td>
<td>op0</td>
<td>101</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The A32 encoding of the Floating-point and Advanced SIMD load/store and 64-bit register moves group is:

| 31 | 27 | 24 | 21 20| | 12 | 11 | 8 | 0 |
|----|----|----|------||----|----|---|---|
| !=1111 | 110 | op0 | 101 |

The encodings in the group are identified by:

• hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
  — Has the value 0b1110 in the T32 encoding.
  — Can have any value other than 0b1111 in the A32 encoding.
  This range of values is required because A32 instructions in this group can be executed conditionally, see Conditional execution on page F2-4121.

• hw1[11:9] of the T32 encoding is equivalent to bits[27:25] of the A32 encoding, and has the value 0b110.

• hw2[11:9] of the T32 encoding is equivalent to bits[11:9] of the A32 encoding, and has the value 0b101.

op0 is the field that identifies the instructions, or instruction encodings, within this group, and is in equivalent positions in the T32 and A32 encodings.

Floating-point and Advanced SIMD 32-bit register moves

The T32 encoding of the Floating-point and Advanced SIMD 32-bit register moves group is:

| 15 | | 7 5 4 | 0 | 12 | 11 | 8 | 7 5 4 | 0 |
|----||-----|---|----|----|---|-----|---|
| 11101110 | op0 | 101 | 1 |

The A32 encoding of the Advanced SIMD 32-bit register moves group is:

| 31 | 27 | 23 | 21 20| | 12 | 11 | 8 | 7 5 4 | 0 |
|----|----|----|------||----|----|---|-----|---|
| !=1111 | 1110 | op0 | 101 | 1 |
The encodings in this group are identified by:

- hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
  - Has the value 0b1110 in the T32 encoding.
  - Can have any value other than 0b1111 in the A32 encoding.
  - This range of values is required because A32 instructions in this group can be executed conditionally, see Conditional execution on page F2-4121.

- hw1[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and has the value 0b1110.
- hw1[4] of the T32 encoding is equivalent to bit[4] of the A32 encoding, and has the value 0b1.

op0 is the field that identifies the instructions, or instruction encodings, within this group, and is in equivalent positions in the T32 and A32 encodings.

**Floating-point data-processing**

The T32 encoding of the Floating-point data-processing group is:

<table>
<thead>
<tr>
<th>15</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
<th>15</th>
<th>12</th>
<th>10</th>
<th>9</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>11101110</td>
<td>op0</td>
<td>10</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The A32 encoding of the Floating-point data-processing group is:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>!=1111</td>
<td>1110</td>
<td>op0</td>
<td>10</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The encodings in this group are identified by:

- hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
  - In the T32 encoding, hw1[15:13] has the value 0b111, and hw1[12] is the op0 parameter used in identifying instruction encodings within this group.
  - In the A32 encoding, cond is the cond field and also implies the value of bit[28] of some A32 instruction encodings within this group, as the following table shows:

<table>
<thead>
<tr>
<th>cond</th>
<th>Significance of bit[28] in A32 encodings</th>
</tr>
</thead>
<tbody>
<tr>
<td>!= 0b1111</td>
<td>Part of the cond field.</td>
</tr>
<tr>
<td>0b1111</td>
<td>Has fixed value of 1.</td>
</tr>
</tbody>
</table>

The range of cond values other than 0b1111 is required because A32 instructions in this group can be executed conditionally, see Conditional execution on page F2-4121.

- hw1[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and has the value 0b1110.
- hw1[4] of the T32 encoding is equivalent to bit[4] of the A32 encoding, and has the value 0b0.
This table shows the equivalence of the fields that identify the instructions, or instruction encodings, within this group:

<table>
<thead>
<tr>
<th>T32 encoding</th>
<th>A32 encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0</td>
<td>Bit[28] of the instruction encoding is 1 when cond is 0b1111.</td>
</tr>
<tr>
<td>op1</td>
<td>op0</td>
</tr>
<tr>
<td>op2</td>
<td>op1</td>
</tr>
<tr>
<td>op3</td>
<td>op2</td>
</tr>
</tbody>
</table>

**F2.7.5 The PC and the use of 0b1111 as a register specifier in T32 and A32 instructions**

Restrictions on the use of PC or 0b1111 as a register specifier differ between the T32 and the A32 instruction sets, as described in:

- T32 restrictions on the use of the PC, and use of 0b1111 as a register specifier.
- A32 restrictions on the use of PC or 0b1111 as a register specifier on page F2-4134.

**T32 restrictions on the use of the PC, and use of 0b1111 as a register specifier**

The use of 0b1111 as a register specifier is not normally permitted in T32 instructions. When a value of 0b1111 is permitted, a variety of meanings is possible. For register reads, these meanings include:

- Read the PC value, that is, the address of the current instruction + 4. The base register of the table branch instructions TBB and TBH can be the PC. This means branch tables can be placed in memory immediately after the instruction.

  _________ Note _________

  Arm deprecates use of the PC as the base register in the STC instruction.

- Read the word-aligned PC value, that is, the address of the current instruction + 4, with bits[1:0] forced to zero. The base register of LDC, LDR, LDRB, LDRD (pre-indexed, no writeback), LDRH, LDRSB, and LDRSH instructions can be the word-aligned PC. This provides PC-relative data addressing. In addition, some encodings of the ADD and SUB instructions permit their source registers to be 0b1111 for the same purpose.

- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

For register writes, these meanings include:

- The PC can be specified as the destination register of an LDR instruction. This is done by encoding Rt as 0b1111. The loaded value is treated as an address, and the effect of execution is a branch to that address. Bit[0] of the loaded value selects whether to execute A32 or T32 instructions after the branch.

- Some other instructions write the PC in similar ways. An instruction can specify that the PC is written:
  - Implicitly, for example, branch instructions.
  - Explicitly by a register specifier of 0b1111, for example 16-bit MOV (register) instructions.
  - Explicitly by using a register mask, for example LDM instructions.

  The address to branch to can be:
  - A loaded value, for example, RFE.
  - A register value, for example, BX.
  - The result of a calculation, for example, TBB or TBH.
The method of choosing the instruction set used after the branch can be:

- Similar to the LDR case, for example, LDM or BX.
- A fixed instruction set other than the one currently being used, for example, the immediate form of BLX.
- Unchanged, for example, branch instructions or 16-bit MOV (register) instructions.
- Set from the SPSR.T bit, for RFE and SUBS PC, LR, #imm8.

- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

- If the destination register specifier of an LDRB, LDRH, LDRSB, or LDRSH instruction is 0b1111, the instruction is a memory hint instead of a load operation.

- If the destination register specifier of an MRC instruction is 0b1111, bits[31:28] of the value transferred from the System register are written to the N, Z, C, and V Condition flags in the APSR, and bits[27:0] are discarded.

**A32 restrictions on the use of PC or 0b1111 as a register specifier**

In A32 instructions, the use of 0b1111 as a register specifier specifies the PC.

Many instructions are CONSTRAINED UNPREDICTABLE if they use 0b1111 as a register specifier. This is specified by pseudocode in the instruction description. Armv8-A constrains the resulting CONSTRAINED UNPREDICTABLE behavior, see *Using R15 on page K1-7941.*

---

**Note**

Arm deprecates use of the PC as the base register in any store instruction.

---

**F2.7.6 The SP and the use of 0b1101 as a register specifier in T32 and A32 instructions**

In the T32 and A32 instruction sets, Arm recommends that the use of 0b1101 as a register specifier specifies the SP.

---

**Note**

- The recommendation that the register specifier 0b1101 is only used to specify the SP applies to both the T32 and the A32 instruction sets.

- Despite this recommendation, T32 instructions that can access R13, or the SP, behave predictably in Armv8. This differs from Armv7, where many uses of R13 are defined as UNPREDICTABLE. For more information about these cases, see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.*

---

**F2.7.7 Modified immediate constants in T32 and A32 instructions**

The following sections describe the encoding of modified immediate constants:

- *Modified immediate constants in T32 instructions on page F2-4135.*
- *Modified immediate constants in A32 instructions on page F2-4136.*
- *Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-4137.*
- *Modified immediate constants in T32 and A32 floating-point instructions on page F2-4138.*
Modified immediate constants in T32 instructions

The encoding of a modified immediate constant in a 32-bit T32 instruction is:

Table F2-2 shows the range of modified immediate constants available in T32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, h, and i bits, and the imm3 field, in the instruction.

Table F2-2 Encoding of modified immediates in T32 data-processing instructions

<table>
<thead>
<tr>
<th>i:imm3:a</th>
<th>&lt;const&gt; a</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000x</td>
<td>00000000 00000000 00000000 abcdefgh</td>
</tr>
<tr>
<td>0001x</td>
<td>00000000 abcdefgh 00000000 abcdefgh b</td>
</tr>
<tr>
<td>0010x</td>
<td>abcdefgh 00000000 abcdefgh 00000000 b</td>
</tr>
<tr>
<td>0011x</td>
<td>abcdefgh abcdefgh abcdefgh abcdefgh b</td>
</tr>
<tr>
<td>01000</td>
<td>1bcdefgh 00000000 00000000 00000000</td>
</tr>
<tr>
<td>01001</td>
<td>01bcdefgh 00000000 00000000 00000000 c</td>
</tr>
<tr>
<td>01010</td>
<td>001bcdefgh 00000000 00000000 00000000 c</td>
</tr>
<tr>
<td>01011</td>
<td>0001bcdefgh 00000000 00000000 00000000 c</td>
</tr>
<tr>
<td>11101</td>
<td>00000000 00000000 000001bcdefgh000 c</td>
</tr>
<tr>
<td>11110</td>
<td>00000000 00000000 00000001bcdefgh0</td>
</tr>
<tr>
<td>11111</td>
<td>00000000 00000000 0000000001bcdefgh0 c</td>
</tr>
</tbody>
</table>

a. This table shows the immediate constant value in binary form, to relate abcdefgh to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).
b. Arm deprecates using a modified immediate with abcdefgh == 00000000, and these cases are CONSTRAINED UNPREDICTABLE, see UNPREDICTABLE cases in immediate constants in T32 data-processing instructions on page K1-7944.
c. Not available in A32 instructions if h == 1.

Note

As the footnotes to Table F2-2 show, the range of values available in T32 modified immediate constants is slightly different from the range of values available in A32 instructions. See Modified immediate constants in A32 instructions on page F2-4136 for the A32 values.

Carry out

A logical instruction with i:imm3:a == '00xxx' does not affect the Carry flag. Otherwise, a logical flag-setting instruction sets the Carry flag to the value of bit[31] of the modified immediate constant.

Operation of modified immediate constants, T32 instructions

For a T32 data-processing instruction, the T32ExpandImm() pseudocode function returns the value of the 32-bit immediate constant, calling T32ExpandImm_C() to evaluate the constant.
Modified immediate constants in A32 instructions

The encoding of a modified immediate constant in an A32 instruction is:

<table>
<thead>
<tr>

<tr>
<td>1101</td>
<td>00000000 00000000 000000ab 000000cd</td>
</tr>
</tbody>
</table>

The range of values available in A32 modified immediate constants is slightly different from the range of values available in 32-bit T32 instructions. See Modified immediate constants in T32 instructions on page F2-4135.

---

**Note**

A logical instruction with the rotation field set to 0b0000 does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

---

**Carry out**

A logical instruction with the rotation field set to 0b0000 does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

---

**Constants with multiple encodings**

Some constant values have multiple possible encodings. In this case, a UAL assembler must select the encoding with the lowest unsigned value of the rotation field. This is the encoding that appears first in Table F2-3. For example, the constant #3 must be encoded with (rotation, abcdefgh) = (0b0000, 0b00000001), not (0b0001, 0b00001100), (0b0010, 0b00110000), or (0b0011, 0b11000000).
In particular, this means that all constants in the range 0-255 are encoded with rotation == 0b0000, and permitted constants outside that range are encoded with rotation != 0b0000. A flag-setting logical instruction with a modified immediate constant therefore leaves APSR.C unchanged if the constant is in the range 0-255 and sets it to the most significant bit of the constant otherwise. This matches the behavior of T32 modified immediate constants for all constants that are permitted in both the A32 and T32 instruction sets.

An alternative syntax is available for a modified immediate constant that permits the programmer to specify the encoding directly. In this syntax, #<const> is instead written as #<byte>, #<rot>, where:

<byte>  Is the numeric value of abcdefgh, in the range 0-255.
<rot>  Is twice the numeric value of rotation, an even number in the range 0-30.

This syntax permits all A32 data-processing instructions with modified immediate constants to be disassembled to assembler syntax that assembles to the original instruction.

This syntax also makes it possible to write variants of some flag-setting logical instructions that have different effects on APSR.C to those obtained with the normal #<const> syntax. For example, ANDS R1, R2, #12, #2 has the same behavior as ANDS R1, R2, #3 except that it sets APSR.C to 0 instead of leaving it unchanged. Such variants of flag-setting logical instructions do not have equivalents in the T32 instruction set, and Arm deprecates their use.

**Operation of modified immediate constants, A32 instructions**

For an A32 data-processing instruction, the A32ExpandImm() pseudocode function returns the value of the 32-bit immediate constant, calling A32ExpandImm_C() to evaluate the constant.

**Modified immediate constants in T32 and A32 Advanced SIMD instructions**

Table F2-4 shows the modified immediate constants available with Advanced SIMD instructions, and how they are encoded.

</table>

a. In this table, the immediate value is shown in binary form, to relate abcdefgh to the encoding diagram. In assembler syntax, the constant is specified by a data type and a value of that type. That value is specified in the normal way (a decimal number by default) and is replicated enough times to fill the 64-bit immediate. For example, a data type of I32 and a value of 10 specify the 64-bit constant 0x0000000A0000000A.
b. This specifies the data type used when the instruction is disassembled. On assembly, the data type must be matched in the table if possible. Other data types are permitted as pseudo-instructions when a program is assembled, provided the 64-bit constant specified by the data type and value is available for the instruction. If a constant is available in more than one way, the first entry in the table that can produce it is used. For example, \texttt{VMOV.I64 D0, #0x8000000080000000} does not specify a 64-bit constant that is available from the I64 line of the table, but does specify one that is available from the fourth I32 line or the F32 line. It is assembled to the first of these, and therefore is disassembled as \texttt{VMOV.I32 D0, #0x80000000}.

c. This constant is available for the \texttt{VBLE}, \texttt{VMax}, \texttt{VMin}, and \texttt{VORR} instructions.

d. \texttt{CONSTRAINED UNPREDICTABLE} if \texttt{abcdefgh = 0b00000000}, see \texttt{UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions} on page F1-7945. The required behavior is that these encodings produce an immediate constant of zero.

e. This constant is available for the \texttt{VMOV} and \texttt{VMVN} instructions only.

f. This constant is available for the \texttt{VMOV} instruction only.

g. In this entry, \texttt{B} = \texttt{NOT(b)}. The bit pattern represents the floating-point number \((-1)^s \times 2^{\text{exp}} \times \text{mantissa}, \text{where} \ S = \text{UInt(a)}, \text{exp} = \text{UInt(NOT(b):c:d)}-3\) and \text{mantissa} = \((16+\text{UInt(e:f:g:h)})/16.

---

### Operation of modified immediate constants, Advanced SIMD instructions

For a T32 or A32 Advanced SIMD instruction that uses a modified immediate constant, the operation described by the \texttt{AdvSIMDEnumExpandImm()} pseudocode function returns the value of the 64-bit immediate constant.

### Modified immediate constants in T32 and A32 floating-point instructions

Table F2-5 shows the immediate constants available in the \texttt{VMOV} (immediate) floating-point instruction, and Table F2-6 shows the resulting floating-point values.

#### Table F2-5 Floating-point modified immediate constants

**Operation of modified immediate constants, floating-point instructions**

For a T32 or A32 floating-point instruction that uses a modified immediate constant, the operation described by the `VFPExpandImm()` pseudocode function returns the value of the immediate constant.
F2.8 Additional pseudocode support for instruction descriptions

Earlier sections of this chapter include pseudocode that describes features of the execution of A32 and T32 instructions, see:

- Pseudocode description of conditional execution on page F2-4122.
- Pseudocode description of instruction-specified shifts and rotates on page F2-4124.

The following subsection gives additional pseudocode support functions for some of the instructions described in Alphabetical list of T32 and A32 base instruction set instructions on page F5-4280. See also Pseudocode support for the banked register transfer instructions on page F5-4992.

F2.8.1 Pseudocode description of operations for System register access instructions

The AArch32.SysRegRead() function obtains the word for an MRC instruction from the System register.

The AArch32.SysRegRead64() function obtains the two words for an MRRC instruction from the System register.

Note

The relative significance of the two words returned is IMPLEMENTATION DEFINED, but all uses within this manual present the two words in the order (most significant, least significant).

The AArch32.SysRegWrite() procedure sends the word for an MCR instruction to the System register.

The AArch32.SysRegWrite64() procedure sends the two words for an MCRR instruction to the System register.

Note

The relative significance of word2 and word1 is IMPLEMENTATION DEFINED, but all uses within this manual treat word2 as more significant than word1.

F2.8.2 Pseudocode details of system calls

The AArch32.CallSupervisor() pseudocode function generates a Supervisor Call exception. Valid execution of the SVC instruction calls this function.

The AArch32.CallHypervisor() pseudocode function generates an HVC exception. Valid execution of the HVC instruction calls this function.
F2.9 Additional information about Advanced SIMD and floating-point instructions

The following subsections give additional information about the Advanced SIMD and floating-point instructions:

- Advanced SIMD and floating-point instruction syntax.
- The Advanced SIMD addressing mode.
- Advanced SIMD instruction modifiers on page F2-4142.
- Advanced SIMD operand shapes on page F2-4142.
- Data type specifiers on page F2-4143.
- Register specifiers on page F2-4144.
- Register lists on page F2-4145.
- Register encoding on page F2-4145.
- Advanced SIMD scalars on page F2-4146.

--- Note ---

The Advanced SIMD architecture, its associated implementations, and supporting software, are commonly referred to as NEON™ technology.

F2.9.1 Advanced SIMD and floating-point instruction syntax

Advanced SIMD and floating-point instructions use the general conventions of the T32 and A32 instruction sets. Advanced SIMD and floating-point data-processing instructions use the following general format:

V{<modifier>}<operation>{<shape>}{<c>}{<q>}{.<dt>} {<dest>,} <src1>, <src2>

All Advanced SIMD and floating-point instructions begin with a V. This distinguishes Advanced SIMD vector and floating-point instructions from scalar instructions.

The main operation is specified in the <operation> field. It is usually a three letter mnemonic the same as or similar to the corresponding scalar integer instruction.

The <c> and <q> fields are standard assembler syntax fields. For details, see Standard assembler syntax fields on page F2-4120.

F2.9.2 The Advanced SIMD addressing mode

All the element and structure load/store instructions use this addressing mode. There is a choice of three formats:

[<Rn>{:<align>}] The address is contained in general-purpose register Rn.

Rn is not updated by this instruction.

Encoded as Rm = 0b11111.

If Rn is encoded as 0b11111, the instruction is CONSTRAINED UNPREDICTABLE.

[<Rn>{:<align}>!] The address is contained in general-purpose register Rn.

Rn is updated by this instruction: Rn = Rn + transfer_size

Encoded as Rm = 0b11101.

transfer_size is the number of bytes transferred by the instruction. This means that, after the instruction is executed, Rn points to the address in memory immediately following the last address loaded from or stored to.

If Rn is encoded as 0b11111, the instruction is CONSTRAINED UNPREDICTABLE.

This addressing mode can also be written as:

[<Rn>{:<align}], #<transfer_size>

However, disassembly produces the [<Rn>{:<align}>!] form.
The address is contained in general-purpose register \(<Rn>\).

\(<Rn>\) is updated by this instruction: \(Rn = Rn + Rm\)

Encoded as \(Rm = Rn\). \(Rm\) must not be encoded as 0b1111 or 0b1101, the PC or the SP.

If \(Rn\) is encoded as 0b1111, the instruction is CONSTRAINED UNPREDICTABLE.

The CONSTRAINED UNPREDICTABLE behavior of encodings where \(Rn\) is 0b1111 is described in the section: Using \(R15\) on page K1-7941.

In all cases, \(<align>\) specifies an alignment, as specified by the individual instruction descriptions.

Previous versions of the manual used the @ character for alignment. So, for example, the first format in this section was shown as \(<Rn>@<align>\). Both @ and : are supported. However, to ensure portability of code to assemblers that treat @ as a comment character, : is preferred.

### F2.9.3 Advanced SIMD instruction modifiers

The \(<modifier>\) field provides additional variants of some instructions. Table F2-7 provides definitions of the modifiers. Modifiers are not available for every instruction.

<table>
<thead>
<tr>
<th>(&lt;modifier&gt;)</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q</td>
<td>The operation uses saturating arithmetic.</td>
</tr>
<tr>
<td>R</td>
<td>The operation performs rounding.</td>
</tr>
<tr>
<td>D</td>
<td>The operation doubles the result (before accumulation, if any).</td>
</tr>
<tr>
<td>H</td>
<td>The operation halves the result.</td>
</tr>
</tbody>
</table>

### F2.9.4 Advanced SIMD operand shapes

The \(<shape>\) field provides additional variants of some instructions. Table F2-8 provides definitions of the shapes. Operand shapes are not available for every instruction.

<table>
<thead>
<tr>
<th>(&lt;shape&gt;)</th>
<th>Meaning</th>
<th>Typical register shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>(none)</td>
<td>The operands and result are all the same width.</td>
<td>Dd, Dn, Dm Qd, Qn, Qm</td>
</tr>
<tr>
<td>L</td>
<td>Long operation - result is twice the width of both operands</td>
<td>Qd, Dn, Dm</td>
</tr>
<tr>
<td>N</td>
<td>Narrow operation - result is half the width of both operands</td>
<td>Dd, Qn, Qm</td>
</tr>
<tr>
<td>W</td>
<td>Wide operation - result and first operand are twice the width of the second operand</td>
<td>Qd, Qn, Dm</td>
</tr>
</tbody>
</table>

**Note**

- Some assemblers support a Q shape specifier, that requires all operands to be Q registers. An example of using this specifier is VADDQ.S32 q0, q1, q2. This is not standard UAL, and Arm recommends that programmers do not use a Q shape specifier.

- A disassembler must not generate any shape specifier not shown in Table F2-8.
F2.9.5 Data type specifiers

The `<dt>` field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, this indicates the data type contained in:

- The second operand, if any.
- The operand, if there is no second operand.
- The result, if there are no operand registers.

The data types of the other operand and result are implied by the `<dt>` field combined with the instruction shape. For information about data type formats, see "Data types supported by the Advanced SIMD implementation on page E1-4002".

In the instruction syntax descriptions in Chapter F2 About the T32 and A32 Instruction Descriptions, the `<dt>` field is usually specified as a single field. However, where more convenient, it is sometimes specified as a concatenation of two fields, `<type><size>`.

Syntax flexibility

There is some flexibility in the data type specifier syntax:

- Software can specify three data types, specifying the result and both operand data types. For example:
  
  \[ \text{VSUBW.I16.I16.S8 Q3, Q5, D0 instead of VSUBW.S8 Q3, Q5, D0} \]

- Software can specify two data types, specifying the data types of the two operands. The data type of the result is implied by the instruction shape. For example:
  
  \[ \text{VSUBW.I16.S8 Q3, Q5, D0 instead of VSUBW.S8 Q3, Q5, D0} \]

- Software can specify two data types, specifying the data types of the single operand and the result. For example:
  
  \[ \text{VMOVN.I16.I32 D0, Q1 instead of VMOVN.I32 D0, Q1} \]

- Where an instruction requires a less specific data type, software can instead specify a more specific type, as shown in Table F2-9.

- Where an instruction does not require a data type, software can provide one.

- The F32 data type can be abbreviated to F.

- The F64 data type can be abbreviated to D.

In all cases, if software provides additional information, the additional information must match the instruction shape. Disassembly does not regenerate this additional information.

<table>
<thead>
<tr>
<th>Specified data type</th>
<th>Permitted more specific data types</th>

</tr>
</tbody>
</table>
F2.9.6 Register specifiers

The <dest>, <src1>, and <src2> fields contain register specifiers, or in some cases scalar specifiers or register lists. Table F2-10 shows the register and scalar specifier formats that appear in the instruction descriptions.

If <dest> is omitted, it is the same as <src1>.

Table F2-10 Advanced SIMD and floating-point register specifier formats

<td>Both</td>
</tr>
<tr>
<td>&lt;Rm&gt;</td>
<td>A general-purpose register, used as a post-indexed address source.</td>
<td>Both</td>
</tr>
</tbody>
</table>

a. In some instructions the roles of registers are different.
b. In the floating-point instructions, <Dn[x]> is used only in VMOV (scalar to general-purpose register), see VMOV (scalar to general-purpose register) on page F6-5373.
F2.9.7   Register lists

A register list is a list of register specifiers separated by commas and enclosed in brackets { and }. There are restrictions on what registers can appear in a register list. These restrictions are described in the individual instruction descriptions. Table F2-11 shows some register list formats, with examples of actual register lists corresponding to those formats.

---Note---

Register lists must not wrap around the end of the register bank.

---Syntax flexibility---

There is some flexibility in the register list syntax:

- Where a register list contains consecutive registers, they can be specified as a range, instead of listing every register, for example {D0-D3} instead of {D0, D1, D2, D3}.
- Where a register list contains an even number of consecutive doubleword registers starting with an even numbered register, it can be written as a list of quadword registers instead, for example {Q1, Q2} instead of {D2-D5}.
- Where a register list contains only one register, the enclosing braces can be omitted, for example VLD1.8 D0, [R0] instead of VLD1.8 {D0}, [R0].

<table>

<td>{D0[3], D2[3]}</td>
<td>-</td>
</tr>
<tr>
<td>{&lt;Dd[&gt;]}</td>
<td>{D7[]}</td>
<td>D7[]</td>
</tr>
</tbody>
</table>

F2.9.8   Register encoding

An Advanced SIMD register is either:

- **Quadword**, meaning it is 128 bits wide.
- **Doubleword**, meaning it is 64 bits wide.

Some instructions have options for either doubleword or quadword registers. This is normally encoded in Q, bit[6], as Q = 0 for doubleword operations, or Q = 1 for quadword operations.

A floating-point register is either:

- Double-precision, meaning it is 64 bits wide.
- Single-precision, meaning it is 32 bits wide.

This is encoded in the sz field, bit[8], as sz = 1 for double-precision operations, or sz = 0 for single-precision operations.

The T32 instruction encoding of Advanced SIMD or floating-point registers is:

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>D Vn Vd sz N Q M Vm</th>
</tr>
</thead>
</table>

The A32 instruction encoding of Advanced SIMD or floating-point registers is:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>D Vn Vd sz N Q M Vm</th>
</tr>
</thead>
</table>
Some instructions use only one or two registers, and use the unused register fields as additional opcode bits.

Table F2-12 shows the encodings for the registers.

<td></td>
<td>Floating-point</td>
</tr>
</tbody>
</table>

<sup>a</sup> Bit numbers given for the A32 instruction encoding. See the figures in this section for the equivalent bits in the T32 encoding.

<sup>b</sup> If this bit is 1, the instruction is UNDEFINED.

### F2.9.9 Advanced SIMD scalars

Advanced SIMD scalars can be 8-bit, 16-bit, 32-bit, or 64-bit. Instructions other than multiply instructions can access any element in the register set. The instruction syntax refers to the scalars using an index into a doubleword vector. The descriptions of the individual instructions contain details of the encodings.

Table F2-13 shows the form of encoding for scalars used in multiply instructions. These instructions cannot access scalars in some registers. The descriptions of the individual instructions contain cross references to this section where appropriate.

32-bit Advanced SIMD scalars, when used as single-precision floating-point numbers, are equivalent to Floating-point single-precision registers. That is, <Dm[x]> in a 32-bit context (0 <= m <= 15, 0 <= x <= 1) is equivalent to S(2m + x).

### Table F2-13 Encoding of scalars in multiply instructions

Chapter F3
T32 Instruction Set Encoding

This chapter describes the encoding of the T32 instruction set. It contains the following sections:

- T32 instruction set encoding on page F3-4148.
- About the T32 Advanced SIMD and floating-point instructions and their encoding on page F3-4216.

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.
F3.1 T32 instruction set encoding

The T32 instruction stream is a sequence of halfword-aligned halfwords. Each T32 instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

If the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:

- \(0b11101\)
- \(0b11110\)
- \(0b11111\).

Otherwise, the halfword is a 16-bit instruction.

The T32 instruction encoding is:

<table>
<thead>
<tr>
<th>15 13 12 11 10</th>
<th>0 15 0 0 0</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0</td>
<td>op1</td>
<td></td>
</tr>
</tbody>
</table>

F3.1.8 Advanced SIMD data-processing

This section describes the encoding of the Advanced SIMD data-processing group. The encodings in this section are decoded from System register access, Advanced SIMD, and floating-point on page F3-4164.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the T32 Advanced SIMD and floating-point instructions and their encoding on page F3-4216.

#### F3.1.11 Advanced SIMD and System register load/store and 64-bit move

This section describes the encoding of the Advanced SIMD and System register load/store and 64-bit move group. The encodings in this section are decoded from *System register access, Advanced SIMD, and floating-point on page F3-4164*.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see *About the T32 Advanced SIMD and floating-point instructions and their encoding on page F3-4216*.
Advanced SIMD and floating-point 64-bit move

This section describes the encoding of the Advanced SIMD and floating-point 64-bit move instruction class. The encodings in this section are decoded from Advanced SIMD and System register load/store and 64-bit move on page F3-4176.

F3.1.12 Floating-point data-processing

This section describes the encoding of the Floating-point data-processing group. The encodings in this section are decoded from System register access, Advanced SIMD, and floating-point on page F3-4164.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the T32 Advanced SIMD and floating-point instructions and their encoding on page F3-4216.

Floating-point data-processing (two registers)

This section describes the encoding of the Floating-point data-processing (two registers) instruction class. The encodings in this section are decoded from Floating-point data-processing.

Floating-point minNum/maxNum

This section describes the encoding of the Floating-point minNum/maxNum instruction class. The encodings in this section are decoded from *Additional Advanced SIMD and floating-point instructions* on page F3-4183.
T32 Instruction Set Encoding
F3.1 T32 instruction set encoding

Floating-point extraction and insertion

This section describes the encoding of the Floating-point extraction and insertion instruction class. The encodings in this section are decoded from Additional Advanced SIMD and floating-point instructions on page F3-4183.

Floating-point directed convert to integer

This section describes the encoding of the Floating-point directed convert to integer instruction class. The encodings in this section are decoded from Additional Advanced SIMD and floating-point instructions on page F3-4183.
Advanced SIMD and floating-point multiply with accumulate

This section describes the encoding of the Advanced SIMD and floating-point multiply with accumulate instruction class. The encodings in this section are decoded from Additional Advanced SIMD and floating-point instructions on page F3-4183.

### Load/store, signed (positive immediate)

This section describes the encoding of the Load/store, signed (positive immediate) instruction class. The encodings in this section are decoded from *Load/store single on page F3-4201*.

```
<table>
<thead>
<tr>
<th>15 14 13 12</th>
<th>11 10 9 8</th>
<th>7 6 5 4</th>
<th>3 0</th>
<th>15 12</th>

</tr>
<tr>
<td>01</td>
<td>LDRSH (immediate)</td>
</tr>
<tr>
<td>1x</td>
<td>Unallocated.</td>
</tr>
</tbody>
</table>

### Load/store single

The load/store single instruction set is used for loading and storing data in memory. Different formats are available to handle various types of data and addresses.

- **LDRSBT**: Load half word signed with back pointer
- **LDRSHT**: Load half word signed with high pointer
- **Unallocated**: Indicates unused fields
- **LDRSB (immediate)**: Load word signed with immediate
- **LDRSH (immediate)**: Load half word signed with immediate
- **Reserved hint, behaves as NOP**: Indicates a reserved instruction that behaves as no operation

These instructions are fundamental in memory management and data manipulation within ARM architectures.
Load, signed (literal)

This section describes the encoding of the Load, signed (literal) instruction class. The encodings in this section are decoded from Load/store single on page F3-4201.

```
|15|14|13|12|11|10|9|8|7|6|5|4|3|2|1|0|15|
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
|1|1|1|1|1|0|0|1|U|size|1|1|1|1|1|Rt|imm12|
```

F3.1.20 Data-processing (register)

This section describes the encoding of the Data-processing (register) group. The encodings in this section are decoded from 32-bit on page F3-4159.

```
<table>
<thead>
<tr>
<th>15</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>0</th>

F3.2 About the T32 Advanced SIMD and floating-point instructions and their encoding

The Advanced SIMD and floating-point instructions are common to the T32 and A32 instruction sets. These instructions perform Advanced SIMD and floating-point operations on a common register file, the SIMD&FP register file. This means:

- In general, the instructions that load or store registers in this file, or move data between general-purpose registers and this register file, are common to the Advanced SIMD and floating-point instructions.
- There are distinct Advanced SIMD data-processing instructions and floating-point data-processing instructions.

All T32 Advanced SIMD and floating-point instructions have 32-bit encodings. Different groups of these instructions are decoded from different points in the 32-bit T32 instruction decode structure. Table F3-23 shows these instruction groups, and where each group is decoded from the overall T32 decode structure:

<table>

Chapter F4
A32 Instruction Set Encoding

This chapter describes the encoding of the A32 instruction set. It contains the following sections:

- *A32 instruction set encoding* on page F4-4218.
- *About the A32 Advanced SIMD and floating-point instructions and their encoding* on page F4-4278.

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.
F4.1 A32 instruction set encoding

The A32 instruction stream is a sequence of word-aligned words. Each A32 instruction is either a single 32-bit word in that stream.

Most A32 instructions can be conditional, with a condition determined by bits[31:28] of the instruction, the cond field. For more information see The Condition code field in A32 instruction encodings on page F2-4122. This applies to all instructions except those with the cond field equal to 0b111.

The behavior of an attempt to execute an unallocated instruction is described in UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space on page F2-4128.

For more information on A32 instruction encodings see Chapter F2 About the T32 and A32 Instruction Descriptions.

The A32 instruction encoding is:

```
[31  28|27  25  24| | | |  5  4  3  0 ]
cond  op0    op1
```

| SVC   |  |

F4.14 Unconditional Advanced SIMD and floating-point instructions

This section describes the encoding of the Unconditional Advanced SIMD and floating-point instructions group. The encodings in this section are decoded from System register access, Advanced SIMD, floating-point, and Supervisor call on page F4-4246.
This decode also imposes the constraint:

- \( \text{op0}<2:1> \neq 11. \)

### Table F4-13 Encoding table for the Unconditional Advanced SIMD and floating-point instructions group

F4.1.15 Advanced SIMD and System register load/store and 64-bit move

This section describes the encoding of the Advanced SIMD and System register load/store and 64-bit move group. The encodings in this section are decoded from System register access, Advanced SIMD, floating-point, and Supervisor call on page F4-4246.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the A32 Advanced SIMD and floating-point instructions and their encoding on page F4-4278.
Advanced SIMD and floating-point 64-bit move

This section describes the encoding of the Advanced SIMD and floating-point 64-bit move instruction class. The encodings in this section are decoded from Advanced SIMD and System register load/store and 64-bit move on page F4-4252.

F4.1.16 Floating-point data-processing

This section describes the encoding of the Floating-point data-processing group. The encodings in this section are decoded from System register access, Advanced SIMD, floating-point, and Supervisor call on page F4-4246.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the A32 Advanced SIMD and floating-point instructions and their encoding on page F4-4278.

Floating-point move special register

This section describes the encoding of the Floating-point move special register instruction class. The encodings in this section are decoded from Advanced SIMD and System register 32-bit move.
Advanced SIMD 8/16/32-bit element move/duplicate

This section describes the encoding of the Advanced SIMD 8/16/32-bit element move/duplicate instruction class. The encodings in this section are decoded from Advanced SIMD and System register 32-bit move on page F4-4259.

System register 32-bit move

This section describes the encoding of the System register 32-bit move instruction class. The encodings in this section are decoded from Advanced SIMD and System register 32-bit move on page F4-4259.
F4.1.18   Unconditional instructions

This section describes the encoding of the Unconditional instructions group. The encodings in this section are decoded from A32 instruction set encoding on page F4-4218.

</table>
The behavior of the CONSTRAINED UNPREDICTABLE encodings in this table is described in CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings on page K1-7952.

Change Process State

This section describes the encoding of the Change Process State instruction class. The encodings in this section are decoded from Miscellaneous on page F4-4261.

F4.1.20 Advanced SIMD data-processing

This section describes the encoding of the Advanced SIMD data-processing group. The encodings in this section are decoded from Unconditional instructions on page F4-4261.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the A32 Advanced SIMD and floating-point instructions and their encoding on page F4-4278.
Advanced SIMD three registers of the same length

This section describes the encoding of the Advanced SIMD three registers of the same length instruction class. The encodings in this section are decoded from Advanced SIMD data-processing on page F4-4262.

### F4.1.24 Advanced SIMD element or structure load/store

This section describes the encoding of the Advanced SIMD element or structure load/store group. The encodings in this section are decoded from Unconditional instructions on page F4-4261.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the A32 Advanced SIMD and floating-point instructions and their encoding on page F4-4278.
### Advanced SIMD load/store multiple structures

This section describes the encoding of the Advanced SIMD load/store multiple structures instruction class. The encodings in this section are decoded from Advanced SIMD element or structure load/store on page F4-4274.

F4.2 About the A32 Advanced SIMD and floating-point instructions and their encoding

The Advanced SIMD and floating-point instructions are common to the T32 and A32 instruction sets. These instructions perform Advanced SIMD and floating-point operations on a common register file, the SIMD&FP register file. This means:

- In general, the instructions that load or store registers in this file, or move data between general-purpose registers and this register file, are common to the Advanced SIMD and floating-point instructions.
- There are distinct Advanced SIMD data-processing instructions and floating-point data-processing instructions.

All A32 Advanced SIMD and floating-point instructions have 32-bit encodings. Different groups of these instructions are decoded from different points in the 32-bit A32 instruction decode structure. Table F4-24 shows these instruction groups, and where each group is decoded from the overall A32 decode structure:

<table>

Chapter F5
T32 and A32 Base Instruction Set Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

• *Alphabetical list of T32 and A32 base instruction set instructions* on page F5-4280.
• *Encoding and use of banked register transfer instructions* on page F5-4989.
F5.1 Alphabetical list of T32 and A32 base instruction set instructions

This section lists every instruction in the T32 and A32 base instruction sets. For details of the format used see *Format of instruction descriptions* on page F2-4116.

This section is formatted so that each instruction description starts on a new page.
F5.1.1 ADC, ADCS (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-5766.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\]

**ADCS variant**

Applies when \(S = 1\).
ADCS{<c>}{<q>} {<Rd>,} <Rn>, #<const>

**Decode for all variants of this encoding**

\[ d = \text{UInt}(Rd); \quad n = \text{UInt}(Rn); \quad \text{setflags} = (S == '1'); \quad \text{imm32} = \text{T32ExpandImm}(i:imm3:imm8); \]

\[ \text{if } d == 15 || n == 15 \text{ then UNPREDICTABLE}; \quad // \text{Armv8-A removes UNPREDICTABLE for R13} \]

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-4120.
- `<q>` See Standard assembler syntax fields on page F2-4120.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. Arm deprecates using the PC as the destination register, but if the PC is used:
  - For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
  - For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.

- `<Rn>` For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
  - For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

- `<const>` For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F2-4136 for the range of values.
  - For encoding T1: an immediate value. See Modified immediate constants in T32 instructions on page F2-4135 for the range of values.

**Operation for all encodings**

if ConditionPassed() then
   EncodingSpecificOperations();
   (result, nzcv) = AddWithCarry(R[n], imm32, PSTATE.C);
   if d == 15 then          // Can only occur for A32 encoding
      if setflags then
         ALUExceptionReturn(result);
      else
         ALUWritePC(result);
   else
      R[d] = result;
      if setflags then
         PSTATE.<N,Z,C,V> = nzcv;

**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
The values of the NZCV flags.

The response of this instruction to asynchronous exceptions does not vary based on:

- The values of the data supplied in any of its registers.
- The values of the NZCV flags.
F5.1.2 ADC, ADCS (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-5766.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\]

\[
(shift_t, shift_n) = \text{DecodeImmShift(stype, imm3:imm2)};
\]

if \( d = 15 \) \&\& \( n = 15 \) \&\& \( m = 15 \) then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13

#### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<c>  See Standard assembler syntax fields on page F2-4120.

<q>  See Standard assembler syntax fields on page F2-4120.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

• For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.

• For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if ADCS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADCS <Rd>, <Rn> had been written.

- Inside an IT block, if ADC<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADC<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
  if d == 15 then          // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
else
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.3 ADC, ADCS (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

Flag setting variant

Applies when $S = 1$.

$ADCS\{<c>\}{<q>\} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>$

Not flag setting variant

Applies when $S = 0$.

$ADC\{<c>\}{<q>\} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>$

Decode for all variants of this encoding

\[
d = \text{UInt}(Rd); \quad n = \text{UInt}(Rn); \quad m = \text{UInt}(Rm); \quad s = \text{UInt}(Rs);
setflags = (S == '1'); \quad \text{shift}_t = \text{DecodeRegShift}(stype);
\]

if $d == 15 \lor n == 15 \lor m == 15 \lor s == 15$ then UNPREDICTABLE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

$<c>$ See Standard assembler syntax fields on page F2-4120.

$<q>$ See Standard assembler syntax fields on page F2-4120.

$<Rd>$ Is the general-purpose destination register, encoded in the "Rd" field.

$<Rn>$ Is the first general-purpose source register, encoded in the "Rn" field.

$<Rm>$ Is the second general-purpose source register, encoded in the "Rm" field.

$<shift>$ Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>00</td>
</tr>
<tr>
<td>LSR</td>
<td>01</td>
</tr>
<tr>
<td>ASR</td>
<td>10</td>
</tr>
<tr>
<td>ROR</td>
<td>11</td>
</tr>
</tbody>
</table>

$<Rs>$ Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.4  ADD, ADDS (immediate)

Add (immediate) adds an immediate value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-5766.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\(<c>\)  See Standard assembler syntax fields on page F2-4120.
\(<q>\)  See Standard assembler syntax fields on page F2-4120.
\(<Rdn>\) Is the general-purpose source and destination register, encoded in the "Rdn" field.
\(<\text{imm8}>\) Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
\(<\text{Rd}>\) For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:
  \[\text{• For the ADD variant, the instruction is a branch to the address calculated by the operation.}
  
  \text{This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.}
  
  \text{• For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. Arm deprecates use of this instruction.}
  \]
For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
\(<\text{Rn}>\) For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus immediate). If the PC is used, see ADR.
For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus immediate).
\(<\text{imm3}>\) Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.
\(<\text{imm12}>\) Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.
\(<\text{const}>\) For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F2-4136 for the range of values.
For encoding T3: an immediate value. See Modified immediate constants in T32 instructions on page F2-4135 for the range of values.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the ADDW syntax). Encoding T1 is preferred to encoding T2 if <Rd> is specified and encoding T2 is preferred to encoding T1 if <Rd> is omitted.

Operation for all encodings

if CurrentInstrSet() == InstrSet_A32 then
if ConditionPassed() then
  EncodingSpecificOperations();
  (result, nzcv) = AddWithCarry(R[n], imm32, '0');
  if d == 15 then // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
ALUWritePC(result);
else
  R[d] = result;
  if setflags then
    PSTATE.<N,Z,C,V> = nzcv;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], imm32, '0');
    R[d] = result;
  if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.5  ADD, ADDS (register)

Add (register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-5766.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

// Armv8-A removes UNPREDICTABLE for R13

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<c>`
  - See *Standard assembler syntax fields* on page F2-4120.
- `<q>`
  - See *Standard assembler syntax fields* on page F2-4120.
- `<Rdn>`
  - Is the general-purpose source and destination register, encoded in the "DN:Rdn" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
  
  The assembler language allows `<Rdn>` to be specified once or twice in the assembler syntax. When used inside an IT block, and `<Rdn>` and `<Rm>` are in the range R0 to R7, `<Rdn>` must be specified once so that encoding T2 is preferred to encoding T1. In all other cases there is no difference in behavior when `<Rdn>` is specified once or twice.
- `<Rd>`
  - For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. If the PC is used:
    - For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
    - For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. Arm deprecates use of this instruction.
  
  For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.
  
  When used inside an IT block, `<Rd>` must be specified. When used outside an IT block, `<Rd>` is optional, and:
    - If omitted, this register is the same as `<Rn>`.
    - If present, encoding T1 is preferred to encoding T2.
  
  For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.
- `<Rn>`
  - For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used. If the SP is used, see ADD, ADDS (SP plus register).
For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

For encoding T3: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus register).

<rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T3: is the second general-purpose source register, encoded in the "Rm" field.

For encoding T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<amount>
For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Inside an IT block, if ADD<op> <Rd>, <Rn>, <Rd> cannot be assembled using encoding T1, it is assembled using encoding T2 as though ADD<op> <Rd>, <Rn> had been written. To prevent this happening, use the .w qualifier.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzcv) = AddWithCarry(R[n], shifted, '0');
  if d == 15 then
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
    if setflags then
      PSTATE.<N,Z,C,V> = nzcv;

**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.6 ADD, ADDS (register-shifted register)

Add (register-shifted register) adds a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

- `<c>` See Standard assembler syntax fields on page F2-4120.
- `<q>` See Standard assembler syntax fields on page F2-4120.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
  - LSL when stype = 00
  - LSR when stype = 01
  - ASR when stype = 10
  - ROR when stype = 11
- `<Rs>` Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.7   ADD, ADDS (SP plus immediate)

Add to SP (immediate) adds an immediate value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-5766.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<<c>>  See Standard assembler syntax fields on page F2-4120.

<<q>>  See Standard assembler syntax fields on page F2-4120.

SP,  Is the stack pointer.

<imm7>  Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.

<Rd>  For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:
•  For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
•  For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.

For encoding T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<imm8>  Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.

<imm12>  Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const>  For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F2-4136 for the range of values.

For encoding T3: an immediate value. See Modified immediate constants in T32 instructions on page F2-4135 for the range of values.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(SP, imm32, '0');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;

F5.1.8 ADD, ADDS (SP plus register)

Add to SP (register) adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
- The ADDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-5766.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

For more information about the CONstrained UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-4120.
- `<q>` See Standard assembler syntax fields on page F2-4120.
- `SP`, Is the stack pointer.
- `<Rdm>` Is the general-purpose destination and second source register, encoded in the "Rdm" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:
  - For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
  - For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

- `<Rm>` For encoding A1 and T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T3: is the second general-purpose source register, encoded in the "Rm" field.

- `<\text{shift}>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
  - LSL when stype = 00
  - LSR when stype = 01
  - ASR when stype = 10
  - ROR when stype = 11

- `<\text{amount}>` For encoding A1: is the shift amount, in the range 1 to 31 (when `<\text{shift}>` = LSL or ROR) or 1 to 32 (when `<\text{shift}>` = LSR or ASR) encoded in the "imm5" field as `<\text{amount}>` modulo 32.

For encoding T3: is the shift amount, in the range 1 to 31 (when `<\text{shift}>` = LSL or ROR) or 1 to 32 (when `<\text{shift}>` = LSR or ASR), encoded in the "imm3:imm2" field as `<\text{amount}>` modulo 32.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(SP, shifted, '0');
    if d == 15 then
        if setflags then
            ALUEntireReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
F5.1.9 ADD (immediate, to PC)

Add to PC adds an immediate value to the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias.

This instruction is a pseudo-instruction of the ADR instruction. This means that:

- The encodings in this description are named to match the encodings of ADR.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of ADR gives the operational pseudocode for this instruction.

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

T3 variant

ADDW<{c}>{q} <Rd>, PC, #<imm12> // <Rd>, <imm12> can be represented in T1

is equivalent to

ADR<{c}>{q} <Rd>, <label>

and is never the preferred disassembly.
ADD{<c>}{<q>} <Rd>, PC, #<imm12>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is never the preferred disassembly.

**Assembler symbols**

- `<c>`: See *Standard assembler syntax fields on page F2-4120.*
- `<q>`: See *Standard assembler syntax fields on page F2-4120.*
- `<Rd>`: For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.*

For encoding T1 and T3: is the general-purpose destination register, encoded in the "Rd" field.

- `<label>`: For encoding A1: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.

If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset.

If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are any of the constants described in *Modified immediate constants in A32 instructions on page F2-4136.*

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T3: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.

If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset.

If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are 0-4095.

- `<imm8>`: Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as `<imm8>/4`.

- `<imm12>`: Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:mm8" field.

- `<const>`: An immediate value. See *Modified immediate constants in A32 instructions on page F2-4136* for the range of values.

**Operation for all encodings**

The description of ADR gives the operational pseudocode for this instruction.
F5.1.10   ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the
result to the destination register.

This instruction is used by the pseudo-instructions ADD (immediate, to PC) and SUB (immediate, from PC). The
pseudo-instruction is never the preferred disassembly.

**Assembler symbols**

- **<c>**
  
  See Standard assembler syntax fields on page F2-4120.

- **<p>**
  
  See Standard assembler syntax fields on page F2-4120.

- **<Rd>**
  
  For encoding A1 and A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.

  For encoding T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

- **<label>**
  
  For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.

  If the offset is zero or positive, encoding A1 is used, with \( \text{imm32} \) equal to the offset.

  If the offset is negative, encoding A2 is used, with \( \text{imm32} \) equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of \( \text{imm32} \).
Permitted values of the size of the offset are any of the constants described in Modified immediate constants in A32 instructions on page F2-4136.

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.

If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset.

If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are 0-4095.

The instruction aliases permit the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-4077.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    result = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if d == 15 then          // Can only occur for A32 encodings
        ALUWritePC(result);
    else
        R[d] = result;
```
F5.1.11  AND, ANDS (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-5766.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

- **AND variant**
  - Applies when S == 0.
  - AND{<c>}{<q>} {<Rd>,} <Rn>, #<const>

- **ANDS variant**

          PSTATE.Z = IsZeroBit(result);
          PSTATE.C = carry;
          // PSTATE.V unchanged
Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.12 AND, ANDS (register)

Bitwise AND (register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.

- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-5766.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\]

\[
\text{// Armv8-A removes UNPREDICTABLE for R13}
\]

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<\c>
See Standard assembler syntax fields on page F2-4120.

<\q>
See Standard assembler syntax fields on page F2-4120.

<\Rdn>
Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<\Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \<\Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:
  • For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
  • For the ANDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \<\Rn>.

<\Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<\Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<\shift>
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

| Shift Type | Binary Value
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>00</td>
</tr>
<tr>
<td>LSR</td>
<td>01</td>
</tr>
<tr>
<td>ASR</td>
<td>10</td>
</tr>
<tr>
<td>ROR</td>
<td>11</td>
</tr>
</tbody>
</table>

<\amount>
For encoding A1: is the shift amount, in the range 1 to 31 (when <\shift> = LSL or ROR) or 1 to 32 (when <\shift> = LSR or ASR) encoded in the "imm5" field as <\amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <\shift> = LSL or ROR) or 1 to 32 (when <\shift> = LSR or ASR), encoded in the "imm3:imm2" field as <\amount> modulo 32.

In T32 assembly:

- Outside an IT block, if ANDS <\Rd>, <\Rn>, <\Rd> has <\Rd> and <\Rn> both in the range R0-R7, it is assembled using encoding T1 as though ANDS <\Rd>, <\Rn> had been written.
- Inside an IT block, if AND<< <\Rd>, <\Rn>, <\Rd> has <\Rd> and <\Rn> both in the range R0-R7, it is assembled using encoding T1 as though AND<< <\Rd>, <\Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
  result = R[n] AND shifted;
  if d == 15 then          // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
else
    \texttt{R[d] = result;}
    if \texttt{setflags} then
        \texttt{PSTATE.N = result<31>;;}
        \texttt{PSTATE.Z = IsZeroBit(result);}
        \texttt{PSTATE.C = carry;}
        // \texttt{PSTATE.V} unchanged

\textbf{Operational information}

If \texttt{CPSR.DIT} is 1 and this instruction does not use \texttt{R15} as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.13   AND, ANDS (register-shifted register)

Bitwise AND (register-shifted register) performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

<table>

Flag setting variant

Applies when \( S == 1 \).

\[ \text{ANDS} \{<c>\}{<q>} \{<Rd>,\} <Rn>, <Rm>, <shift> <Rs> \]

Not flag setting variant

Applies when \( S == 0 \).

\[ \text{AND} \{<c>\}{<q>} \{<Rd>,\} <Rn>, <Rm>, <shift> <Rs> \]

Decode for all variants of this encoding

\[
d = \text{UInt}(Rd); \; n = \text{UInt}(Rn); \; m = \text{UInt}(Rm); \; s = \text{UInt}(Rs);
setflags = (S == '1'); \; \text{shift}_t = \text{DecodeRegShift}(stype);
if d == 15 \| n == 15 \| m == 15 \| s == 15 \text{ then UNPREDICTABLE;}
\]

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-4120.

\(<q>\) See Standard assembler syntax fields on page F2-4120.

\(<Rd>\) Is the general-purpose destination register, encoded in the "Rd" field.

\(<Rn>\) Is the first general-purpose source register, encoded in the "Rn" field.

\(<Rm>\) Is the second general-purpose source register, encoded in the "Rm" field.

\(<\text{shift}>\) Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

\(<Rs>\) Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.14 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

**MOV, shift or rotate by value variant**

ASR{<c>{<q>} {<Rd>,} <Rm>, #<imm>

is equivalent to

MOV{<c>{<q>} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

**T2 variant**

ASR<>{<q>} {<Rd>,} <Rm>, #<imm> // Inside IT block

is equivalent to

MOV<>{<q>} <Rd>, <Rm>, ASR #<imm>

and is the preferred disassembly when InITBlock().

**MOV, shift or rotate by value variant**

ASR<>{<q>} .W {<Rd>,} <Rm>, #<imm> // Inside IT block, and <Rd>, <Rm>, #<imm> can be represented in T2

is equivalent to

MOV<>{<q>} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

ASR<>{<q>} {<Rd>,} <Rm>, #<imm>
is equivalent to

\[ MOV\{c\}\{q\}\ <Rd>, <Rm>, ASR #<imm> \]

and is always the preferred disassembly.

**Assembler symbols**

- **<c>**  
  See *Standard assembler syntax fields* on page F2-4120.

- **<q>**  
  See *Standard assembler syntax fields* on page F2-4120.

- **<Rd>**  
  For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3993.
  For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

- **<Rm>**  
  For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
  For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

- **<imm>**  
  For encoding A1 and T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as <imm> modulo 32.
  For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as <imm> modulo 32.

**Operation for all encodings**

The description of MOV, MOVX (register) gives the operational pseudocode for this instruction.
F5.1.15   ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its
sign bit, and writes the result to the destination register. The variable number of bits is read from the bottom byte of
a register

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

• The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted
register).

• The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this
instruction.

A1

Not flag setting variant

ASR{<c>}{<q>} {<Rd>,} <Rm>, <Rs>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>

and is always the preferred disassembly.

T1

Arithmetic shift right variant

ASR{<c>}{<q>} {<Rdm>,} <Rdm>, <Rs> // Inside IT block

is equivalent to

MOV{<c>}{<q>} <Rdm>, <Rdm>, ASR <Rs>

and is the preferred disassembly when InITBlock().

T2

Not flag setting variant

ASR{<c>}.W {<Rd>,} <Rm>, <Rs> // Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>
ASR{<c>}{<q>} {<Rd>,} <Rm>, <Rs>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>

and is always the preferred disassembly.

Assembler symbols

<\text{c}> \quad \text{See Standard assembler syntax fields on page F2-4120.}
<\text{q}> \quad \text{See Standard assembler syntax fields on page F2-4120.}
<\text{Rdm}> \quad \text{Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.}
<\text{Rd}> \quad \text{Is the general-purpose destination register, encoded in the "Rd" field.}
<\text{Rm}> \quad \text{Is the first general-purpose source register, encoded in the "Rm" field.}
<\text{Rs}> \quad \text{Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.}

Operation for all encodings

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
**F5.1.16 ASRS (immediate)**

Arithmetic Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for `<Rd>` identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See **Illegal return events from AArch32 state** on page G1-5766.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVVS (register).
- The description of MOV, MOVVS (register) gives the operational pseudocode for this instruction.

ASRS.W {<Rd>,} <Rm>, #<imm> // Outside IT block, and <Rd>, <Rm>, <imm> can be represented in T2 is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

ASRS{<c>}{<q>} {<Rd>,} <Rm>, #<imm>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields* on page F2-4120.
- `<q>` See *Standard assembler syntax fields* on page F2-4120.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.
  
  For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.
- `<Rm>` For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
  
  For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.
- `<imm>` For encoding A1 and T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as `<imm>` modulo 32.
  
  For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as `<imm>` modulo 32.

**Operation for all encodings**

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.
F5.1.17 ASRS (register)

Arithmetic Shift Right, setting flags (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

### A1

Flag setting variant

ASRS{<c>}{<q>} {<Rd>,} <Rm>, <Rs>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>

and is always the preferred disassembly.

### T1

Arithmetic shift right variant

ASRS{<q>} {<Rdm>,} <Rdm>, <Rs> // Outside IT block

is equivalent to

MOVS{<q>} <Rdm>, <Rdm>, ASR <Rs>

and is the preferred disassembly when !InITBlock().

### T2

Flag setting variant

ASRS.W {<Rd>,} <Rm>, <Rs> // Outside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>
and is always the preferred disassembly.

\[
\text{ASRS}\{<c>\}{<q>}{<Rd>,}{<Rm>,}{<Rs>}
\]

is equivalent to

\[
\text{MOVS}\{<c>\}{<q>}{<Rd>,}{<Rm>,}{\text{ASR}<Rs>}
\]

and is always the preferred disassembly.

**Assembler symbols**

- \(<c>\) See *Standard assembler syntax fields* on page F2-4120.
- \(<q>\) See *Standard assembler syntax fields* on page F2-4120.
- \(<Rdm>\) Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.
- \(<Rd>\) Is the general-purpose destination register, encoded in the "Rd" field.
- \(<Rm>\) Is the first general-purpose source register, encoded in the "Rm" field.
- \(<Rs>\) Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If msbit < lsbit, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The value in the destination register is UNKNOWN.

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.21  **BIC, BICS (immediate)**

Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3993.
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5766.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

  — The values of the NZCV flags.
F5.1.22 BIC, BICS (register)

Bitwise Bit Clear (register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-5766.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<c>  See Standard assembler syntax fields on page F2-4120.

<q>  See Standard assembler syntax fields on page F2-4120.

<Rdn>  Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd>  For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

•  For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-3993.

•  For the BICS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>  For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>  For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift>  Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>Stype Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>00</td>
</tr>
<tr>
<td>LSR</td>
<td>01</td>
</tr>
<tr>
<td>ASR</td>
<td>10</td>
</tr>
<tr>
<td>ROR</td>
<td>11</td>
</tr>
</tbody>
</table>

<amount>  For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  (shifted, carry) = Shift.Car(R[m], shift_t, shift_n, PSTATE.C);
  result = R[n] AND NOT(shifted);
  if d == 15 then  // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
  if setflags then
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
**F5.1.23   BIC, BICS (register-shifted register)**

Bitwise Bit Clear (register-shifted register) performs a bitwise AND of a register value and the complement of a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

**A1**

| 31  | 28|27|26|25|24|23|22|21|20|19|16|15|12|11| 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| ![1111] | 0 | 0 | 0 | 1 | 1 | 0 | S | Rn | Rd | Rs | 0 | stype | 1 | Rm |

**Flag setting variant**

Applies when $S == 1$.

BICS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>

**Not flag setting variant**

Applies when $S == 0$.

BIC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>

**Decode for all variants of this encoding**

\[
d = \text{UInt}(Rd); \quad n = \text{UInt}(Rn); \quad m = \text{UInt}(Rm); \quad s = \text{UInt}(Rs);
\]

\[
\text{setflags} = (S == '1'); \quad \text{shift}_t = \text{DecodeRegShift}(stype);
\]

\[
\text{if } d == 15 \quad \text{|| } n == 15 \quad \text{|| } m == 15 \quad \text{|| } s == 15 \text{ then UNPREDICTABLE;}
\]

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields on page F2-4120*.
- `<q>` See *Standard assembler syntax fields on page F2-4120*.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
  - LSL when stype = 00
  - LSR when stype = 01
  - ASR when stype = 10
  - ROR when stype = 11
- `<Rs>` Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    R[d] = result;
if setflags then
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.24   BKPT

Breakpoint causes a Breakpoint Instruction exception.
Breakpoint is always unconditional, even when inside an IT block.

A1

![A1 variant](image)

**Decode for this encoding**

\[
\text{imm16} = \text{imm12:imm4};
\]

if cond != '1110' then UNPREDICTABLE;  // BKPT must be encoded with AL condition

**CONSTRAINED UNPREDICTABLE behavior**

If cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

![T1 variant](image)

**Decode for this encoding**

\[
\text{imm16} = \text{ZeroExtend}(\text{imm8}, 16);
\]

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

\(<q>\)

See Standard assembler syntax fields on page F2-4120. An BKPT instruction must be unconditional.
<imm> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value:

- Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
- Is ignored otherwise.

For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value:

- Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
- Is ignored otherwise.

**Operation for all encodings**

```
EncodingSpecificOperations();
AArch32.SoftwareBreakpoint(imm16);
```
F5.1.25 BL, BLX (immediate)

Branch with Link calls a subroutine at a PC-relative address, and setting LR to the return address.

Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, setting LR to the return address, and changes the instruction set from A32 to T32, or from T32 to A32.

Assembler symbols

<
For encoding A1, T1 and T2: see Standard assembler syntax fields on page F2-4120.
For encoding A2: see Standard assembler syntax fields on page F2-4120. < must be AL or omitted.

quad
See Standard assembler syntax fields on page F2-4120.

<label>
For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding that sets imm32 to that offset.
Permitted offsets are multiples of 4 in the range –33554432 to 33554428.
For encoding A2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset.
Permitted offsets are even numbers in the range –33554432 to 33554430.
For encoding T1: the label of the instruction that is to be branched to.
The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset.
Permitted offsets are even numbers in the range –16777216 to 16777214.
For encoding T2: the label of the instruction that is to be branched to.
The assembler calculates the required value of the offset from the Align(PC, 4) value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset.
Permitted offsets are multiples of 4 in the range –16777216 to 16777212.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  if CurrentInstrSet() == InstrSet_A32 then
    LR = PC - 4;
  else
    LR = PC<31:1> : '1';

- `<c>`  See Standard assembler syntax fields on page F2-4120.
- `<q>`  See Standard assembler syntax fields on page F2-4120.
- `<Rm>` Is the general-purpose register holding the address to be branched to, encoded in the "Rm" field.

**Operation for all encodings**

\[ \text{if ConditionPassed()} \text{ then} \]
\[ \text{EncodingSpecificOperations();} \]
\[ \text{BXWritePC(R[m], BranchType_INDIR);} \]
F5.1.29  CBNZ, CBZ

Compare and Branch on Nonzero and Compare and Branch on Zero compare the value in a register with zero, and conditionally branch forward a constant value. They do not affect the condition flags.

**T1**

```
<table>
<thead>
<tr>
<th>15 14 13 12</th>
<th>11 10  9  8</th>
<th>7</th>
<th>3  2  0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  0  1</td>
<td>0  1</td>
<td>1</td>
<td>imm5</td>
</tr>
</tbody>
</table>
```

**CBNZ variant**

Applies when \( \text{op} == 1 \).

```
CBNZ{<q>} <Rn>, <label>
```

**CBZ variant**

Applies when \( \text{op} == 0 \).

```
CBZ{<q>} <Rn>, <label>
```

**Decode for all variants of this encoding**

```
n = UInt(Rn);  imm32 = ZeroExtend(i:imm5:'0', 32);  nonzero = (op == '1');  if InITBlock() then UNPREDICTABLE;
```

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- \(<q>\)  See Standard assembler syntax fields on page F2-4120.
- \(<Rn>\)  Is the general-purpose register to be tested, encoded in the "Rn" field.
- \(<label>\)  Is the program label to be conditionally branched to. Its offset from the PC, a multiple of 2 and in the range 0 to 126, is encoded as "i:imm5" times 2.

**Operation**

```
EncodingSpecificOperations();  
if nonzero != IsZero(R[n]) then  
    BranchWritePC(PC + imm32, BranchType_DIR);
```
F5.1.30 CLREX

Clear-Exclusive clears the local monitor of the executing PE.

**A1**

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>

*Decode for this encoding*

// No additional decoding required

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

• `<c>` For encoding A1: see Standard assembler syntax fields on page F2-4120. Must be AL or omitted.
  For encoding T1: see Standard assembler syntax fields on page F2-4120.

• `<q>` See Standard assembler syntax fields on page F2-4120.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();
  ClearExclusiveLocal(ProcessorID());
F5.1.31   CLZ

Count Leading Zeros returns the number of binary zero bits before the first binary one bit in a value.
