- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( \text{shift} = 00 \)
  - LSR when \( \text{shift} = 01 \)
ASR  when shift = 10
ROR  when shift = 11

<amount>  For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

**Operation**

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
result = operand1 OR operand2;
X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.205 ORR (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate register value, and writes the result to the destination register.

This instruction is used by the alias MOV (bitmask immediate). See Alias conditions for details of when each alias is preferred.

32-bit variant

Applies when \( sf = 0 \) \&\& \( N = 0 \).

\[
\text{ORR <Wd|WSP>, <Wn>, #<imm>}
\]

64-bit variant

Applies when \( sf = 1 \).

\[
\text{ORR <Xd|SP>, <Xn>, #<imm>}
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d & = \text{UInt}(Rd); \\
\text{integer } n & = \text{UInt}(Rn); \\
\text{integer } \text{datasize} & = \text{if } sf \text{ == '1' then 64 else 32; } \\
\text{bits(datasize) imm} & ; \\
\text{if } sf \text{ == '0' \&\& } N \text{ != '0' then UNDEFINED; } \\
(\text{imm, -}) & = \text{DecodeBitMasks}(N, \text{imms, immr, TRUE});
\end{align*}
\]

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

bits(datasize) operand1 = X[n];
b bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

result = operand1 OR operand2;
X[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.207  PACDA, PACDZA

Pointer Authentication Code for Data address, using key A. This instruction computes and inserts a pointer authentication code for a data address, using a modifier and key A.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDA.
- The value zero, for PACDZA.

ARMv8.3

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9  |  5  4  |  0 |
| 1 1 0 1 1 0 1 1 0 0 0 0 1 0 0 | Z | 0 1 0 |
```

**PACDA variant**

Applies when Z == 0.

PACDA <Xd>, <Xn|SP>

**PACDZA variant**

Applies when Z == 1 && Rn == 11111.

PACDZA <Xd>

**Decode for all variants of this encoding**

```java
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UNDEFINED;

if Z == '0' then // PACDA
    if n == 31 then source_is_sp = TRUE;
else // PACDZA
    if n != 31 then UNDEFINED;
```

**Assembler symbols**

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

**Operation**

```java
if source_is_sp then
    X[d] = AddPACDA(X[d], SP[]);
else
    X[d] = AddPACDA(X[d], X[n]);
```
C6.2.208 PACDB, PACDZB

Pointer Authentication Code for Data address, using key B. This instruction computes and inserts a pointer authentication code for a data address, using a modifier and key B.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDB.
- The value zero, for PACDZB.

ARMv8.3

**PACDB variant**

Applies when Z == 0.

PACDB <Xd>, <Xn|SP>

**PACDZB variant**

Applies when Z == 1 && Rn == 11111.

PACDZB <Xd>

**Decode for all variants of this encoding**

```c
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HavePACExt() then
   UNDEFINED;
if Z == '0' then // PACDB
   if n == 31 then source_is_sp = TRUE;
else // PACDZB
   if n != 31 then UNDEFINED;
```

**Assembler symbols**

- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

**Operation**

```c
if source_is_sp then
   X[d] = AddPACDB(X[d], SP[]);
else
   X[d] = AddPACDB(X[d], X[n]);
```
C6.2.209   PACGA

Pointer Authentication Code, using Generic key. This instruction computes the pointer authentication code for an address in the first source register, using a modifier in the second source register, and the Generic key. The computed pointer authentication code is returned in the upper 32 bits of the destination register.

ARMv8.3

<table>

Decode for this encoding

```c
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if !HavePACExt() then 
    UNDEFINED;

if m == 31 then source_is_sp = TRUE;
```

Assembler symbols

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm|SP>` Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Rm" field.

Operation

```c
if source_is_sp then 
    X[d] = AddPACGA(X[n], SP[]);
else 
    X[d] = AddPACGA(X[n], X[m]);
```
C6.2.210   PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA

Pointer Authentication Code for Instruction address, using key A. This instruction computes and inserts a pointer authentication code for an instruction address, using a modifier and key A.

The address is:

• In the general-purpose register that is specified by \langle Xd \rangle for PACIA and PACIZA.
• In X17, for PACIA1716.
• In X30, for PACIASP and PACIAZ.

The modifier is:

• In the general-purpose register or stack pointer that is specified by \langle Xn|SP \rangle for PACIA.
• The value zero, for PACIZA and PACIAZ.
• In X16, for PACIA1716.
• In SP, for PACIASP.

    else
        X[d] = AddPACIB(X[d], X[n]);
C6.2.212 PRFM (immediate)

Prefetch Memory (immediate) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory on page C3-218.

For information about memory accesses, see Load/Store addressing modes on page C1-187.

<table>
<thead>
<tr>
<th>[31 30 29 28]</th>

</thead>
<tbody>
<tr>
<td>1 1 1 1 0 0 1 1 0</td>
<td>imm12</td>
<td>Rn</td>
<td>Rt</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Encoding

PRFM (<prfop> | #<imm5>), [<Xn|SP>{{, #<pimm>}}]

Decode for this encoding

bits(64) offset = LSL(ZeroExtend(imm12, 64), 3);

Assembler symbols

- **<prfop>** Is the prefetch operation, defined as <type><target><policy>.
  - **<type>** is one of:
    - PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
    - PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
    - PST Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.
  - **<target>** is one of:
    - L1 Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
    - L2 Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
    - L3 Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.
  - **<policy>** is one of:
    - KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
    - STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory on page C3-218.

For other encodings of the "Rt" field, use <imm5>.

- **<imm5>** Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

- **<Xn|SP>** Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

- **<pimm>** Is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.
Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);

Operation

if HaveMTEExt() then
    SetTagCheckedInstruction(FALSE);

bits(64) address;

if n == 31 then
    address = SP[];
else
    address = X[n];

address = address + offset;

Prefetch(address, t<4:0>);

PRFM (literal)

Prefetch Memory (literal) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory on page C3-218.

For information about memory accesses, see Load/Store addressing modes on page C1-187.

Encoding

PRFM (<prfop>|#<imm5>), <label>

Decode for this encoding

integer t = UInt(Rt);
bits(64) offset;
offset = SignExtend(imm19:'00', 64);

Assembler symbols

<prfop>  Is the prefetch operation, defined as <type><target><policy>.
<type> is one of:
PLD    Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
PLI    Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
PST    Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.
<target> is one of:
L1     Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
L2     Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
L3     Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.
<policy> is one of:
KEEP    Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
STRM    Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory on page C3-218.
For other encodings of the "Rt" field, use <imm5>.

<imm5>  Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.
Operation

bits(64) address = PC[] + offset;

if HaveMTEExt() then
    SetTagCheckedInstruction(FALSE);

    Prefetch(address, t<4:0>);
C6.2.214 PRFM (register)

Prefetch Memory (register) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory on page C3-218.

For information about memory accesses, see Load/Store addressing modes on page C1-187.

Decode for this encoding

if option1 == '0' then UNDEFINED;  // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 3 else 0;

Assembler symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.

<type> is one of:
PLD  Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
PLI  Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
PST  Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

<target> is one of:
L1  Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
L2  Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
L3  Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

<policy> is one of:
KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory on page C3-218.

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<dm> When option0 is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
<Xm>  When option<@> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend>  Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>UXTW</td>
<td>010</td>
</tr>
<tr>
<td>LSL</td>
<td>011</td>
</tr>
<tr>
<td>SXTW</td>
<td>110</td>
</tr>
<tr>
<td>SXTX</td>
<td>111</td>
</tr>
</tbody>
</table>

<amount>  Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>#0</td>
<td>0</td>
</tr>
<tr>
<td>#3</td>
<td>1</td>
</tr>
</tbody>
</table>

Shared decode for all encodings

```c
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

Operation

```c
bits(64) offset = ExtendReg(m, extend_type, shift);
if HaveMTEExt() then
    SetTagCheckedInstruction(FALSE);

bits(64) address;
if n == 31 then
    address = SP[);
else
    address = X[n];
address = address + offset;
Prefetch(address, t<4:0>);
```
C6.2.215   PRFUM

Prefetch Memory (unscaled offset) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFUM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory on page C3-218.

For information about memory accesses, see Load/Store addressing modes on page C1-187.

Encoding

PRFUM (<prfop>|#<imm5>), [<Xn|SP>], #<simm>]

Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<prfop>   Is the prefetch operation, defined as <type><target><policy>.
<type>   is one of:
  PLD      Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
  PLI      Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
  PST      Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.
<target>   is one of:
  L1      Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
  L2      Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
  L3      Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.
<policy>   is one of:
  KEEP   Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
  STRM   Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory on page C3-218.

For other encodings of the "Rt" field, use <imm5>.

<imm5>   Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field.
This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP>   Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm>   Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
Shared decode for all encodings

    integer n = UInt(Rn);
    integer t = UInt(Rt);

Operation

    if HaveMTEExt() then
        SetTagCheckedInstruction(FALSE);

    bits(64) address;

    if n == 31 then
        address = SP[];
    else
        address = X[n];

    address = address + offset;

    Prefetch(address, t<4:0>);
C6.2.216 PSB CSYNC

Profiling Synchronization Barrier. This instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following DSB instruction completes when the writes to the profiling buffer have completed.

If the Statistical Profiling Extension is not implemented, this instruction executes as a NOP.

**Operation**

ProfilingSynchronizationBarrier();
C6.2.217   PSSBB

Physical Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same physical address.

The semantics of the Physical Speculative Store Bypass Barrier are:

• When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  — The store is to the same location as the load.
  — The store appears in program order before the PSSBB.

• When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  — The store is to the same location as the load.
  — The store appears in program order after the PSSBB.

| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11  8  7  6  5  4  3  2  1  0 |

Decode for this encoding

// No additional decoding required

Operation

SpeculativeStoreBypassBarrierToPA();
C6.2.218   RBIT

Reverse Bits reverses the bit order in a register.

32-bit variant
Applies when \(sf = 0\).

\[
\text{RBIT} \ <Wd>, \ <Wn>
\]

64-bit variant
Applies when \(sf = 1\).

\[
\text{RBIT} \ <Xd>, \ <Xn>
\]

Operation

\[
\begin{align*}
\text{bits}(
\text{datasize}) \ \& \ \text{operand} &= X[n]; \\
\text{bits}(
\text{datasize}) \ \& \ \text{result} &= ; \\
\text{for} \ i &= 0 \ \text{to} \ \text{datasize} - 1 \\
\text{result}<\text{datasize} - 1 - i> &= \text{operand}<i>; \\
X[d] &= \text{result};
\end{align*}
\]

Operational information
If \text{PSTATE.DIT} is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.219 RET

Return from subroutine branches unconditionally to an address in a register, with a hint that this is a subroutine return.

Encoding

RET \{<Xn>\}

Decode for this encoding

integer n = UInt(Rn);

Assembler symbols

\(<Xn>\) Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field. Defaults to X30 if absent.

Operation

bits(64) target = X[n];

BranchTo(target, BranchType_RET);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.220 RETAA, RETAB

Return from subroutine, with pointer authentication. This instruction authenticates the address that is held in LR, using SP as the modifier and the specified key, branches to the authenticated address, with a hint that this instruction is a subroutine return.

Key A is used for RETAA, and key B is used for RETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to LR.

```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Reverse Bytes reverses the byte order in a 64-bit general-purpose register.

When assembling for Armv8.2, an assembler must support this pseudo-instruction. It is OPTIONAL whether an assembler supports this pseudo-instruction when assembling for an architecture earlier than Armv8.2.

This instruction is a pseudo-instruction of the REV instruction. This means that:

- The encodings in this description are named to match the encodings of REV.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of REV gives the operational pseudocode for this instruction.

### 64-bit variant

REV64 <Xd>, <Xn>

is equivalent to

REV <Xd>, <Xn>

and is never the preferred disassembly.

#### Assembler symbols

- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

#### Operation

The description of REV gives the operational pseudocode for this instruction.

#### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.225  RMIF

Performs a rotation right of a value held in a general purpose register by an immediate value, and then inserts a selection of the bottom four bits of the result of the rotation into the PSTATE flags, under the control of a second immediate mask.

ARMv8.4

Encoding

RMIF <Xn>, #<shift>, #<mask>

Decode for this encoding

if !HaveFlagManipulateExt() then UNDEFINED;
integer lsb = UInt(imm6);
integer n = UInt(Rn);

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<shift> Is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
<mask> Is the flag bit mask, an immediate in the range 0 to 15, which selects the bits that are inserted into the NZCV condition flags, encoded in the "mask" field.

Operation

bits(4) tmp;
bits(64) tmpreg = X[n];
tmp = (tmpreg:tmpreg)<lsb+3:lsb>;
if mask<3> == '1' then PSTATE.N = tmp<3>;
if mask<2> == '1' then PSTATE.Z = tmp<2>;
if mask<1> == '1' then PSTATE.C = tmp<1>;
if mask<0> == '1' then PSTATE.V = tmp<0>;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.226  ROR (immediate)

Rotate right (immediate) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This instruction is an alias of the EXTR instruction. This means that:

- The encodings in this description are named to match the encodings of EXTR.
- The description of EXTR gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf == 0 \&\& N == 0 \&\& \text{imms} == 0xxxxx \).

\[
\text{ROR} <Wd>, <Ws>, \#<shift>
\]

is equivalent to

\[
\text{EXTR} <Wd>, <Ws>, <Ws>, \#<shift>
\]

and is the preferred disassembly when \( Rn == Rm \).

### 64-bit variant

Applies when \( sf == 1 \&\& N == 1 \).

\[
\text{ROR} <Xd>, <Xs>, \#<shift>
\]

is equivalent to

\[
\text{EXTR} <Xd>, <Xs>, <Xs>, \#<shift>
\]

and is the preferred disassembly when \( Rn == Rm \).

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Ws>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xs>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- \(<\text{shift}>\) For the 32-bit variant: is the amount by which to rotate, in the range 0 to 31, encoded in the "imms" field.
  
  For the 64-bit variant: is the amount by which to rotate, in the range 0 to 63, encoded in the "imms" field.

### Operation

The description of EXTR gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.227   ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the RORV instruction. This means that:

- The encodings in this description are named to match the encodings of RORV.
- The description of RORV gives the operational pseudocode for this instruction.

32-bit variant
Applies when $sf == 0$.

$ROR <Wd>, <Wn>, <Wm>$
is equivalent to

$RORV <Wd>, <Wn>, <Wm>$
and is always the preferred disassembly.

64-bit variant
Applies when $sf == 1$.

$ROR <Xd>, <Xn>, <Xm>$
is equivalent to

$RORV <Xd>, <Xn>, <Xm>$
and is always the preferred disassembly.

Assembler symbols

- $<Wd>$ is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wn>$ is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<Wm>$ is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- $<Xd>$ is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xn>$ is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<Xm>$ is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation
The description of RORV gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.228   RORV

Rotate Right Variable provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ROR (register). The alias is always the preferred disassembly.

32-bit variant
Applies when sf == 0.
RORV <Wd>, <Wn>, <Wm>

64-bit variant
Applies when sf == 1.
RORV <Xd>, <Xn>, < Xm>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Rd> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

bits(datasize) result;
bits(datasize) operand2 = X[m];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.229   SB

Speculation Barrier is a barrier that controls speculation.

The semantics of the Speculation Barrier are that the execution, until the barrier completes, of any instruction that appears later in the program order than the barrier:

- Cannot be performed speculatively to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception.

In particular, any instruction that appears later in the program order than the barrier cannot cause a speculative allocation into any caching structure where the allocation of that entry could be indicative of any data value present in memory or in the registers.

The SB instruction:

- Cannot be speculatively executed as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception. The potentially exception generating instruction can complete once it is known not to be speculative, and all data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

When the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after an uncompleted SB instruction, the SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched.

Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;
operand2 = NOT(operand2);
(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.232   SBFIZ

Signed Bitfield Insert in Zeros copies a bitfield of \(<\text{width}\>\) bits from the least significant bits of the source register to bit position \(<\text{lsb}\>\) of the destination register, setting the destination bits below the bitfield to zero, and the bits above the bitfield to a copy of the most significant bit of the bitfield.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

**32-bit variant**

Applies when \(sf == 0 \&\& N == 0\).

\[
\text{SBFIZ} \,<\text{Wd}, \,<\text{Wn}, \, #<\text{lsb}, \, #<\text{width}\>
\]

is equivalent to

\[
\text{SBFM} \,<\text{Wd}, \,<\text{Wn}, \, #(-<\text{lsb} \mod 32), \, #(<\text{width}-1)
\]

and is the preferred disassembly when \(\text{UInt}(\text{imms}) < \text{UInt}(\text{immr})\).

**64-bit variant**

Applies when \(sf == 1 \&\& N == 1\).

\[
\text{SBFIZ} \,<\text{Xd}, \,<\text{Xn}, \, #<\text{lsb}, \, #<\text{width}\>
\]

is equivalent to

\[
\text{SBFM} \,<\text{Xd}, \,<\text{Xn}, \, #(-<\text{lsb} \mod 64), \, #(<\text{width}-1)
\]

and is the preferred disassembly when \(\text{UInt}(\text{imms}) < \text{UInt}(\text{immr})\).

**Assembler symbols**

<\text{Wd}> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<\text{Wn}> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<\text{Xd}> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<\text{Xn}> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<\text{lsb}> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.

For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<\text{width}> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<\text{lsb}>.

For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<\text{lsb}>.

**Operation**

The description of SBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.233   SBFM

Signed Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.

If \(<iimms>\) is greater than or equal to \(<immr>\), this copies a bitfield of (\(<iimms>-<immr>+1\)) bits starting from bit position \(<immr>\) in the source register to the least significant bits of the destination register.

If \(<iimms>\) is less than \(<immr>\), this copies a bitfield of (\(<iimms>+1\)) bits from the least significant bits of the source register to bit position (regsize-\(<immr>\)) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases the destination bits below the bitfield are set to zero, and the bits above the bitfield are set to a copy of the most significant bit of the bitfield.

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW. See Alias conditions on page C6-1193 for details of when each alias is preferred.

32-bit variant

Applies when \(sf == 0 \&\& N == 0\).

SBFM \(<Wd>, <Wn>, #<immr>, #<iimms>\)

64-bit variant

Applies when \(sf == 1 \&\& N == 1\).

SBFM \(<Xd>, <Xn>, #<immr>, #<iimms>\)

Decode for all variants of this encoding

\[
\begin{align*}

integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMULL</td>
<td>Ra == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

<Xd>  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>  Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>  Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>  Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

bits(32) operand1 = X[n];
bits(32) operand2 = X[m];
bits(64) operand3 = X[a];
integer result;
result = Int(operand3, FALSE) + (Int(operand1, FALSE) * Int(operand2, FALSE));
X[d] = result<63:0>;}
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
Secure Monitor Call causes an exception to EL3.

SMC is available only for software executing at EL1 or higher. It is UNDEFINED in EL0.

If the values of HCR_EL2.TSC and SCR_EL3.SMD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception, recording it in ESR_ELx, using the EC value 0x17, that is taken to EL3.

If the value of HCR_EL2.TSC is 1 and EL2 is enabled in the current Security state, execution of an SMC instruction at EL1 generates an exception that is taken to EL2, regardless of the value of SCR_EL3.SMD. For more information, see Traps to EL2 of EL1 execution of SMC instructions on page D1-2379.

If the value of HCR_EL2.TSC is 0 and the value of SCR_EL3.SMD is 1, the SMC instruction is UNDEFINED.

Encoding

SMC #<imm>

Decode for this encoding

// Empty.

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

AArch64.CheckForSMCUndefOrTrap(imm16);
AArch64.CallSecureMonitor(imm16);
C6.2.241  SMNEGL

Signed Multiply-Negate Long multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This instruction is an alias of the SMSUBL instruction. This means that:

- The encodings in this description are named to match the encodings of SMSUBL.
- The description of SMSUBL gives the operational pseudocode for this instruction.

```
| 31 30 29 28 27 26 25 24 23 22 21 20 | 16 15 14 | 10 9  | 5 4  | 0 |
+-------------------------------------+---------+-------+-----+---+
| 1 0 0 1 1 0 1 0 0 1 | Rm       | 1 1 1 1 |
| 0 1                       | Rd       |
+--------------------------+---------+-------+-----+---+
```

**Encoding**

SMNEGL <Xd>, <Wn>, <Wm>

is equivalent to

SMSUBL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

**Assembler symbols**

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

**Operation**

The description of SMSUBL gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.242   SMSUBL

Signed Multiply-Subtract Long multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMNEGL. See Alias conditions for details of when each alias is preferred.

Encoding

`SMSUBL <Xd>, <Wn>, <Wm>, <Xa>`

Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
```

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMNEGL</td>
<td>Ra == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

- `<Xd>`  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`  Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- `<Wm>`  Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- `<Xa>`  Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

```plaintext
bits(32) operand1 = X[n];
bits(32) operand2 = X[m];
bits(64) operand3 = X[a];

integer result;

result = Int(operand3, FALSE) - (Int(operand1, FALSE) * Int(operand2, FALSE));
X[d] = result<63:0>;
```
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.243  SMULH

Signed Multiply High multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.

**Encoding**

SMULH <Xd>, <Xn>, <Xm>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

**Assembler symbols**

<Xd>  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn>  Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Xm>  Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

**Operation**

bits(64) operand1 = X[n];
bits(64) operand2 = X[m];

integer result;

result = Int(operand1, FALSE) * Int(operand2, FALSE);

X[d] = result<127:64>;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.244   SMULL

Signed Multiply Long multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This instruction is an alias of the SMADDL instruction. This means that:

• The encodings in this description are named to match the encodings of SMADDL.
• The description of SMADDL gives the operational pseudocode for this instruction.

| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15|14|10| 9| 5| 4| 0 |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 1 | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 1 |

| U | Rm | 0 | 1 | 1 | 1 | 1 | Rn | Rd |
| Uo | Ra |

Encoding

SMULL <Xd>, <Wn>, <Wm>

is equivalent to

SMADDL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMADDL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.245  SSBB

Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the SSBB.

- When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order after the SSBB.

Encoding

SSBB

Decode for this encoding

// No additional decoding required

Operation

SpeculativeStoreBypassBarrierToVA();
C6.2.246   ST2G

Store Allocation Tags stores an Allocation Tag to two Tag granules of memory. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

Post-index
ARMv8.5

C6.2.247 STADDB, STADDLB

Atomic add on byte in memory, without return, atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory.

- STADDB does not have release semantics.
- STADDLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDADDB, LDADDAB, LDADDALB, LDADDLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDADDB, LDADDAB, LDADDALB, LDADDLB.
- The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when \( R = 0 \).

STADDB \(<\text{ws}>, [<\text{xn}|\text{SP}>]\)

is equivalent to

LDADDB \(<\text{ws}>, \text{WZR}, [<\text{xn}|\text{SP}>]\)

and is always the preferred disassembly.

Release variant

Applies when \( R = 1 \).

STADDLB \(<\text{ws}>, [<\text{xn}|\text{SP}>]\)

is equivalent to

LDADDLB \(<\text{ws}>, \text{WZR}, [<\text{xn}|\text{SP}>]\)

and is always the preferred disassembly.

Assembler symbols

- \(<\text{ws}>\) is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- \(<\text{xn} | \text{SP}>\) is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.248  STADDH, STADDLH

Atomic add on halfword in memory, without return, atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory.

- STADDH does not have release semantics.
- STADDLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDADDH, LDADDAH, LDADDALH, LDADDLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDADDH, LDADDAH, LDADDALH, LDADDLH.
- The description of LDADDH, LDADDAH, LDADDALH, LDADDLH gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when $R == 0$.

STADDH $<Ws>$, $[<Xn|SP>]$
is equivalent to

LDADDH $<Ws>$, WZR, $[<Xn|SP>]$
and is always the preferred disassembly.

Release variant

Applies when $R == 1$.

STADDLH $<Ws>$, $[<Xn|SP>]$
is equivalent to

LDADDLH $<Ws>$, WZR, $[<Xn|SP>]$
and is always the preferred disassembly.

Assembler symbols

- $<Ws>$ Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- $<Xn|SP>$ Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADDH, LDADDAH, LDADDALH, LDADDLH gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.249   **STADD, STADDL**

Atomic add on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory.

- **STADD** does not have release semantics.
- **STADDL** stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-139.

For information about memory accesses see *Load/Store addressing modes* on page C1-187.

This instruction is an alias of the LDADD, LDADDA, LDADDAL, LDADDL instruction. This means that:

- The encodings in this description are named to match the encodings of LDADD, LDADDA, LDADDAL, LDADDL.
- The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode for this instruction.

**ARMv8.1**

| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14|12|11 10 9 | 5 4 | 0 |

| 1 | x | 1 | 1 | 1 | 0 | 0 | 0 | R | 1 |
| size | A | opc | | | | | | Rn | 1 | 1 | 1 | 1 | 1 |

**32-bit LDADD alias variant**

Applies when \(size == 10 \&\& R == 0\).

STADD <Ws>, [Xn|SP]

is equivalent to

LDADD <Ws>, WZR, [Xn|SP]

and is always the preferred disassembly.

**32-bit LDADDL alias variant**

Applies when \(size == 10 \&\& R == 1\).

STADDL <Ws>, [Xn|SP]

is equivalent to

LDADDL <Ws>, WZR, [Xn|SP]

and is always the preferred disassembly.

**64-bit LDADD alias variant**

Applies when \(size == 11 \&\& R == 0\).

STADD <Xs>, [Xn|SP]

is equivalent to

LDADD <Xs>, XZR, [Xn|SP]

and is always the preferred disassembly.
64-bit LDADDL alias variant

Applies when size == 11 && R == 1.

STADDL <Xs>, [<Xn|SP>]

is equivalent to

LDADDL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.250  STCLRB, STCLRLB

Atomic bit clear on byte in memory, without return, atomically loads an 8-bit byte from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

- STCLRB does not have release semantics.
- STCLRLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB.
- The description of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when \( R = 0 \).

STCLRB \(<Ws>, [<Xn|SP>]\)

is equivalent to

LDCLRB \(<Ws>, WZR, [<Xn|SP>]\)

and is always the preferred disassembly.

Release variant

Applies when \( R = 1 \).

STCLRLB \(<Ws>, [<Xn|SP>]\)

is equivalent to

LDCLRLB \(<Ws>, WZR, [<Xn|SP>]\)

and is always the preferred disassembly.

Assembler symbols

\(<Ws>\)  Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

\(<Xn|SP>\)  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.251   STCLRH, STCLRLH

Atomic bit clear on halfword in memory, without return, atomically loads a 16-bit halfword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

- STCLRH does not have release semantics.
- STCLRLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH.
- The description of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when \( R == 0 \).

STCLRH \(<Ws>, [<Xn]\) is equivalent to

LDCLRH \(<Ws>, WZR, [<Xn]\)

and is always the preferred disassembly.

Release variant

Applies when \( R == 1 \).

STCLRLH \(<Ws>, [<Xn]\) is equivalent to

LDCLRLH \(<Ws>, WZR, [<Xn]\)

and is always the preferred disassembly.

Assembler symbols

- \(<Ws>\) is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- \(<Xn|SP>\) is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.252  STCLR, STCLRL

Atomic bit clear on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

- STCLR does not have release semantics.
- STCLRL stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDCLR, LDCLRA, LDCLRAL, LDCLRL instruction. This means that:

- The encodings in this description are named to match the encodings of LDCLR, LDCLRA, LDCLRAL, LDCLRL.
- The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational pseudocode for this instruction.

ARMv8.1

32-bit LDCLR alias variant

Applies when size == 10 && R == 0.

STCLR <Ws>, [<Xn|SP>]

is equivalent to

LDCLR <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

32-bit LDCLRL alias variant

Applies when size == 10 && R == 1.

STCLRL <Ws>, [<Xn|SP>]

is equivalent to

LDCLRL <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

64-bit LDCLR alias variant

Applies when size == 11 && R == 0.

STCLR <Xs>, [<Xn|SP>]

is equivalent to

LDCLR <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.
64-bit LDCLRL alias variant

Applies when size == 11 && R == 1.

STCLRL <Xs>, [<Xn|SP>]

is equivalent to

LDCLRL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.253  STEORB, STEORLB

Atomic exclusive OR on byte in memory, without return, atomically loads an 8-bit byte from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory.

- STEORB does not have release semantics.
- STEORLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDEORB, LDEORAB, LDEORALB, LDEORLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDEORB, LDEORAB, LDEORALB, LDEORLB.
- The description of LDEORB, LDEORAB, LDEORALB, LDEORLB gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when \( R = 0 \).

STEORB \(<Ws>, [<Xn|SP>]\)

is equivalent to

LDEORB \(<Ws>, WZR, [<Xn|SP>]\)

and is always the preferred disassembly.

Release variant

Applies when \( R = 1 \).

STEORLB \(<Ws>, [<Xn|SP>]\)

is equivalent to

LDEORLB \(<Ws>, WZR, [<Xn|SP>]\)

and is always the preferred disassembly.

Assembler symbols

\(<Ws>\) Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDEORB, LDEORAB, LDEORALB, LDEORLB gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.254 STEORH, STEORLH

Atomic exclusive OR on halfword in memory, without return, atomically loads a 16-bit halfword from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory.

- **STEORH** does not have release semantics.
- **STEORLH** stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-139.

For information about memory accesses see *Load/Store addressing modes on page C1-187*.

This instruction is an alias of the LDEORH, LDEORAH, LDEORALH, LDEORLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDEORH, LDEORAH, LDEORALH, LDEORLH.
- The description of LDEORH, LDEORAH, LDEORALH, LDEORLH gives the operational pseudocode for this instruction.

**ARMv8.1**

No memory ordering variant

Applies when \( R = 0 \).

STEORH \(<Ws>, [<Xn|SP>]\)

is equivalent to

LDEORH \(<Ws>, WZR, [<Xn|SP>]\)

and is always the preferred disassembly.

Release variant

Applies when \( R = 1 \).

STEORLH \(<Ws>, [<Xn|SP>]\)

is equivalent to

LDEORLH \(<Ws>, WZR, [<Xn|SP>]\)

and is always the preferred disassembly.

Assembler symbols

- \(<Ws>\) Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- \(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDEORH, LDEORAH, LDEORALH, LDEORLH gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.255   STEOR, STEORL

Atomic exclusive OR on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory.

• STEOR does not have release semantics.

• STEORL stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDEOR, LDEORA, LDEORAL, LDEORL instruction. This means that:

• The encodings in this description are named to match the encodings of LDEOR, LDEORA, LDEORAL, LDEORL.

• The description of LDEOR, LDEORA, LDEORAL, LDEORL gives the operational pseudocode for this instruction.

C6.2.268  STLXP

Store-Release Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-166. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and, if the Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. The instruction also has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139. For information about memory accesses see Load/Store addressing modes on page C1-187.

32-bit variant

 Applies when sz == 0.

 STLXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{,#0}]

64-bit variant

 Applies when sz == 1.

 STLXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

```java
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);  // ignored by load/store single register
integer s = UInt(Rs);    // ignored by all loads and store-release

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly STLXP on page K1-7977.

Assembler symbols

<Ws>  Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
0 If the operation updates memory.
1 If the operation fails to update memory.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if HaveMTEExt() then
  SetTagCheckedInstruction(tag_checked);

  bits(datasize DIV 2) el1 = X[t];
  bits(datasize DIV 2) el2 = X[t2];
  data = if BigEndian() then el1:el2 else el2:el1;
  bit status = '1';
  // Check whether the Exclusives monitors are set to include the
  // physical memory locations corresponding to virtual address
  // range [address, address+dbytes-1].
  if AArch64.ExclusiveMonitorsPass(address, dbytes) then
// This atomic write will be rejected if it does not refer
// to the same physical locations after address translation.
Mem[address, dbytes, AccType_ORDEREDATOMIC] = data;
status = ExclusiveMonitorsStatus();
X[s] = ZeroExtend(status, 32);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.269   STLXR

Store-Release Exclusive Register stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-166. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139. For information about memory accesses see Load/Store addressing modes on page C1-187.

32-bit variant
Applies when size == 10.

STLXR <Ws>, <Wt>, [<Xn|SP>{,#0}]

64-bit variant
Applies when size == 11.

STLXR <Ws>, <Xt>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);  // ignored by all loads and store-release

integer elsize = 8 << UInt(size);
boolean tag_checked = n != 31;

Notes for all encodings
For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly STLXR on page K1-7977.

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
0 If the operation updates memory.
1 If the operation fails to update memory.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<dt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment
If a synchronous Data Abort exception is generated by the execution of this instruction:
• Memory is not updated.
• <Ws> is not updated.
Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```plaintext

    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.279 STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a 32-bit register to the calculated address. For information about memory accesses, see Load/Store addressing modes on page C1-187.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.

Encoding

```
| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 13 12|11 10 9 | 5 4 | 0 |
|---|---|---|---|
|addr| opc  |
```

Decoding for this encoding

```
if option[3] == '0' then UNDEFINED; // sub-word index
Extendype extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 1 else 0;
```

Assembler symbols

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<Wm>` When option[0] is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<Xm>` When option[0] is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<extend>` Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when `<amount>` is omitted. encoded in the "option" field. It can have the following values:
  - `UXTW` when option = 010
  - `LSL` when option = 011
  - `SXTW` when option = 110
  - `SXTX` when option = 111
- `<amount>` Is the index shift amount, optional only when `<extend>` is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:
  - #0 when S = 0
  - #1 when S = 1

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```
Operation

bits(64) offset = ExtendReg(m, extend_type, shift);
if HaveMTEExt() then
  SetTagCheckedInstruction(TRUE);

bits(64) address;
bits(16) data;

if n == 31 then
  CheckSPAilgnment();
  address = SP[];
else
  address = X[n];

address = address + offset;

data = X[t];
Mem[address, 2, AccType_NORMAL] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.280   STSETB, STSETLB

Atomic bit set on byte in memory, without return, atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- STSETB does not have release semantics.
- STSETLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDSETB, LDSETAB, LDSETALB, LDSETLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDSETB, LDSETAB, LDSETALB, LDSETLB.
- The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode for this instruction.

**No memory ordering variant**

Applies when \( R = 0 \).

STSETB \( <Ws> \), \[<Xn|SP>\]

is equivalent to

LDSETB \( <Ws> \), WZR, \[<Xn|SP>\]

and is always the preferred disassembly.

**Release variant**

Applies when \( R = 1 \).

STSETLB \( <Ws> \), \[<Xn|SP>\]

is equivalent to

LDSETLB \( <Ws> \), WZR, \[<Xn|SP>\]

and is always the preferred disassembly.

**Assembler symbols**

- \( <Ws> \) is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- \( <Xn|SP> \) is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.281 STSETH, STSETLH

Atomic bit set on halfword in memory, without return, atomically loads a 16-bit halfword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- STSETH does not have release semantics.
- STSETLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDSETH, LDSETAH, LDSETALH, LDSETLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDSETH, LDSETAH, LDSETALH, LDSETLH.
- The description of LDSETH, LDSETAH, LDSETALH, LDSETLH gives the operational pseudocode for this instruction.

**32-bit LDSET alias variant**

Applies when `size == 10 && R == 0`.

STSET `<Ws>`, `[<Xn|SP>]`

is equivalent to

LDSET `<Ws>`, WZR, `[<Xn|SP>]`

and is always the preferred disassembly.

**32-bit LDSETL alias variant**

Applies when `size == 10 && R == 1`.

STSETL `<Ws>`, `[<Xn|SP>]`

is equivalent to

LDSETL `<Ws>`, WZR, `[<Xn|SP>]`

and is always the preferred disassembly.

**64-bit LDSET alias variant**

Applies when `size == 11 && R == 0`.

STSET `<Xs>`, `[<Xn|SP>]`

is equivalent to

LDSET `<Xs>`, XZR, `[<Xn|SP>]`

and is always the preferred disassembly.
64-bit LDSETL alias variant

Applies when size == 11 && R == 1.

STSETL <Xs>, [<Xn|SP>]

is equivalent to

LDSETL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSET, LDSETA, LDSETL, LDSETL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.283  STSMAXB, STSMAXLB

Atomic signed maximum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- **STSMAXB** does not have release semantics.
- **STSMAXLB** stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-139.

For information about memory accesses see *Load/Store addressing modes* on page C1-187.

This instruction is an alias of the LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB.
- The description of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB gives the operational pseudocode for this instruction.

**ARMv8.1**

No memory ordering variant

Applies when \( R = 0 \).

STSMAXB \(<\text{ws}>, \ [<Xn|SP>]\)

is equivalent to

LDSMAXB \(<\text{ws}>, \ \text{WZR}, \ [<Xn|SP>]\)

and is always the preferred disassembly.

Release variant

Applies when \( R = 1 \).

STSMAXLB \(<\text{ws}>, \ [<Xn|SP>]\)

is equivalent to

LDSMAXLB \(<\text{ws}>, \ \text{WZR}, \ [<Xn|SP>]\)

and is always the preferred disassembly.

Assembler symbols

- \(<\text{ws}>\)  Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- \(<Xn|SP>\)  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation
The description of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB gives the operational pseudocode for this instruction.

Operational information
If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.284 STSMAXH, STSMAXLH

Atomic signed maximum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- STSMAXH does not have release semantics.
- STSMAXLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH.
- The description of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when \( R = 0 \).

STSMAXH \(<\text{Ws}>, [<\text{Xn}\mid\text{SP}>]\)

is equivalent to

LDSMAXH \(<\text{Ws}>, \text{WZR}, [<\text{Xn}\mid\text{SP}>]\)

and is always the preferred disassembly.

Release variant

Applies when \( R = 1 \).

STSMAXLH \(<\text{Ws}>, [<\text{Xn}\mid\text{SP}>]\)

is equivalent to

LDSMAXLH \(<\text{Ws}>, \text{WZR}, [<\text{Xn}\mid\text{SP}>]\)

and is always the preferred disassembly.

Assembler symbols

- \(<\text{Ws}>\) is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- \(<\text{Xn}\mid\text{SP}>\) is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.285  **STSMAX, STSMAXL**

Atomic signed maximum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- **STSMAX** does not have release semantics.
- **STSMAXL** stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-139.

For information about memory accesses see *Load/Store addressing modes* on page C1-187.

This instruction is an alias of the **LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL** instruction. This means that:

- The encodings in this description are named to match the encodings of **LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL**.
- The description of **LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL** gives the operational pseudocode for this instruction.

**32-bit LDSMAX alias variant**

Applies when `size == 10 && R == 0`.

STSMAX `<Ws>`, `<Xn|SP>`

is equivalent to

LDSMAX `<Ws>`, WZR, `<Xn|SP>`

and is always the preferred disassembly.

**32-bit LDSMAXL alias variant**

Applies when `size == 10 && R == 1`.

STSMAXL `<Ws>`, `<Xn|SP>`

is equivalent to

LDSMAXL `<Ws>`, WZR, `<Xn|SP>`

and is always the preferred disassembly.

**64-bit LDSMAX alias variant**

Applies when `size == 11 && R == 0`.

STSMAX `<Xs>`, `<Xn|SP>`

is equivalent to

LDSMAX `<Xs>`, XZR, `<Xn|SP>`

and is always the preferred disassembly.
**64-bit LDSMAXL alias variant**

Applies when `size == 11 && R == 1`.

STSMAXL `<Xs>`, `[<Xn|SP>]`

is equivalent to

LDSMAXL `<Xs>`, XZR, `[<Xn|SP>]`

and is always the preferred disassembly.

**Assembler symbols**

- `<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- `<Xs>` Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

The description of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.286  STSMINB, STSMINLB

Atomic signed minimum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers.

- **STSMINB** does not have release semantics.
- **STSMINLB** stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-139.

For information about memory accesses see *Load/Store addressing modes* on page C1-187.

This instruction is an alias of the LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB.
- The description of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB gives the operational pseudocode for this instruction.

**ARMv8.1**

No memory ordering variant

Applies when \( R = 0 \).

STSMINB <Ws>, [<Xn|SP>]  
is equivalent to  
LDSMINB <Ws>, WZR, [<Xn|SP>]  
and is always the preferred disassembly.

Release variant

Applies when \( R = 1 \).

STSMINLB <Ws>, [<Xn|SP>]  
is equivalent to  
LDSMINLB <Ws>, WZR, [<Xn|SP>]  
and is always the preferred disassembly.

Assembler symbols

- `<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.287  STSMINH, STSMINLH

Atomic signed minimum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers.

- STSMINH does not have release semantics.
- STSMINLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH.
- The description of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when $R == 0$.

STSMINH $<\text{Rs}>$, [<$Xn$|SP>]

is equivalent to

LDSMINH $<\text{Rs}>$, WZR, [<$Xn$|SP>]

and is always the preferred disassembly.

Release variant

Applies when $R == 1$.

STSMINLH $<\text{Rs}>$, [<$Xn$|SP>]

is equivalent to

LDSMINLH $<\text{Rs}>$, WZR, [<$Xn$|SP>]

and is always the preferred disassembly.

Assembler symbols

$<\text{Rs}>$  Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

$<\text{Xn}\mid\text{SP}>$  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.288  STSMIN, STSMINL

Atomic signed minimum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers.

- STSMIN does not have release semantics.
- STSMINL stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDSMIN, LDSMINA, LDSMINAL, LDSMINL instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMIN, LDSMINA, LDSMINAL, LDSMINL.
- The description of LDSMIN, LDSMINA, LDSMINAL, LDSMINL gives the operational pseudocode for this instruction.

ARMv8.1

| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14 12|11 10 9 | 5 4 | 0 |
| 1 x 1 1 1|0 0 0 0 R 1 | Rs 0 1 0 1 0 0 | Rn | 1 1 1 1 | 1 |

32-bit LDSMIN alias variant

Applies when size == 10 && R == 0.

STSMIN <Ws>, [<Xn|SP>] is equivalent to
LDSMIN <Ws>, WZR, [<Xn|SP>]
and is always the preferred disassembly.

32-bit LDSMINL alias variant

Applies when size == 10 && R == 1.

STSMINL <Ws>, [<Xn|SP>] is equivalent to
LDSMINL <Ws>, WZR, [<Xn|SP>]
and is always the preferred disassembly.

64-bit LDSMIN alias variant

Applies when size == 11 && R == 0.

STSMIN <Xs>, [<Xn|SP>] is equivalent to
LDSMIN <Xs>, XZR, [<Xn|SP>]
and is always the preferred disassembly.
64-bit LDSMINL alias variant

Applies when size == 11 & R == 1.

STSMINL <Xs>, [<Xn|SP>]

is equivalent to

LDSMINL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSMIN, LDSMINA, LDSMINAL, LDSMINL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.289   STTR

Store Register (unprivileged) stores a word or doubleword from a register to memory. The address that is used for
the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of
PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is \{1, 1\}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the
instruction is executed. For information about memory accesses, see Load/Store addressing modes on page C1-187.

32-bit variant

Applies when size == 10.

STTR \<Wt>, \[<Xn|SP>{, #<simm>}\]

64-bit variant

Applies when size == 11.

STTR \<Xt>, \[<Xn|SP>{, #<simm>}\]

Decode for all variants of this encoding

integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

\<Wt>  Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
\<Xt>  Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
\<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
\<simm>  Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded
           in the "imm9" field.

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVEExt() && HCR_EL2.<NV,NV1> == '11');
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
    acctype = AccType_UNPRIV;
else
    acctype = AccType_NORMAL;

address = address + offset;

data = X[t];
Mem[address, datasize DIV 8, acctype] = data;

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.290  STTRB

Store Register Byte (unprivileged) stores a byte from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes on page C1-187.

```
[31 30 29 28][27 26 25 24][23 22 21 20] | 12|11 10 9 | 5 4 | 0 |
0 0 1 1 1 0 0 0 0 0 | imm9 | 1 0 | Rn | Rt |
```

**Encoding**

STTRB <Wt>, [<Xn|SP>{, #<simm>}]

**Decode for this encoding**

bits(64) offset = SignExtend(imm9, 64);

**Assembler symbols**

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

**Shared decode for all encodings**

```
integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11';
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
  acctype = AccType_UNPRIV;
else
  acctype = AccType_NORMAL;

boolean tag_checked = n != 31;
```

**Operation**

```
if HaveMTEExt() then
  SetTagCheckedInstruction(tag_checked);

bits(64) address;
bits(8) data;
```
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 1, acctype] = data;

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.291  STTRH

Store Register Halfword (unprivileged) stores a halfword from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes on page C1-187.

### Encoding

STTRH <Wt>, [<Xn|SP>{, #<simm>}]

### Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

### Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

### Shared decode for all encodings

```c
integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
    acctype = AccType_UNPRIV;
else
    acctype = AccType_NORMAL;

boolean tag_checked = n != 31;
```

### Operation

```c
if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
bits(16) data;
```
if n == 31 then
  CheckSPA\text{Alignment}();
  address = SP[];
else
  address = X[n];

address = address + offset;

data = X[t];
Mem[address, 2, acctype] = data;

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.292 STUMAXB, STUMAXLB

Atomic unsigned maximum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- STUMAXB does not have release semantics.
- STUMAXLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB.
- The description of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when R == 0.

STUMAXB <Rs>, [<Xn|SP>]
is equivalent to

LDUMAXB <Rs>, WZR, [<Xn|SP>]
and is always the preferred disassembly.

Release variant

Applies when R == 1.

STUMAXLB <Rs>, [<Xn|SP>]
is equivalent to

LDUMAXLB <Rs>, WZR, [<Xn|SP>]
and is always the preferred disassembly.

Assembler symbols

<Rs> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.293   STUMAXH, STUMAXLH

Atomic unsigned maximum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- STUMAXH does not have release semantics.
- STUMAXLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH.
- The description of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when \( R = 0 \).

STUMAXH <ws>, [<Xn|SP>]

is equivalent to

LDUMAXH <ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Release variant

Applies when \( R = 1 \).

STUMAXLH <ws>, [<Xn|SP>]

is equivalent to

LDUMAXLH <ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.294  STUMAX, STUMAXL

Atomic unsigned maximum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- **STUMAX** does not have release semantics.
- **STUMAXL** stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-139.

For information about memory accesses see *Load/Store addressing modes* on page C1-187.

This instruction is an alias of the LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.
- The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode for this instruction.

### 32-bit LDUMAX alias variant

Applies when \(\text{size} = 10 \&\& R = 0\).

**STUMAX <Ws>, [Xn|SP]**

is equivalent to

**LDUMAX <Ws>, WZR, [Xn|SP]**

and is always the preferred disassembly.

### 32-bit LDUMAXL alias variant

Applies when \(\text{size} = 10 \&\& R = 1\).

**STUMAXL <Ws>, [Xn|SP]**

is equivalent to

**LDUMAXL <Ws>, WZR, [Xn|SP]**

and is always the preferred disassembly.

### 64-bit LDUMAX alias variant

Applies when \(\text{size} = 11 \&\& R = 0\).

**STUMAX <Xs>, [Xn|SP]**

is equivalent to

**LDUMAX <Xs>, XZR, [Xn|SP]**

and is always the preferred disassembly.
64-bit LDUMAXL alias variant

Applies when size == 11 & R == 1.

STUMAXL <Xs>, [<Xn|SP>]

is equivalent to

LDUMAXL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.295   STUMINB, STUMINLB

Atomic unsigned minimum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

- STUMINB does not have release semantics.
- STUMINLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB.
- The description of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when \( R = 0 \).

STUMINB <\( \text{<Ws>} \)>, [<Xn|SP>]

is equivalent to

LDUMINB <\( \text{<Ws>} \)>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Release variant

Applies when \( R = 1 \).

STUMINLB <\( \text{<Ws>} \)>, [<Xn|SP>]

is equivalent to

LDUMINLB <\( \text{<Ws>} \)>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

- \(<\text{<Ws>}>\) Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- \(<\text{Xn}|\text{SP}>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.296  STUMINH, STUMINLH

Atomic unsigned minimum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

- STUMINH does not have release semantics.
- STUMINLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

This instruction is an alias of the LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH.
- The description of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH gives the operational pseudocode for this instruction.

STUMIN <Xs>, [<Xn|SP>]
is equivalent to
LDUMIN <Xs>, XZR, [<Xn|SP>]
and is always the preferred disassembly.
64-bit LDUMINL alias variant

Applies when \texttt{size == 11 && R == 1}.

\texttt{STUMINL <Xs>, [<Xn|SP>]} 

is equivalent to 

\texttt{LDUMINL <Xs>, XZR, [<Xn|SP>]} 

and is always the preferred disassembly.

Assembler symbols

\texttt{<Ws>} is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

\texttt{<Xs>} is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

\texttt{<Xn|SP>} is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDUMIN, LDUMINA, LDUMINAL, LDUMINL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.298   STUR

Store Register (unscaled) calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about memory accesses, see Load/Store addressing modes on page C1-187.

32-bit variant
Applies when size == 10.
STUR <Wt>, [<Xn|SP>{, #<simm>}]  

64-bit variant
Applies when size == 11.
STUR <Xt>, [<Xn|SP>{, #<simm>}]  

Decode for all variants of this encoding
integer scale = UInt(size);  
bits(64) offset = SignExtend(imm9, 64);

Assembler symbols
<Wt>  
Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xt>  
Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP>  
Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm>  
Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings
integer n = UInt(Rn);  
integer t = UInt(Rt);

integer datasize = 8 << scale;  
boolean tag_checked = n != 31;

Operation
if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];
address = address + offset;

data = X[t];

Mem[address, datasize DIV 8, AccType_NORMAL] = data;

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.299   STURB

Store Register Byte (unscaled) calculates an address from a base register value and an immediate offset, and stores a byte to the calculated address, from a 32-bit register. For information about memory accesses, see Load/Store addressing modes on page C1-187.

[31 30 29 28|27 26 25 24|23 22 21 20] | 12|11 10 9 | 5 4 | 0 |

Encoding

STURB <Wt>, [<Xn|SP>{, #<simm>}]

Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);
boolean tag_checked = n != 31;

Operation

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
bites(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 1, AccType_NORMAL] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.300   STURH

Store Register Halfword (unscaled) calculates an address from a base register value and an immediate offset, and
stores a halfword to the calculated address, from a 32-bit register. For information about memory accesses, see
Load/Store addressing modes on page C1-187.

Encoding

STURH <Wt>, [<Xn|SP>{, #<simm>}]

Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded
in the "imm9" field.

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;

Operation

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 2, AccType_NORMAL] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.301 STXP

Store Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-166. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and, if the Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about memory accesses see Load/Store addressing modes on page C1-187.

32-bit variant

Applies when $sz == 0$.

STXP $<Ws>$, $<Wt1>$, $<Wt2>$, [$<Xn|SP>{$#,0}]

64-bit variant

Applies when $sz == 1$.

STXP $<Ws>$, $<Xt1>$, $<Xt2>$, [$<Xn|SP>{$#,0}]

Decode for all variants of this encoding

\[
\begin{align*}
&\text{integer } n = \text{UInt}(Rn) ; \\
&\text{integer } t = \text{UInt}(Rt) ; \\
&\text{integer } t2 = \text{UInt}(Rt2) ; \quad / / \text{ignored by load/store single register} \\
&\text{integer } s = \text{UInt}(Rs) ; \quad / / \text{ignored by all loads and store-release} \\
&\text{integer } elsize = 32 \times \text{UInt}(sz) ; \\
&\text{integer } datasize = elsize \times 2 ; \\
&\text{boolean } tag\_checked = n \neq 31 ;
\end{align*}
\]

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly STXP on page K1-7979.

Assembler symbols

\[

\end{align*}
\]
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);
if s == t || (s == t2) then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE; // store UNKNOWN value
        when Constraint_NONE rt_unknown = FALSE; // store original value
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();

if s == n && n != 31 then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rn_unknown = TRUE; // address is UNKNOWN
        when Constraint_NONE rn_unknown = FALSE; // address is original base
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];
if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    bits(datasize DIV 2) e11 = X[t];
    bits(datasize DIV 2) e12 = X[t2];
    data = if BigEndian() then e11:e12 else e12:e11;
    bit status = '1';
    // Check whether the Exclusives monitors are set to include the
    // physical memory locations corresponding to virtual address
    // range [address, address+dbytes-1].
    if AArch64.ExclusiveMonitorsPass(address, dbytes) then
// This atomic write will be rejected if it does not refer
// to the same physical locations after address translation.
Mem[address, dbytes, AccType_ATOMIC] = data;
status = ExclusiveMonitorsStatus();
X[s] = ZeroExtend(status, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.302 STXR

Store Exclusive Register stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-166. For information about memory access see Load/Store addressing modes on page C1-187.

### 32-bit variant

Applies when `size == 10`.

\[
\text{STXR} \ <Ws>, \ <Wt>, \ [\langle Xn|SP\rangle\{,#0\}]
\]

### 64-bit variant

Applies when `size == 11`.

\[
\text{STXR} \ <Ws>, \ <Xt>, \ [\langle Xn|SP\rangle\{,#0\}]
\]

**Decode for all variants of this encoding**

```plaintext
decode = \begin{aligned}
\text{integer } n &= \text{ UInt}(Rn); \\
\text{integer } t &= \text{ UInt}(Rt); \\
\text{integer } s &= \text{ UInt}(Rs); \quad \text{// ignored by all loads and store-release} \\
\text{integer } elsize &= 8 \ll \text{ UInt}(size); \\
\text{boolean } tag\_\text{checked} &= n \neq 31;
\end{aligned}
```

### Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly STXR on page K1-7979.

**Assembler symbols**

- `<Ws>` Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
  - 0 If the operation updates memory.
  - 1 If the operation fails to update memory.
- `<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Aborts and alignment**

&Wm> & \text{Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.} \\
&Xd|SP> & \text{Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.} \\
&Xn|SP> & \text{Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.} \\
&R> & \text{Is a width specifier, encoded in the "option" field. It can have the following values:} \\
&W & \text{when option } = 00x \\
&W & \text{when option } = 010 \\
&X & \text{when option } = 111 \\
&W & \text{when option } = 10x \\
&W & \text{when option } = 110 \\
<m> & \text{Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.}
\end{align*}
\]
For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

#### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');

X[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.311  SUBG

Subtract with Tag subtracts an immediate value scaled by the Tag granule from the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

ARMv8.5

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>

</thead>
<tbody>
<tr>
<td>CMP (extended register) Rd == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- <R> Is a width specifier, encoded in the "option" field. It can have the following values:
  W when option = 00x
W when option = 010
X when option = x11
W when option = 10x
W when option = 110

<extend>
Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend>
For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:
- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:
- UXTB when option = 000
- UXTH when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:
- UXTB when option = 000
- UXTH when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount>
Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

### Operation

```plaintext
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;
operand2 = NOT(operand2);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');
PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
```
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.315 SUBS (immediate)

Subtract (immediate), setting flags, subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMP (immediate). See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when \( sf = 0 \).

\[

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

```c
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(4) nzcv;

operand2 = NOT(operand2);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');

PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.317 SVC

Supervisor Call causes an exception to be taken to EL1.

On executing an SVC instruction, the PE records the exception as a Supervisor Call exception in ESR_ELx, using the EC value 0x15, and the value of the immediate argument.

```
|31 30 29 28|27 26 25 24|23 22 21 20|   |   |   | 5 4 3 2 1 0 |
|1 1 0 1 0 1 0 0 0 0 0| imm16|   | 0 0 0 0 1|
```

**Encoding**

SVC #<imm>

**Decode for this encoding**

// Empty.

**Assembler symbols**

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

**Operation**

```c
AArch64.CheckForSVCTrap(imm16);
AArch64.CallSupervisor(imm16);
```
C6.2.318    SWPB, SWPAB, SWPALB, SWPLB

Swap byte in memory atomically loads an 8-bit byte from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, SWPAB and SWPALB load from memory with acquire semantics.
- SWPLB and SWPALB store to memory with release semantics.
- SWPB has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

For information about memory accesses see Load/Store addressing modes on page C1-187.

```
C6.2.321   SXTB

Signed Extend Byte extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

• The encodings in this description are named to match the encodings of SBFM.
• The description of SBFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \) \&\& \( N = 0 \).

\( \text{SXTB} \ <Wd>, \ <Wn> \)

is equivalent to

\( \text{SBFM} \ <Wd>, \ <Wn>, \ #0, \ #7 \)

and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \) \&\& \( N = 1 \).

\( \text{SXTB} \ <Xd>, \ <Xn> \)

is equivalent to

\( \text{SBFM} \ <Xd>, \ <Xn>, \ #0, \ #7 \)

and is always the preferred disassembly.

Assembler symbols

\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

\(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If \( \text{PSTATE.DIT} \) is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.322  SXTH

Sign Extend Halfword extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf == 0 \) && \( N == 0 \).

\[ \text{SXTH} \langle \text{Wd} \rangle, \langle \text{Wn} \rangle \]

is equivalent to

\[ \text{SBFM} \langle \text{Wd} \rangle, \langle \text{Wn} \rangle, \#0, \#15 \]

and is always the preferred disassembly.

64-bit variant

Applies when \( sf == 1 \) && \( N == 1 \).

\[ \text{SXTH} \langle \text{Xd} \rangle, \langle \text{Wn} \rangle \]

is equivalent to

\[ \text{SBFM} \langle \text{Xd} \rangle, \langle \text{Xn} \rangle, \#0, \#15 \]

and is always the preferred disassembly.

Assembler symbols

- \( \langle \text{Wd} \rangle \) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( \langle \text{Xd} \rangle \) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( \langle \text{Xn} \rangle \) is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \( \langle \text{Wn} \rangle \) is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.323   SXTW

Sign Extend Word sign-extends a word to the size of the register, and writes the result to the destination register. This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

**Operation**

The description of SBFM gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.324   SYS

System instruction. For more information, see op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-377 for the encodings of System instructions.

This instruction is used by the aliases AT, CFP, CPP, DC, DVP, IC, and TLBI. See Alias conditions for details of when each alias is preferred.

**Assembler symbols**

- **<op1>** Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- **<Cn>** Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
- **<Cm>** Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- **<op2>** Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
- **<Xt>** Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.
Operation

```
AArch64.SysInstr(1, sys_op1, sys_crn, syscrm, sys_op2, X[t]);
```
### C6.2.325 SYSL

System instruction with result. For more information, see op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-377 for the encodings of System instructions.

#### Encoding

SYSL <Xt>, #<op1>, <Cn>, <Cm>, #<op2>

#### Decode for this encoding

```c
AArch64.CheckSystemAccess('01', op1, CRn, CRm, op2, Rt, L);
integer t = UInt(Rt);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
```

#### Assembler symbols

- `<Xt>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
- `<op1>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- `<Cn>` Is a name 'Cn', with ‘n’ in the range 0 to 15, encoded in the "CRn" field.
- `<Cm>` Is a name 'Cm', with ‘m’ in the range 0 to 15, encoded in the "CRm" field.
- `<op2>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

#### Operation

// No architecturally defined instructions here.
```c
X[t] = AArch64.SysInstrWithResult(1, sys_op1, sys_crn, sys_crm, sys_op2);
```
C6.2.326  TBNZ

Test bit and Branch if Nonzero compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

Encoding

TBNZ <R><t>, #<imm>, <label>

Decode for this encoding

integer t = UInt(Rt);
integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);

Assembler symbols

<R>  Is a width specifier, encoded in the "b5" field. It can have the following values:
W   when b5 = 0
X   when b5 = 1
In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.
<tt>  Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.
<imm>  Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".
<label>  Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

bits(datasize) operand = X[t];
if operand<bit_pos> == op then
    BranchTo(PC[] + offset, BranchType_DIR);
C6.2.327   TBZ

Test bit and Branch if Zero compares the value of a test bit with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

```
[31 30 29 28][27 26 25 24][23]
|19 18 | | | 5 4 | 0 |

b5 0 1 1 0 1 1 0 b40

|imm14| Rt|
```

**Encoding**

TBZ <R><t>, #<imm>, <label>

**Decode for this encoding**

integer t = UInt(Rt);

integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);

**Assembler symbols**

- **<R>** Is a width specifier, encoded in the "b5" field. It can have the following values:
  - 'W' when b5 = 0
  - 'X' when b5 = 1
  - In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.
- **<t>** Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.
- **<imm>** Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".
- **<label>** Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

**Operation**

bits(datasize) operand = X[t];

if operand<bit_pos> == op then
    BranchTo(PC[] + offset, BranchType_DIR);
C6.2.328 TLBI

TLB Invalidate operation. For more information, see op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-377.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

**Encoding**

TLBI <tlbi_op>{, <Xt>}

is equivalent to

SYS #<op1>, C8, #<Cm>, #<op2>{, <Xt>}

and is the preferred disassembly when SysOp(op1,'1000',CRm,op2) == Sys_TLBI.

**Assembler symbols**

- **<op1>** Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- **<Cm>** Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- **<op2>** Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
- **<tlbi_op>** Is a TLBI instruction name, as listed for the TLBI system instruction group, encoded in the "op1:CRm:op2" field. It can have the following values:
  - VMALLE1IS when op1 = 000, CRm = 0011, op2 = 000
  - VAE1IS when op1 = 000, CRm = 0011, op2 = 001
  - ASIDE1IS when op1 = 000, CRm = 0011, op2 = 010
  - VAAE1IS when op1 = 000, CRm = 0011, op2 = 011
  - VALE1IS when op1 = 000, CRm = 0011, op2 = 101
  - VAALE1IS when op1 = 000, CRm = 0011, op2 = 111
  - VMALLE1 when op1 = 000, CRm = 0111, op2 = 000
  - VAE1 when op1 = 000, CRm = 0111, op2 = 001
  - ASIDE1 when op1 = 000, CRm = 0111, op2 = 010
  - VAAE1 when op1 = 000, CRm = 0111, op2 = 011
  - VALE1 when op1 = 000, CRm = 0111, op2 = 101
  - VAALE1 when op1 = 000, CRm = 0111, op2 = 111
  - IPAS2E1IS when op1 = 100, CRm = 0000, op2 = 001
  - IPAS2LE1IS when op1 = 100, CRm = 0000, op2 = 101
  - ALLE2IS when op1 = 100, CRm = 0011, op2 = 000
  - VAE2IS when op1 = 100, CRm = 0011, op2 = 001
  - ALLE1IS when op1 = 100, CRm = 0011, op2 = 100
VALE2IS when op1 = 100, CRm = 0011, op2 = 101
VMALLS12E1IS when op1 = 100, CRm = 0011, op2 = 110
IPAS2E1 when op1 = 100, CRm = 0100, op2 = 001
IPAS2LE1 when op1 = 100, CRm = 0100, op2 = 101
ALLE2 when op1 = 100, CRm = 0111, op2 = 000
VAE2 when op1 = 100, CRm = 0111, op2 = 001
ALLE1 when op1 = 100, CRm = 0111, op2 = 100
VALE2 when op1 = 100, CRm = 0111, op2 = 101
VMALLS12E1 when op1 = 100, CRm = 0111, op2 = 110
ALLE3IS when op1 = 110, CRm = 0011, op2 = 000
VAE3IS when op1 = 110, CRm = 0011, op2 = 001
VALE3IS when op1 = 110, CRm = 0011, op2 = 100
ALLE3 when op1 = 110, CRm = 0111, op2 = 000
VAE3 when op1 = 110, CRm = 0111, op2 = 001
VALE3 when op1 = 110, CRm = 0111, op2 = 101

When FEAT_TLBIOS is implemented, the following values are also valid:
VMALLE1OS when op1 = 000, CRm = 0001, op2 = 000
VAE1OS when op1 = 000, CRm = 0001, op2 = 001
ASIDE1OS when op1 = 000, CRm = 0001, op2 = 010
VAAE1OS when op1 = 000, CRm = 0001, op2 = 011
VALE1OS when op1 = 000, CRm = 0001, op2 = 100
VAAE1OS when op1 = 000, CRm = 0001, op2 = 101
ALLE1OS when op1 = 000, CRm = 0001, op2 = 100
VALE1OS when op1 = 000, CRm = 0001, op2 = 101
VMALLS12E1OS when op1 = 100, CRm = 0001, op2 = 110

RVAE3OS when op1 = 110, CRm = 0101, op2 = 001
RVALE3OS when op1 = 110, CRm = 0101, op2 = 101
RVAE3 when op1 = 110, CRm = 0110, op2 = 001
RVALE3 when op1 = 110, CRm = 0110, op2 = 101

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
C6.2.329   TSB CSYNC

Trace Synchronization Barrier. This instruction is a barrier that synchronizes the trace operations of instructions. If FEAT_TRF is not implemented, this instruction executes as a NOP.

ARMv8.4

```
|31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 8|7|5|4|3|2|1|0 |
|1 |1 |0 |1 |0 |1 |0 |0 |0 |0 |1 |1 |0 |0 |1 |0 |0 |1 |0 |1 |0 |1 |1 |1 |1 |

CRm   op2
```

**Encoding**

TSB  CSYNC

**Decode for this encoding**

if !HaveSelfHostedTrace() then EndOfInstruction();

**Operation**

TraceSynchronizationBarrier();
C6.2.330   TST (immediate)

Test bits (immediate), setting the condition flags and discarding the result: \( Rn \ AND \ imm \)

This instruction is an alias of the ANDS (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf == 0 && N == 0 \).

\[
\text{TST } <\text{n}>, \ #<\text{imm}>
\]

is equivalent to

\[
\text{ANDS } \text{WZR}, \ <\text{n}>, \ #<\text{imm}>
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf == 1 \).

\[
\text{TST } <\text{n}>, \ #<\text{imm}>
\]

is equivalent to

\[
\text{ANDS } \text{XZR}, \ <\text{n}>, \ #<\text{imm}>
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<\text{n}>\): Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{n}>\): Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{imm}>\): For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

### Operation

The description of ANDS (immediate) gives the operational pseudocode for this instruction.
C6.2.331  TST (shifted register)

Test (shifted register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ANDS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when sf == 0.

TST <Wn>, <Wm>{, <shift> #<amount>}

is equivalent to

ANDS WZR, <Wn>, <Wm>{, <shift> #<amount>}

and is always the preferred disassembly.

### 64-bit variant

Applies when sf == 1.

TST <Xn>, <Xm>{, <shift> #<amount>}

is equivalent to

ANDS XZR, <Xn>, <Xm>{, <shift> #<amount>}

and is always the preferred disassembly.

### Assembler symbols

- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when shift = 00
  - LSR when shift = 01
  - ASR when shift = 10
  - ROR when shift = 11
- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.332 UBFIZ

Unsigned Bitfield Insert in Zeros copies a bitfield of &lt;width&gt; bits from the least significant bits of the source register to bit position &lt;lsb&gt; of the destination register, setting the destination bits above and below the bitfield to zero.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \land N = 0 \).

\[
\text{UBFIZ} <Wd>, <Wn>, #<lsb>, #<width>
\]

is equivalent to

\[
\text{UBFM} <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
\]

and is the preferred disassembly when \( \text{UInt}(\text{immr}) < \text{UInt}(\text{imms}) \).

64-bit variant

Applies when \( sf = 1 \land N = 1 \).

\[
\text{UBFIZ} <Xd>, <Xn>, #<lsb>, #<width>
\]

is equivalent to

\[
\text{UBFM} <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
\]

and is the preferred disassembly when \( \text{UInt}(\text{imms}) < \text{UInt}(\text{immr}) \).

Assembler symbols

- \(<Wd>&gt;\): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>&gt;\): Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>&gt;\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>&gt;\): Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<lsb>&gt;\): For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- \(<width>&gt;\): For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

\[
\begin{array}{cccc|cccccccc}
\text{sf} & 1 & 0 & 1 & 0 & 0 & 1 & 1 & 0 & N & \text{immr} & \text{imms} & \text{Rn} & \text{Rd} \\
o pc
\end{array}
\]
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.333   UBFM

Unsigned Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.

If \(<\text{imms}>\) is greater than or equal to \(<\text{immr}>\), this copies a bitfield of \((<\text{imms}>-<\text{immr}>+1)\) bits starting from bit position \(<\text{immr}>\) in the source register to the least significant bits of the destination register.

If \(<\text{imms}>\) is less than \(<\text{immr}>\), this copies a bitfield of \((<\text{imms}>+1)\) bits from the least significant bits of the source register to bit position \((\text{regsize}-<\text{immr}>)\) of the destination register, where \(\text{regsize}\) is the destination register size of 32 or 64 bits.

In both cases the destination bits below and above the bitfield are set to zero.

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH. See Alias conditions on page C6-1374 for details of when each alias is preferred.

32-bit variant

Applies when \(sf == 0 \&\& N == 0\).

UBFM \(<Wd>, <Wn>, #<immr>, #<imms>\)

64-bit variant

Applies when \(sf == 1 \&\& N == 1\).

UBFM \(<Xd>, <Xn>, #<immr>, #<imms>\)

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer data} & = \text{if } sf = '1' \text{ then } 64 \text{ else } 32; \\
\text{integer } R; \\
\text{bits(data)} &= \text{w} \text{mask}; \\
\text{bits(data)} &= \text{t} \text{mask}; \\
\text{if } sf &= '1' \&\& N != '1' \text{ then UNDEFINED; } \\
\text{if } sf &= '0' \&\& \left(N != '0' || \text{immr}<5> != '0' || \text{imms}<5> != '0' \right) \text{ then UNDEFINED; } \\
R &= \text{UInt}(\text{immr}); \\
(\text{w} \text{mask}, \text{t} \text{mask}) &= \text{DecodeBitMasks}(\text{N}, \text{imms}, \text{immr}, \text{false});
\end{align*}
\]

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.334   UBFX

Unsigned Bitfield Extract copies a bitfield of $<\text{width}>$ bits starting from bit position $<\text{lsb}>$ in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to zero.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf == 0 \&\& N == 0$.

UBFX $<Wd>$, $<Wn>$, $#<\text{lsb}>$, $#<\text{width}>$

is equivalent to

UBFM $<Wd>$, $<Wn>$, $#<\text{lsb}>$, $#(<\text{lsb}>+<\text{width}>-1)$

and is the preferred disassembly when $\text{BFXPreferred}(sf, opc, imms, immr)$.

64-bit variant

Applies when $sf == 1 \&\& N == 1$.

UBFX $<Xd>$, $<Xn>$, $#<\text{lsb}>$, $#<\text{width}>$

is equivalent to

UBFM $<Xd>$, $<Xn>$, $#<\text{lsb}>$, $#(<\text{lsb}>+<\text{width}>-1)$

and is the preferred disassembly when $\text{BFXPreferred}(sf, opc, imms, immr)$.

Assembler symbols

$<Wd>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Wn>$ Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

$<Xd>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Xn>$ Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

$<\text{lsb}>$ For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.

For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.

$<\text{width}>$ For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-$<\text{lsb}>$.

For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-$<\text{lsb}>$.

Operation

The description of UBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.335  UDF

Permanently Undefined generates an Undefined Instruction exception (ESR_ELx.EC = 0b000000). The encodings for UDF used in this section are defined as permanently UNDEFINED in the Armv8-A architecture.

![Instruction Encoding](attachment:image.png)

**Encoding**

UDF #<imm>

**Decode for this encoding**

// The imm16 field is ignored by hardware.
UNDEFINED;

**Assembler symbols**

<imm> is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field. The PE ignores the value of this constant.

**Operation**

// No operation.
C6.2.336   UDIV

Unsigned Divide divides an unsigned integer register value by another unsigned integer register value, and writes
the result to the destination register. The condition flags are not affected.

32-bit variant
Applies when sf == 0.
UDIV <Wd>, <Wn>, <Wm>

64-bit variant
Applies when sf == 1.
UDIV <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Assembler symbols
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
integer result;
if IsZero(operand2) then
  result = 0;
else
  result = RoundTowardsZero(Real(Int(operand1, TRUE)) / Real(Int(operand2, TRUE)));
X[d] = result<datasize-1:0>;
C6.2.337  UMADDL

Unsigned Multiply-Add Long multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMULL. See Alias conditions for details of when each alias is preferred.

Encoding

UMADDL <Xd>, <Wn>, <Wm>, <Xa>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>UMULL</td>
<td>Ra == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

bits(32) operand1 = X[n];
bits(32) operand2 = X[m];
bits(64) operand3 = X[a];

integer result;
result = Int(operand3, TRUE) + (Int(operand1, TRUE) * Int(operand2, TRUE));
X[d] = result<63:0>;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.338  UMNEGL

Unsigned Multiply-Negate Long multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This instruction is an alias of the UMSUBL instruction. This means that:

- The encodings in this description are named to match the encodings of UMSUBL.
- The description of UMSUBL gives the operational pseudocode for this instruction.

Encoding

<table>
<thead>

  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.344   WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a
wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any
PE in the multiprocessor system. For more information, see Wait for Event mechanism and Send event on
page D1-2391.

As described in Wait for Event mechanism and Send event on page D1-2391, the execution of a WFE instruction that
would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-2371.
- Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions on page D1-2380.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-2387.

```

Chapter C7
A64 Advanced SIMD and Floating-point Instruction Descriptions

This chapter describes the A64 Advanced SIMD and floating-point instructions.

It contains the following sections:

•   About the A64 SIMD and floating-point instructions on page C7-1396.
•   Alphabetical list of A64 Advanced SIMD and floating-point instructions on page C7-1398.
C7.1 About the A64 SIMD and floating-point instructions

Alphabetical list of A64 Advanced SIMD and floating-point instructions on page C7-1398 gives full descriptions of the A64 instructions that are in the following instruction groups:

• Loads and store instructions associated with the SIMD and floating-point registers.
• Data processing instructions with SIMD and floating-point registers.

A64 instruction set encoding on page C4-266 in the A64 Instruction Encodings chapter provides an overview of the instruction encodings as part of an instruction class within a functional group.

The rest of this section is a general description of the SIMD and floating-point instructions. It contains the following subsections:

• Register size.
• Data types.
• Condition flags and related instructions on page C7-1397.

C7.1.1 Register size

A64 provides a comprehensive set of packed Single Instruction Multiple Data (SIMD) and scalar operations using data held in the 32 entry 128-bit wide SIMD and floating-point register file.

Each SIMD and floating-point register can be used to hold:

• A single scalar value of the floating-point or integer type.
• A 64-bit wide vector containing one or more elements.
• A 128-bit wide vector containing two or more elements.

Where the entire 128-bit wide register is not fully utilized, the vector or scalar quantity is held in the least significant bits of the register, with the most significant bits being cleared to zero on a write, see Vector formats on page A1-41.

The following instructions can insert data into individual elements within a SIMD and floating-pointer register without clearing the remaining bits to zero:

• Insert vector element from another vector element or general-purpose register, INS.
• Load structure into a single lane, for example LD3.
• All second-part narrowing operations, for example SHR2.

C7.1.2 Data types

The A64 instruction set provides support for arithmetic, conversion, and bitwise operations on:

• Half-precision, single-precision, and double-precision floating-points.
• Signed and unsigned integers.
• Polynomials over \{0, 1\}.
• When FEAT_FCMA is implemented, complex numbers.

For all AArch64 floating-point operations, including SIMD operations, the rounding mode and exception trap handling are controlled by the FPCR.

Note

• AArch32 Advanced SIMD operations always use Arm standard floating-point arithmetic, regardless of the rounding mode specified by the AArch64 FPCR or the AArch32 FPSCR.

• In AArch64 state, floating-point multiply-add operations are always performed as fused operations, but AArch32 state provides both fused and chained multiply-add instructions.
In addition to operations that consume and produce values of the same width and type, the A64 instruction set supports SIMD and scalar operations that produce a wider or narrower vector result:

- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the A64 instruction set provides a second-part operation, for example SHRN2, that can pack the result of a second operation into the upper part of the same destination register.

- Where a SIMD operation widens a 64-bit vector to a 128-bit vector, the A64 instruction set provides a second-part operation, for example SMAL2, that can extract the source from the upper 64 bits of the source registers.

All SIMD operations that could produce side-effects that are not limited to the destination SIMD and floating-point register, for example a potential update of FPSR.Q or FPSR.IDC, have a dedicated scalar variant to support the use of SIMD with loops requiring specialised head or tail handling, or both.

### C7.1.3 Condition flags and related instructions

The A64 instruction set provides support for flag setting and conditional operations on the SIMD and floating-point register file:

- Floating-point FCSEL and FCMP instructions are equivalent to the integer CSEL and CMP instructions.

- Floating-point FOE, FOEO, FCMP, and FCMP instructions set the PSTATE.[N, Z, C, V] flags based on the result of the floating-point comparison.

- Floating-point FJCVTZS instruction sets the PSTATE.Z flag if the result of the conversion, when converted back to a double-precision floating-point number, gives precisely the same value as the original. Other PSTATE flags are cleared by this instruction.

- Floating-point and integer instructions provide a means of producing either a scalar or a vector mask based on a comparison in a SIMD and floating-point register, for example FOEO.

---

Note

FOE and FOEO differ from the A32/T32 VOE and VOEO instructions, which use the dedicated FPSCR.NZCV field for the result. A64 instructions store the result of an FOE or FOEO operation in the PSTATE.[N, Z, C, V] field.

If FEAT_FlagM2 is implemented, base instructions XAFLAG and AXFLAG convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format. See Table C6-1 on page C6-770.
C7.2 Alphabetical list of A64 Advanced SIMD and floating-point instructions

This section lists every section in the Advanced SIMD and floating-point categories of the A64 instruction set. For details of the format used, see Structure of the A64 assembler language on page C1-181.
C7.2.1   ABS

Absolute value (vector). This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 |  5  4 |  0  ]

ABS <Vd>.<T>, <Vn>.<T>

Decode for this encoding

- integer d = UInt(Rd);
- integer n = UInt(Rn);
- if size:Q == '110' then UNDEFINED;
- integer esize = 8 << UInt(size);
- integer datasize = if Q == '1' then 128 else 64;
- integer elements = datasize DIV esize;
- boolean neg = (U == '1');

Assembler symbols

- <V> Is a width specifier, encoded in the "size" field. It can have the following values:
  - D when size = 11
  - The following encodings are reserved:
    - size = 0x.
    - size = 10.
<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;

for e = 0 to elements-1
   element = SInt(Elem[operand, e, esize]);
   if neg then
      element = -element;
   else
      element = Abs(element);
   Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.2 ADD (vector)

Add (vector). This instruction adds corresponding elements in the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

\(<V>\)

Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.
<d> Is the number of the SIMD&FP destination register, in the "Rd" field.
<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
</d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size-Q" field. It can have the following values:
- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1
  The encoding size = 11, Q = 0 is reserved.

</n> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

</m> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
for e = 0 to elements-1
  element1 = Elem[operand1, e, esize];
  element2 = Elem[operand2, e, esize];
  if sub_op then
    Elem[result, e, esize] = element1 - element2;
  else
    Elem[result, e, esize] = element1 + element2;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.3  ADDHN, ADDHN2

Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are truncated. For rounded results, see RADDHN, RADDHN2.

The ADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the ADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

ADDHN(2) <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

Decode for this encoding

\[
\begin{array}{c|c|c|c|c|c|c|c} 
| & | & | & | & | Rm & \ \ \ \ \ \ \ \ \ \ | \ \ \ \ \ \ \ \ \ \ | Rd \ | \ \ \ \ \ \ \ \ \ | \\
| Q | & 0 & 0 & 1 & 1 & 0 & size | 1 | 10 & 1 & 9 | 5 & 4 | 0 | \\
\end{array}
\]

Integer encoding: [31 30 29 28] [27 26 25 24] [23 22 21 20] [16 15 14 13] [12 11 10 9] [5 4] 0

Uo 1

Assembler symbols

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
   [absent]  when Q = 0
   [present]  when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
   8B  when size = 00, Q = 0
   16B when size = 00, Q = 1
   4H  when size = 01, Q = 0
   8H  when size = 01, Q = 1
   2S  when size = 10, Q = 0
   4S  when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
- 4S when size = 01
- 2D when size = 10
The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bias(2*datasize) operand1 = V[n];
bias(2*datasize) operand2 = V[m];
bias(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bias(2*esize) element1;
bias(2*esize) element2;
bias(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.4 ADDP (scalar)

Add Pair of elements (scalar). This instruction adds two vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

ADDP <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size != '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = esize * 2;

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
0 when size = 11
The following encodings are reserved:
• size = 0x.
• size = 10.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is the source arrangement specifier, encoded in the "size" field. It can have the following values:
2D when size = 11
The following encodings are reserved:
• size = 0x.
• size = 10.

Operation

CheckFPAdvSIMDEnabled64();
bias(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_ADD, operand, esize);
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.5 ADDP (vector)

Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

ADDP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  8B when size = 00, Q = 0
  16B when size = 00, Q = 1
  4H when size = 01, Q = 0
  8H when size = 01, Q = 1
  2S when size = 10, Q = 0
  4S when size = 10, Q = 1
  2D when size = 11, Q = 1
The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdjSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
bits(esize) element1;
bits(esize) element2;
for e = 0 to elements-1
    element1 = Elem[concat, 2*e, esize];
    element2 = Elem[concat, (2*e)+1, esize];
    Elem[result, e, esize] = element1 + element2;

V[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.6 ADDV

Add across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

ADDV <V><d>, <Vn>.<T>

### Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
if size:Q == '100' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
```

### Assembler symbols

- `<V>` Is the destination width specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - The encoding size = 11 is reserved.

- `<d>` Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 4S when size = 10, Q = 1
  - The following encodings are reserved:
    - size = 10, Q = 0.
    - size = 11, Q = x.
```

### Operation

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_ADD, operand, esize);
```
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.7 AESD

AES single round decryption.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9  |  5 4 |  0  |
0 1 0 0 1 1 1 0 | 0 0 1 0 1 0 0 0 | 0 1 0 1 1 0 | Rn  | Rd  |
```

**Advanced SIMD variant**

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.13 BFCVT

Floating-point convert from single-precision to BFloat16 format (scalar) converts the single-precision floating-point value in the 32-bit SIMD&FP source register to BFloat16 format and writes the result in the 16-bit SIMD&FP destination register.

Unlike the BFloat16 multiplication instructions, this instruction honors all the control bits in the FPCR that apply to single-precision arithmetic, including the rounding mode. This instruction can generate a floating-point exception that causes a cumulative exception bit in the FPSR to be set, or a synchronous exception to be taken, depending on the enable bits in the FPCR. ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

**Single-precision to BFloat16 variant**

BFCVT <Hd>, <Sn>

**Decode for this encoding**

if !HaveBF16Ext() then UNDEFINED;
integer n = UInt(Rn);
integer d = UInt(Rd);

**Assembler symbols**

<Hd>  Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sn>  Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(32) operand = V[n];
bits(16) result;
result = FPConvertBF(operand, FPCR);
V[d] = result;
C7.2.14  BFCVTN, BFCVTN2

Floating-point convert from single-precision to BFloat16 format (vector) reads each single-precision element in the SIMD&FP source vector, converts each value to BFloat16 format, and writes the results in the lower or upper half of the SIMD&FP destination vector. The result elements are half the width of the source elements.

The BFCVTN instruction writes the half-width results to the lower half of the destination vector and clears the upper half to zero, while the BFCVTN2 instruction writes the results to the upper half of the destination vector without affecting the other bits in the register.

Unlike the BFloat16 multiplication instructions, this instruction honors all of the control bits in the FPCR that apply to single-precision arithmetic, including the rounding mode. It can also generate a floating-point exception that causes cumulative exception bits in the FPSR to be set, or a synchronous exception to be taken, depending on the enable bits in the FPCR.

bits(64) result;
for e = 0 to elements-1
\texttt{Elem[result, e, 16] = FPConvertBF(Elem[operand, e, 32], FPCR);} \\
\texttt{Vpart[d, part] = result;}

C7.2.15 BFDOT (by element)

BF16 floating-point dot product (vector, by element). This instruction delimits the source vectors into pairs of 16-bit BF16 elements. Each pair of elements in the first source vector is multiplied by the specified pair of elements in the second source vector. The resulting single-precision products are then summed and added destructively to the single-precision element of the destination vector that aligns with the pair of BF16 values in the first source vector. The instruction ignores the FPCR and does not update the FPSR exception status.

The BF16 pair within the second source vector is specified using an immediate index. The index range is from 0 to 3 inclusive. ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

    bits(32) addend = Elem[operand3, e, 32];
    Elem[result, e, 32] = FPMulAdd(addend, element1, element2, FPCR);
V[d] = result;
C7.2.19  BFMMLA

BFLOAT16 floating-point matrix multiply-accumulate into 2x2 matrix. This instruction multiplies the 2x4 matrix of BFLOAT16 values held in the first 128-bit source vector by the 4x2 BFLOAT16 matrix in the second 128-bit source vector. The resulting 2x2 single-precision matrix product is then added destructively to the 2x2 single-precision matrix in the 128-bit destination vector. This is equivalent to performing a 4-way dot product per destination element. The instruction ignores the FPCR and does not update the FPSR exception status.

--- Note ---

Arm expects that the BFMMLA instruction will deliver a peak BFLOAT16 multiply throughput that is at least as high as can be achieved using two BFDOT instructions, with a goal that it should have significantly higher throughput.

Three registers of the same type variant

BIT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
88 when Q = 0
168 when Q = 1
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];
operand1 = V[d];
operand3 = V[m];
V[d] = operand1 EOR ((operand1 EOR operand4) AND operand3);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C7.2.24   **BSL**

Bitwise Select. This instruction sets each bit in the destination SIMD&FP register to the corresponding bit from the first source SIMD&FP register when the original destination bit was 1, otherwise from the second source SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

BSL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

**Decode for this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 8B when Q = 0
- 16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];
operand1 = V[m];
operand3 = V[d];
V[d] = operand1 EOR ((operand1 EOR operand4) AND operand3);
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C7.2.25   CLS (vector)

Count Leading Sign bits (vector). This instruction counts the number of consecutive bits following the most significant bit that are the same as the most significant bit in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The count does not include the most significant bit itself.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Vector variant**

CLS <Vd>.<T>, <Vn>.<T>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

CountOp countop = if U == '1' then CountOp_CLZ else CountOp_CLS;

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B  when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H  when size = 01, Q = 0
- 8H  when size = 01, Q = 1
- 2S  when size = 10, Q = 0
- 4S  when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

integer count;
for e = 0 to elements-1
  if countop == CountOp_CLS then
    count = CountLeadingSignBits(Elem[operand, e, esize]);
  else

count = CountLeadingZeroBits(Elem[operand, e, esize]);
Elem[result, e, esize] = count<esize-1:0>;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.26   CLZ (vector)

Count Leading Zero bits (vector). This instruction counts the number of consecutive zeros, starting from the most significant bit, in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.31 CMGT (register)

Compare signed Greater than (vector). This instruction compares each vector element in the first source SIMD&FP register with the corresponding vector element in the second source SIMD&FP register and if the first signed integer value is greater than the second signed integer value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11
The following encodings are reserved:

- \( \text{size} = 0x \).
- \( \text{size} = 10 \).

\( <d> \) Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

\( <n> \) Is the number of the SIMD&FP source register, encoded in the "Rn" field.

\( <V_d> \) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\( <T> \) Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- \( 8B \) when \( \text{size} = 00 \), \( Q = 0 \)
- \( 16B \) when \( \text{size} = 00 \), \( Q = 1 \)
- \( 4H \) when \( \text{size} = 01 \), \( Q = 0 \)
- \( 8H \) when \( \text{size} = 01 \), \( Q = 1 \)
- \( 2S \) when \( \text{size} = 10 \), \( Q = 0 \)
- \( 4S \) when \( \text{size} = 10 \), \( Q = 1 \)
- \( 2D \) when \( \text{size} = 11 \), \( Q = 1 \)

The encoding \( \text{size} = 11 \), \( Q = 0 \) is reserved.

\( <V_n> \) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.37  CMTST

Compare bitwise Test bits nonzero (vector). This instruction reads each vector element in the first source SIMD&FP register, performs an AND with the corresponding vector element in the second source SIMD&FP register, and if the result is not zero, sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\hspace{1em} \text{V}[d] &= \text{result};
\end{align*}
\]
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.39  DUP (element)

Duplicate vector element to vector or scalar. This instruction duplicates the vector element at the specified element index in the source SIMD&FP register into a scalar or each element in a vector, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (scalar). The alias is always the preferred disassembly.

Scalar

```
[31 30 29 28|27 26 25 24|23 22 21 20]  16|15 14 13 12|11 10  9 |  5  4 |  0 |
  0 1 0 1 1 1 1 0 0 0 0  |imm5  0 0 0 0 0 1| Rd  Rd
```

Scalar variant

DUP <V><d>, <Vn>.<T>[<index>]

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

integer esize = 8 << size;
integer datasize = esize;
integer elements = 1;

Vector

```
[31 30 29 28|27 26 25 24|23 22 21 20]  16|15 14 13 12|11 10  9 |  5  4 |  0 |
  0 0 0 0 0 0 0 0 1 0 1 1 |imm5  0 0 0 0 0 1| Rd  Rd
```

Vector variant

DUP <Vd>.<T>, <Vn>.<Ts>[<index>]

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

if size == 3 && Q == '0' then UNDEFINED;
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
Assembler symbols

<T>
For the scalar variant: is the element width specifier, encoded in the "imm5" field. It can have the following values:

- B when imm5 = xxxx1
- H when imm5 = xx10
- S when imm5 = xx100
- D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

For the vector variant: is an arrangement specifier, encoded in the "imm5:Q" field. It can have the following values:

- 8B when imm5 = xxxx1, Q = 0
- 16B when imm5 = xxxx1, Q = 1
- 4H when imm5 = xx10, Q = 0
- 8H when imm5 = xx10, Q = 1
- 2S when imm5 = xx100, Q = 0
- 4S when imm5 = xx100, Q = 1
- 2D when imm5 = x1000, Q = 1

The following encodings are reserved:
- imm5 = x0000, Q = x.
- imm5 = x1000, Q = 0.

<Ts>
Is an element size specifier, encoded in the "imm5" field. It can have the following values:

- B when imm5 = xxxx1
- H when imm5 = xx10
- S when imm5 = xx100
- D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<V>
Is the destination width specifier, encoded in the "imm5" field. It can have the following values:

- B when imm5 = xxxx1
- H when imm5 = xx10
- S when imm5 = xx100
- D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<Vn>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index>
Is the element index encoded in the "imm5" field. It can have the following values:

- imm5<4:1> when imm5 = xxxx1
- imm5<4:2> when imm5 = xx10
- imm5<4:3> when imm5 = xx100
- imm5<4> when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<d>
Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vd>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
baby(idx, size) operand = V[n];
baby(data size) result;
baby(element size) element;

element = Elem[operand, index, esize];
for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.40   DUP (general)

Duplicate general-purpose register to vector. This instruction duplicates the contents of the source general-purpose register into a scalar or each element in a vector, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

DUP <Vd>.<T>, <R><n>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;
// imm5<4:size+1> is IGNORED
if size == 3 && Q == '0' then UNDEFINED;
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "imm5:Q" field. It can have the following values:
8B when imm5 = xxxx1, Q = 0
16B when imm5 = xxxx1, Q = 1
4H when imm5 = xxx10, Q = 0
8H when imm5 = xxx10, Q = 1
2S when imm5 = xx100, Q = 0
4S when imm5 = xx100, Q = 1
2D when imm5 = x1000, Q = 1
The following encodings are reserved:
• imm5 = x0000, Q = x.
• imm5 = x1000, Q = 0.

<R> Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:
W when imm5 = xxxx1
W when imm5 = xx10
W when imm5 = xx100
X when imm5 = x1000
The encoding imm5 = x0000 is reserved. Unspecified bits in "imm5" are ignored but should be set to zero by an assembler.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.41   EOR (vector)

Bitwise Exclusive OR (vector). This instruction performs a bitwise Exclusive OR operation between the two source SIMD&FP registers, and places the result in the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

EOR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

\[
\text{integer } d = \text{UInt}(Rd); \\
\text{integer } n = \text{UInt}(Rn); \\
\text{integer } m = \text{UInt}(Rm); \\
\text{integer } \text{datasize} = \text{if } Q == '1' \text{ then 128 else 64};
\]

Assembler symbols

\(<Vd>\) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
\(<T>\) Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
- 8B when \(Q = 0\)
- 16B when \(Q = 1\)
\(<Vn>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
\(<Vm>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

\[
\text{CheckFPAdvSIMDEnabled64();} \\
\text{bits(dataSize)} \text{ operand1;} \\
\text{bits(dataSize)} \text{ operand2;} \\
\text{bits(dataSize)} \text{ operand3;} \\
\text{bits(dataSize)} \text{ operand4} = V[n]; \\
\text{operand1} = V[m]; \\
\text{operand2} = \text{Zeros();} \\
\text{operand3} = \text{Ones();} \\
V[d] = \text{operand1 EOR ((operand2 EOR operand4) AND operand3);}
\]

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
The values of the NZCV flags.
C7.2.42 EOR3

Three-way Exclusive OR performs a three-way exclusive OR of the values in the three source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when FEAT_SHA3 is implemented.

ARMv8.2

```
[31 30 29 28|27 26 25 24|23 22 21 20]|  16|15 14 |  10 9 |  5 4 |  0 |
 1 1 0 0 1 1 1 0 | 0 0 | Rm  0 | Ra | Rn | Rd
```

**Advanced SIMD variant**

EOR3 <Vd>.16B, <Vn>.16B, <Vm>.16B, <Va>.16B

**Decode for this encoding**

```
if !HaveSHA3Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
```

**Assembler symbols**

- `<Vd>`  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Vn>`  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>`  Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<Va>`  Is the name of the third SIMD&FP source register, encoded in the "Ra" field.

**Operation**

```
AArch64.CheckFPAdvSIMDEnabled();

bits(128) Vm = V[m];
bits(128) Vn = V[n];
bits(128) Va = V[a];
V[d] = Vn EOR Vm EOR Va;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.43 EXT

Extract vector from pair of vectors. This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

The following figure shows the operation of EXT doubleword operation for Q = 0 and imm4<2:0> = 3.

![Diagram showing the operation of EXT](image)

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
[31 30 29 28][27 26 25 24][23 22 21 20] 16|15 14 |11 10 9 | 5 4 | 0 |
 0 Q 1 0 1 1 0 0 0 0 Rm 0 imm4 0 Rn Rd
```

---

**Advanced SIMD variant**

EXT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>, #<index>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if Q == '0' & imm4<3> == '1' then UNDEFINED;

integer datasize = if Q == '1' then 128 else 64;
integer position = UInt(imm4) << 3;

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 8B when Q = 0
  - 16B when Q = 1
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<index>` Is the lowest numbered byte element to be extracted, encoded in the "Q:imm4" field. It can have the following values:
  - imm4<2:0> when Q = 0, imm4<3> = 0
  - imm4 when Q = 1, imm4<3> = x
The encoding Q = 0, imm4<3> = 1 is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
b_bits(datasize) hi = V[m];
b_bits(datasize) lo = V[n];
b_bits(datasize*2) concat = hi:lo;
V[d] = concat<position:datasize-1:position>;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.44   FABD

Floating-point Absolute Difference (vector). This instruction subtracts the floating-point values in the elements of the second source SIMD&FP register, from the corresponding floating-point values in the elements of the first source SIMD&FP register, places the absolute value of each result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
S when sz = 0
D when sz = 1
<db> Is the number of the SIMD&FP destination register, in the "Rd" field.
<bn> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0
8H when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0
4S when sz = 0, Q = 1
2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) diff;

for e = 0 to elements-1

    diff = FPSub(element1, element2, FPCR);
    Elem[result, e, esize] = if abs then FPAbs(diff) else diff;

V[d] = result;
C7.2.45  FABS (vector)

Floating-point Absolute value (vector). This instruction calculates the absolute value of each vector element in the source SIMD&FP register, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Assembler symbols**

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T>  For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 4H when Q = 0
For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- **2S** when \(\text{sz} = 0, Q = 0\)
- **4S** when \(\text{sz} = 0, Q = 1\)
- **2D** when \(\text{sz} = 1, Q = 1\)

The encoding \(\text{sz} = 1, Q = 0\) is reserved.

\(<Vn>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    if neg then
        element = FPNeg(element);
    else
        element = FPAbs(element);
    Elem[result, e, esize] = element;
V[d] = result;
```
C7.2.46  FABS (scalar)

Floating-point Absolute value (scalar). This instruction calculates the absolute value in the SIMD&FP source register and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant
Applies when ftype == 11.
FABS <Hd>, <Hn>

Single-precision variant
Applies when ftype == 00.
FABS <Sd>, <Sn>

Double-precision variant
Applies when ftype == 01.
FABS <Dd>, <Dn>

Decode for all variants of this encoding

```plaintext
d = UInt(Rd);

datasize;
case ftype of
  when '00' datasize = 32;
  when '01' datasize = 64;
  when '10' UNDEFINED;
  when '11'
    if HaveFP16Ext() then
      datasize = 16;
    else
      UNDEFINED;
```

Assembler symbols

- <Dd>  Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Dn>  Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
- <Hd>  Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Hn>  Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
- <Sd>  Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Sn>  Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
**Operation**

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) result;
bits(datasize) operand = V[n];

result = FPAbs(operand);
V[d] = result;
```
C7.2.47 FACGE

Floating-point Absolute Compare Greater than or Equal (vector). This instruction compares the absolute value of each floating-point value in the first source SIMD&FP register with the absolute value of the corresponding floating-point value in the second source SIMD&FP register and if the first value is greater than or equal to the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  V[d] = result;
C7.2.49  FADD (vector)

Floating-point Add (vector). This instruction adds corresponding vector elements in the two source SIMD&FP registers, writes the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- \( \text{bits(datasize)} \) \( \text{operand} = V[n] \);
- \( V[d] = \text{Reduce(ReduceOp_FADD, operand, esize);} \)
C7.2.52 FADDP (vector)

Floating-point Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.53 FCADD

Floating-point Complex Add.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

        when '1'
            element1 = Elem[operand2, e*2+1, esize];
            element3 = FPNeg(Elem[operand2, e*2, esize]);
        Elem[result, e*2, esize] = FPAdd(Elem[operand1, e*2, esize], element1, FPCR);
        Elem[result, e*2+1, esize] = FPAdd(Elem[operand1, e*2+1, esize], element3, FPCR);
    V[d] = result;
```
C7.2.54  FCCMP

Floating-point Conditional quiet Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE, {N, Z, C, V} flags. If the condition does not pass then the PSTATE, {N, Z, C, V} flags are set to the flag bit specifier.

It raises an Invalid Operation exception only if either operand is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant

Applies when ftype == 11.

FCCMP <Hn>, <Hm>, #<nzcv>, <cond>

Single-precision variant

Applies when ftype == 00.

FCCMP <Sn>, <Sm>, #<nzcv>, <cond>

Double-precision variant

Applies when ftype == 01.

FCCMP <Dn>, <Dm>, #<nzcv>, <cond>

Decode for all variants of this encoding

integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case ftype of
when '00' datasize = 32;
when '01' datasize = 64;
when '10' UNDEFINED;
when '11'
    if HaveFP16Ext() then
datasize = 16;
else
    UNDEFINED;

bits(4) flags = nzcv;

Assembler symbols

<Dn>  Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Sm>  Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<Hn>  Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<hm>  Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sm>  Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Sm>  Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<nzcv>  Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit
         NZCV condition flags, encoded in the "nzcv" field.

<cond>  Is one of the standard conditions, encoded in the "cond" field in the standard way.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either
or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 ==
Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1,
and V=1.

Operation

    CheckFPAdvSIMDEnabled64();

    bits(datasize) operand1 = V[n];
    bits(datasize) operand2;
    operand2 = V[m];

    if ConditionHolds(cond) then
        flags = FPCompare(operand1, operand2, FALSE, FPCR);
        PSTATE.<N,Z,C,V> = flags;
C7.2.55   FCCMPE

Floating-point Conditional signaling Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.{N, Z, C, V} flags. If the condition does not pass then the PSTATE.{N, Z, C, V} flags are set to the flag bit specifier.

If either operand is any type of NaN, or if either operand is a signaling NaN, the instruction raises an Invalid Operation exception.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

FCOMPE raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

Operation

CheckFPADVSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = V[m];

if ConditionHolds(cond) then
    flags = FPCompare(operand1, operand2, TRUE, FPCR);
PSTATE.<N,Z,C,V> = flags;
C7.2.56   FCMEQ (register)

Floating-point Compare Equal (vector). This instruction compares each floating-point value from the first source SIMD&FP register, with the corresponding floating-point value from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

        when CompareOp_GT test_passed = FPCompareGT(element1, element2, FPCR);
    Elem[result, e, esize] = if test_passed then Ones() else Zeros();

V[d] = result;
C7.2.57 FCMEQ (zero)

Floating-point Compare Equal to zero (vector). This instruction reads each floating-point value in the source
SIMD&FP register and if the value is equal to zero sets every bit of the corresponding vector element in the
destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the
destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results
in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
S  when sz = 0
D  when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
4H  when Q = 0
8H  when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
2S  when sz = 0, Q = 0
4S  when sz = 0, Q = 1
2D  when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bv<datasize> operand = V[n];
bv<datasize> result;

    Elem[result, e, esize] = if test_passed then Ones() else Zeros();
  V[d] = result;
C7.2.60   FCMGT (register)

Floating-point Compare Greater than (vector). This instruction reads each floating-point value in the first source SIMD&FP register and if the value is greater than the corresponding floating-point value in the second source SIMD&FP register sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;
C7.2.62 FCMLA (by element)

Floating-point Complex Multiply Accumulate (by element).

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on complex numbers from the first source register and the destination register with the specified complex number from the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.63 FCMLA

Floating-point Complex Multiply Accumulate.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers and the destination register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.64 FCMLE (zero)

Floating-point Compare Less than or Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Assembler symbols

- `<Dn>`
  - For the double-precision variant: is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
  - For the double-precision, zero variant: is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

- `<Dm>`
  - Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

- `<Hn>`
  - For the half-precision variant: is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
  - For the half-precision, zero variant: is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

- `<Hm>`
  - Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

- `<Sn>`
  - For the single-precision variant: is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
  - For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

- `<Sm>`
  - Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

### NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

### Operation

```plaintext
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = if cmp_with_zero then FPZero('0') else V[m];

PSTATE.<N,Z,C,V> = FPCMPare(operand1, operand2, signal_all_nans, FPCR);
```
C7.2.67 FCMPE

Floating-point signaling Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE.\{N, Z, C, V\} flags.

If either operand is any type of NaN, or if either operand is a signaling NaN, the instruction raises an Invalid Operation exception.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant

Applies when \texttt{ftype == 11 && opc == 10}.

\texttt{FCMPE <Hn>, <Hm>}

Half-precision, zero variant

Applies when \texttt{ftype == 11 && Rm == (00000) && opc == 11}.

\texttt{FCMPE <Hn>, #0.0}

Single-precision variant

Applies when \texttt{ftype == 00 && opc == 10}.

\texttt{FCMPE <Sn>, <Sm>}

Single-precision, zero variant

Applies when \texttt{ftype == 00 && Rm == (00000) && opc == 11}.

\texttt{FCMPE <Sn>, #0.0}

Double-precision variant

Applies when \texttt{ftype == 01 && opc == 10}.

\texttt{FCMPE <Dn>, <Dm>}

Double-precision, zero variant

Applies when \texttt{ftype == 01 && Rm == (00000) && opc == 11}.

\texttt{FCMPE <Dn>, #0.0}

Decode for all variants of this encoding

Assembler symbols

<Dn> For the double-precision variant: is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
For the double-precision, zero variant: is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Hn> For the half-precision variant: is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
For the half-precision, zero variant: is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sn> For the single-precision variant: is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPCR flags being set to N=0, Z=0, C=1, and V=1.

FCMP raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = if cmp_with_zero then FPZero('0') else V[m];
PSTATE.<N,Z,C,V> = FPCMP(operand1, operand2, signal_all_nans, FPCR);
C7.2.68 FCSEL

Floating-point Conditional Select (scalar). This instruction allows the SIMD&FP destination register to take the value from either one or the other of two SIMD&FP source registers. If the condition passes, the first SIMD&FP source register value is taken, otherwise the second SIMD&FP source register value is taken.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 r registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
result = if ConditionHolds(cond) then V[n] else V[m];
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.69 FCVT

Floating-point Convert precision (scalar). This instruction converts the floating-point value in the SIMD&FP source register to the precision for the destination register data type using the rounding mode that is determined by the FPCR and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
S when sz = 0
D when sz = 1
<\d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
Is the number of the SIMD&FP source register, encoded in the "Rn" field.

\( V_d \)

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\( T \)

For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- \( 4H \) when \( Q = 0 \)
- \( 8H \) when \( Q = 1 \)

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- \( 2S \) when \( sz = 0, Q = 0 \)
- \( 4S \) when \( sz = 0, Q = 1 \)
- \( 2D \) when \( sz = 1, Q = 1 \)

The encoding \( sz = 1, Q = 0 \) is reserved.

\( V_n \)

Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);
V[d] = result;
```
C7.2.71 FCVTAS (scalar)

Floating-point Convert to Signed integer, rounding to nearest with ties to Away (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round to Nearest with Ties to Away rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:

S when sz = 0

D when sz = 1

<db> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0
8H when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0
4S when sz = 0, Q = 1
2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
   element = Elem[operand, e, esize];
   Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);

V[d] = result;
```
C7.2.73 FCVTAU (scalar)

Floating-point Convert to Unsigned integer, rounding to nearest with ties to Away (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round to Nearest with Ties to Away rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision to 32-bit variant
Applies when sf == 0 && ftype == 11.
FCVTAU <Wd>, <Hn>

Half-precision to 64-bit variant
Applies when sf == 1 && ftype == 11.
FCVTAU <Xd>, <Hn>

Single-precision to 32-bit variant
Applies when sf == 0 && ftype == 00.
FCVTAU <Wd>, <Sn>

Single-precision to 64-bit variant
Applies when sf == 1 && ftype == 00.
FCVTAU <Xd>, <Sn>

Double-precision to 32-bit variant
Applies when sf == 0 && ftype == 01.
FCVTAU <Wd>, <Dn>

Double-precision to 64-bit variant
Applies when sf == 1 && ftype == 01.
FCVTAU <Xd>, <Dn>

Decode for all variants of this encoding

```c
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;

integer case ftype of
when '00'
  fltsize = 32;
when '01'
  fltsize = 64;
when '10'
  UNDEFINED;
when '11'
  if HaveFP16Ext() then
    fltsize = 16;
  else
    UNDEFINED;

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(fltsize) fltval;
bits(intsize) intval;

fltval = V[n];
intval = FPToFixed(fltval, 0, TRUE, FPCR, FPRounding_TIEAWAY);
X[d] = intval;
C7.2.74  FCVTL, FCVTL2

Floating-point Convert to higher precision Long (vector). This instruction reads each element in a vector in the SIMD&FP source register, converts each value to double the precision of the source element using the rounding mode that is determined by the FPCR, and writes each result to the equivalent element of the vector in the SIMD&FP destination register.

Where the operation lengthens a 64-bit vector to a 128-bit vector, the FCVTL2 variant operates on the elements in the top 64 bits of the source register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector single-precision and double-precision variant

FCVTL[(2]<Vd>.<Ta>, <Vn>.<Tb>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16 << UInt(sz);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "sz" field. It can have the following values:

4S when sz = 0
2D when sz = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

4H when sz = 0, Q = 0
8H when sz = 0, Q = 1
2S when sz = 1, Q = 0
4S when sz = 1, Q = 1
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(2*datasize) result;

for e = 0 to elements-1
    Elem[result, e, 2*esize] = FPConvert(Elem[operand, e, esize], FPCR);

V[d] = result;
C7.2.75 FCVTMS (vector)

Floating-point Convert to Signed integer, rounding toward Minus infinity (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Minus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

intval = FPToFixed(fltval, 0, TRUE, FPCR, rounding);
X[d] = intval;
C7.2.79  FCVTN, FCVTN2

Floating-point Convert to lower precision Narrow (vector). This instruction reads each vector element in the SIMD&FP source register, converts each result to half the precision of the source element, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The rounding mode is determined by the FPCR.

The FCVTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

**Vector single-precision and double-precision variant**

FCVTN(2) <Vd>.<Tb>, <Vn>.<Ta>

**Decode for this encoding**

```plaintext
type d = UInt(Rd);
type n = UInt(Rn);

integer esize = 16 << UInt(sz);
integer data_size = 64;
integer part = UInt(Q);
integer elements = data_size DIV esize;
```

**Assembler symbols**

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>  Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- 4H when sz = 0, Q = 0
- 8H when sz = 0, Q = 1
- 2S when sz = 1, Q = 0
- 4S when sz = 1, Q = 1

<Vn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>  Is an arrangement specifier, encoded in the "sz" field. It can have the following values:

- 4S when sz = 0
2D when sz = 1

Operation

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = FPConvert(Elem[operand, e, 2*esize], FPCR);

Vpart[d, part] = result;
C7.2.80 FCVTNS (vector)

Floating-point Convert to Signed integer, rounding to nearest with ties to even (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

- D when sz = 1

<db> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
   4H when Q = 0
   8H when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
   2S when sz = 0, Q = 0
   4S when sz = 0, Q = 1
   2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
   element = Elem[operand, e, esize];
   Elem[result, e, esize] = FPtoFixed(element, 0, unsigned, FPCR, rounding);

V[d] = result;
C7.2.85   FCVTPS (scalar)

Floating-point Convert to Signed integer, rounding toward Plus infinity (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round towards Plus Infinity rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

X[d] = intval;
C7.2.88   FCVTXN, FCVTXN2

Floating-point Convert to lower precision Narrow, rounding to odd (vector). This instruction reads each vector element in the source SIMD&FP register, narrows each value to half the precision of the source element using the Round to Odd rounding mode, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

--- Note ---

This instruction uses the Round to Odd rounding mode which is not defined by the IEEE 754-2008 standard. This rounding mode ensures that if the result of the conversion is inexact the least significant bit of the mantissa is forced to 1. This rounding mode enables a floating-point value to be converted to a lower precision format via an intermediate precision format while avoiding double rounding errors. For example, a 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value by first using this instruction to produce a 32-bit value and then using another instruction with the wanted rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

The FCVTXN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTXN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer elements = datasize DIV esize;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

**Assembler symbols**

- **<Hd>** Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<Hn>** Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
- **<V>** Is a width specifier, encoded in the "sz" field. It can have the following values:
  - S when sz = 0
  - D when sz = 1
- **<d>** Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>Encoding</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>4H</td>
<td>Q = 0</td>
</tr>
<tr>
<td>8H</td>
<td>Q = 1</td>
</tr>
</tbody>
</table>

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>Encoding</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2S</td>
<td>sz = 0, Q = 0</td>
</tr>
<tr>
<td>4S</td>
<td>sz = 0, Q = 1</td>
</tr>
<tr>
<td>2D</td>
<td>sz = 1, Q = 1</td>
</tr>
</tbody>
</table>

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bite(datasize) operand = V[n];
bite(datasize) result;
bite(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);
V[d] = result;
```
C7.2.91 **FCVTZS (scalar, fixed-point)**

Floating-point Convert to Signed fixed-point, rounding toward Zero (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit fixed-point signed integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

### Half-precision to 32-bit variant

Assembler symbols

<V> is a width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 001x
S when immh = 01xx
D when immh = 1xxx

The encoding immh = 000x is reserved.

<d> is the number of the SIMD&FP destination register, in the "Rd" field.

<n> is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1
2D when immh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.

The following encodings are reserved:

- immh = 0001, Q = x.
- immh = 1xxx, Q = 0.

<Vn> is the name of the SIMD&FP source register, encoded in the "Rn" field.

<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:

(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx
(128-UInt(immh:immb)) when immh = 1xxx

The encoding immh = 000x is reserved.

For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:

(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx
(128-UInt(immh:immb)) when immh = 1xxx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.

The encoding immh = 0001 is reserved.

Operation for all encodings

<fbits> For the double-precision to 32-bit, half-precision to 32-bit and single-precision to 32-bit variant: is the number of bits after the binary point in the fixed-point destination, in the range 1 to 32, encoded as 64 minus "scale".
For the double-precision to 64-bit, half-precision to 64-bit and single-precision to 64-bit variant: is the number of bits after the binary point in the fixed-point destination, in the range 1 to 64, encoded as 64 minus "scale".

Operation

CheckFPAdvSIMDEnabled64();

bits(fltsize) fltval;
bite(intsize) intval;

fltval = V[n];
intval = FPToFixed(fltval, fracbits, TRUE, FPCR, FPRounding_ZERO);
X[d] = intval;
C7.2.96 FCVTZU (scalar, integer)

Floating-point Convert to Unsigned integer, rounding toward Zero (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.97   FDIV (vector)

Floating-point Divide (vector). This instruction divides the floating-point values in the elements in the first source SIMD&FP register, by the floating-point values in the corresponding elements in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

bits(datasize) operand2 = V[m];
result = FPDiv(operand1, operand2, FPCR);
V[d] = result;
```
C7.2.99  FJCVTZS

Floating-point Javascript Convert to Signed fixed-point, rounding toward Zero. This instruction converts the double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register. If the result is too large to be accommodated as a signed 32-bit integer, then the result is the integer modulo 2^{32}, as held in a 32-bit signed integer.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

bits(datasize) operand2 = V[m];
result = FPMax(operand1, operand2, FPCR);
V[d] = result;
```
C7.2.103  FMAXNM (vector)

Floating-point Maximum Number (vector). This instruction compares corresponding vector elements in the two
source SIMD&FP registers, writes the larger of the two floating-point values into a vector, and writes the vector to
the destination SIMD&FP register.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet
NaN, the result placed in the vector is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results
in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;
C7.2.104  FMAXNM (scalar)

Floating-point Maximum Number (scalar). This instruction compares the first and second source SIMD&FP register values, and writes the larger of the two floating-point values to the destination SIMD&FP register.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result that is placed in the vector is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant

Applies when ftype == 11.

FMAXNM <Hd>, <Hn>, <Hm>

Single-precision variant

Applies when ftype == 00.

FMAXNM <Sd>, <Sn>, <Sm>

Double-precision variant

Applies when ftype == 01.

FMAXNM <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```plaintext
type = Rm[5:4];
Rd = UInt(Rd);
Rn = UInt(Rn);
if HaveFP16Ext() then
  if type == '00' then
    datasize = 32;
  elseif type == '01' then
    datasize = 64;
  else
    datasize = 16;
else
  datasize = 16;
```

Assembler symbols

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Dn>` Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Dm>` Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_FMAXNUM, operand, esize);
```
C7.2.106 FMAXNMP (vector)

Floating-point Maximum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

8H when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
2S when sz = 0, Q = 0
4S when sz = 0, Q = 1
2D when sz = 1, Q = 1
The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
bits(esize) element1;
bits(esize) element2;
for e = 0 to elements-1
  if pair then
    element1 = Elem[concat, 2*e, esize];
    element2 = Elem[concat, (2*e)+1, esize];
  else
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
  if minimum then
    Elem[result, e, esize] = FPMin(element1, element2, FPCR);
  else
    Elem[result, e, esize] = FPMax(element1, element2, FPCR);
V[d] = result;
C7.2.110  FMAXV

Floating-point Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPMin(operand1, operand2, FPCR);
V[d] = result;
```
C7.2.113  FMINNM (vector)

Floating-point Minimum Number (vector). This instruction compares corresponding vector elements in the two source SIMD&FP registers, writes the smaller of the two floating-point values into a vector, and writes the vector to the destination SIMD&FP register.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result placed in the vector is the numerical value, otherwise the result is identical to FMIN (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_FMINNUM, operand, esize);
C7.2.116 FMINNMP (vector)

Floating-point Minimum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of floating-point values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMIN (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if minimum then
        Elem[result, e, esize] = FPMinNum(element1, element2, FPCR);
    else
        Elem[result, e, esize] = FPMaxNum(element1, element2, FPCR);
V[d] = result;
C7.2.117  FMINNMV

Floating-point Minimum Number across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result of the comparison is the numerical value, otherwise the result is identical to FMIN (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = Reduce(ReduceOp_FMIN, operand, esize);
C7.2.119  FMINP (vector)

Floating-point Minimum Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, writes the smaller of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.123 FMLAL, FMLAL2 (by element)

Floating-point fused Multiply-Add Long to accumulator (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an optional instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

FMLAL2 variant

FMLAL2 <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.H[<index>]
**Decode for this encoding**

```plaintext
if !HaveFP10MulNoRoundingToFP32Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt('0':Rm); // Vm can only be in bottom 16 registers.
if sz == '1' then UNDEFINED;
integer index = UInt(H:L:M);

integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean sub_op = (S == '1');
integer part = 1;
```

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Ta>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 2S when Q = 0
  - 4S when Q = 1
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Tb>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 2H when Q = 0
  - 4H when Q = 1
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<index>` Is the element index, encoded in the "H:L:M" fields.

**Operation for all encodings**

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize DIV 2) operand1 = Vpart[n, part];
bits(128) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
bits(esize DIV 2) element1;
bits(esize DIV 2) element2 = Elem[operand2, index, esize DIV 2];

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize DIV 2];
    if sub_op then element1 = FPNeg(element1);
    Elem[result, e, esize] = FPMulAddH(Elem[operand3, e, esize], element1, element2, FPCR);
V[d] = result;
```
C7.2.124 FMLAL, FMLAL2 (vector)

Floating-point fused Multiply-Add Long to accumulator (vector). This instruction multiplies corresponding half-precision floating-point values in the vectors in the two source SIMD&FP registers, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

```
C7.2.125 FMLS (by element)

Floating-point fused Multiply-Subtract from accumulator (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and subtracts the results from the vector elements of the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Hd>  Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn>  Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<V>  Is a width specifier, encoded in the "sz" field. It can have the following values:
S  when sz = 0
D  when sz = 1

<d>  Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n>  Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T>  For the vector, half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
4H  when Q = 0
8H  when Q = 1
For the vector, single-precision and double-precision variant: is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:
2S  when Q = 0, sz = 0
4S  when Q = 1, sz = 0
2D  when Q = 1, sz = 1
The encoding Q = 0, sz = 1 is reserved.

<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm>  For the half-precision variant: is the name of the second SIMD&FP source register, in the range V0 to V15, encoded in the "Rm" field.
For the single-precision and double-precision variant: is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.

<Ts>  Is an element size specifier, encoded in the "sz" field. It can have the following values:
S  when sz = 0
D  when sz = 1

<index>  For the half-precision variant: is the element index, in the range 0 to 7, encoded in the "H:L:M" fields.
For the single-precision and double-precision variant: is the element index, encoded in the "sz:L:H" field. It can have the following values:
H:L  when sz = 0, L = x
H  when sz = 1, L = 0
The encoding sz = 1, L = 1 is reserved.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxsizdsize) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ta> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
      2S when Q = 0
      4S when Q = 1
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Tb> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
      2H when Q = 0
      4H when Q = 1
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<index> Is the element index, encoded in the "H:L:M" fields.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize DIV 2) operand1 = Vpart[n, part];
bits(128) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
bits(esize DIV 2) element1;
bits(esize DIV 2) element2 = Elem[operand2, index, esize DIV 2];

for e = 0 to elements-1
   element1 = Elem[operand1, e, esize DIV 2];
   if sub_op then element1 = FPNeg(element1);
   Elem[result, e, esize] = FPMulAddH(Elem[operand3, e, esize], element1, element2, FPCR);
V[d] = result;
C7.2.128 FMLSL, FMLSL2 (vector)

Floating-point fused Multiply-Subtract Long from accumulator (vector). This instruction negates the values in the vector of one SIMD&FP register, multiplies these with the corresponding values in another vector, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an optional instruction. From Armv8.4 it is mandatory for all implementations to support it.

--- Note ---

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

---

FMLSL

ARMv8.2

```
[31 30 29 28 27 26 25 24 23 22 21 20 | 16 15 14 13 12 11 10 9 | 5 4 | 0 | 0 0 0 1 1 0 1 0 1]
S sz
```

FMLSL variant

FMLSL <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

if !HaveFP16MulNoRoundingToFP32Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz == '1' then UNDEFINED;
integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (S == '1');
integer part = 0;

FMLSL2

ARMv8.2

```
[31 30 29 28 27 26 25 24 23 22 21 20 | 16 15 14 13 12 11 10 9 | 5 4 | 0 | 0 1 1 1 0 1 0 1]
S sz
```

FMLSL2 variant

FMLSL2 <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>
Decode for this encoding

```cpp
if !HaveFP16MulNoRoundingToFP32Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz == '1' then UNDEFINED;
integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (S == '1');
integer part = 1;
```

Assembler symbols

- `<Vd>` is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Ta>` is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 2S when Q = 0
  - 4S when Q = 1
- `<Vn>` is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Tb>` is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 2H when Q = 0
  - 4H when Q = 1
- `<Vm>` is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```cpp
CheckFPAdvSIMDEnabled64();
bits(datasize DIV 2) operand1 = Vpart[n, part];
bits(datasize DIV 2) operand2 = Vpart[m, part];
bits(datasize) operand3 = V[d];
bits(datasize) result;

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operanda = V[a];
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

operand1 = FPNeg(operand1);
result = FPMulAdd(operanda, operand1, operand2, FPCR);
V[d] = result;
```
C7.2.134 FMUL (by element)

Floating-point Multiply (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Assembler symbols**

- `<Hd>` is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Hn>` is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<V>` is a width specifier, encoded in the "sz" field. It can have the following values:
  - `S` when `sz = 0`
  - `D` when `sz = 1`
- `<d>` is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- `<n>` is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vd>` is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` for the vector, half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - `4H` when `Q = 0`
  - `8H` when `Q = 1`
  For the vector, single-precision and double-precision variant: is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:
    - `2S` when `Q = 0, sz = 0`
    - `4S` when `Q = 1, sz = 0`
    - `2D` when `Q = 1, sz = 1`
  The encoding `Q = 0, sz = 1` is reserved.
- `<Vn>` is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` for the half-precision variant: is the name of the second SIMD&FP source register, in the range V0 to V15, encoded in the "Rm" field.
  For the single-precision and double-precision variant: is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.
- `<Ts>` is an element size specifier, encoded in the "sz" field. It can have the following values:
  - `S` when `sz = 0`
  - `D` when `sz = 1`
- `<index>` for the half-precision variant: is the element index, in the range 0 to 7, encoded in the "H:L:M" fields.
  For the single-precision and double-precision variant: is the element index, encoded in the "sz:L:H" field. It can have the following values:
    - `H:L` when `sz = 0, L = x`
    - `H` when `sz = 1, L = 0`
  The encoding `sz = 1, L = 1` is reserved.

**Operation for all encodings**

<Sn>  Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Sm>  Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

CheckFPAdvSIMDEnabled64();
bias(datasize) result;
bias(datasize) operand1 = V[n];
bias(datasize) operand2 = V[m];

result = FPMul(operand1, operand2, FPCR);

V[d] = result;
C7.2.137  FMULX (by element)

Floating-point Multiply extended (by element). This instruction multiplies the floating-point values in the vector elements in the first source SIMD&FP register by the specified floating-point value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If one value is zero and the other value is infinite, the result is 2.0. In this case, the result is negative if only one of the values is negative, otherwise the result is positive.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

boolean neg = (U == '1');
```

**Single-precision and double-precision**

```
[31 30 29 28][27 26 25 24][23 22 21 20][19 18 17 16][15 14 13 12][11 10 9] | 5 4 | 0 |
0 | Q | 1 | 0 | 1 | 1 | 1 | 0 | 1 | sz | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 0 |
U
```

**Single-precision and double-precision variant**

FNEG <Vd>.<T>, <Vn>.<T>

**Decode for this encoding**

```c
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then UNDEFINED;
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');
```

**Assembler symbols**

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T>  For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H  when Q = 0
For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- **2S** when \( sz = 0, Q = 0 \)
- **4S** when \( sz = 0, Q = 1 \)
- **2D** when \( sz = 1, Q = 1 \)

The encoding \( sz = 1, Q = 0 \) is reserved.

\(<Vn>\) is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    if neg then
        element = FPNeg(element);
    else
        element = FPAbs(element);
    Elem[result, e, esize] = element;
V[d] = result;
```
C7.2.140   FNEG (scalar)

Floating-point Negate (scalar). This instruction negates the value in the SIMD&FP source register and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant
Applies when ftype == 11.
FNEG <Hd>, <Hn>

Single-precision variant
Applies when ftype == 00.
FNEG <Sd>, <Sn>

Double-precision variant
Applies when ftype == 01.
FNEG <Dd>, <Dn>

Decode for all variants of this encoding

Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) result;
bits(datasize) operand = V[n];

result = FPNeg(operand);
V[d] = result;
C7.2.141 FNMADD

Floating-point Negated fused Multiply-Add (scalar). This instruction multiplies the values of the first two
SIMD&FP source registers, negates the product, subtracts the value of the third SIMD&FP source register, and
writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results
in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant

V[d] = result;
C7.2.147  FRINT32X (vector)

Floating-point Round to 32-bit Integer, using current rounding mode (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values that fit into a 32-bit integer size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

A zero input returns a zero result with the same sign. When one of the result values is not numerically equal to the corresponding input value, an Inexact exception is raised. When an input is infinite, NaN or out-of-range, the instruction returns for the corresponding result value the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

ARMv8.5

Vector single-precision and double-precision variant

FRINT32X <Vd>.<T>, <Vn>.<T>

Decode for this encoding

if !HaveFrintExt() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
if sz:Q == '10' then UNDEFINED;
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer intsize = if op == '0' then 32 else 64;
FPRounding rounding = if U == '0' then FPRounding_ZERO else FPRoundingMode(FPCR);

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S  when sz = 0, Q = 0
4S  when sz = 0, Q = 1
2D  when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPRoundIntN(element, FPCR, rounding, intsize);

V[d] = result;
C7.2.148    FRINT32X (scalar)

Floating-point Round to 32-bit Integer, using current rounding mode (scalar). This instruction rounds a
floating-point value in the SIMD&FP source register to an integral floating-point value that fits into a 32-bit integer
size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination
register.

A zero input returns a zero result with the same sign. When the result value is not numerically equal to the input
value, an Inexact exception is raised. When the input is infinite, NaN or out-of-range, the instruction returns {for
the corresponding result value} the most negative integer representable in the destination size, and an Invalid
Operation floating-point exception is raised.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception
results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

      UNDEFINED;

**Assembler symbols**

<Db>       Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Db>       Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Db>       Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```c
CheckFPAvSIMDEnabled64();

bits(datasize) result;
bits(datasize) operand = V[n];

result = FPRoundInt(operand, FPCR, FPRounding_TIEAWAY, FALSE);
V[d] = result;
```
C7.2.157 FRINTI (vector)

Floating-point Round to Integral, using current rounding mode (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- `8H` when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- `2S` when sz = 0, Q = 0
- `4S` when sz = 0, Q = 1
- `2D` when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```cpp
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FPRoundInt(element, FPCR, rounding, exact);

V[d] = result;
```
C7.2.164 FRINTP (scalar)

Floating-point Round to Integral, toward Plus infinity (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round towards Plus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant

Applies when ftype == 11.

FRINTP <Hd>, <Hn>

Single-precision variant

Applies when ftype == 00.

FRINTP <Sd>, <Sn>

Double-precision variant

    end if

FPRounding rounding;
rounding = FPDekodeRounding('01');

Assembler symbols

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

CheckFPAdvSIMDEnabled64();

bits(datasize) result;
bits(datasize) operand = V[n];

result = FPRoundInt(operand, FPCR, rounding, FALSE);

V[d] = result;
C7.2.165  FRINTX (vector)

Floating-point Round to Integral exact, using current rounding mode (vector). This instruction rounds a vector of
floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the
rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

When a result value is not numerically equal to the corresponding input value, an Inexact exception is raised. A zero
input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN
is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception
results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

</tbody>
</table>

The encoding \( sz = 1, Q = 0 \) is reserved.

\(<Vn>\) is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FPRSqrtEstimate(element, FPCR);

V[d] = result;
```
C7.2.170 FRSQRTS

Floating-point Reciprocal Square Root Step. This instruction multiplies corresponding floating-point values in the vectors of the two source SIMD&FP registers, subtracts each of the products from 3.0, divides these results by 2.0, places the results into a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

if sz:Q == '10' then UNDEFINED;
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 4H when Q = 0
- 8H when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- 2S when sz = 0, Q = 0
- 4S when sz = 0, Q = 1
- 2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPSqrt(element, FPCR);

V[d] = result;
```
C7.2.172  FSQRT (scalar)

Floating-point Square Root (scalar). This instruction calculates the square root of the value in the SIMD&FP source register and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant
Applies when \( ftype = 11 \).

FSQRT \(<Hd>, <Hn>\)

Single-precision variant
Applies when \( ftype = 00 \).

FSQRT \(<Sd>, <Sn>\)

Double-precision variant
Applies when \( ftype = 01 \).

FSQRT \(<Dd>, <Dn>\)

Decode for all variants of this encoding

\( \quad \quad \text{else} \)
\( \quad \quad \quad \text{UNDEFINED;} \)
```

Assembler symbols

\(<Dd>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

\(<Dn>\) Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

\(<Hd>\) Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

\(<Hn>\) Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

\(<Sd>\) Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<s>n</s> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) result;
bits(datasize) operand = V[n];

result = FPSqrt(operand, FPCR);
V[d] = result;
```
C7.2.173  FSUB (vector)

Floating-point Subtract (vector). This instruction subtracts the elements in the vector in the second source
SIMD&FP register, from the corresponding elements in the vector in the first source SIMD&FP register, places each
result into elements of a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results
in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPSub(operand1, operand2, FPCR);
V[d] = result;
C7.2.175  **INS (element)**

Insert vector element from another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias **MOV (element)**. The alias is always the preferred disassembly.

---

### Advanced SIMD variant

**INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]**

#### Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;

integer dst_index = UInt(imm5<4:size+1>);
integer src_index = UInt(imm4<3:size>);
integer idxdsizes = if imm4<3> == '1' then 128 else 64;
// imm4<size-1:0> is IGNORED

integer esize = 8 << size;
```

#### Assembler symbols

- **<Vd>**  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<Ts>**  Is an element size specifier, encoded in the "imm5" field. It can have the following values:
  - B  when imm5 = xxxx1
  - H  when imm5 = xxx10
  - S  when imm5 = xx100
  - D  when imm5 = x1000
  The encoding imm5 = x0000 is reserved.
- **<index1>**  Is the destination element index encoded in the "imm5" field. It can have the following values:
  - imm5<4:3>  when imm5 = xxxx1
  - imm5<4:2>  when imm5 = xxx10
  - imm5<4:3>  when imm5 = xx100
  - imm5<4>   when imm5 = x1000
  The encoding imm5 = x0000 is reserved.
- **<Vn>**  Is the name of the SIMD&FP source register, encoded in the "Rn" field.
```
<index2> Is the source element index encoded in the "imm5:imm4" field. It can have the following values:

- \(imm4<3:0>\) when \(imm5 = xxxx1\)
- \(imm4<3:1>\) when \(imm5 = xxx10\)
- \(imm4<3:2>\) when \(imm5 = xx100\)
- \(imm4<3>\) when \(imm5 = x1000\)

The encoding \(imm5 = x0000\) is reserved.

Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bhits(idxsize) operand = V[n];
bhits(128) result;

result = V[d];
Elem[result, dst_index, esize] = Elem[operand, src_index, esize];
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.176   INS (general)

Insert vector element from general-purpose register. This instruction copies the contents of the source
general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining
bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (from general). The alias is always the preferred disassembly.

Advanced SIMD variant

INS <Vd>.<Ts>[<index>], <R><n>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;
integer index = UInt(imm5<4:size+1>);
integer esize = 8 << size;

Assembler symbols

<Vd>     Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ts>     Is an element size specifier, encoded in the "imm5" field. It can have the following values:
        B when imm5 = xxxx1
        H when imm5 = xxx10
        S when imm5 = xx100
        D when imm5 = x1000
        The encoding imm5 = x0000 is reserved.
<index>  Is the element index encoded in the "imm5" field. It can have the following values:
        imm5<4:1> when imm5 = xxxx1
        imm5<4:2> when imm5 = xxx10
        imm5<4:3> when imm5 = xx100
        imm5<4> when imm5 = x1000
        The encoding imm5 = x0000 is reserved.
<R>      Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can
        have the following values:
        W when imm5 = xxxx1
        W when imm5 = xxx10
\[ W \] when \(\text{imm5} = \text{xx100}\)
\[ X \] when \(\text{imm5} = \text{x1000}\)

The encoding \(\text{imm5} = \text{x0000}\) is reserved.

The number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

**Operation**

\[
\text{CheckFPAdvSIMDEnabled64();}
\text{bits(\text{esize}) element} = \text{X}[n];
\text{bits(128) result;}
\]

\[
\text{result} = \text{V}[d];
\text{Elem[result, index, esize]} = \text{element};
\text{V}[d] = \text{result};
\]

**Operational information**

If \(\text{PSTATE.DIT}\) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.177  LD1 (multiple structures)

Load multiple single-element structures to one, two, three, or four registers. This instruction loads multiple single-element structures from memory and writes the result to one, two, three, or four SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer \( m = \text{UInt}(Rm) \);
boolean wback = TRUE;
boolean tag_checked = wback || n \neq 31;

**Assembler symbols**

\(<Vt>\) Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

\(<T>\) Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- \( 8B \) when \( \text{size} = 00, Q = 0 \)
- \( 16B \) when \( \text{size} = 00, Q = 1 \)
- \( 4H \) when \( \text{size} = 01, Q = 0 \)
- \( 8H \) when \( \text{size} = 01, Q = 1 \)
- \( 2S \) when \( \text{size} = 10, Q = 0 \)
- \( 4S \) when \( \text{size} = 10, Q = 1 \)
- \( 1D \) when \( \text{size} = 11, Q = 0 \)
- \( 2D \) when \( \text{size} = 11, Q = 1 \)

\(<Vt2>\) Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

\(<Vt3>\) Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.
<Vt4>  Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm>  For the one register, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#8     when Q = 0
#16    when Q = 1

For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#16    when Q = 0
#32    when Q = 1

For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#24    when Q = 0
#48    when Q = 1

For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#32    when Q = 0
#64    when Q = 1

<Xm>   Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

### Assembler symbols

**<Vt>**

Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

**<T>**

Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- **8B** when size = 00, Q = 0
- **16B** when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
1D when size = 11, Q = 0
2D when size = 11, Q = 1

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> Is the post-index immediate offset, encoded in the "size" field. It can have the following values:
#1 when size = 00
#2 when size = 01
#4 when size = 10
#8 when size = 11

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

Operational information
If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.180  LD2 (multiple structures)

Load multiple 2-element structures to two registers. This instruction loads multiple 2-element structures from
memory and writes the result to the two SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see LD3 (multiple structures).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

**Assembler symbols**

\(<Vt>\) Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

\(<T>\) Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- **88** when size = 00, Q = 0
- **168** when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
1D when size = 11, Q = 0
2D when size = 11, Q = 1

\(<Vt2>\) Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

\(<Vt3>\) Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

\(<imm>\) Is the post-index immediate offset, encoded in the "size" field. It can have the following values:
- #3 when size = 00
- #6 when size = 01
- #12 when size = 10
- #24 when size = 11

\(<Xm>\) Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.186   LD4 (multiple structures)

Load multiple 4-element structures to four registers. This instruction loads multiple 4-element structures from memory and writes the result to the four SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see LD3 (multiple structures).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

No offset

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.189   LDNP (SIMD&FP)

Load Pair of SIMD&FP registers, with Non-temporal hint. This instruction loads a pair of SIMD&FP registers from memory, issuing a hint to the memory system that the access is non-temporal. The address that is used for the load is calculated from a base register value and an optional immediate offset.

For information about non-temporal pair instructions, see Load/Store SIMD and Floating-point Non-temporal pair on page C3-216.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

32-bit variant
Applies when \( \text{opc} == 00 \).

\[
\text{LDNP} <\text{St}1>, <\text{St}2>, [<\text{Xn}|\text{SP}>{{, #<\text{imm}>}}]
\]

64-bit variant
Applies when \( \text{opc} == 01 \).

\[
\text{LDNP} <\text{Dt}1>, <\text{Dt}2>, [<\text{Xn}|\text{SP}>{{, #<\text{imm}>}}]
\]

128-bit variant
Applies when \( \text{opc} == 10 \).

\[
\text{LDNP} <\text{Qt}1>, <\text{Qt}2>, [<\text{Xn}|\text{SP}>{{, #<\text{imm}>}}]
\]

Decode for all variants of this encoding
// Empty.

Notes for all encodings
For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly LDNP (SIMD&FP) on page K1-7973.

Assembler symbols

- \(<\text{Dt}1>\)  
  Is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.

- \(<\text{Dt}2>\)  
  Is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.

- \(<\text{Qt}1>\)  
  Is the 128-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.

- \(<\text{Qt}2>\)  
  Is the 128-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.

- \(<\text{St}1>\)  
  Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.

- \(<\text{St}2>\)  
  Is the 32-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.

- \(<\text{Xn}|\text{SP}>\)  
  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

- \(<\text{imm}>\)  
  For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as \(<\text{imm}>/4\).
For the 64-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

For the 128-bit variant: is the optional signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the "imm7" field as <imm>/16.

Shared decode for all encodings

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);
if opc == '11' then UNDEFINED;
integer scale = 2 + UInt(opc);
integer datasize = 8 << scale;
bits(64) offset = LSL(SignExtend(imm7, 64), scale);
boolean tag_checked = n != 31;
```

Operation

```plaintext
CheckFPAdvSIMDEnabled64();
```

```plaintext
bits(64) address;
bits(datasize) data1;
bits(datasize) data2;
constant integer dbytes = datasize DIV 8;
boolean rt_unknown = FALSE;
if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);
if t == t2 then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE; // result is UNKNOWN
        when Constraint_UNDEF undefined;
        when Constraint_NOP EndOfInstruction();
if n == 31 then
    CheckSPAlignment();
else
    address = X[n];

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> For the 8-bit variant: is the index extend specifier, encoded in the "option" field. It can have the following values:

- UXTW when option = 010
- SXTW when option = 110
- SXTX when option = 111

For the 128-bit, 16-bit, 32-bit and 64-bit variant: is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

- UXTW when option = 010
- LSL when option = 011
- SXTW when option = 110
- SXTX when option = 111

<amount> For the 8-bit variant: is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

For the 16-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #1 when S = 1

For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #2 when S = 1

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #3 when S = 1

For the 128-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #4 when S = 1
Shared decode for all encodings

integer n = UInt(Rn);

Operational information

If PSTATE.D1T is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.194   LDUR (SIMD&FP)

Load SIMD&FP Register (unscaled offset). This instruction loads a SIMD&FP register from memory. The address that is used for the load is calculated from a base register value and an optional immediate offset.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

8-bit variant
Applies when \( \text{size} == 00 && \text{opc} == 01 \).
LDUR \( \langle Bt \rangle, \langle Xn|SP \rangle\{, \#<\text{simm}>\} \)

16-bit variant
Applies when \( \text{size} == 01 && \text{opc} == 01 \).
LDUR \( \langle Ht \rangle, \langle Xn|SP \rangle\{, \#<\text{simm}>\} \)

32-bit variant
Applies when \( \text{size} == 10 && \text{opc} == 01 \).
LDUR \( \langle St \rangle, \langle Xn|SP \rangle\{, \#<\text{simm}>\} \)

64-bit variant
Applies when \( \text{size} == 11 && \text{opc} == 01 \).
LDUR \( \langle Dt \rangle, \langle Xn|SP \rangle\{, \#<\text{simm}>\} \)

128-bit variant
Applies when \( \text{size} == 00 && \text{opc} == 11 \).
LDUR \( \langle Qt \rangle, \langle Xn|SP \rangle\{, \#<\text{simm}>\} \)

Decode for all variants of this encoding
integer scale = UInt(opc<1>:size);
if scale > 4 then UNDEFINED;
bits(64) offset = SignExtend(imm9, 64);

Assembler symbols
\(<Bt>\) Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
\(<Dt>\) Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
\(<Ht>\) Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
\(<Qt>\) Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
\(<St>\) Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
\(<\langle Xn|SP \rangle>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

**Shared decode for all encodings**

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = 8 << scale;
boolean tag_checked = memop != MemOp_PREFETCH && (n != 31);
```

**Operation**

```plaintext
if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

CheckFPAdvSIMDEnabled64();
bits(64) address;
bits(datasize) data;
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];
address = address + offset;
```

```plaintext
case memop of
    when MemOp_STORE
        data = V[t];
        Mem[address, datasize DIV 8, AccType_VEC] = data;
    when MemOp_LOAD
        data = Mem[address, datasize DIV 8, AccType_VEC];
        V[t] = data;
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.195   MLA (by element)

Multiply-Add to accumulator (vector, by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.199   MOV (scalar)

Move vector element to scalar. This instruction duplicates the specified vector element in the SIMD&FP source register into a scalar, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the DUP (element) instruction. This means that:

- The encodings in this description are named to match the encodings of DUP (element).
- The description of DUP (element) gives the operational pseudocode for this instruction.

Scalar variant

MOV <V><d>, <Vn>.<T>[<index>]

is equivalent to

DUP  <V><d>, <Vn>.<T>[<index>]

and is always the preferred disassembly.

Assembler symbols

<V>     Is the destination width specifier, encoded in the "imm5" field. It can have the following values:
    B when imm5 = xxxx1
    H when imm5 = xxx10
    S when imm5 = xx100
    D when imm5 = x1000

    The encoding imm5 = x0000 is reserved.

<d>     Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn>    Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T>     Is the element width specifier, encoded in the "imm5" field. It can have the following values:
    B when imm5 = xxxx1
    H when imm5 = xxx10
    S when imm5 = xx100
    D when imm5 = x1000

    The encoding imm5 = x0000 is reserved.

<index> Is the element index encoded in the "imm5" field. It can have the following values:
    imm5<4:1> when imm5 = xxxx1
    imm5<4:2> when imm5 = xxx10
    imm5<4:3> when imm5 = xx100
    imm5<4> when imm5 = x1000

    The encoding imm5 = x0000 is reserved.
Operation
The description of **DUP (element)** gives the operational pseudocode for this instruction.

Operational information
If `PSTATE.DIT` is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.200 MOV (element)

Move vector element to another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the INS (element) instruction. This means that:

- The encodings in this description are named to match the encodings of INS (element).
- The description of INS (element) gives the operational pseudocode for this instruction.

**Advanced SIMD variant**

MOV <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

is equivalent to

INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

and is always the preferred disassembly.

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Ts>` Is an element size specifier, encoded in the "imm5" field. It can have the following values:
  - B when imm5 = xxxx1
  - H when imm5 = xxx10
  - S when imm5 = xx100
  - D when imm5 = x1000
  - The encoding imm5 = x0000 is reserved.
- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- `<index1>` Is the destination element index encoded in the "imm5" field. It can have the following values:
  - imm5<4:1> when imm5 = xxxx1
  - imm5<4:2> when imm5 = xxx10
  - imm5<4:3> when imm5 = xx100
  - imm5<4> when imm5 = x1000
  - The encoding imm5 = x0000 is reserved.
- `<index2>` Is the source element index encoded in the "imm5:imm4" field. It can have the following values:
  - imm4<3:0> when imm5 = xxxx1
  - imm4<3:1> when imm5 = xxx10
  - imm4<3:2> when imm5 = xx100
imm4<3> when imm5 = x1000
The encoding imm5 = x0000 is reserved.
Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

Operation
The description of INS (element) gives the operational pseudocode for this instruction.

Operational information
If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.201  MOV (from general)

Move general-purpose register to a vector element. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the INS (general) instruction. This means that:

• The encodings in this description are named to match the encodings of INS (general).
• The description of INS (general) gives the operational pseudocode for this instruction.

Advanced SIMD variant

MOV <Vd>.<Ts>[<index>], <R><n>

is equivalent to

INS  <Vd>.<Ts>[<index>], <R><n>

and is always the preferred disassembly.

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ts> Is an element size specifier, encoded in the "imm5" field. It can have the following values:

| B | when imm5 = xxxx1 |
| H | when imm5 = xxx10 |
| S | when imm5 = xx100 |
| D | when imm5 = x1000 |

The encoding imm5 = x0000 is reserved.

<index> Is the element index encoded in the "imm5" field. It can have the following values:

| imm5<4:1> | when imm5 = xxxx1 |
| imm5<4:2> | when imm5 = xxx10 |
| imm5<3> | when imm5 = xx100 |
| imm5<4> | when imm5 = x1000 |

The encoding imm5 = x0000 is reserved.

<R> Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:

| W | when imm5 = xxxx1 |
| W | when imm5 = xxx10 |
| W | when imm5 = xx100 |
| X | when imm5 = x1000 |
The encoding imm5 = x0000 is reserved.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

**Operation**

The description of INS (general) gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.202  MOV (vector)

Move vector. This instruction copies the vector in the source SIMD&FP register into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the ORR (vector, register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (vector, register).
- The description of ORR (vector, register) gives the operational pseudocode for this instruction.

Three registers of the same type variant

MOV <Vd>.<T>, <Vn>.<T>

is equivalent to

ORR <Vd>.<T>, <Vn>.<T>, <Vn>.<T>

and is the preferred disassembly when Rm == Rn.

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 8B when Q = 0
  - 16B when Q = 1
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

Operation

The description of ORR (vector, register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.203 MOV (to general)

Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the UMOV instruction. This means that:

- The encodings in this description are named to match the encodings of UMOV.
- The description of UMOV gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( Q = 0 \) \&\& \( \text{imm5} = \text{xx100} \).

\[
\text{MOV} \ <Wd>, \ <Vn>.S[<index>] \\
\text{is equivalent to} \\
\text{UMOV} \ <Wd>, \ <Vn>.S[<index>]
\]

and is always the preferred disassembly.

64-reg,UMOV-64-reg variant

Applies when \( Q = 1 \) \&\& \( \text{imm5} = \text{x1000} \).

\[
\text{MOV} \ <Xd>, \ <Vn>.D[<index>] \\
\text{is equivalent to} \\
\text{UMOV} \ <Xd>, \ <Vn>.D[<index>]
\]

and is always the preferred disassembly.

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Vn>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- \(<\text{index}>\) For the 32-bit variant: is the element index encoded in "\text{imm5}<4:3>".
  For the 64-reg,UMOV-64-reg variant: is the element index encoded in "\text{imm5}<4>".

Operation

The description of UMOV gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
### C7.2.204 MOVI

Move Immediate (vector). This instruction places an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### 8-bit variant
Applies when \( \text{op} == 0 \&\& \text{cmode} == 1110 \).

\[
\text{MOVI} \ <Vd>.<T>, \ #<imm8>{, \ LSL \ #0}\]

#### 16-bit shifted immediate variant
Applies when \( \text{op} == 0 \&\& \text{cmode} == 10x0 \).

\[
\text{MOVI} \ <Vd>.<T>, \ #<imm8>{, \ LSL \ #<amount>}\]

#### 32-bit shifted immediate variant
Applies when \( \text{op} == 0 \&\& \text{cmode} == 0xx0 \).

\[
\text{MOVI} \ <Vd>.<T>, \ #<imm8>{, \ LSL \ #<amount>}\]

#### 32-bit shifting ones variant
Applies when \( \text{op} == 0 \&\& \text{cmode} == 110x \).

\[
\text{MOVI} \ <Vd>.<T>, \ #<imm8>, \ MSL \ #<amount>\]

#### 64-bit scalar variant
Applies when \( Q == 0 \&\& \text{op} == 1 \&\& \text{cmode} == 1110 \).

\[
\text{MOVI} \ <Dd>, \ #<imm>\]

#### 64-bit vector variant
Applies when \( Q == 1 \&\& \text{op} == 1 \&\& \text{cmode} == 1110 \).

\[
\text{MOVI} \ <Vd>.2D, \ #<imm>\]

#### Decode for all variants of this encoding

```plaintext

when '11111'
   // FMOV Dn,#imm is in main FP instruction set
   if Q == '0' then UNDEFINED;
   operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);

Assembler symbols

<DD>  Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<imm> Is a 64-bit immediate 'aaaaaaaaabbbbbbcdddddddeeeeffffgggggggghhhhhhh', encoded in "a:b:c:d:e:f:g:h".

<T>  For the 8-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
   8B  when Q = 0
   16B when Q = 1

For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
   4H  when Q = 0
   8H  when Q = 1

For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
   2S  when Q = 0
   4S  when Q = 1

<immB>  Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

<amount>  For the 16-bit shifted immediate variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:
   0  when cmode<1> = 0
   8  when cmode<1> = 1
defaulting to 0 if LSL is omitted.

For the 32-bit shifted immediate variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:
   0  when cmode<2:1> = 00
   8  when cmode<2:1> = 01
   16 when cmode<2:1> = 10
   24 when cmode<2:1> = 11
defaulting to 0 if LSL is omitted.

For the 32-bit shifting ones variant: is the shift amount encoded in the "cmode<0>" field. It can have the following values:
   8  when cmode<0> = 0
   16 when cmode<0> = 1
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);

        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.205  MUL (by element)

Multiply (vector, by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

MUL <Vd>.<T>, <Vn>.<T>, <Vm>.<Ts>[<index>]

Decode for this encoding

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  4H when size = 01, Q = 0
  8H when size = 01, Q = 1
  2S when size = 10, Q = 0
  4S when size = 10, Q = 1
The following encodings are reserved:
  • size = 00, Q = x.
  • size = 11, Q = x.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
  0:Rm when size = 01
  M:Rm when size = 10
The following encodings are reserved:
• size = 00.
• size = 11.
Restricted to V0-V15 when element size <Ts> is H.

<Ts>
Is an element size specifier, encoded in the "size" field. It can have the following values:

H when size = 01
S when size = 10

The following encodings are reserved:
• size = 00.
• size = 11.

<index>
Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

H:L:M when size = 01
H:L when size = 10

The following encodings are reserved:
• size = 00.
• size = 11.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxdsize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) product;

element2 = UInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
   element1 = UInt(Elem[operand1, e, esize]);
   product = (element1*element2)<esize-1:0>;
   Elem[result, e, esize] = product;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.206   MUL (vector)

Multiply (vector). This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

else
  product = (UInt(element1)*UInt(element2))<esize-1:0>;
Elem[result, e, esize] = product;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.207 MVN

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the NOT instruction. This means that:

- The encodings in this description are named to match the encodings of NOT.
- The description of NOT gives the operational pseudocode for this instruction.

Vector variant

MVN <Vd>.<T>, <Vn>.<T>

is equivalent to

NOT  <Vd>.<T>, <Vn>.<T>

and is always the preferred disassembly.

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8B</td>
<td>when Q = 0</td>
</tr>
<tr>
<td>16B</td>
<td>when Q = 1</td>
</tr>
</tbody>
</table>

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

The description of NOT gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.208   MVNI

Move inverted Immediate (vector). This instruction places the inverse of an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

16-bit shifted immediate variant

Applies when cmode == 10x0.

MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}

32-bit shifted immediate variant

Applies when cmode == 0xx0.

MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}

32-bit shifting ones variant

Applies when cmode == 110x.

MVNI <Vd>.<T>, #<imm8>, MSL #<amount>

Decode for all variants of this encoding

```
integer rd = UInt(Rd);
integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
    when '0xx01' operation = ImmediateOp_MVNI;
    when '0xx11' operation = ImmediateOp_BIC;
    when '10x01' operation = ImmediateOp_MVNI;
    when '10x11' operation = ImmediateOp_BIC;
    when '110x1' operation = ImmediateOp_MVNI;
    when '1110x' operation = ImmediateOp_MOVI;
    when '11111'
        // FMOV Dn,#imm is in main FP instruction set
        if Q == '0' then UNDEFINED;
        operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:gh);
imm = Replicate(imm64, datasize DIV 64);
```

Assembler symbols

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` For the 16-bit variant: an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 4H when Q = 0
For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 2S when Q = 0
- 4S when Q = 1

<imm8> Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

<amount> For the 16-bit shifted immediate variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:

- 0 when cmode<1> = 0
- 8 when cmode<1> = 1

defaulting to 0 if LSL is omitted.

For the 32-bit shifted immediate variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

- 0 when cmode<2:1> = 00
- 8 when cmode<2:1> = 01
- 16 when cmode<2:1> = 10
- 24 when cmode<2:1> = 11

defaulting to 0 if LSL is omitted.

For the 32-bit shifting ones variant: is the shift amount encoded in the "cmode<0>" field. It can have the following values:

- 8 when cmode<0> = 0
- 16 when cmode<0> = 1

Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;
case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);
V[rd] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C7.2.209   NEG (vector)

Negate (vector). This instruction reads each vector element from the source SIMD&FP register, negates each value, puts the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

\[

Assembler symbols

<\textstyle{V}>  

Is a width specifier, encoded in the "size" field. It can have the following values:

\[
\begin{align*}
D & \text{ when size} = 11 \\
\text{The following encodings are reserved: } \\
\bullet & \text{ size} = 0x. \\
\bullet & \text{ size} = 10.
\end{align*}
\]
Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n>
Is the number of the SIMD&FP source register, encoded in the "Rn" field.

</d>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T>
Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

</n>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bias(datasize) result;
integer element;

for e = 0 to elements-1
  element = SInt(Elem[operand, e, esize]);
  if neg then
  element = -element;
  else
  element = Abs(element);
  Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.210   NOT

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MVN. The alias is always the preferred disassembly.

Vector variant

NOT <Vd>.<T>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  8B when Q = 0
  16B when Q = 1
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
  element = Elem[operand, e, esize];
  Elem[result, e, esize] = NOT(element);

V[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.211  ORN (vector)

Bitwise inclusive OR NOT (vector). This instruction performs a bitwise OR NOT between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
0 Q 0 1 1 1 0 1 1 1  Rm 0 0 0 1 1 1  Rn  Rd
size
```

Three registers of the same type variant

ORN <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decoding for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

Assembler symbols

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>  Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
operand2 = NOT(operand2);
result = operand1 OR operand2;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C7.2.212  **ORR (vector, immediate)**

Bitwise inclusive OR (vector, immediate). This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise OR between each result and an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**16-bit variant**

Applies when \( \text{cmode} == 10x1 \).

\[
\text{ORR} <\text{Vd}.T>, #<\text{imm8}>, LSL #\text{amount}
\]

**32-bit variant**

Applies when \( \text{cmode} == 0xx1 \).

\[
\text{ORR} <\text{Vd}.T>, #<\text{imm8}>, LSL #\text{amount}
\]

**Decode for all variants of this encoding**

```c
integer rd = UInt(Rd);
integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
  when '0xx00' operation = ImmediateOp_MOVI;
  when '0xx10' operation = ImmediateOp_ORR;
  when '10x00' operation = ImmediateOp_MOVI;
  when '10x10' operation = ImmediateOp_ORR;
  when '110x0' operation = ImmediateOp_MOVI;
  when '1110x' operation = ImmediateOp_MOVI;
  when '11110' operation = ImmediateOp_MOVI;
imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

**Assembler symbols**

- `<Vd>`  Is the name of the SIMD&FP register, encoded in the "Rd" field.
- `<T>`  For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 4H  when \( Q = 0 \)
  - 8H  when \( Q = 1 \)

- `<imm8>`  Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

---

[0x0] Q0 0111100000 a b c x x x 1 0 1 d e f g h  Rd

\[
0 | Q | 0 1 1 1 1 0 0 0 0 | a b c x x x 1 0 1 d e f g h | 0 |
\]

\[\text{op} \quad \text{cmode}\]
<amount>  For the 16-bit variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:
  0     when cmode<1> = 0
  8     when cmode<1> = 1
defaulting to 0 if LSL is omitted.
For the 32-bit variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:
  0     when cmode<2:1> = 00
  8     when cmode<2:1> = 01
  16    when cmode<2:1> = 10
  24    when cmode<2:1> = 11
defaulting to 0 if LSL is omitted.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;
case operation of
  when ImmediateOp_MOVI
    result = imm;
  when ImmediateOp_MVNI
    result = NOT(imm);
  when ImmediateOp_ORR
    operand = V[rd];
    result = operand OR imm;
  when ImmediateOp_BIC
    operand = V[rd];
    result = operand AND NOT(imm);
V[rd] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.213 ORR (vector, register)

Bitwise inclusive OR (vector, register). This instruction performs a bitwise OR between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (vector). See Alias conditions for details of when each alias is preferred.

### Three registers of the same type variant

ORR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

### Alias conditions

<table>

  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.214   PMUL

Polynomial Multiply. This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

For information about multiplying polynomials see *Polynomial arithmetic over \( \{0, 1\} \) on page A1-50.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

else
  product = (UInt(element1)*UInt(element2))<esize-1:0>;
Elem[result, e, esize] = product;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.215  PMULL, PMULL2

Polynomial Multiply Long. This instruction multiplies corresponding elements in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials see *Polynomial arithmetic over \{0, 1\}* on page A1-50.

The PMULL instruction extracts each source vector from the lower half of each source register, while the PMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14 13 12|11 10 9 | 5 4 | 0 |
| 0 | Q | 0 | 0 | 1 | 1 | 1 | 0 | size | 1 | Rm | 1 | 1 | 1 | 0 | 0 | Rn | Rd |

Three registers, not all the same type variant

PMULL{2} <Vd>,<Ta>, <Vn>,<Tb>, <Vm>,<Tb>

Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '01' || size == '10' then UNDEFINED;
if size == '11' && !HaveBit128PMULLExt() then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

Assembler symbols

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when \( Q = 0 \)
- [present] when \( Q = 1 \)

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H when size = 00
- 1Q when size = 11

The following encodings are reserved:

- size = 01.
- size = 10.

The '1Q' arrangement is only allocated in an implementation that includes the Cryptographic Extension, and is otherwise RESERVED.

<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8B</td>
<td>when size = 00, Q = 0</td>
</tr>
<tr>
<td>16B</td>
<td>when size = 00, Q = 1</td>
</tr>
<tr>
<td>1D</td>
<td>when size = 11, Q = 0</td>
</tr>
<tr>
<td>2D</td>
<td>when size = 11, Q = 1</td>
</tr>
</tbody>
</table>

The following encodings are reserved:

- size = 01, Q = x.
- size = 10, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, 2*esize] = PolynomialMult(element1, element2);

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.216  RADDHN, RADDHN2

Rounding Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The results are rounded. For truncated results, see ADDHN, ADDHN2.

The RADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

RADDHN[2] <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean round = (U == '1');

Assembler symbols

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[a]absent] when Q = 0
[present] when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B  when size = 00, Q = 0
16B  when size = 00, Q = 1
4H  when size = 01, Q = 0
8H  when size = 01, Q = 1
2S  when size = 10, Q = 0
4S  when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8H</td>
<td>when size = 00</td>
</tr>
<tr>
<td>4S</td>
<td>when size = 01</td>
</tr>
<tr>
<td>2D</td>
<td>when size = 10</td>
</tr>
</tbody>
</table>

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bids(2*datasize) operand2 = V[m];
bids(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bids(2*esize) element1;
bids(2*esize) element2;
bids(2*esize) sum;
for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;
Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**C7.2.217  RAX1**

Rotate and Exclusive OR rotates each 64-bit element of the 128-bit vector in a source SIMD&FP register left by 1, performs a bitwise exclusive OR of the resulting 128-bit vector and the vector in another source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when `FEAT_SHA3` is implemented.

**Advanced SIMD variant**

RAX1 `<Vd>.2D, <Vn>.2D, <Vm>.2D`

**Decode for this encoding**

```
if !HaveSHA3Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
```

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```
AArch64.CheckFPAdvSIMDEnabled();

bits(128) Vm = V[m];
bits(128) Vn = V[n];
V[d] = Vn EOR (ROL(Vm<127:64>, 1):ROL(Vm<63:0>, 1));
```
**C7.2.218 RBIT (vector)**

Reverse Bit order (vector). This instruction reads each vector element from the source SIMD&FP register, reverses the bits of the element, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Vector variant**

RBIT <Vd>.<T>, <Vn>.<T>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;
bits(esize) rev;
for e = 0 to elements-1
   element = Elem[operand, e, esize];
   for i = 0 to esize-1
      rev<esize-1-i> = element<i>;
      Elem[result, e, esize] = rev;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.219  REV16 (vector)

Reverse elements in 16-bit halfwords (vector). This instruction reverses the order of 8-bit elements in each halfword of the vector in the source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

REV16 <Vd>.<T>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

// size=size:  B(0),  H(1),  S(1), D(S)
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;

// op=REVx: 64(0), 32(1), 16(2)
bits(2) op = o0:U;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Rounding Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the vector in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SHRN, SHRN2.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

RSHRN(2) <Vd>.<Tb>, <Vn>.<Ta>, #<shift>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');

Assembler symbols

2 is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8 B when immh = 0001, Q = 0
16 B when immh = 0001, Q = 1
4 H when immh = 001x, Q = 0
8 H when immh = 001x, Q = 1
2 S when immh = 01xx, Q = 0
4 S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.
The encoding $\text{immh} = 1\text{xxx}$, $Q = x$ is reserved.

<Vn>  
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>  
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when $\text{immh} = 0001$
- 4S when $\text{immh} = 001x$
- 2D when $\text{immh} = 01xx$

See Advanced SIMD modified immediate on page C4-351 when $\text{immh} = 0000$.

The encoding $\text{immh} = 1\text{xxx}$ is reserved.

<shift>  
Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- $(16-\text{UInt}(\text{immh:immb}))$ when $\text{immh} = 0001$
- $(32-\text{UInt}(\text{immh:immb}))$ when $\text{immh} = 001x$
- $(64-\text{UInt}(\text{immh:immb}))$ when $\text{immh} = 01xx$

See Advanced SIMD modified immediate on page C4-351 when $\text{immh} = 0000$.

The encoding $\text{immh} = 1\text{xxx}$ is reserved.

**Operation**

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.223 RSUBHN, RSUBHN2

Rounding Subtract returning High Narrow. This instruction subtracts each vector element of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see SUBHN, SUBHN2.

The RSUBHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.226   SABD

Signed Absolute Difference. This instruction subtracts the elements of the vector of the second source SIMD&FP register from the corresponding elements of the first source SIMD&FP register, places the absolute values of the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant
SABD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decoding for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean accumulate = (ac == '1');

Assembler symbols

<Vd>   Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>    Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  8B   when size = 00, Q = 0
  16B  when size = 00, Q = 1
  4H   when size = 01, Q = 0
  8H   when size = 01, Q = 1
  2S   when size = 10, Q = 0
  4S   when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn>   Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>   Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) absdiff;
result = if accumulate then V[d] else Zeros();
for e = 0 to elements–1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  absdiff = Abs(element1–element2)<esize–1:0>;
  Elem[result, e, esize] = Elem[result, e, esize] + absdiff;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.227  SABDL, SABDL2

Signed Absolute Difference Long. This instruction subtracts the vector elements of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, places the absolute value of the results into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SABDL instruction writes the vector to the lower half of the destination register and clears the upper half, while the SABDL2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.233  SCVTF (vector, fixed-point)

Signed fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

```
integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);

Assembler symbols

<V>  Is a width specifier, encoded in the "immh" field. It can have the following values:
    H    when immh = 001x
    S    when immh = 01xx
    D    when immh = 1xxx

    The encoding immh = 000x is reserved.

<d>  Is the number of the SIMD&FP destination register, in the "Rd" field.

<n>  Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T>  Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
    4H    when immh = 001x, Q = 0
    8H    when immh = 001x, Q = 1
    2S    when immh = 01xx, Q = 0
    4S    when immh = 01xx, Q = 1
    2D    when immh = 1xxx, Q = 1

    See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.

    The following encodings are reserved:
    •   immh = 0001, Q = x.
    •   immh = 1xxx, Q = 0.

<Vn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded
    in the "immh:immb" field. It can have the following values:
    (32-UInt(immh:immb)) when immh = 001x
    (64-UInt(immh:immb)) when immh = 01xx
    (128-UInt(immh:immb)) when immh = 1xxx

    The encoding immh = 000x is reserved.

    For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded
    in the "immh:immb" field. It can have the following values:
    (32-UInt(immh:immb)) when immh = 001x
    (64-UInt(immh:immb)) when immh = 01xx
    (128-UInt(immh:immb)) when immh = 1xxx

    See Advanced SIMD modified immediate on page C4-351 when immh = 0000.

    The encoding immh = 0001 is reserved.

Operation for all encodings

    CheckFPAdvSIMDEnabled64();
    bits(datasize) operand = V[n];
    bits(datasize) result;
    bits(esize) element;

    for e = 0 to elements-1
element = Elem[operand, e, esize];
          Elem[result, e, esize] = FixedToFP(element, fracbits, unsigned, FPCR, rounding);

V[d] = result;
C7.2.234  SCVTF (vector, integer)

Signed integer Convert to Floating-point (vector). This instruction converts each element in a vector from signed integer to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Scalar half precision

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:

S when sz = 0
D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0
8H when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0
4S when sz = 0, Q = 1
2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
FPRounding rounding = FPRoundingMode(FPCR);
bits(esize) element;
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FixedToFP(element, 0, unsigned, FPCR, rounding);
V[d] = result;
```
C7.2.235 SCVTF (scalar, fixed-point)

Signed fixed-point Convert to Floating-point (scalar). This instruction converts the signed value in the 32-bit or 64-bit general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

32-bit to half-precision variant
Applies when sf == 0 && ftype == 11.
SCVTF <Hd>, <Wn>, #<fbits>

32-bit to single-precision variant
Applies when sf == 0 && ftype == 00.
SCVTF <Sd>, <Wn>, #<fbits>

32-bit to double-precision variant
Applies when sf == 0 && ftype == 01.
SCVTF <Dd>, <Wn>, #<fbits>

64-bit to half-precision variant
Applies when sf == 1 && ftype == 11.
SCVTF <Hd>, <Xn>, #<fbits>

64-bit to single-precision variant
Applies when sf == 1 && ftype == 00.
SCVTF <Sd>, <Xn>, #<fbits>

64-bit to double-precision variant
Applies when sf == 1 && ftype == 01.
SCVTF <Dd>, <Xn>, #<fbits>

Decode for all variants of this encoding

intval = X[n];
fltval = FixedToFP(intval, fracbits, FALSE, FPCR, rounding);
V[d] = fltval;
C7.2.236   SCVTF (scalar, integer)

Signed integer Convert to Floating-point (scalar). This instruction converts the signed integer value in the
general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and
writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception
results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

32-bit to half-precision variant
Applies when sf == 0 && ftype == 11.
SCVTF <Hd>, <Wn>

32-bit to single-precision variant
Applies when sf == 0 && ftype == 00.
SCVTF <Sd>, <Wn>

32-bit to double-precision variant
Applies when sf == 0 && ftype == 01.
SCVTF <Dd>, <Wn>

64-bit to half-precision variant
Applies when sf == 1 && ftype == 11.
SCVTF <Hd>, <Xn>

64-bit to single-precision variant
Applies when sf == 1 && ftype == 00.
SCVTF <Sd>, <Xn>

64-bit to double-precision variant
Applies when sf == 1 && ftype == 01.
SCVTF <Dd>, <Xn>

Decoding for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPRounding rounding;
case ftype of
  when '00'

  when '11'
    if HaveFP16Ext() then
      fltsize = 16;
    else
      UNDEFINED;
  rounding = FPRoundingMode(FPCR);

Assembler symbols

<DD> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<HD> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<SD> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<XN> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<WN> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(fltsize) fltval;
bits(intsize) intval;

intval = X[n];
fltval = FixedToFP(intval, 0, FALSE, FPCR, rounding);
V[d] = fltval;
SDOT (by element)

Dot Product signed arithmetic (vector, by element). This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an optional instruction. From Armv8.4 it is mandatory for all implementations to support it.

--- Note ---
ID_AA64ISAR0_EL1.DP indicates whether this instruction is supported.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C7.2.253   SHADD

Signed Halving Add. This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SRHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

SHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size-Q" field. It can have the following values:
  8B when size = 00, Q = 0
  16B when size = 00, Q = 1
  4H when size = 01, Q = 0
  8H when size = 01, Q = 1
  2S when size = 10, Q = 0
  4S when size = 10, Q = 1
The encoding size = 11, Q = 'X' is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    sum = element1 + element2;
    Elem[result, e, esize] = sum<esize:1>;
    V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.254 SHL

Shift Left (immediate). This instruction reads each value from a vector, left shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer shift = UInt(immh:immb) - esize;

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:

D when immh = 1xxx

The encoding immh = 0xxx is reserved.
<db> Is the number of the SIMD&FP destination register, in the "Rd" field.
</db>

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
</n>

<d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
</d>

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8B</td>
<td>when immh = 0001, Q = 0</td>
</tr>

<tr>
<td>2D</td>
<td>when immh = 1xxx, Q = 1</td>
</tr>
</tbody>
</table>

See [Advanced SIMD modified immediate](#) on page C4-351 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = 0 is reserved.

<vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
</vn>

<shift> For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the "immh:immb" field. It can have the following values:

( UInt(immh:immb)-64) when immh = 1xxx

The encoding immh = 0xxx is reserved.

For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

( UInt(immh:immb)-8) when immh = 0001
( UInt(immh:immb)-16) when immh = 001x
( UInt(immh:immb)-32) when immh = 01xx
( UInt(immh:immb)-64) when immh = 1xxx

See [Advanced SIMD modified immediate](#) on page C4-351 when immh = 0000.

---

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bidx(datasize) operand = V[n];
bidx(datasize) result;
for e = 0 to elements-1
  Elem[result, e, esize] = LSL(Elem[operand, e, esize], shift);
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.255  SHLL, SHLL2

Shift Left Long (by element size). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, left shifts each result by the element size, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SHLL instruction extracts vector elements from the lower half of the source register, while the SHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

SHLL[2] <Vd>,<Ta>, <Vn>,<Tb>, #<shift>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = esize;
boolean unsigned = FALSE;    // Or TRUE without change of functionality

Assembler symbols

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
   [absent] when Q = 0
   [present] when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:
   8H  when size = 00
   4S  when size = 01
   2D  when size = 10
   The encoding size = 11 is reserved.

<Vn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
   8B  when size = 00, Q = 0
   16B when size = 00, Q = 1
4H when size = 0, Q = 0
8H when size = 0, Q = 1
2S when size = 1, Q = 0
4S when size = 1, Q = 1
The encoding size = 11, Q = x is reserved.

<shift> Is the left shift amount, which must be equal to the source element width in bits, encoded in the
"size" field. It can have the following values:
8 when size = 00
16 when size = 01
32 when size = 10
The encoding size = 11 is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bite(datasize) operand = Vpart[n, part];
bits(2*datasize) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.256   SHRN, SHRN2

Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are truncated. For rounded results, see RSHRN, RSHRN2.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer n = UInt(Rn);
if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');

**Assembler symbols**

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

-absent when Q = 0
-present when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>  Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B  when immh = 0001, Q = 0
16B  when immh = 0001, Q = 1
4H  when immh = 001x, Q = 0
8H  when immh = 01x, Q = 1
2S  when immh = 01xx, Q = 0
4S  when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when immh = 0001
- 4S when immh = 001x
- 2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.

The encoding immh = 1xxx is reserved.

<shift> Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- (16-UInt(immh:immb)) when immh = 0001
- (32-UInt(immh:immb)) when immh = 001x
- (64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
for e = 0 to elements-1
   element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
   Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.257 SHSUB

Signed Halving Subtract. This instruction subtracts the elements in the vector in the second source SIMD&FP register from the corresponding elements in the vector in the first source SIMD&FP register, shifts each result right one bit, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

-three registers of the same type variant-

**SHSUB** <Vd>..<T>, <Vn>..<T>, <Vm>..<T>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;
for e = 0 to elements-1
   element1 = Int(Elem[operand1, e, esize], unsigned);
element2 = Int(Elem[operand2, e, esize], unsigned);
diff = element1 - element2;
Elem[result, e, esize] = diff<esize:1>;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Shift Left and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, left shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the left of each vector element in the source register are lost.

The following figure shows the operation of shift left by 3 for an 8-bit vector element.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  — The values of the NZCV flags.
C7.2.261 SM3SS1

SM3SS1 rotates the top 32 bits of the 128-bit vector in the first source SIMD&FP register by 12, and adds that 32-bit value to the two other 32-bit values held in the top 32 bits of each of the 128-bit vectors in the second and third source SIMD&FP registers, rotating this result left by 7 and writing the final result into the top 32 bits of the vector in the destination SIMD&FP register, with the bottom 96 bits of the vector being written to 0.

This instruction is implemented only when FEAT_SM3 is implemented.

Vd<95:0> = Zeros();
V[d] = Vd;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.262   SM3TT1A

SM3TT1A takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive OR.
- The result of the exclusive OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector,Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

This instruction is implemented only when FEAT_SM3 is implemented.

integer element2;
```
integer maxmin;
for e = 0 to elements-1
    element1 = Int(Elem[concat, 2*e, esize], unsigned);
    element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
    Elem[result, e, esize] = maxmin<esize-1:0>;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.270 SMAXV

Signed Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are signed integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9  | 5 4  | 0  |
|-----------|-----------|-----------|-----------|-----------|-----------|     |
| 0 | Q | 0 | 1 | 1 | 1 | 0 | size | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 1 | 0 |
  | Rn | Rd  
```

**Advanced SIMD variant**

\]

\[
V[d] = \text{result};
\]

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.277    SMLSL, SMLSL2 (vector)

Signed Multiply-Subtract Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLSL instruction extracts each source vector from the lower half of each source register, while the SMLSL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant
SMLSL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2    Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>absent</th>
<th>present</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q = 0</td>
<td>Q = 1</td>
</tr>
</tbody>
</table>

<Vd>    Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>    Is an arrangement specifier, encoded in the "size" field. It can have the following values:

<table>
<thead>
<tr>
<th>8H</th>
<th>4S</th>
<th>2D</th>
</tr>
</thead>
<tbody>
<tr>
<td>size = 00</td>
<td>size = 01</td>
<td>size = 10</td>
</tr>

</table>

The encoding size = 11 is reserved.

<Vn>    Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb>    Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>8B</th>
<th>16B</th>
</tr>
</thead>
<tbody>
<tr>
<td>size = 00, Q = 0</td>
<td>size = 00, Q = 1</td>
</tr>
</tbody>
</table>
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<\m> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
bits(2*esize) accum;

for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  product = (element1*element2)<2*esize-1:0>;
  if sub_op then
    accum = Elem[operand3, e, 2*esize] - product;
  else
    accum = Elem[operand3, e, 2*esize] + product;
  Elem[result, e, 2*esize] = accum;

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.278   SMMLA (vector)

Signed 8-bit integer matrix multiply-accumulate. This instruction multiplies the 2x8 matrix of signed 8-bit integer values in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

- <V> Is a width specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
D when size = 11

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;

  element2 = Int(Elem[operand2, e, esize], unsigned);
  sum = element1 + element2;
  (Elem[result, e, esize], sat) = SatQ(sum, esize, unsigned);
  if sat then FPSR.QC = '1';
V[d] = result;
C7.2.284   SQDMLAL, SQDMLAL2 (by element)

Signed saturating Doubling Multiply-Add Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMLAL instruction extracts vector elements from the lower half of the first source register, while the SQDMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 4S when size = 01
- 2D when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:

- size = 00, Q = x.
- size = 11, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<Va> Is the destination width specifier, encoded in the "size" field. It can have the following values:

- S when size = 01
- D when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<vb> Is the source width specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;

integer element2;
bits(2*esize) product;
integer accum;
boolean sat1;
boolean sat2;

for e = 0 to elements-1
  element1 = SInt(Elem[operand1, e, esize]);
  element2 = SInt(Elem[operand2, e, esize]);
  (product, sat1) = SignedSatQ(2 * element1 * element2, 2 * esize);
  if sub_op then
    accum = SInt(Elem[operand3, e, 2*esize]) - SInt(product);
  else
    accum = SInt(Elem[operand3, e, 2*esize]) + SInt(product);
  (Elem[result, e, 2*esize], sat2) = SignedSatQ(accum, 2 * esize);
  if sat1 || sat2 then FPSR.QC = '1';

V[d] = result;
C7.2.288 SQDMULH (by element)

Signed saturating Doubling Multiply returning High half (by element). This instruction multiplies each vector element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SQRDMULH (by element).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\end{verbatim}
C7.2.293  SQRDMLAH (by element)

Signed Saturating Rounding Doubling Multiply Accumulate returning High Half (by element). This instruction multiplies the vector elements of the first source SIMD&FP register with the value of a vector element of the second source SIMD&FP register without saturating the multiply results, doubles the results, and accumulates the most significant half of the final results with the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSR.QC, is set if saturation occurs.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- size = 00.
- size = 11.

Restricted to V0-V15 when element size <Ts> is H.

**<Ts>** Is an element size specifier, encoded in the "size" field. It can have the following values:

- **H** when size = 01
- **S** when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.
<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

- H:L:M when size = 01
- H:L when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxsize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
integer element1;
integer element2;
integer product;
boolean sat;

element2 = SInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
   element1 = SInt(Elem[operand1, e, esize]);
   product = (2 * element1 * element2) + round_const;
   // The following only saturates if element1 and element2 equal -(2^(esize-1))
   (Elem[result, e, esize], sat) = SignedSatQ(product >> esize, esize);
   if sat then FPSR.QC = '1';

V[d] = result;
```
# SQRDMULH (vector)

Signed saturating Rounding Doubling Multiply returning High half. This instruction multiplies the values of corresponding elements of the two source SIMD&FP registers, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see SQRDMULH (vector).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  (Elem[result, e, esize], sat) = SignedSatQ(product >> esize, esize);
  if sat then FPSR.QC = '1';
V[d] = result;
```
C7.2.299   **SQRSHL**

Signed saturating Rounding Shift Left (register). This instruction takes each vector element in the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see SQSHL (register).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    V[d] = result;
C7.2.300  SQRSHRN, SQRSHRN2

Signed saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SQRSHRN, SQRSHRN2.

The SQRSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
boolean unsigned = (U == '1');

Assembler symbols

2
Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1
See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<Vn>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx
See Advanced SIMD modified immediate on page C4-351 when immh = 0000.
The encoding immh = 1xxx is reserved.

<Vb>
Is the destination width specifier, encoded in the "immh" field. It can have the following values:
B when immh = 0001
H when immh = 001x
S when immh = 01xx
The following encodings are reserved:
• immh = 0000.
• immh = 1xxx.

<d>
Is the number of the SIMD&FP destination register, in the "Rd" field.

</a>
Is the source width specifier, encoded in the "immh" field. It can have the following values:
H when immh = 0001
S when immh = 001x
D when immh = 01xx
The following encodings are reserved:

- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

\(<n>\)

Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

\(<shift>\)

For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

- \( (16-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 0001 \)
- \( (32-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 001x \)
- \( (64-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 01xx \)

The following encodings are reserved:

- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- \( (16-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 0001 \)
- \( (32-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 001x \)
- \( (64-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 01xx \)

See *Advanced SIMD modified immediate* on page C4-351 when \( \text{immh} = 0000 \).

The encoding \( \text{immh} = 1xxx \) is reserved.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bis(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';
Vpart[d, part] = result;
```

C7.2.301 SQRSHRUN, SQRSHRUN2

Signed saturating Rounded Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are rounded. For truncated results, see SQRSHRUN, SQRSHRUN2.

The SQRSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

   4S  when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-351 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<Vn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>  Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
   8H  when immh = 0001
   4S  when immh = 001x
   2D  when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-351 when immh = 0000.
The encoding immh = 1xxx is reserved.

<Vb>  Is the destination width specifier, encoded in the "immh" field. It can have the following values:
   B   when immh = 0001
   H   when immh = 001x
   S   when immh = 01xx

The following encodings are reserved:
   • immh = 0000.
   • immh = 1xxx.

<d>  Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va>  Is the source width specifier, encoded in the "immh" field. It can have the following values:
   H   when immh = 0001
   S   when immh = 001x
   D   when immh = 01xx

The following encodings are reserved:
   • immh = 0000.
   • immh = 1xxx.
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift>
For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

The following encodings are reserved:
• immh = 0000.
• immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

    element = (SInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    (Elem[result, e, esize], sat) = UnsignedSatQ(element, esize);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
C7.2.302   SQSHL (immediate)

Signed saturating Shift Left (immediate). This instruction reads each vector element in the source SIMD&FP
register, shifts each result by an immediate value, places the final result in a vector, and writes the vector to the
destination SIMD&FP register. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation
bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:
  B  when immh = 0001
  H  when immh = 001x
  S  when immh = 01xx
  D  when immh = 1xxx
The encoding immh = 0000 is reserved.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.
<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
  8B  when immh = 0001, Q = 0
  16B when immh = 0001, Q = 1
  4H  when immh = 001x, Q = 0
  8H  when immh = 001x, Q = 1
  2S  when immh = 01xx, Q = 0
  4S  when immh = 01xx, Q = 1
  2D  when immh = 1xxx, Q = 1
See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = 0 is reserved.

<vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<shift> For the scalar variant: is the left shift amount, in the range 0 to the operand width in bits minus 1,
encoded in the "immh:immb" field. It can have the following values:
  (UInt(immh:immb)-8) when immh = 0001
  (UInt(immh:immb)-16) when immh = 001x
  (UInt(immh:immb)-32) when immh = 01xx
  (UInt(immh:immb)-64) when immh = 1xxx
The encoding immh = 0000 is reserved.
For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1,
encoded in the "immh:immb" field. It can have the following values:
  (UInt(immh:immb)-8) when immh = 0001
  (UInt(immh:immb)-16) when immh = 001x
  (UInt(immh:immb)-32) when immh = 01xx
  (UInt(immh:immb)-64) when immh = 1xxx
See *Advanced SIMD modified immediate on page C4-351* when immh = 0000.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], src_unsigned) << shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.303  SQSHL (register)

Signed saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see SQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.

**Operation for all encodings**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], src_unsigned) << shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.305 SQSHRN, SQSHRN2

Signed saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts and truncates each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. For rounded results, see SQRSHRN, SQRSHRN2.

The SQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

2
Is the second and upper half specifier. If present it causes the operation to be performed on the upper
64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have
the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1
See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<Vn>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx
See Advanced SIMD modified immediate on page C4-351 when immh = 0000.
The encoding immh = 1xxx is reserved.

<Vb>
Is the destination width specifier, encoded in the "immh" field. It can have the following values:
B when immh = 0001
H when immh = 001x
S when immh = 01xx
The following encodings are reserved:
• immh = 0000.
• immh = 1xxx.

<d>
Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va>
Is the source width specifier, encoded in the "immh" field. It can have the following values:
H when immh = 0001
S when immh = 001x
D when immh = 01xx
The following encodings are reserved:

- $\text{immh} = 0000$.
- $\text{immh} = 1xxx$.

$n$ is the number of the first SIMD&FP source register, encoded in the "Rn" field.

$\text{shift}$ for the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

- $(16-\text{UInt}(\text{immh:immb}))$ when $\text{immh} = 0001$
- $(32-\text{UInt}(\text{immh:immb}))$ when $\text{immh} = 001x$
- $(64-\text{UInt}(\text{immh:immb}))$ when $\text{immh} = 01xx$

The following encodings are reserved:

- $\text{immh} = 0000$.
- $\text{immh} = 1xxx$.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- $(16-\text{UInt}(\text{immh:immb}))$ when $\text{immh} = 0001$
- $(32-\text{UInt}(\text{immh:immb}))$ when $\text{immh} = 001x$
- $(64-\text{UInt}(\text{immh:immb}))$ when $\text{immh} = 01xx$

See Advanced SIMD modified immediate on page C4-351 when $\text{immh} = 0000$.

The encoding $\text{immh} = 1xxx$ is reserved.

### Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (\text{shift} - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements-1
    element = (\text{Int}(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';
Vpart[d, part] = result;
```
C7.2.306 SQSHRUN, SQSHRUN2

Signed saturating Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see SQRSRUN, SQRSRUN2.

The SQSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

The encoding immh = 1xxx, Q = x is reserved.

</n>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.
The encoding immh = 1xxx is reserved.

<Vb>
Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001
H when immh = 001x
S when immh = 01xx

The following encodings are reserved:
• immh = 0000.
• immh = 1xxx.

<db>
Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va>
Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001
S when immh = 001x
D when immh = 01xx

The following encodings are reserved:
• immh = 0000.
• immh = 1xxx.
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

- \((16-\text{UInt}(\text{immh}:\text{immb}))\) when \(\text{immh} = 0001\)
- \((32-\text{UInt}(\text{immh}:\text{immb}))\) when \(\text{immh} = 001x\)
- \((64-\text{UInt}(\text{immh}:\text{immb}))\) when \(\text{immh} = 01xx\)

The following encodings are reserved:
- \(\text{immh} = 0000\).
- \(\text{immh} = 1xxx\).

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- \((16-\text{UInt}(\text{immh}:\text{immb}))\) when \(\text{immh} = 0001\)
- \((32-\text{UInt}(\text{immh}:\text{immb}))\) when \(\text{immh} = 001x\)
- \((64-\text{UInt}(\text{immh}:\text{immb}))\) when \(\text{immh} = 01xx\)

See Advanced SIMD modified immediate on page C4-351 when \(\text{immh} = 0000\).

The encoding \(\text{immh} = 1xxx\) is reserved.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bv<datasize*2> operand = V[n];
bv<datasize> result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements-1
  element = (SInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
  (Elem[result, e, esize], sat) = UnsignedSatQ(element, esize);
  if sat then FPSR.QC = '1';
Vpart[d, part] = result;
```
C7.2.307 SQSUB

Signed saturating Subtract. This instruction subtracts the element values of the second source SIMD&FP register from the corresponding element values of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

```
[31 30 29 28][27 26 25 24][23 22 21 20]  16|15|14|13|12|11|10|  9 |  5 |  4 |  0 |
  0 | 1 | 0 | 1 | 1 | 1 | 0 | size | 1 | Rm | 0 | 0 | 1 | 0 | 1 | 1 | Rn | Rd
```

C7.2.308  SQXTN, SQXTN2

Signed saturating extract Narrow. This instruction reads each vector element from the source SIMD&FP register, saturates the value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQXTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQXTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

```

- integer datasize = if Q == '1' then 128 else 64;
- integer elements = datasize DIV esize;
- boolean unsigned = (U == '1');

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
  - 4S when size = 10, Q = 1
- The encoding size = 11, Q = x is reserved.
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  Elem[result, e, esize] = (element1+element2+1)<esize:1>;

V[d] = result;
C7.2.311  SRI

Shift Right and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the right of each vector element of the source register are lost.

The following figure shows the operation of shift right by 3 for an 8-bit vector element.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  Elem[result, e, esize] = (Elem[operand2, e, esize] AND NOT(mask)) OR shifted;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### C7.2.312 SRSHL

Signed Rounding Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see SSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1);  // 0 for left shift, 2^(n-1) for right shift
        element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else
        Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
\end{verbatim}
C7.2.313 SRSHR

Signed Rounding Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, places the final result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are rounded. For truncated results, see SSHR.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

- `<V>` is a width specifier, encoded in the "immh" field. It can have the following values:
  - D when `immh = 1xxx`
  - The encoding `immh = 0xxx` is reserved.

- `<d>` is the number of the SIMD&FP destination register, in the "Rd" field.

- `<n>` is the number of the first SIMD&FP source register, encoded in the "Rn" field.

- `<Vd>` is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- `<T>` is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
  - 8B when `immh = 0001`, `Q = 0`
  - 16B when `immh = 0001`, `Q = 1`
  - 4H when `immh = 001x`, `Q = 0`
  - 8H when `immh = 001x`, `Q = 1`
  - 2S when `immh = 01xx`, `Q = 0`
  - 4S when `immh = 01xx`, `Q = 1`
  - 2D when `immh = 1xxx`, `Q = 1`

  See Advanced SIMD modified immediate on page C4-351 when `immh = 0000, Q = x`. The encoding `immh = 1xxx, Q = 0` is reserved.

- `<Vn>` is the name of the SIMD&FP source register, encoded in the "Rn" field.

- `<shift>` For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:
  - `(128-UInt(immh:immb))` when `immh = 1xxx`
  - The encoding `immh = 0xxx` is reserved.

  For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:
  - `(16-UInt(immh:immb))` when `immh = 0001`
  - `(32-UInt(immh:immb))` when `immh = 001x`
  - `(64-UInt(immh:immb))` when `immh = 01xx`
  - `(128-UInt(immh:immb))` when `immh = 1xxx`

  See Advanced SIMD modified immediate on page C4-351 when `immh = 0000`.

Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bite(datasetsize) operand = V[n];
bite(datasetsize) operand2;
bite(datasetsize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;
V[d] = result;
```
Signed Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts each value by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift. For a rounding shift, see SRSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.316 SSHLL, SSHLL2

Signed Shift Left Long (immediate). This instruction reads each vector element from the source SIMD&FP register, left shifts each vector element by the specified shift amount, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SSHLL instruction extracts vector elements from the lower half of the source register, while the SSHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias SXTL, SXTL2. See Alias conditions for details of when each alias is preferred.

<td>immh == 001x</td>
</tr>
</tbody>
</table>
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.

The encoding immh = 1xxx is reserved.

</n> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<shift> Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

(UInt(immh:immb)-8) when immh = 0001
(UInt(immh:immb)-16) when immh = 001x
(UInt(immh:immb)-32) when immh = 01xx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;
for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.317  SSHR

Signed Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, places the final result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are truncated. For rounded results, see SRSHR.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

   Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;
V[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.318 SSRA

Signed Shift Right and Accumulate (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, and accumulates the final results with the vector elements of the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are truncated. For rounded results, see SRSRA.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;
V[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.319  SSUBL, SSUBL2

Signed Subtract Long. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are twice as long as the source vector elements.

The SSUBL instruction extracts each source vector from the lower half of each source register, while the SSUBL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

SSUBL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```plaintext

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- **absent** when Q = 0
- **present** when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- **8H** when size = 00
- **4S** when size = 01
- **2D** when size = 10

The encoding size = 11 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- **88** when size = 00, Q = 0
- **168** when size = 00, Q = 1
The encoding size = 11, Q = x is reserved.

<\m> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
b bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.320 SSUBW, SSUBW2

Signed Subtract Wide. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. All the values in this instruction are signed integer values.

The SSUBW instruction extracts the second source vector from the lower half of the second source register, while the SSUBW2 instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.322  **ST1 (single structure)**

Store a single-element structure from one lane of one register. This instruction stores the specified element of a SIMD&FP register to memory.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.326   ST3 (single structure)

Store single 3-element structure from one lane of three registers. This instruction stores a 3-element structure to memory from corresponding elements of three SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer m = UInt(Rm);
boolean wback = TRUE;
boolean tag_checked = wback || n != 31;

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
When size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

\( <Vt2> \) Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

\( <Vt3> \) Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

\( <Vt4> \) Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.

\( <Xn|SP> \) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

\( <imm> \) Is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

\[ \begin{align*}
#32 & \text{ when } Q = 0 \\
#64 & \text{ when } Q = 1
\end{align*} \]

\( <Xm> \) Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.329   STNP (SIMD&FP)

Store Pair of SIMD&FP registers, with Non-temporal hint. This instruction stores a pair of SIMD&FP registers to memory, issuing a hint to the memory system that the access is non-temporal. The address used for the store is calculated from an address from a base register value and an immediate offset. For information about non-temporal pair instructions, see Load/Store SIMD and Floating-point Non-temporal pair on page C3-216.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

32-bit variant

Applies when $opc == 00$.

$\text{STNP} \ <St1>, \ <St2>, \ [<Xn|SP>{, \ #<imm>}]$

64-bit variant

Applies when $opc == 01$.

$\text{STNP} \ <Dt1>, \ <Dt2>, \ [<Xn|SP>{, \ #<imm>}]$

128-bit variant

Applies when $opc == 10$.

$\text{STNP} \ <Qt1>, \ <Qt2>, \ [<Xn|SP>{, \ #<imm>}]$

Decode for all variants of this encoding

// Empty.

Assembler symbols

$<Dt1>$ Is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.

$<Dt2>$ Is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.

$<Qt1>$ Is the 128-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.

$<Qt2>$ Is the 128-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.

$<St1>$ Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.

$<St2>$ Is the 32-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.

<Xn> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4. For the 64-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8. For the 128-bit variant: is the optional signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the "imm7" field as <imm>/16.

        data = V[t];
        Mem[address, datasize DIV 8, AccType_VEC] = data;
    when MemOp_LOAD
        data = Mem[address, datasize DIV 8, AccType_VEC];
        V[t] = data;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.334   SUB (vector)

Subtract (vector). This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

boolean sub_op = (U == '1');

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:
D when size = 11

The following encodings are reserved:
• size = 0x.
• size = 10.
Is the number of the SIMD&FP destination register, in the "Rd" field.

<n>
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m>
Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<d>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T>
Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>Encoding</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8B</td>
<td>when size = 00, Q = 0</td>
</tr>
<tr>
<td>16B</td>
<td>when size = 00, Q = 1</td>
</tr>
<tr>
<td>4H</td>
<td>when size = 01, Q = 0</td>
</tr>
<tr>
<td>8H</td>
<td>when size = 01, Q = 1</td>
</tr>
<tr>
<td>2S</td>

</tr>
<tr>
<td>4S</td>
<td>when size = 10, Q = 1</td>
</tr>
<tr>
<td>2D</td>
<td>when size = 11, Q = 1</td>
</tr>
</tbody>
</table>

The encoding size = 11, Q = 0 is reserved.

<n>
Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<m>
Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.335  SUBHN, SUBHN2

Subtract returning High Narrow. This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values.

The results are truncated. For rounded results, see RSUBHN, RSUBHN2.

The SUBHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
0  Q 0  0 1 1 0  size 1  Rd  0 1 1 0 0  Rn  0 1 0 0  Rm
```

Three registers, not all the same type variant

SUBHN(2) <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

Decode for this encoding

- integer d = UInt(Rd);
- integer n = UInt(Rn);
- integer m = UInt(Rm);

- if size == '11' then UNDEFINED;
- integer esize = 8 << UInt(size);
- integer datasize = 64;
- integer part = UInt(Q);
- integer elements = datasize DIV esize;

- boolean sub_op = (o1 == '1');
- boolean round = (U == '1');

Assembler symbols

<table>
<thead>
<tr>
<th>2</th>

<td>01</td>
<td>4S</td>
<td>when size = 01</td>
</tr>
<tr>
<td>10</td>
<td>2D</td>
<td>when size = 10</td>
</tr>
</tbody>
</table>

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bv<2*datasize> operand1 = V[n];
bv<2*datasize> operand2 = V[m];
bv<datasize> result;
integer round_const = if round then 1 << (esize - 1) else 0;
bv<2*esize> element1;
bv<2*esize> element2;
bv<2*esize> sum;

for e = 0 to elements-1
  element1 = Elem[operand1, e, 2*esize];
  element2 = Elem[operand2, e, 2*esize];
  if sub_op then
    sum = element1 - element2;
  else
    sum = element1 + element2;
  sum = sum + round_const;
  Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.336  SUDOT (by element)

Dot product index form with signed and unsigned integers. This instruction performs the dot product of the four signed 8-bit integer values in each 32-bit element of the first source register with the four unsigned 8-bit integer values in an indexed 32-bit element of the second source register, accumulating the result into the corresponding 32-bit element of the destination vector.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.18MM indicates whether this instruction is supported.

ARMv8.6

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20</th>

Vector variant

SUDOT <Vd>..<Ta>, <Vn>.<Tb>, <Vm>.4B[<index>]

Decode for this encoding

if !HaveInt8MatMulExt() then UNDEFINED;
boolean op1_unsigned = (US == '1');
boolean op2_unsigned = (US == '0');
integer n = UInt(Rn);
integer m = UInt(M:Rm);
integer d = UInt(Rd);
integer i = UInt(H:L);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 32;

Assembler symbols

<Vd>  Is the name of the SIMD&FP third source and destination register, encoded in the "Rd" field.
<Ta>  Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
    2S when Q = 0
    4S when Q = 1
<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Tb>  Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
    8B when Q = 0
    16B when Q = 1
<Vm>  Is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.
<index>  Is the immediate index of a quadtuplet of four 8-bit elements in the range 0 to 3, encoded in the "H:L" fields.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(128) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
for e = 0 to elements-1
    bits(32) res = Elem[operand3, e, 32];
    for b = 0 to 3
        integer element1 = Int(Elem[operand1, 4*e+b, 8], op1_unsigned);
        integer element2 = Int(Elem[operand2, 4*i+b, 8], op2_unsigned);
        res = res + element1 * element2;
    Elem[result, e, 32] = res;
V[d] = result;
C7.2.337   SUQADD

Signed saturating Accumulate of Unsigned value. This instruction adds the unsigned integer values of the vector elements in the source SIMD&FP register to corresponding signed integer values of the vector elements in the destination SIMD&FP register, and writes the resulting signed integer values to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

```
[31 30 29 28][27 26 25 24][23 22 21 20][19 18 17 16][15 14 13 12][11 10 9] | 5 4 | 0 |
0 1 0 1 1 1 1 0 | size 1 0 0 0 0 0 0 1 1 0 | Rd 5 | Rn 4 | 0 0
```

0 1 0 1 1 1 0 | size 1 0 0 0 0 0 1 1 0 | Rd 5 | Rn 4 | 0 0
```

Vector variant

SUQADD <Vd>.<T>, <Vn>.<T>

Decode for this encoding

```java
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

```markdown
<V>
Is a width specifier, encoded in the "size" field. It can have the following values:

- 8 when size = 00
```
when size = 01
S when size = 10
D when size = 11

\(<d>\) Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

\(<n>\) Is the number of the SIMD&FP source register, encoded in the "Rn" field.

\(<Vd>\) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\(<T>\) Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

\(<Vn>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(datasize) operand2 = V[d];
integer op1;
integer op2;
boolean sat;

for e = 0 to elements-1
    op1 = Int(Elem[operand, e, esize], !unsigned);
    op2 = Int(Elem[operand2, e, esize], unsigned);
    (Elem[result, e, esize], sat) = SatQ(op1 + op2, esize, unsigned);
    if sat then FPSR.QC = '1';
V[d] = result;
```
C7.2.338  SXTL, SXTL2

Signed extend Long. This instruction duplicates each vector element in the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SXTL instruction extracts the source vector from the lower half of the source register, while the SXTL2 instruction extracts the source vector from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the SSHLL, SSHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of SSHLL, SSHLL2.
- The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

### Vector variant

\[
\text{\texttt{SXTL}\{2\} <Vd>.<Ta>, <Vn>.<Tb>}
\]

is equivalent to

\[
\text{\texttt{SSHLL}\{2\}  <Vd>.<Ta>, <Vn>.<Tb>, #0}
\]

and is the preferred disassembly when \(\text{BitCount(immh)} = 1\).

### Assembler symbols

- \(2\) is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  - \([\text{absent}]\) when \(Q = 0\)
  - \([\text{present}]\) when \(Q = 1\)

- \(<Vd>\) is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- \(<Ta>\) is an arrangement specifier, encoded in the "immh" field. It can have the following values:
  - \(8H\) when \(\text{immh} = 0001\)
  - \(4S\) when \(\text{immh} = 001x\)
  - \(2D\) when \(\text{immh} = 01xx\)

  See Advanced SIMD modified immediate on page C4-351 when \(\text{immh} = 0000\).

  The encoding \(\text{immh} = 1xxx\) is reserved.

- \(<Vn>\) is the name of the SIMD&FP source register, encoded in the "Rn" field.

- \(<Tb>\) is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
  - \(8B\) when \(\text{immh} = 0001, Q = 0\)
  - \(16B\) when \(\text{immh} = 0001, Q = 1\)
  - \(4H\) when \(\text{immh} = 001x, Q = 0\)
  - \(8H\) when \(\text{immh} = 001x, Q = 1\)
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

**Operation**
The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

**Operational information**
If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.339  TBL

Table vector Lookup. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the result for that lookup is 0. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Two register table variant
Applies when len == 01.
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B }, <Vm>.<Ta>

Three register table variant
Applies when len == 10.
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B }, <Vm>.<Ta>

Four register table variant
Applies when len == 11.
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B, <Vn+3>.16B }, <Vm>.<Ta>

Single register table variant
Applies when len == 00.
TBL <Vd>.<Ta>, { <Vn>.16B }, <Vm>.<Ta>

Decode for all variants of this encoding

\[
\begin{array}{cccccccccccccccc}
\hline
0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & Rm & 0 & len & 0 & 0 & Rn & 0 & Rd
\end{array}
\]

Assembler symbols

</Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ta>  Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>16B</th>
<th>8B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

</Vn>  For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the "Rn" field.
For the single register table variant: is the name of the SIMD&FP table register, encoded in the "Rn" field.

<Vn+1> Is the name of the second SIMD&FP table register, encoded as "Rn" plus 1 modulo 32.

<Vn+2> Is the name of the third SIMD&FP table register, encoded as "Rn" plus 2 modulo 32.

<Vn+3> Is the name of the fourth SIMD&FP table register, encoded as "Rn" plus 3 modulo 32.

<Vm> Is the name of the SIMD&FP index register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) indices = V[m];
bits(128*regs) table = Zeros();
bits(datasize) result;
integer index;

// Create table from registers
for i = 0 to regs-1
    table<128*i+127:128*i> = V[n];
    n = (n + 1) MOD 32;
result = if is_tbl then Zeros() else V[d];
for i = 0 to elements-1
    index = UInt(Elem[indices, i, 8]);
    if index < 16 * regs then
        Elem[result, i, 8] = Elem[table, index, 8];
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.340   TBX

Table vector lookup extension. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the existing value in the vector element of the destination register is left unchanged. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Two register table variant
Applies when \( \text{len} = 01 \).

\[
\text{TBX} \ <V_d>.<Ta>, \ \{ \ <V_n>.16B, \ <V_{n+1}>.16B \} \ , \ <V_m>.<Ta>
\]

Three register table variant
Applies when \( \text{len} = 10 \).

\[
\text{TBX} \ <V_d>.<Ta>, \ \{ \ <V_n>.16B, \ <V_{n+1}>.16B, \ <V_{n+2}>.16B \} \ , \ <V_m>.<Ta>
\]

Four register table variant
Applies when \( \text{len} = 11 \).

\[
\text{TBX} \ <V_d>.<Ta>, \ \{ \ <V_n>.16B, \ <V_{n+1}>.16B, \ <V_{n+2}>.16B, \ <V_{n+3}>.16B \} \ , \ <V_m>.<Ta>
\]

Single register table variant
Applies when \( \text{len} = 00 \).

\[
\text{TBX} \ <V_d>.<Ta>, \ \{ \ <V_n>.16B \} \ , \ <V_m>.<Ta>
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \ \text{UInt}(Rd); \\
\text{integer } n &= \ \text{UInt}(Rn); \\
\text{integer } m &= \ \text{UInt}(Rm); \\
\text{integer } \text{datasize} &= \text{if } Q == '1' \text{ then } 128 \text{ else } 64; \\
\text{integer } \text{elements} &= \text{datasize DIV } 8; \\
\text{integer } \text{regs} &= \ \text{UInt}(\text{len}) + 1; \\
\text{boolean } \text{is_tbl} &= (\text{op} == '0');
\end{align*}
\]

Assembler symbols

\(<V_d>\)          Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
\(<Ta>\)           Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
                   \(8B\) when \( Q = 0 \)
                   \(16B\) when \( Q = 1 \)
<Vn> For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the "Rn" field.
For the single register table variant: is the name of the SIMD&FP table register, encoded in the "Rn" field.

<Vn+1> Is the name of the second SIMD&FP table register, encoded as "Rn" plus 1 modulo 32.

<Vn+2> Is the name of the third SIMD&FP table register, encoded as "Rn" plus 2 modulo 32.

<Vn+3> Is the name of the fourth SIMD&FP table register, encoded as "Rn" plus 3 modulo 32.

<Vm> Is the name of the SIMD&FP index register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
b_bits(datasize) indices = V[m];
b_bits(128*regs) table = Zeros();
b_bits(datasize) result;
integer index;

// Create table from registers
for i = 0 to regs-1
    table<128*i+127:128*i> = V[n];
    n = (n + 1) MOD 32;

result = if is_tbl then Zeros() else V[d];
for i = 0 to elements-1
    index = UInt(Elem[indices, i, 8]);
    if index < 16 * regs then
        Elem[result, i, 8] = Elem[table, index, 8];

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.341   TRN1

Transpose vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

--- Note ---

By using this instruction with TRN2, a 2 x 2 matrix can be transposed.

The following figure shows the operation of TRN1 and TRN2 halfword operations where Q = 0.

![Figure showing operation of TRN1 and TRN2 halfword operations](image)

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

TRN1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

Assembler symbols

```plaintext

Assembler symbols

2     Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H when size = 00
- 4S when size = 01
- 2D when size = 10

The encoding size = 11 is reserved.

<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<\m> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.349  UADDP

Unsigned Add Long Pairwise. This instruction adds pairs of adjacent unsigned integer values from the vector in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
[31 30 29 28][27 26 25 24][23 22 21 20][19 18 17 16][15 14 13 12][11 10 9] | [5 4] [0]

**Decode for this encoding**

- integer d = UInt(Rd);
- integer n = UInt(Rn);
- if size:Q == '100' then UNDEFINED;
- if size == '11' then UNDEFINED;
- integer esize = 8 << UInt(size);
- integer datasize = if Q == '1' then 128 else 64;
- integer elements = datasize DIV esize;
- boolean unsigned = (U == '1');

**Assembler symbols**

- <V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
  - H when size = 00
  - S when size = 01
  - D when size = 10

  The encoding size = 11 is reserved.

- <d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 4S when size = 10, Q = 1

  The following encodings are reserved:
  - size = 10, Q = 0.
  - size = 11, Q = x.
**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer sum;

sum = int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    sum = sum + int(Elem[operand, e, esize], unsigned);

V[d] = sum<2*esize-1:0>;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.351 UADDW, UADDW2

Unsigned Add Wide. This instruction adds the vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. The vector elements of the destination register and the first source register are twice as long as the vector elements of the second source register. All the values in this instruction are unsigned integer values.

The UADDW instruction extracts vector elements from the lower half of the second source register, while the UADDW2 instruction extracts vector elements from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

\]

### 64-bit to double-precision variant

Applies when \( sf = 1 \) \&\& \( ftype = 01 \).

\[
UCVTF <Dd>, <Xn>, #<fbits>
\]

#### Decode for all variants of this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPRounding rounding;
```
case ftype of
  when '00' fltsize = 32;
  when '01' fltsize = 64;
  when '10' UNDEFINED;
  when '11'
    if HaveFP16Ext() then
      fltsize = 16;
    else
      UNDEFINED;
if sf == '0' && scale<5> == '0' then UNDEFINED;
integer fracbits = 64 - UInt(scale);
rounding = FPRoundingMode(FPCR);

Assembler symbols

<Dr> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<fbits> For the 32-bit to double-precision, 32-bit to half-precision and 32-bit to single-precision variant: is the number of bits after the binary point in the fixed-point source, in the range 1 to 32, encoded as 64 minus "scale".
For the 64-bit to double-precision, 64-bit to half-precision and 64-bit to single-precision variant: is the number of bits after the binary point in the fixed-point source, in the range 1 to 64, encoded as 64 minus "scale".

Operation

CheckFPAdvSIMDEnabled64();
bits(fltsize) fltval;
bits(intsize) intval;
intval = X[n];
fltval = FixedToFP(intval, fracbits, TRUE, FPCR, rounding);
V[d] = fltval;
C7.2.355 **UCVTF (scalar, integer)**

Unsigned integer Convert to Floating-point (scalar). This instruction converts the unsigned integer value in the general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-2354.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

intval = X[n];
fltval = FixedToFP(intval, 0, TRUE, FPCR, rounding);
V[d] = fltval;
C7.2.356   UDOT (by element)

Dot Product unsigned arithmetic (vector, by element). This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

--- Note ---
ID_AA64ISAR0_EL1.DP indicates whether this instruction is supported.

---

  element2 = Int(Elem[operand2, e, esize], unsigned);
  maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
  Elem[result, e, esize] = maxmin<esize-1:0>;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.364  UMINP

Unsigned Minimum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant
UMINP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.366  **UMLAL, UMLAL2 (by element)**

Unsigned Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The **UMLAL** instruction extracts vector elements from the lower half of the first source register, while the **UMLAL2** instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

\[ \text{UMLAL}\{2\}<Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>] \]

### Decode for this encoding

```
integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
```

### Assembler symbols

- **2**  
  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  - [absent] when \( Q = 0 \)
  - [present] when \( Q = 1 \)

- **<Vd>**  
  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- **<Ta>**  
  Is an arrangement specifier, encoded in the "size" field. It can have the following values:
    - 4S when size = 01
    - 2D when size = 10

The following encodings are reserved:
- size = 00.
size = 11.

\(<Vn>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<Tb>\) Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

\(4H\) when \(size = 01, Q = 0\)

\(8H\) when \(size = 01, Q = 1\)

\(2S\) when \(size = 10, Q = 0\)

\(4S\) when \(size = 10, Q = 1\)

The following encodings are reserved:

- \(size = 00, Q = x\).
- \(size = 11, Q = x\).

\(<Vm>\) Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

\(0:Rm\) when \(size = 01\)

\(M:Rm\) when \(size = 10\)

The following encodings are reserved:

- \(size = 00\).
- \(size = 11\).

Restricted to V0-V15 when element size \(<Ts>\) is H.

\(<Ts>\) Is an element size specifier, encoded in the "size" field. It can have the following values:

\(H\) when \(size = 01\)

\(S\) when \(size = 10\)

The following encodings are reserved:

- \(size = 00\).
- \(size = 11\).

\(<index>\) Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

\(H:L:M\) when \(size = 01\)

\(H:L\) when \(size = 10\)

The following encodings are reserved:

- \(size = 00\).
- \(size = 11\).

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsized) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else
```

```c
```
\[
\text{Elem}[\text{result}, e, 2\times \text{esize}] = \text{Elem}[\text{operand3}, e, 2\times \text{esize}] + \text{product};
\]

\[V[d] = \text{result};\]

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.367   UMLAL, UMLAL2 (vector)

Unsigned Multiply-Add Long (vector). This instruction multiplies the vector elements in the lower or upper half of the first source SIMD&FP register by the corresponding vector elements of the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLAL instruction extracts vector elements from the lower half of the first source register, while the UMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
8H when size = 00
4S when size = 01
2D when size = 10
The encoding size = 11 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H  when size = 01, Q = 0
8H  when size = 01, Q = 1
2S  when size = 10, Q = 0
4S  when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

\(<Vm>\)  Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bias(datasize) operand1 = Vpart[n, part];
bias(datasize) operand2 = Vpart[m, part];
bias(2*datasize) operand3 = V[d];
bias(2*datasize) result;
integer element1;
integer element2;
bias(2*esize) product;
bias(2*esize) accum;

for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  product = (element1*element2)<2*esize-1:0>;
  if sub_op then
    accum = Elem[operand3, e, 2*esize] - product;
  else
    accum = Elem[operand3, e, 2*esize] + product;

  Elem[result, e, 2*esize] = accum;

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.368  UMLSL, UMLSL2 (by element)

Unsigned Multiply-Subtract Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLSL instruction extracts vector elements from the lower half of the first source register, while the UMLSL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

\[ \text{UMLSL} \{2\} \begin{array}{c} \langle Vd \rangle, \langle Ta \rangle, \langle Vn \rangle, \langle Tb \rangle, \langleVm \rangle, \langle Ts \rangle \end{array}[\langle index \rangle] \]

### Decode for this encoding

```plaintext
integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
```

### Assembler symbols

- **2**: Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  - [absent] when Q = 0
  - [present] when Q = 1

        accum = Elem[operand3, e, 2*biasize] - product;
    else
        accum = Elem[operand3, e, 2*biasize] + product;
    Elem[result, e, 2*biasize] = accum;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.370 UMMLA (vector)

Unsigned 8-bit integer matrix multiply-accumulate. This instruction multiplies the 2x8 matrix of unsigned 8-bit integer values in the first source vector by the 8x2 matrix of unsigned 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

ARMv8.6

Vector variant

UMMLA <Vd>.4S, <Vn>.16B, <Vm>.16B

Decode for this encoding

if !HaveInt8MatMulExt() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);
integer d = UInt(Rd);

Assembler symbols

<Vd> Is the name of the SIMD&FP third source and destination register, encoded in the "Rd" field.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(128) operand1 = V[n];
bits(128) operand2 = V[m];
bits(128) addend = V[d];
V[d] = MatMulAdd(addend, operand1, operand2, TRUE, TRUE);
C7.2.371 UMOV

Unsigned Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (to general). See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when Q == 0.
UMOV <Wd>, <Vn>.<Ts>[<index>]

64-reg, UMOV-64-reg variant
Applies when Q == 1 && imm5 == x1000.
UMOV <Xd>, <Vn>.<Ts>[<index>]

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size;
case Q:imm5 of
  when '0xxxx1' size = 0;    // UMOV Wd, Vn.B

</tbody>
</table>

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ts> For the 32-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>imm5 = xxxx1</td>
</tr>
<tr>
<td>H</td>
<td>imm5 = xx10</td>
</tr>
<tr>
<td>S</td>
<td>imm5 = xx100</td>
</tr>
</tbody>
</table>

The encoding imm5 = xx000 is reserved.

For the 64-reg, UMOV-64-reg variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>imm5 = x1000</td>
</tr>
</tbody>
</table>

The following encodings are reserved:

- imm5 = x0000
- imm5 = xxxx1
- imm5 = xxx10
- imm5 = xx100

@index> For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:

<table>
<thead>
<tr>
<th>Encoding</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>imm5&lt;4:1&gt;</td>
<td>imm5 = xxxx1</td>
</tr>
<tr>
<td>imm5&lt;4:2&gt;</td>
<td>imm5 = xx10</td>
</tr>
<tr>
<td>imm5&lt;4:3&gt;</td>
<td>imm5 = xx100</td>
</tr>
</tbody>
</table>

The encoding imm5 = xx000 is reserved.

For the 64-reg, UMOV-64-reg variant: is the element index encoded in "imm5<4>".

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];

X[d] = ZeroExtend(Elem[operand, index, esize], datasize);
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.372 UMULL, UMULL2 (by element)

Unsigned Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMULL instruction extracts vector elements from the lower half of the first source register, while the UMULL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  [absent] when Q = 0
  [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  45 when size = 01
  20 when size = 10
The following encodings are reserved:
  • size = 00.
  • size = 11.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:
- size = 00, Q = x.
- size = 11, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
- 0:Rm when size = 01
- M:Rm when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
- H when size = 01
- S when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

:index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- H:L:M when size = 01
- H:L when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsize) operand2 = V[m];
bits(2*datasize) result;
integer element1;
integer element2;

  (Elem[result, e, esize], sat) = SatQ(sum, esize, unsigned);
  if sat then FPSR.QC = '1';
V[d] = result;
C7.2.375   UQRSHL

Unsigned saturating Rounding Shift Left (register). This instruction takes each vector element of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see UQSHL (immediate).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

        Elem[result, e, esize] = element<esize-1:0>;
V[d] = result;
```

### C7.2.376  **UQRSHRN, UQRSHRN2**

Unsigned saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are rounded. For truncated results, see **UQSHRN, UQSHRN2**.

The **UQRSHRN** instruction writes the vector to the lower half of the destination register and clears the upper half, while the **UQRSHRN2** instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit **FPSR.QC** is set.

Depending on the settings in the **CPACR_EL1, CPTR_EL2, and CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- \( \text{immb} = 01xx \):
  - \(64-\text{UInt}(\text{immh:immb}) \) when \( \text{immh} = 01xx\)

See Advanced SIMD modified immediate on page C4-351 when \( \text{immh} = 0000. \)

The encoding \( \text{immh} = 1xxx \) is reserved.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';
Vpart[d, part] = result;
```
C7.2.377  UQSHL (immediate)

Unsigned saturating Shift Left (immediate). This instruction takes each vector element in the source SIMD&FP register, shifts it by an immediate value, places the results in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.
C7.2.378  UQSHL (register)

Unsigned saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

---

As a helpful assistant, I can provide you with a summary or specific information from the document. Please let me know how I can assist you further.
C7.2.379 UQSHRN, UQSHRN2
Unsigned saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see UQRSHRN, UQRSHRN2.

The UQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper
64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have
the following values:
[absent]  when Q = 0
[present]  when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>  Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
  8B  when immh = 0001, Q = 0
  16B when immh = 0001, Q = 1
  4H  when immh = 001x, Q = 0
  8H  when immh = 001x, Q = 1
  2S  when immh = 01xx, Q = 0
  4S  when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<Vn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>  Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
  8H  when immh = 0001
  4S  when immh = 001x
  2D  when immh = 01xx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.
The encoding immh = 1xxx is reserved.

<Vb>  Is the destination width specifier, encoded in the "immh" field. It can have the following values:
  B  when immh = 0001
  H  when immh = 001x
  S  when immh = 01xx

The following encodings are reserved:
  • immh = 0000.
  • immh = 1xxx.

<d>  Is the number of the SIMD&FP destination register, in the "Rd" field.

<va> Is the source width specifier, encoded in the "immh" field. It can have the following values:
  H  when immh = 0001
  S  when immh = 001x
  D  when immh = 01xx
The following encodings are reserved:
- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

\(<n>\) Is the number of the first SIMD\&FP source register, encoded in the "Rn" field.

\(<\text{shift}>\) For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:
- \(16\text{-UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 0001\)
- \(32\text{-UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 001x\)
- \(64\text{-UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 01xx\)

The following encodings are reserved:
- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:
- \(16\text{-UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 0001\)
- \(32\text{-UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 001x\)
- \(64\text{-UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 01xx\)

See Advanced SIMD modified immediate on page C4-351 when \(\text{immh} = 0000\).

The encoding \( \text{immh} = 1xxx \) is reserved.

**Operation for all encodings**

    element2 = Int(Elem[operand2, e, esize], unsigned);
    diff = element1 - element2;
    (Elem[result, e, esize], sat) = SatQ(diff, esize, unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.381 UQXTN, UQXTN2

Unsigned saturating extract Narrow. This instruction reads each vector element from the source SIMD&FP register, saturates each value to half the original width, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The UQXTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQXTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when $Q = 0$
[present] when $Q = 1$

$<Vd>$

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

$<Tb>$

Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when $\text{size} = 00, Q = 0$
16B when $\text{size} = 00, Q = 1$
4H when $\text{size} = 01, Q = 0$
8H when $\text{size} = 01, Q = 1$
2S when $\text{size} = 10, Q = 0$
4S when $\text{size} = 10, Q = 1$

The encoding $\text{size} = 11, Q = x$ is reserved.

$<Vn>$

Is the name of the SIMD&FP source register, encoded in the "Rn" field.

$<Ta>$

Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when $\text{size} = 00$
4S when $\text{size} = 01$
2D when $\text{size} = 10$

The encoding $\text{size} = 11$ is reserved.

$<Vb>$

Is the destination width specifier, encoded in the "size" field. It can have the following values:

B when $\text{size} = 00$
H when $\text{size} = 01$
S when $\text{size} = 10$

The encoding $\text{size} = 11$ is reserved.

$<d>$

Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

$<Va>$

Is the source width specifier, encoded in the "size" field. It can have the following values:

H when $\text{size} = 00$
S when $\text{size} = 01$
D when $\text{size} = 10$

The encoding $\text{size} = 11$ is reserved.

$<n>$

Is the number of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;
boolean sat;

for e = 0 to elements-1
  element = Elem[operand, e, 2*esize];
  (Elem[result, e, esize], sat) = SatQ(Int(element, unsigned), esize, unsigned);
if sat then FPSR.QC = '1';

Vpart[d, part] = result;
**C7.2.382 URECPE**

Unsigned Reciprocal Estimate. This instruction reads each vector element from the source SIMD&FP register, calculates an approximate inverse for the unsigned integer value, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
<table>
<thead>
<tr>

</table>

Rn   Rd
```

**Vector variant**

URECPE <Vd>.<T>, <Vn>.<T>

**Decode for this encoding**

- integer d = UInt(Rd);
- integer n = UInt(Rn);
- if sz == '1' then UNDEFINED;
- integer esize = 32;
- integer datasize = if Q == '1' then 128 else 64;
- integer elements = datasize DIV esize;

**Assembler symbols**

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
  - 2S when sz = 0, Q = 0
  - 4S when sz = 0, Q = 1
  - The encoding sz = 1, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(32) element;
for e = 0 to elements-1
    element = Elem[operand, e, 32];
    Elem[result, e, 32] = UnsignedRecipEstimate(element);
V[d] = result;
```
C7.2.383  URHADD

Unsigned Rounding Halving Add. This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see UHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

URHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>  Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  Elem[result, e, esize] = (element1+element2+1)\<esize:1>;

V[d] = result;
C7.2.384 URSHL

Unsigned Rounding Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

        res = res + element1 * element2;
        Elem[result, e, 32] = res;
    V[d] = result;
C7.2.390  USHL

Unsigned Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift. For a rounding shift, see URSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.391 USHLL, USHLL2

Unsigned Shift Left Long (immediate). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, shifts the unsigned integer value left by the specified number of bits, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The USHLL instruction extracts vector elements from the lower half of the source register, while the USHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias UXTL, UXTL2. See Alias conditions for details of when each alias is preferred.

Vector variant

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx
See Advanced SIMD modified immediate on page C4-351 when imm = 0000.
The encoding immh = 1xxx is reserved.

\(<\text{n}>\)

Is the name of the SIMD&FP source register, encoded in the "Rn" field.

\(<\text{Tb}>\)

Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

\(<\text{shift}>\)

Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.
The encoding immh = 1xxx is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.392 USHR

Unsigned Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see URSHR.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  - The values of the NZCV flags.
C7.2.393   **USMMLA (vector)**

Unsigned and signed 8-bit integer matrix multiply-accumulate. This instruction multiplies the 2x8 matrix of unsigned 8-bit integer values in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2 to Armv8.5, this is an optional instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

**ARMv8.6**

```
[31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14 13 12|11 10 9 | 5 4 | 0 ]
0 | 1 0 1 1 0 1 0 0 | Rm | 1 0 1 0 1 1 | Rn | Rd |
```

if !HaveInt8MatMulExt() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);
integer d = UInt(Rd);
```

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP third source and destination register, encoded in the "Rd" field.
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(128) operand1 = V[n];
bits(128) operand2 = V[m];
bits(128) addend = V[d];
V[d] = MatMulAdd(addend, operand1, operand2, TRUE, FALSE);
```
C7.2.394  USQADD

Unsigned saturating Accumulate of Signed value. This instruction adds the signed integer values of the vector elements in the source SIMD&FP register to corresponding unsigned integer values of the vector elements in the destination SIMD&FP register, and accumulates the resulting unsigned integer values with the vector elements of the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sat then FPSR.QC = '1';
V[d] = result;
```

C7.2.395 USRA

Unsigned Shift Right and Accumulate (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, and accumulates the final results with the vector elements of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see URSRA.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Scalar**

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:
   D when immh = 1xxx
   The encoding immh = 0xxx is reserved.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
   8B when immh = 0001, Q = 0
   16B when immh = 0001, Q = 1
   4H when immh = 001x, Q = 0
   8H when immh = 001x, Q = 1
   2S when immh = 01xx, Q = 0
   4S when immh = 01xx, Q = 1
   2D when immh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-351 when immh = 0000, Q = x.
   The encoding immh = 1xxx, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:
   (128-UInt(immh:immb)) when immh = 1xxx
   The encoding immh = 0xxx is reserved.

For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:
   (16-UInt(immh:immb)) when immh = 0001
   (32-UInt(immh:immb)) when immh = 001x
   (64-UInt(immh:immb)) when immh = 01xx
   (128-UInt(immh:immb)) when immh = 1xxx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;
V[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.396 USUBL, USUBL2

Unsigned Subtract Long. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The destination vector elements are twice as long as the source vector elements.

The USUBL instruction extracts each source vector from the lower half of each source register, while the USUBL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8 when size = 00
- 4 when size = 01
- 2 when size = 10

The encoding size = 11 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- **8B** when \(size = 00, Q = 0\)
- **16B** when \(size = 00, Q = 1\)
- **4H** when \(size = 01, Q = 0\)
- **8H** when \(size = 01, Q = 1\)
- **2S** when \(size = 10, Q = 0\)
- **4S** when \(size = 10, Q = 1\)

The encoding \(size = 11, Q = x\) is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>:

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.398 UXTL, UXTL2

Unsigned extend Long. This instruction copies each vector element from the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The UXTL instruction extracts vector elements from the lower half of the source register, while the UXTL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the USHLL, USHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of USHLL, USHLL2.
- The description of USHLL, USHLL2 gives the operational pseudocode for this instruction.

Vector variant

UXTL2 {2} <Vd>.<Ta>, <Vn>.<Tb>

is equivalent to

USHLL2 {2} <Vd>.<Ta>, <Vn>.<Tb>, #0

and is the preferred disassembly when BitCount(immh) == 1.

Assembler symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd>

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>

Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when immh = 0001
- 4S when immh = 001x
- 2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-351 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn>

Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb>

Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
25 when immh = 01xx, Q = 0
45 when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-351 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

**Operation**

The description of USHLL, USHLL2 gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.399   UZP1

Unzip vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

--- Note ---

This instruction can be used with UZP2 to de-interleave two vectors.

The following figure shows the operation of UZP1 and UZP2 with the arrangement specifier 8B.

```
Vn
A7 A6 A5 A4 A3 A2 A1 A0
Vm
B7 B6 B5 B4 B3 B2 B1 B0

UZP1.8, doubleword

Vd B6 B4 B2 B0 A8 A6 A4 A2 A0

UZP2.8, doubleword

Vd B7 B5 B3 B1 A7 A5 A3 A1
```

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

UZP1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);

bits(128) Vm = V[m];
bits(128) Vn = V[n];
bits(128) tmp;
tmp = Vn EOR Vm;
V[d] = ROR(tmp<127:64>, UInt(imm6))::ROR(tmp<63:0>, UInt(imm6));

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.402  XTN, XTN2

Extract Narrow. This instruction reads each vector element from the source SIMD&FP register, narrows each value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

The XTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the XTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

Decode for this encoding

The encoding size = 11, Q = x is reserved.

<Vn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00
when size = 01
20 when size = 10

The encoding size = 11 is reserved.

### Operation

```plaintext
checkFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, 2*esize];
    Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.403 ZIP1

Zip vectors (primary). This instruction reads adjacent vector elements from the lower half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

--- Note ---

This instruction can be used with ZIP2 to interleave two vectors.

The following figure shows the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.

![Vector Diagram]

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

ZIP1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8B</td>
<td>when size = 00, Q = 0</td>
</tr>
<tr>
<td>16B</td>
<td>when size = 00, Q = 1</td>
</tr>
<tr>
<td>4H</td>
<td>when size = 01, Q = 0</td>
</tr>
<tr>
<td>8H</td>
<td>when size = 01, Q = 1</td>
</tr>
<tr>
<td>2S</td>
<td>when size = 10, Q = 0</td>
</tr>
</tbody>
</table>
45 when size = 10, Q = 1
20 when size = 11, Q = 1
The encoding size = 11, Q = 0 is reserved.

\(<Vn>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<Vm>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer base = part * pairs;

for p = 0 to pairs-1
    Elem[result, 2*p+0, esize] = Elem[operand1, base+p, esize];
    Elem[result, 2*p+1, esize] = Elem[operand2, base+p, esize];

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.404 ZIP2

Zip vectors (secondary). This instruction reads adjacent vector elements from the upper half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

___ Note ___

This instruction can be used with ZIP1 to interleave two vectors.

The following figure shows the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.

```
| Vn | A7 | A6 | A5 | A4 | A3 | A2 | A1 | A0 |
| Vm | B7 | B6 | B5 | B4 | B3 | B2 | B1 | B0 |
```

```
ZIP1.8, doubleword
```

```
ZIP2.8, doubleword
```

```
| Vd  | B3 | A3 | B2 | A2 | B1 | A1 | B0 | A0 |
| Vm  | B7 | A7 | B6 | A6 | B5 | A5 | B4 | A4 |
```

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

ZIP2 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

Assembler symbols

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
The encoding \( \text{size} = 11, Q = 0 \) is reserved.

\(<Vn>\) Is the name of the first SIMD&FP source register, encoded in the \( \text{"Rn"} \) field.

\(<Vm>\) Is the name of the second SIMD&FP source register, encoded in the \( \text{"Rm"} \) field.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer base = part \times pairs;

for p = 0 to pairs-1
    Elem[result, 2*p+0, esize] = Elem[operand1, base+p, esize];
    Elem[result, 2*p+1, esize] = Elem[operand2, base+p, esize];

V[d] = result;
```

**Operational information**

If \( \text{PSTATE.DIT} \) is 1:

  - The values of the NZCV flags.
Part D

The AArch64 System Level Architecture
Chapter D1
The AArch64 System Level Programmers’ Model

This chapter describes the AArch64 system level programmers’ model. It contains the following sections:

• Exception levels on page D1-2312.
• Exception terminology on page D1-2313.
• Execution state on page D1-2315.
• Security state on page D1-2316.
• Virtualization on page D1-2318.
• Registers for instruction processing and exception handling on page D1-2321.
• Process state, PSTATE on page D1-2324.
• Program counter and stack pointer alignment on page D1-2327.
• Reset on page D1-2329.
• Exception entry on page D1-2333.
• Exception return on page D1-2344.
• Synchronous exception types, routing and priorities on page D1-2348.
• Asynchronous exception types, routing, masking and priorities on page D1-2357.
• Configurable instruction enables and disables, and trap controls on page D1-2367.
• System calls on page D1-2390.
• Mechanisms for entering a low-power state on page D1-2391.
• Self-hosted debug on page D1-2397.
• Event monitors on page D1-2399.
• Interprocessing on page D1-2400.
• The effect of implementation choices on the programmers’ model on page D1-2413.
D1.1 Exception levels

The Armv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If ELn is the Exception level, increased values of n indicate increased software execution privilege.
- Execution at EL0 is called unprivileged execution.
- EL2 provides support for virtualization.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

--- Note ---
A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

The effect of implementation choices on the programmers’ model on page D1-2413 shows some example implementations.

When executing in AArch64 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the target Exception level of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

Exception levels exist within a particular Security state. The Armv8-A security model on page D1-2316 describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.

- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then when execution is at EL3, the PE can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see Chapter D5 The AArch64 Virtual Memory System Architecture.

D1.1.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

<table>
<thead>
<tr>
<th>Exception Level</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>Applications</td>
</tr>
<tr>
<td>EL1</td>
<td>OS kernel and associated functions that are typically described as privileged.</td>
</tr>
<tr>
<td>EL2</td>
<td>Hypervisor</td>
</tr>
<tr>
<td>EL3</td>
<td>Secure monitor</td>
</tr>
</tbody>
</table>
D1.2 Exception terminology

The following subsections define the terms used when describing exceptions:

- Terminology for taking an exception.
- Terminology for returning from an exception.
- Exception levels.
- Definition of a precise exception.
- Definitions of synchronous and asynchronous exceptions on page D1-2314.

D1.2.1 Terminology for taking an exception

An exception is generated when the PE first responds to an exceptional condition. The PE state at this time is the state the exception is taken from. The PE state immediately after taking the exception is the state the exception is taken to.

D1.2.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception returns from. The PE state immediately after the execution of that instruction is the state the exception returns to.

D1.2.3 Exception levels

An Exception level, EL\(_n\), with a larger value of \(n\) than another Exception level, is described as being a higher Exception level than the other Exception level. For example, EL3 is a higher Exception level than EL1.

An Exception level with a smaller value of \(n\) than another Exception level is described as being a lower Exception level than the other Exception level. For example, EL0 is a lower Exception level than EL1.

An Exception level is described as:

- Using AArch64 when execution in that Exception level is in the AArch64 Execution state.
- Using AArch32 when execution in that Exception level is in the AArch32 Execution state.

D1.2.4 Definition of a precise exception

An exception is described as precise when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the SError interrupt, all exceptions taken to AArch64 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch64 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by the instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address used by the instruction.

Also, for synchronous Data Aborts and Watchpoints from load or store instructions executed in AArch64 state:

- If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
- If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
- If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.
Examples of instructions that perform more than one single-copy atomic memory access are the AArch32 LDM and STM instructions and the AArch64 LDP and STP instructions.

--- Note ---
For the definition of a single-copy atomic access, see Properties of single-copy atomic accesses on page B2-120.

**D1.2.5 Definitions of synchronous and asynchronous exceptions**

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

For more information about synchronous exceptions, see Synchronous exception types, routing and priorities on page D1-2348.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about asynchronous exceptions, see Asynchronous exception types, routing, masking and priorities on page D1-2357.
D1.3 Execution state

The Execution states are:

- **AArch64** The 64-bit Execution state.
- **AArch32** The 32-bit Execution state. Operation in this state is compatible with Armv7-A operation.

*Execution state on page A1-37* gives more information about them.

Exception levels use Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

--- Note ---

- *Typical Exception level usage model on page D1-2312* shows which Exception levels different software layers might typically use.
- *The effect of implementation choices on the programmers’ model on page D1-2413* gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. For more information on *interprocessing*, see *Interprocessing on page D1-2400*. 
D1.4 Security state

The Armv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

**Secure state**
When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.

**Non-secure state**
When in this state, the PE:
- Can access only the Non-secure physical address space.
- Cannot access the Secure system control resources.

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see *About the Virtual Memory System Architecture (VMSA)* on page D5-2526.

D1.4.1 The Armv8-A security model

The principles of the Armv8-A security model are:

- If the implementation includes EL3, then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If FEAT_SEL2 is not implemented, EL2 exists only in Non-secure state.
  - If FEAT_SEL2 is implemented, EL2 can exist in Secure state. It is enabled when the value of SCR_EL3.EEL2 is 1.

- If the implementation does not include EL3, it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2 or if FEAT_SEL2 is implemented.
  - Non-secure state, if the implementation includes EL2 and FEAT_SEL2 is not implemented.

**Security model when EL3 is using AArch64 state**

Figure D1-1 on page D1-2317 shows the security model when EL3 is using AArch64 state. The figure shows how instances of EL0 and EL1 are present in both Security states. It also shows the expected software usage of the different Exception levels.
For an overview of the Security model when EL3 is using AArch32, see Figure G1-1 on page G1-5720.
D1.5 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2.

When enabled in the current Security state, EL2 provides a set of features that support virtualizing an Armv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between virtual machines. A virtual machine comprises EL1 and EL0.
- A number of Guest operating systems. A Guest OS runs on a virtual machine in EL1.
- For each Guest operating system, applications, that run on the virtual machine of that Guest OS, usually in EL0.

Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The Armv8-A architecture supports both of these models.

The hypervisor assigns a VMID to each virtual machine.

EL2 supports Guest OS management and provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.

- Trap various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2. See Configurable instruction enables and disables, and trap controls on page D1-2367.

- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

Armv8.1 introduces the Virtualization Host Extensions (VHE) that provide enhanced support for Type 2 hypervisors. For more information, see Virtualization Host Extensions on page D5-2632.

In an implementation that includes EL2:

- The implementation provides an independent translation regime for memory accesses from EL2, the EL2 translation regime. An implementation that includes FEAT_VHE also supports an alternative EL2&0 translation regime.

Note

An implementation that includes FEAT_VHE can be configured so that the EL2&0 translation regime is used both for accesses from EL2 and for accesses from EL0.

- For the EL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the virtual address (VA) to an intermediate physical address (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the physical address (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

- When FEAT_NV is implemented, a Guest Hypervisor can be run at EL1. For more information on how this affects address translation, see Nested virtualization on page D5-2638.
When FEAT_NV2 is implemented, then accesses of EL1 and EL2 registers that would be trapped are instead transformed into memory accesses. For more information, see Enhanced support for nested virtualization on page D5-2640.

For more information on the translation regimes, see Chapter D5 The AArch64 Virtual Memory System Architecture.

D1.5.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

• *HVC* on page C6-930.
• Traps to EL2. *EL2 configurable controls* on page D1-2372, describes these.
• All of the virtual interrupts:
  — Virtual SError.
  — Virtual IRQ.
  — Virtual FIQ.

All virtual interrupts are always taken to EL1, and can only be taken from EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See *Virtual interrupts*.

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3.

For more information, see *Asynchronous exception types, routing, masking and priorities* on page D1-2357.

An implementation that includes EL2 also:

• Provides controls that can be used to route some synchronous exceptions. For more information, see:
  — *Routing exceptions from EL0 to EL2* on page D1-2348.
  — *Routing debug exceptions* on page D2-2423.

• Provides mechanisms to trap PE operations to EL2. For more information, see *EL2 configurable controls* on page D1-2372.

When an operation is trapped to EL2, the hypervisor typically either:

— Emulates the required operation. The application running in the Guest OS is unaware of the trap.
— Returns an error to the Guest OS.

### Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in Table D1-1.

<table>
<thead>
<tr>
<th>Physical interrupt</th>
<th>Corresponding virtual interrupt</th>
</tr>
</thead>
<tbody>
<tr>
<td>SError</td>
<td>Virtual SError</td>
</tr>
<tr>
<td>IRQ</td>
<td>Virtual IRQ</td>
</tr>
<tr>
<td>FIQ</td>
<td>Virtual FIQ</td>
</tr>
</tbody>
</table>

Software executing in EL2 can use virtual interrupts to signal physical interrupts to EL1 and EL0. Example D1-1 on page D1-2320 shows a usage model for virtual interrupts.
Example D1-1 Virtual interrupt usage model

A virtual interrupt usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.

2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
   • If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
   • If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

A hypervisor can prevent EL1 and EL0 from distinguishing a virtual interrupt from a physical interrupt.
D1.6 Registers for instruction processing and exception handling

In the Arm architecture, registers fall into two main categories:

- Registers that provide system control or status reporting. These are described in Chapter D13 AArch64 System Register Descriptions.
- Registers that are used in instruction processing, for example to accumulate a result, and in handling exceptions. This section introduces these registers, for execution in AArch64 state.

This section contains the following subsections:

- The general-purpose registers, R0-R30.
- The stack pointer registers.
- The SIMD and floating-point registers, V0-V31 on page D1-2322.
- Saved Program Status Registers (SPSRs) on page D1-2322.
- Exception Link Registers (ELRs) on page D1-2323.

D1.6.1 The general-purpose registers, R0-R30

The general-purpose register bank is used when processing instructions in the base instruction set. It comprises 31 general-purpose registers, R0-R30.

These registers can be accessed as 31 64-bit registers, X0-X30, or 31 32-bit registers, W0-W30. See Register size on page C6-768.

For information on the format of these registers, see Registers in AArch64 state on page B1-107.

D1.6.2 The stack pointer registers

In AArch64 state, in addition to the general-purpose registers, a dedicated stack pointer register is implemented for each implemented Exception level. The stack pointer registers are:

- SP_EL0 and SP_EL1.
- If the implementation includes EL2, SP_EL2.
- If the implementation includes EL3, SP_EL3.

Note

The four stack pointer register names define an architecture state requirement for four registers. For information on how to access these registers, and access restrictions, see Special-purpose registers on page C5-385.

For information on stack pointer alignment restrictions, see SP alignment checking on page D1-2327.

Stack pointer register selection

When executing at EL0, the PE uses the EL0 stack pointer, SP_EL0.

When executing at any other Exception level, the PE can be configured to use either SP_EL0 or the stack pointer for that Exception level, SP_ELx.

By default, taking an exception selects the stack pointer for the target Exception level, SP_ELx. For example, taking an exception to EL1 selects SP_EL1. Software executing at the target Exception level can then choose to change the stack pointer to SP_EL0 by updating PSTATE.SP.

This applies even if taking the exception does not change the Exception level. For example, if the PE is executing at EL1 and the PE is using the SP_EL0 stack pointer, then on taking an exception that targets EL1, the stack pointer changes to SP_EL1.

The selected stack pointer can be indicated by a suffix to the Exception level:

- t Indicates use of the SP_EL0 stack pointer.
- h Indicates use of the SP_ELx stack pointer.
D1.6 Registers for instruction processing and exception handling

D1.6.3 The SIMD and floating-point registers, V0-V31

The SIMD and floating-point instructions share a common bank of registers for floating-point, vector, and other SIMD-related scalar operations.

The SIMD and floating-point register bank comprises 32 quadword (128-bit) registers, V0-V31.

These registers can be accessed as:
- 32 doubleword (64-bit) registers, D0-D31.
- 32 word (32-bit) registers, S0-S31.
- 32 halfword (16-bit) registers, H0-H31.
- 32 byte (8-bit) registers, B0-B31.

For information on the format of these registers, see Registers in AArch64 state on page B1-107.

D1.6.4 Saved Program Status Registers (SPSRs)

The Saved Program Status Registers (SPSRs) are used to save PE state on taking exceptions.

In AArch64 state, there is an SPSR at each Exception level exceptions can be taken to, as follows:
- SPSR_EL1, for exceptions taken to EL1 using AArch64.
- If EL2 is implemented, SPSR_EL2, for exceptions taken to EL2 using AArch64.
- If EL3 is implemented, SPSR_EL3, for exceptions taken to EL3 using AArch64.

Exceptions cannot be taken to EL0.

When the PE takes an exception, the PE state is saved from PSTATE in the SPSR at the Exception level the exception is taken to. For example, if the PE takes an exception to EL1, the PE state is saved in SPSR_EL1. For more information on PSTATE, see Process state, PSTATE on page D1-2324.

Saving the PE state means the exception handler can:
- On return from the exception, restore the PE state to the state stored in the SPSR at the Exception level the exception is returning from. For example, on returning from EL1, the PE state is restored to the state stored in SPSR_EL1.
- Examine the value that PSTATE had when the exception was taken, for example to determine the Execution state and Exception level in which the instruction that caused an exception was executed.
NOTE

- All PSTATE fields are saved, including those which have no direct read and write access, and those that are meaningful only in AArch32 state.
- Those PSTATE fields that are meaningful only in AArch32 state are saved when an exception is taken from AArch32 state to AArch64 state.

The SPSRs are UNKNOWN on reset.

SPSR bits that are defined as RES0 on an exception are ignored:
- If taken from AArch32 state, on any exception return to AArch32 state.
- If taken from AArch64 state, on any exception return to AArch64 state.

Pseudocode description of SPSR operations

The SPSR[] pseudocode function accesses the current SPSR, and is common to AArch32 and AArch64 operations. The SetPSTATEFromPSR() pseudocode function updates PSTATE from an SPSR.

D1.6.5 Exception Link Registers (ELRs)

Exception Link Registers hold preferred exception return addresses.

Whenever the PE takes an exception, the preferred return address is saved in the ELR at the Exception level the exception is taken to. For example, whenever the PE takes an exception to EL1, the preferred return address is saved in ELR_EL1.

On an exception return, the PC is restored to the address stored in the ELR. For example, on returning from EL1, the PC is restored to the address stored in ELR_EL1.

AArch64 state provides an ELR for each Exception level exceptions can be taken to. The ELRs that AArch64 state provides are:
- ELR_EL1, for exceptions taken to EL1.
- If EL2 is implemented, ELR_EL2, for exceptions taken to EL2.
- If EL3 is implemented, ELR_EL3, for exceptions taken to EL3.

On taking an exception from AArch32 state to AArch64 state, bits[63:32] of the ELR are set to zero.

The preferred return address depends on the nature of the exception. For more information, see Preferred exception return address on page D1-2335.
D1.7 Process state, PSTATE

In the Armv8-A architecture, Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:
- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type ProcState. ProcState is defined in Chapter J1 Armv8 Pseudocode.

The PSTATE fields that are meaningful in AArch64 state are:

The Condition flags
- N Negative Condition flag.
- Z Zero Condition flag.
- C Carry Condition flag.
- V Overflow Condition flag.

Process state, PSTATE on page B1-108 gives more information about these flags.

The Execution state controls
- SS Software Step bit, see Software Step exceptions on page D2-2466. On a reset or taking an exception to AArch64 state, this bit is set to 0.
- IL Illegal Execution state bit, see The Illegal Execution state exception on page D1-2347. On a reset or taking an exception to AArch64 state, this bit is set to 0.
- nRW Current Execution state, see Execution state on page D1-2315. This bit is 0 when the current Execution state is AArch64. This bit is set to 0:
  - On reset into an Exception level that is using AArch64.
  - On taking an exception to an Exception level that is using AArch64.
- EL Current Exception level, see Exception levels on page D1-2312. On a reset to AArch64 state, this field holds the encoding for the highest implemented Exception level.

  Note
  The Arm architecture requires that a PE resets into the highest implemented Exception level.

- SP Stack pointer register selection bit, see Stack pointer register selection on page D1-2321. On a reset or taking an exception to AArch64 state, this bit is set to 1, meaning that SP_ELx is selected.

The exception mask bits
- D Debug exception mask bit, see The PSTATE debug mask bit, D on page D1-2397. On a reset or taking an exception to AArch64 state, this bit is set to 1.
- A, I, F Asynchronous exception mask bits:
  - A SError interrupt mask bit.
  - I IRQ interrupt mask bit.
  - F FIQ interrupt mask bit.

See Asynchronous exception types, routing, masking and priorities on page D1-2357.

On a reset or taking an exception to AArch64 state, each of these bits is set to 1.

Access control bits
- PAN Privileged Access Never (PAN) state bit. For more information, see About PSTATE.PAN on page D5-2601.

This bit is implemented only when FEAT_PAN is implemented.
The AArch64 System Level Programmers' Model

D1.7 Process state, PSTATE

UAO  User Access Override (UAO) bit. For more information, see About PSTATE.UAO on page D5-2602.
This bit is implemented only when FEAT_UAO is implemented.

TCO  Tag Check Override (TCO) bit. For more information, see Chapter D6 Memory Tagging Extension.
This bit is implemented only when FEAT_MTE is implemented.

BTYPE Branch target identification bit. For more information, see About PSTATE.BTYPE on page D5-2602.
This bit is implemented only when FEAT_BTI is implemented.

Timing control bits

DIT  Data Independent Timing (DIT) bit. For more information, see About PSTATE.DIT on page B1-113.
This bit is implemented only when FEAT_DIT is implemented.
On a reset to AArch64 state, this bit is set to 0.

Speculation control bits

SSBS Speculative Store Bypass Safe (SSBS) bit. For more information, see Speculative Store Bypass Safe (SSBS) on page B2-133.
This bit is implemented only when FEAT_SSBS is implemented.
On reset, this bit is set to an IMPLEMENTATION DEFINED value.

D1.7.1 Accessing PSTATE fields

In AArch64 state, PSTATE fields can be accessed using Special-purpose registers that can be directly read using the MRS instruction, and directly written using the MSR (register) instructions. Table D1-3 shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state, when the PE is in AArch64 state. All other PSTATE fields do not have direct read and write access.

Table D1-3 Accessing PSTATE fields using MRS and MSR (register)

<table>
<thead>
<tr>
<th>Special-purpose register</th>
<th>PSTATE fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>NZCV</td>
<td>N, Z, C, V</td>
</tr>
<tr>

<td>TCO</td>
</tr>
</tbody>
</table>
Software can also use the **MSR (immediate)** instruction to directly write to PSTATE.\{D, A, I, F, SP, PAN, UAO, SSBS, TCO\}. Table D1-4 shows the **MSR (immediate)** operands that can directly write to these PSTATE fields when the PE is in AArch64 state.

<table>
<thead>
<tr>
<th>Operand</th>

</tr>
<tr>
<td>TCO</td>
<td>TCO(^a)</td>
<td>Directly sets PSTATE.TCO to either 1 or 0</td>
</tr>
</tbody>
</table>

\(^a\) PSTATE.TCO can also be accessed by an **MSR Xt** instruction.

PSTATE.\{N, Z, C, V, TCO\} can be accessed at EL0. Access to PSTATE.\{D, A, I, F\} at EL0 using AArch64 depends on `SCTLR_EL1.UMA`, see [Traps to EL1 of EL0 accesses to the PSTATE.\{D, A, I, F\} interrupt masks on page D1-2371](#). All other PSTATE access instructions can be executed at EL1 or higher and are UNDEFINED at EL0.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects are guaranteed:
- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

### D1.7.2 The Saved Program Status Registers (SPSRs)

On taking an exception, PSTATE is preserved in the SPSR of the Exception level the exception is taken to. The SPSRs are described in [Saved Program Status Registers (SPSRs) on page D1-2322](#).
D1.8 Program counter and stack pointer alignment

This section contains the following:

- **PC alignment checking.**
- **SP alignment checking.**

D1.8.1 PC alignment checking

PC alignment checking generates a PC alignment fault exception associated with the instruction fetch if, in AArch64 state, there is an attempt to architecturally execute an instruction that was fetched with a misaligned PC. A misaligned PC is when bits[1:0] of the PC are not 0b00.

---

**Note**

As with Instruction Aborts, speculative fetching of an instruction does not generate an exception. An exception occurs only on an attempt to architecturally execute the instruction.

---

If an exception is generated as a result of an instruction fetch at EL0, it is taken to EL1. If an exception occurs when HCR_EL2.TGE bit is 1 and EL2 is enabled in the current Security state, it is taken to EL2. If an exception is generated as a result of an instruction fetch at any other Exception level, the Exception level is unchanged.

A PC misalignment sets the EC field in the *Exception Syndrome Register* (ESR) to 0x22, for the ESR associated with the target Exception level.

When the exception is taken to an Exception level using AArch64, the associated Exception Link Register holds the entire PC in its misaligned form, as does the FAR_ELx for the Exception level that the exception is taken to.

*Exception return and PC alignment on page D1-2345* gives more information on PC alignment checking associated with exception returns.

---

**Note**

A misalignment of the PC is a common indication of a serious error, for example software corruption of an address.

---

The pseudocode function `AArch64.CheckPCAlignment()` performs PC alignment checking in AArch64 state. When necessary it calls `AArch64.PCAlignmentFault()` to generate an exception.

D1.8.2 SP alignment checking

A *misaligned stack pointer* is where bits[3:0] of the stack pointer are not 0b0000, when the stack pointer is used as the base address of the calculation, regardless of any offset applied by the instruction.

The PE can be configured so that if a load or store instruction uses a misaligned stack pointer, the PE generates an SP alignment fault exception on the attempt to execute the instruction. In this configuration, `CheckSPAlignment()` performs the stack pointer check, and calls `AArch64.SPAlignmentFault()` if a misaligned stack pointer is found.

---

**Note**

- As with Data Aborts, a speculative data access to memory using the stack pointer does not generate the exception. The exception occurs only on an attempt to architecturally execute the instruction.

- Prefetch memory abort instructions do not cause synchronous exceptions. See *Prefetch memory on page C3-218.*

---

Stack pointer alignment checking is only performed in AArch64 state, and can be enabled for each Exception level as follows:

- `SCTLR_EL1.{SA0, SA}` controls EL0 and EL1, respectively.
- `SCTLR_EL2.SA` controls EL2.
- `SCTLR_EL3.SA` controls EL3.
If an exception is generated as a result of a load or store at EL0, it is taken as an exception to EL1. If an exception occurs when the HCR_EL2.TGE bit is set and EL2 is enabled in the current Security state, it is taken to EL2. If an exception is generated as a result of a load or store at any other Exception level, the Exception level is unchanged.

A stack pointer misalignment sets the EC field to 0x26, in the ESR associated with the target Exception level. If memory alignment checking and stack pointer alignment checking are enabled, then an SP alignment fault has priority in setting the value of the EC field, in the ESR associated with the target Exception level.

The pseudocode function CheckSPAlignment() performs the stack pointer alignment check. When necessary it calls AArch64.SPAlignmentFault() to generate an exception.
D1.9 Reset

The Armv8-A architecture supports the following resets:

**Cold reset**
Reset all of the logic on which the PE executes, including the integrated debug functionality.
In some contexts, this logic is described as belonging to the *Cold reset domain*.

**Warm reset**
Reset some of the logic on which the PE executes. However, some state is purposefully unchanged by a Warm reset.
In some contexts, this logic is described as belonging to the *Warm reset domain*.

All logic on the which the PE executes that is reset by a Warm reset is also reset by a Cold reset.

--- Note ---
The Armv8-A architecture also supports an external debug reset. See *External debug register resets on page H8-7158*.

---

If an RMR_ELx register is implemented:
- A Warm reset permits debugging across a reset of the PE logic.
- Writing 1 to RMR_ELx.RR requests a Warm reset.

The mechanisms, other than RMR_ELx.RR, to assert these resets are IMPLEMENTATION DEFINED. It is IMPLEMENTATION DEFINED whether:
- It is possible to independently assert an External Debug reset and a Cold reset.
- It is possible to assert a Warm reset, as opposed to asserting a Cold reset, other than by the use of RMR_ELx.RR.

--- Note ---
Arm recommends that:
- If separate Core and Debug power domains are implemented, as described in *Reset and debug on page H6-7129*, then a Cold reset can be asserted independently of External Debug reset.
- A Warm reset can be asserted to permit debugging across a reset of the PE logic.

This means that an implementation can define other resets according to the requirements the implementation or system must fulfil. These other resets are outside the scope of the Armv8-A architecture. However, they can be mapped onto the resets described here.

In the description that follows, the term *reset* is used in contexts where there is no difference between the effect of a Cold reset and the effect of a Warm reset.

On a reset, the PE enters the highest implemented Exception level.

If the highest implemented Exception level can use either Execution state, then:
- The implementation must include a *Reset Management Register* (RMR). Only one RMR is implemented. The RMR implemented is the RMR is associated with the highest Exception level.
- On a Cold reset, the Execution state entered is determined by a configuration input signal.
- On a Warm reset, the Execution state entered is determined by RMR_ELx.AA64.

If the highest implemented Exception level is configured to use AArch64 state, then on reset:
- The stack pointer for the highest implemented Exception level, SP_ELx, is selected.
- Execution starts at an IMPLEMENTATION DEFINED address, anywhere in the physical address range. The RVBAR associated with the highest implemented Exception level, RVBAR_EL1, RVBAR_EL2, or RVBAR_EL3, holds this address.
The remainder of this section contains the following:

- **PE state on reset to AArch64 state.**
- **Code sequence to use RMR_ELx.RR to request a Warm reset on page D1-2332.**

For more information about reset, see:

- **Behavior of caches at reset on page D4-2499.**
- **TLB behavior at reset on page D5-2659.**
- **Reset and debug on page H6-7129.**

### D1.9.1 PE state on reset to AArch64 state

**Note**

See the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0 for the reset requirements for GIC System registers.

Immediately after a reset, much of the PE state is **UNKNOWN**. However, some of the PE state is defined. If the PE resets to AArch64 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- Each of the `PSTATE.{D, A, I, F}` interrupt masks is set to 1.
- The Software step control bit, `PSTATE.SS`, is set to 0.
- The IL process state bit, `PSTATE.IL`, is set to 0.
- All general-purpose, and SIMD and floating-point registers are **UNKNOWN**.
- The ELR and SPSR for each Exception level are **UNKNOWN**.
- The stack pointer register for each Exception level is **UNKNOWN**.
- The global exclusive monitor and local exclusive monitor for the PE are **UNKNOWN**.
- Unless explicitly defined in this subsection, each System register at each Exception level is in an architecturally **UNKNOWN** state.
- The TLBs and caches are in an **IMPLEMENTATION DEFINED** state. This means that the TLBs, the caches, or both, might require invalidation using **IMPLEMENTATION DEFINED** invalidation sequences before the memory management system is enabled or Normal memory accesses are permitted to be Cacheable.

**Note**

- On reset, System register Cacheability control fields force all Normal memory accesses to be treated as Non-cacheable. This applies only for the translation regime used by the Exception level and Security state entered on reset. For information about these controls see *Enabling and disabling the caching of memory accesses on page D4-2497.*
- The implementation might include **IMPLEMENTATION DEFINED** resets. If it does, each of these resets might treat the cache and TLB state differently. The Armv8-A architecture permits this.
- Different **IMPLEMENTATION DEFINED** invalidation sequences might be required for different **IMPLEMENTATION DEFINED** resets.
- In some implementations, the **IMPLEMENTATION DEFINED** invalidation sequence might be a NOP.

- In the `SCTLR_ELx` for the highest implemented Exception level:
  - Each of the `{M, C, I}` bits is set to 0
  - The EE bit is set to an **IMPLEMENTATION DEFINED** value, typically defined by a configuration input.
- If an RMR is implemented, `RMR_ELx.RR` is set to 0. ELx in this context is the highest implemented Exception level.
• The enables for the counter event stream are set to 0. This means that the following bits are set to 0:
  — CNTKCTL_EL1.EVNTEN.
  — If the implementation includes EL2, CNTHCTL_EL2.EVNTEN.

• PMCR_EL0.E is set to 0.

  — Note
  This means the Performance Monitors cannot assert interrupts at reset.

• OSDLR_EL1.DLK bit is set to 0.
• Each of MDCCINT_EL1.{TX, RX} is set to 0.
• EDPRCR.CWRR is set to 0.
• EDPRSR.SR is set to 1.
• If the implementation includes EL3, then each of MDCR_EL3.{EPMAD, EDAD, SPME} is set to 0.
• If the implementation includes EL2, then MDCR_EL2.HPMN is set to the value of PMCR_EL0.N.
• EDESR.OSUC is set to 0.
• If FEAT_DoPD is not implemented, EDESR.SS is set to the value of EDECR.SS.
• If FEAT_DoPD is implemented, EDESR.RC is set to the value of CTIDEVCTL.RCE. Otherwise EDESR.RC is set to the value of EDECR.RCE.

  — Note
  On an External debug reset, EDECR.{SS, RCE} are set to 0. If FEAT_DoPD is implemented, CTIDEVCTL.{OSUC, RCE} are set to 0.

Additionally, for a Cold reset into AArch64 state:

• If an RMR is implemented, RMR_ELx.AA64 is set to 1. ELx in this context is the highest implemented Exception level.
• Each of MDCCSR_EL0.{TXfull, RXfull} is set to 0.
• If FEAT_DoPD is not implemented, DBGPRCR_EL1.CORENPDRQ is set to the value of EDPRCR.COREPURQ.

  — Note
  An External Debug reset sets EDPRCR.COREPURQ to 0, see External debug register resets on page H8-7158. If an External Debug reset and a Cold reset coincide, both DBGPRCR_EL1.CORENPDRQ and EDPRCR.COREPURQ are reset to 0.

  — Note
  If FEAT_DoPD is implemented, DBGPRCR_EL1.CORENPDRQ is set to an IMPLEMENTATION DEFINED choice of 0 or 1 if the powerup request is implemented and asserted, otherwise is set to 0.

• The debug CLAIM bits are reset to 0.

  — Note
  These are the bits that are set to 1 by writing to DBGCLAIMSET_EL1.CLAIM, and cleared to 0 by writing to DBGCLAIMCLR_EL1.CLAIM.

• Each of EDSCR.{RXO, TXU, INTdis, TDA, MA, HDE, ERR, RXfull, TXfull} is set to 0.
• Each of EDECCR.{NSE, SE} is set to 0.
• If FEAT_DoPD is implemented, EDECR.SS is set to 0.
• **OSLR_EL1.OSLK** is set to 1.

• In the **EDPRSR**:
  — The SPMAD, SDAD fields are set to 0.
  — The SPD field is set to 1.

• Each field of **AMCNTENCLR0_EL0, AMCNTENCLR1_EL0, AMCNTENSET0_EL0, and AMCNTENSET1_EL0** is set to 0.

• Each of the implemented architected activity monitor counters **AMEVCNTR0<n>_EL0** and each of the implemented auxiliary activity monitor counters **AMEVCNTR1<n>_EL0** are set to 0.

For more information about resets in AArch64 System registers, see Chapter D13 *AArch64 System Register Descriptions*.

### D1.9.2 Code sequence to use RMR_ELx.RR to request a Warm reset

The following assembler sequence uses **RMR_ELx.RR** to request a Warm reset:

```assembly
; in addition, interrupts and debug requests for this PE should be disabled
; in the system before running this sequence to ensure the WFI suspends execution
MOV Wy, #3        ; for AArch64, #2 for AArch32; y is any register
DSB               ; ensure all stores etc are complete
MSR RMR_ELx, Wy   ; request the reset
ISB               ; synchronise change to the RMR
Loop
  WFI               ; enter a quiescent state
  B Loop
```

### D1.9.3 Pseudocode description of reset

The **AArch64.TakeReset()** pseudocode function performs a reset into AArch64 state.

**AArch64.TakeReset()** calls the functions **AArch64.ResetGeneralRegisters(), AArch64.ResetSIMDFPRegisters(), AArch64.ResetSpecialRegisters(), AArch64.ResetSystemRegisters(), and ResetExternalDebugRegisters().**

**AArch64.ResetSystemRegisters()** resets all System registers to their reset state as defined in the register descriptions in *PE state on reset to AArch64 state* on page D1-2330 and Chapter D13 *AArch64 System Register Descriptions*.

**Note**

The **AArch64.ResetSystemRegisters()** function only resets the System registers.

**ResetExternalDebugRegisters()** resets all external debug registers to their reset state as defined in the register descriptions in Chapter H9 *External Debug Register Descriptions*. 
D1.10 Exception entry

Exceptions are targeted at particular Exception levels. The Exception level that an exception targets is either programmed by software, or is determined by the nature of the exception.

Under no circumstances do exceptions cause execution to move to a lower Exception level.

If an asynchronous exception targets a lower Exception level, the exception is not taken and remains pending. See Asynchronous exception routing on page D1-2358 and Asynchronous exception masking on page D1-2361.

Note
The construction of the architecture means that usually, it is impossible for an exception to target a lower Exception level.

The Security state can only change on taking an exception if taken from Non-secure state to EL3.

Note
Taking an exception to EL3 from any Exception level has no effect on the value of the SCR_EL3.NS bit.

On taking an exception to AArch64 state:

- The PE state is saved in the SPSR_ELx at the target Exception level. See Saved Program Status Registers (SPSRs) on page D1-2322.
- The preferred return address is saved in the ELR_ELx at the target Exception level. See Exception Link Registers (ELRs) on page D1-2323.
- All of PSTATE.{D, A, I, F} are set to 1. See Process state, PSTATE on page D1-2324.
- PSTATE.SSBS is set to the value of SCTLR_ELx.DSSBS.
- If FEAT_UAO is implemented, PSTATE.UAO is set to 0. See Process state, PSTATE on page D1-2324.
- If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the exception is saved in the ESR_ELx at the target Exception level. See Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-2336.
- If FEAT_MTE is implemented:
  - PSTATE.TCO is set to 1. See Process state, PSTATE on page D1-2324.
  - A synchronous exception due to a Tag Check Fault is reported to as a Data Abort with a Data Fault Status Code of Synchronous Tag Check Fault and the faulting virtual address is reported in FAR_ELx. For more information, see PE handling of Tag Check Fault on page D6-2690.
- If FEAT_BTI is implemented, on taking an asynchronous exception from AArch64 to AArch64, PSTATE.BTYPE is copied to SPSR_ELx.BTYPE and then set to 0.
- If FEAT_BTI is implemented, on taking certain types of synchronous exception from AArch64 to AArch64, PSTATE.BTYPE is copied to SPSR_ELx.BTYPE and then set to 0. These types of synchronous exceptions are:
  - Software Step exception.
  - PC alignment fault exception.
  - Instruction Abort exception.
  - Breakpoint exceptions or Address Matching Vector Catch exception.
  - Illegal Execution state exception.
  - Software Breakpoint exception.
  - Branch Target exception.
On taking any other synchronous exception from AArch64 to AArch64, it is CONSTRAINED UNPREDICTABLE whether:

- SPSR_ELx.BTYPE is set to the value of PSTATE.BTYPE.
- SPSR_ELx.BTYPE is set to 0.

PSTATE.BTYPE is then set to 0.

- The stack pointer register selected is the dedicated stack pointer register for the target Exception level. See The stack pointer registers on page D1-2321.

- For a physical SError interrupt exception, the pending state of the physical SError is cleared when any of:
  - The SError interrupt is edge-triggered.
  - FEAT_DoubleFault is implemented.
  - If The Reliability, Availability, and Serviceability Extension is implemented, and on taking the SError interrupt, the syndrome recorded in ESR_ELx indicates an SError other than IMPLEMENTATION DEFINED or uncategorized SError interrupt syndrome.

Otherwise, it is IMPLEMENTATION DEFINED whether the pending state of the physical SError is cleared.

This IMPLEMENTATION DEFINED behavior might vary according to the nature of the SError interrupt.

- For a virtual SError interrupt exception, the pending state of the virtual SError, held in the HCR_EL2.VSE bit, is cleared to zero. See Virtual interrupts on page D1-2363.

- If FEAT_IESB is implemented, when the Effective value of the SCTLR_ELx.IESB bit at the target Exception level is 1, the PE inserts an error synchronization event. See ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

- Execution moves to the target Exception level, and starts at the address defined by the exception vector. Which exception vector is used is also an indicator of whether the exception came from a lower Exception level or the current Exception level. See Exception vectors on page D1-2335.

- If an Instruction Abort exception, Data Abort exception, PC alignment fault exception, or a Watchpoint exception is taken to an Exception level using AArch64, the faulting virtual address is saved in FAR_ELx. For more information, see Validity of FAR_ELx on page D1-2342.

- If an Instruction Abort exception, or Data Abort exception is taken to EL2 and the fault is one connected with stage 2 translation, the faulting IPA is saved in HPFAR_EL2. For more information, see Validity of HPFAR_EL2 on page D1-2343.

If FEAT_ExS is implemented and SCTLR_ELx.EIS is 0, though exception entry is not a context synchronization event, the indirect writes to ESR_ELx, FAR_ELx, SPSR_ELx, ELR_ELx, and HPFAR_EL2 due to exception entry are synchronized so that a direct read of the register after exception entry sees the indirectly written value caused by the exception entry.

--- Note ---

On exception entry, the memory transactions, including instruction fetches, from an exception level always use the translation resources associated with that translation regime.

The remainder of this section contains the following:

- Preferred exception return address on page D1-2335.
- Exception vectors on page D1-2335.
- Pseudocode description of exception entry to AArch64 state on page D1-2336.
- Exception classes and the ESR_ELx syndrome registers on page D1-2336.
- Summary of register updates on faults taken to an Exception level that is using AArch64 on page D1-2342.
D1.10.1 Preferred exception return address

For an exception taken to an Exception level using AArch64, the Exception Link Register for that Exception level, ELR_ELx, holds the preferred exception return address. The preferred exception return address depends on the nature of the exception, as follows:

- For asynchronous exceptions, it is the address of the instruction following the instruction boundary at which the interrupt occurs. Therefore, it is the address of the first instruction that did not execute, or did not complete execution, as a result of taking the interrupt.
- For synchronous exceptions other than system calls, it is the address of the instruction that generates the exception.
- For exception generating instructions, it is the address of the instruction that follows the exception generating instruction.

Note

If an exception generating instruction is trapped, disabled, or is UNDEFINED because the Exception level has insufficient privilege to execute the instruction, the preferred exception return address is the address of the exception generating instruction.

When an exception is taken from an Exception level using AArch32 to an Exception level using AArch64, the top 32 bits of the modified ELR_ELx are 0.

D1.10.2 Exception vectors

When the PE takes an exception to an Exception level that is using AArch64, execution is forced to an address that is the exception vector for the exception. The exception vector exists in a vector table at the Exception level the exception is taken to.

A vector table occupies a number of word-aligned addresses in memory, starting at the vector base address.

Each Exception level has an associated Vector Base Address Register (VBAR), that defines the exception base address for the table at that Exception level.

For exceptions taken to AArch64 state, the vector table provides the following information:

- Whether the exception is one of the following:
  - Synchronous exception.
  - SError.
  - IRQ.
  - FIQ.

- Information about the Exception level that the exception came from, combined with information about the stack pointer in use, and the state of the register file.
Table D1-5 shows this.

<table>

- When FEAT_DoubleFault is implemented, SCR_EL3.EASE is set to 1, and the exception is a synchronous External abort taken to EL3, the exception is routed to the offset in the SError or vError column.
- For exceptions taken to EL3, if EL2 is implemented, the level immediately lower than the target level is EL2 if the exception was taken from Non-secure state, but EL1 if the exception was taken from Secure EL1 or EL0.

Reset is treated as a special vector for the highest implemented Exception level. This special vector uses an IMPLEMENTATION DEFINED address that is typically set either by a hardwired configuration of the PE or by configuration input signals. The RVBAR_ELx register contains this reset vector address, where x is the number of the highest implemented Exception level.

### D1.10.3  Pseudocode description of exception entry to AArch64 state

The `AArch64.TakeException()` pseudocode function describes the behavior when the PE takes an exception to an Exception level that is using AArch64. The `AArch64.ExceptionClass()` function determines the EC (Exception class) and IL (Instruction length) values required to report the exception, and `AArch64.ReportException()` reports the exception.

The pseudocode functions `AArch64.TakeException()`, `AArch64.ExceptionClass()`, and `AArch64.ReportException()` are described in Chapter J1  Armv8 Pseudocode.

### D1.10.4  Exception classes and the ESR_ELx syndrome registers

If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the exception is saved in the ESR_ELx at the Exception level the exception is taken to. The information saved is determined at the time the exception is taken, and is not changed as a result of the explicit synchronization that takes place at the start of taking the exception. See Synchronization requirements for AArch64 System registers on page D13-2863. The following sections give more information:

- **Use of the ESR_EL1, ESR_EL2, and ESR_EL3.**
- **The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1 on page D1-2341.**

#### Use of the ESR_EL1, ESR_EL2, and ESR_EL3

An ESR_ELx holds the syndrome information for an exception that is taken to AArch64 state.

---

This use of a syndrome is also the reporting model used for exceptions taken to Hyp mode when they are taken to EL2 using AArch32.

Figure D1-2 on page D1-2337 shows the general format of the ESR_ELx registers.
The ESR_ELx fields are:

**EC, bits[31:26]**  The Exception class field, that indicates the cause of the exception.

**IL, bit[25]**  The Instruction length bit, for synchronous exceptions, that indicates whether a trapped instruction was a 16-bit or a 32-bit instruction.

**ISS, bits[24:0]**  The Instruction specific syndrome field. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Table D1-6 shows the encoding of the ESR_ELx.EC field, the Exception class field. For each EC value, the table references a subsection of the ESR_ELx register definition that describes the ISS format, with links to descriptions of possible causes of the exception, for example the configuration required to enable a trap.

a. See also Reporting AArch32 synchronous exceptions taken to an Exception level using AArch64 on page D1-2341.

b. Exceptions caused by configurable traps, enables, or disables.

c. See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2385.

d. Only for MCRR or MRRC accesses to the PMCCNTR_EL0 or PMCCNTR.
Reserved EC values

For EC values not shown in Table D1-6 on page D1-2337:

- Unused EC values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved by Arm for future use for synchronous exceptions.
- Unused EC values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved by Arm for future use, and might be used for synchronous or asynchronous exceptions.

The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1

When an exception is taken from EL0 to EL2 because the value of HCR_EL2.TGE is 1, the exception is reported in ESR_EL2. The EC value and corresponding ISS encoding used to report the exception in ESR_EL2 depend on how an exception of the same class would be reported in ESR_EL1 when the value of HCR_EL2.{TGE, RW} is {0, 1}:

- If the exception would have been reported in ESR_EL1 using the EC value 0x07 then it is reported in ESR_EL2 using the EC value 0x00 and corresponding ISS encoding.
- Otherwise, the exception is reported in ESR_EL2 using the EC value and ISS encoding that would have been used to report the exception ESR_EL1.

Reporting AArch32 synchronous exceptions taken to an Exception level using AArch64

Although possible exception causes are generally similar for AArch32 state and AArch64 state, AArch32 state has additional exception taxonomy that is not present in AArch64 state. The following sections described named AArch32 exceptions that can, in some contexts, be taken to an Exception level that is using AArch64:

- *Undefined Instruction exception* on page G1-5778.
- *Supervisor Call (SVC) exception* on page G1-5782.
- *Secure Monitor Call (SMC) exception* on page G1-5783.
- *Hypervisor Call (HVC) exception* on page G1-5784.
- *Prefetch Abort exception* on page G1-5785.
- *Data Abort exception* on page G1-5789.
When EL2 is using AArch64 and the value of HCR_EL2.TGE is 1, these exceptions are routed to EL2, and reported in the ESR_EL2. Table D1-7 shows how they are reported.

Table D1-7 Syndrome reporting in ESR_EL2 of HCR_EL2 routing of exceptions

a. The pseudocode in Operation for all encodings on page F5-4733 identifies when the execution of an SMC instruction in AArch32 state generates an exception that is taken to EL3 using AArch64.

D1.10.5 Summary of register updates on faults taken to an Exception level that is using AArch64

For all exceptions taken to an Exception level using AArch64 that are not listed in Validity of FAR_ELx, the FAR_ELx for the Exception level the exception is taken to is UNKNOWN.

For all exceptions taken to EL2 using AArch64 that are not listed in Validity of HPFAR_EL2 on page D1-2343, the HPFAR_EL2 is UNKNOWN.

The following sections give more information:
- Validity of FAR_ELx.
- Validity of HPFAR_EL2 on page D1-2343.

Validity of FAR_ELx

The faulting virtual address is saved in FAR_ELx for the Exception level the exception is taken to if an exception is one of:
- An Instruction Abort exception.
- A Data Abort exception.
- A PC alignment fault exception.
- A Watchpoint exception.

The architecture permits that the FAR_ELx is UNKNOWN for synchronous External aborts other than synchronous External aborts on translation table walks. In this case, the ISS.FnV bit returned in ESR_ELx indicates whether FAR_ELx is valid.

If an exception is taken from an Exception level using AArch32 into an Exception level using AArch64, and that exception writes the FAR_ELx at the Exception level the exception is taken to, the most significant 32 bits of FAR_ELx are all zero, unless both of the following apply, in which case the most significant 32 bits of FAR_ELx are 0x00000001:
- The faulting address was generated by a load or store that sequentially incremented from address 0xFFFFFFFF. Such a load or store instruction is CONstrained UNpredictable, see Out of range VA on page K1-7950.
- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

The FAR_ELx for an Exception level is made UNKNOWN as a result of an exception return from that Exception level.
Validity of HPFAR_EL2

The faulting IPA is saved in HPFAR_EL2 if the exception is an Instruction Abort or Data Abort taken to EL2 and the fault is one of:

• A Translation or Access Flag fault on a stage 2 translation.
• A stage 2 Address Size fault.
• A fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.

HPFAR_EL2 is made UNKNOWN as a result of an exception return from EL2.
### D1.11 Exception return

In the Armv8-A architecture, an exception return is always to the same Exception level or a lower Exception level. An exception return is used for:

- A return to a previously executing thread.
- Entry to a new execution thread. For example:
  - The initialization of a hypervisor by a Secure monitor.
  - The initialization of an operating system by a hypervisor.
  - Application entry from an operating system or hypervisor.

If FEAT_ExS is not implemented, or if FEAT_ExS is implemented and the SCTLR_ELx.EOS field is set, exception return from ELx is a context synchronization event.

An exception return requires the simultaneous restoration of the PC and PSTATE to values that are consistent with the desired state of execution on returning from the exception. The indirect write of the PSTATE information and the PC is synchronized even if the return is not a context synchronization event.

In AArch64 state, an ERET, ERETAa, or ERETAB instruction causes an exception return, see *ERET* on page C6-920, and *ERE TAa, ERETAB* on page C6-921.

If FEAT_IESB is implemented, when the SCTLR_ELx.IESB bit at the Exception level the exception is returning from is 1, the PE inserts an error synchronization event before the Exception return instruction. See *ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*.

On executing an Exception return instruction at ELx:

- The PC is restored with the value held in ELR_ELx.
- PSTATE is restored by using the contents of SPSR_ELx.

ELR_ELx and SPSR_ELx are the ELR_ELx and SPSR_ELx at the Exception level the exception is returning from. The exception return makes this ELR_ELx and SPSR_ELx UNKNOWN.

See *Address tagging in AArch64 state* on page D5-2528 for details of how tagged addresses are handled in an Exception return from an Exception level using AArch64 to an Exception level using AArch64.

**Note**

When returning from an Exception level using AArch64 to an Exception level using AArch32, the top 32 bits of the ELR_ELx are ignored.

An Exception return instruction also:

- Sets the Event Register for the PE executing the Exception return instruction. See *Mechanisms for entering a low-power state* on page D1-2391.
- Resets the local Exclusives monitor for the PE executing the Exception return instruction. This removes the risk of errors that might be caused when a path to an exception return fails to include a CLREX instruction.

**Note**

This behavior prevents self-hosted debug from software stepping through a Load-Exclusive/Store-Exclusive pair. However, when self-hosted debug is using software step, it is highly probable that the Exclusives monitor state would be lost anyway, for other reasons. *Stepping code that uses Exclusives monitors* on page D2-2477 describes this.

It is IMPLEMENTATION DEFINED whether the resetting of the local Exclusives monitor also resets the global Exclusives monitor.

The Exception return instruction is UNDEFINED in EL0.

When returning from an Exception level using AArch64 to an Exception level using AArch32, the AArch32 context is restored. The Armv8-A architecture defines the relationship between AArch64 state and AArch32 state, for:

- General-purpose registers.
- Special-purpose registers.
• System registers.

In an implementation that includes EL3, the Security state can only change on returning from an exception if the return is from EL3 to a lower Exception level.

The following sections give more information:
• Exception return and PC alignment.
• Illegal return events from AArch64 state.
• Legal returns that set PSTATE.IL to 1 on page D1-2347.
• The Illegal Execution state exception on page D1-2347.
• Pseudocode description of exception return on page D1-2347.

D1.11.1 Exception return and PC alignment

When SPSR_ELx.M[4] == 0, indicating an Exception return to AArch64 state, the value of ELR_ELx is transferred to the PC. If this value is misaligned, subsequent execution results in a PC alignment fault exception.

When SPSR_ELx.M[4] == 1, indicating an Exception return to AArch32 state, the value of ELR_ELx is transferred to the PC except that, for a legal exception return:
• If SPSR_ELx.T is 0, ELR_ELx[1:0] are treated as being 0 for restoring the PC.
• If SPSR_ELx.T is 1, ELR_ELx[0] is treated as being 0 for restoring the PC.

This means that a PC alignment fault exception cannot occur following a legal exception return from AArch64 state to AArch32 state. However, where the Exception return with SPSR_ELx.M[4] == 1 is an illegal exception return then it is IMPLEMENTATION DEFINED whether a misaligned value in ELR_ELx is aligned when it is restored to the PC.

Note

In an implementation that forces the alignment of the PC value restored from SPSR_ELx on an illegal exception return with SPSR_ELx.M[4] == 1, if SPSR_ELx.T == 1 the restored PC value might give rise to a PC alignment fault exception, because the PE remains in AArch64 state and only ELR_ELx[0] is treated as being 0 for restoring the PC.

For more information about the illegal exception return cases, see Illegal return events from AArch64 state.

D1.11.2 Illegal return events from AArch64 state

In this section:
Return
• Execution of an Exception return instruction.
• Execution of a DRPS instruction in Debug state.
• Exit from Debug state.

Saved process state value
• The value held in the SPSR_ELx for an Exception return instruction.
• The value held in the SPSR_ELx for a DRPS instruction executed in Debug state.
• The value held in the DSPSR_EL0 for a Debug state exit.

Link address
• The address held in ELR_ELx for an Exception return instruction.
• The address held in DLR_EL0 for a Debug state exit.

Configured from reset
Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.
The Armv8 architecture has a generic mechanism for handling returns to a mode or state that is illegal. In AArch64 state, this can occur as the result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the Exception level being returned to is not implemented. For example a return to EL2 when EL2 is not implemented.
- A return to EL2 when EL3 is implemented and the value of the SCR_EL3.NS bit is 0 if FEAT_SEL2 is not implemented.
- A return to EL1 when EL2 is implemented and the value of the HCR_EL2.TGE bit is 1.
- A return where the value of the saved process state M[4] bit is 0, indicating a return to AArch64 state, and one of the following is true:
  - The M[3:0] bits are 0b0001.
  - The Exception level being returned to is using AArch32 state, as programmed by the SCR_EL3.RW or HCR_EL2.RW bits, or as configured from reset.
- A return where the value of the saved process state M[4] bit is 1, indicating a return to AArch32 state, and one of the following is true:
  - The M field value is not a valid AArch32 state PE mode. Table G1-5 on page G1-5726 shows the valid encoding values for AArch32 state PE modes. This includes the case where M is 0b10000, indicating User mode, and EL0 does not support AArch32 state.
  - The Exception level being returned to is using AArch64 state as determined by the SCR_EL3.RW or HCR_EL2.RW field or the configuration from reset. This includes the case where the Exception level being returned to does not support AArch32 state.

**Note**

This means that, in an implementation that supports only AArch64 state, any attempt to return to AArch32 state is an illegal exception return.

- A Debug state exit from EL0 using AArch64 state, to EL0 using AArch32 state.

In these cases:

- **PSTATE.IL** is set to 1, to indicate an illegal return.
- **PSTATE. {EL, nRW, SP}** are unchanged. This means the Exception level, Execution state, and stack pointer selection do not change as a result of the return.
- The following **PSTATE** bits are restored from the saved process state value:
  - The D, A, I, F exception mask bits.
- If the illegal return is an illegal exception return, the **PSTATE.SS** bit is handled as normal for a return. That is, the SS bit is handled in the same way as an exception return that is not an illegal exception return. See **Software Step exceptions on page D2-2466**.
  
  In all these cases the **PSTATE.SS** bit is handled as it would be for a normal return, as described in **Entering the active-not-pending state on page D2-2468** and **Exiting Debug state on page H2-7051**. DRPS never sets the SS bit. This is indicated in **Entering the active-not-pending state on page D2-2468**.
- If the illegal return is not a DRPS instruction executed in Debug state, the PC is restored from the link address. However, if the value of the M[4] bit of the saved process state is 1, indicating a return to AArch32 state, then:
  - Bits[31:2] of the PC are restored from the link address.
  - Bits[63:32, 1:0] of the PC are **UNKNOWN**.
When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See The Illegal Execution state exception.

All aspects of the illegal return, other than the effects described in this section, occur as they do for a legal return.

D1.11.3 Legal returns that set PSTATE.IL to 1

In this section, return, saved process state value, and link address have the same meaning as defined in Illegal return events from AArch64 state on page D1-2345.

If the value of the IL bit in the saved process state is 1, then it is copied to PSTATE by a return, meaning that PSTATE.IL is set to 1. In this case, if the return is not an illegal return, and targets AArch32 state, then the PSTATE.\{IT, T\} bits are either:
• Set to 0.
• Copied from the saved process state value.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

The PSTATE.\{IT, T\} bits are only valid in AArch32 state, see Process state, PSTATE on page G1-5735.

When the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See The Illegal Execution state exception.

D1.11.4 The Illegal Execution state exception

When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. In AArch64 state, the PSTATE.IL bit can be set to 1 by any of:
• An illegal return, as described in Illegal return events from AArch64 state on page D1-2345.
• A legal return that sets PSTATE.IL to 1, as described in Legal returns that set PSTATE.IL to 1.

If an Illegal Execution state exception is generated at EL0, it is taken to EL1. If the exception occurs when EL2 is implemented and enabled in the current Security state, and HCR_EL2.TGE == 1, then it is taken to EL2. If an Illegal Execution state exception is generated at any other Exception level, the Exception level is unchanged.

An Illegal Execution state exception sets ESR_ELx.EC for the target Exception level to the value of 0x0E.

On taking any exception to an Exception level that is using AArch64 state:

1. The value of the PSTATE.IL bit is copied into the SPSR_ELx.IL bit for the Exception level to which the exception is taken.
2. The PSTATE.IL bit is cleared to 0.

    Note

This means that it is not possible for software to observe the value of PSTATE.IL.

For the priority of this exception class, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2349.

D1.11.5 Pseudocode description of exception return

The AArch64.ExceptionReturn() pseudocode function transfers the return address to the PC, and restores PSTATE to its saved value by calling SetPSTATEFromPSR().

The IllegalExceptionReturn() function checks for an Illegal Execution state exception.
Synchronous exception types, routing and priorities

Synchronous exceptions are:

- Any exception generated by attempting to execute an instruction that is UNDEFINED, including:
  - Attempts to execute instructions at an inappropriate Exception level.
  - Attempts to execute instructions when they are disabled.
  - Attempts to execute instruction bit patterns that have not been allocated.
- Illegal Execution state exceptions. These are caused by attempts to execute an instruction when the value of PSTATE.IL is 1, see Illegal return events from AArch64 state on page D1-2345.
- Exceptions caused by the use of a misaligned SP.
- Exceptions caused by attempting to execute an instruction with a misaligned PC.
- Exceptions caused by the exception-generating instructions SVC, HVC, or SMC.
- Traps on attempts to execute instructions that the System registers define as instructions that are trapped to a higher Exception level. See Configurable instruction enables and disables, and trap controls on page D1-2367.
- Instruction Aborts generated by the memory address translation system that are associated with attempts to execute instructions from areas of memory that generate faults.
- Data Aborts generated by the memory address translation system that are associated with attempts to read or write memory that generate faults.
- Data Aborts caused by a misaligned address.
- Data Aborts caused by a Tag Check Fault if FEAT_MTE is implemented. For more information, see Chapter D6 Memory Tagging Extension.
- All of the debug exceptions:
  - Breakpoint Instruction exceptions.
  - Breakpoint exceptions.
  - Watchpoint exceptions.
  - Vector Catch exceptions.
  - Software Step exceptions.
- In an implementation that supports the trapping of floating-point exceptions, exceptions caused by trapped IEEE floating-point exceptions, see Floating-point exceptions and exception traps on page D1-2354.
- In some implementations, External aborts. External aborts are failed memory accesses, and include accesses to those parts of the memory system that occur during the address translation. The Armv8 architecture permits, but does not require, implementations to treat such exceptions synchronously. See External aborts on page D4-2519.

This remainder of this section contains the following:

- Routing exceptions from EL0 to EL2.
- Routing debug exceptions to EL2 on page D1-2349.
- Routing synchronous External aborts on page D1-2349.
- Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2349.
- Effect of Data Aborts and Watchpoints on page D1-2353.
- Floating-point exceptions and exception traps on page D1-2354.

Routing exceptions from EL0 to EL2

When EL2 is enabled in the current Security state and the value of HCR_EL2.TGE is 1, any exception taken from EL0 that would otherwise be taken to EL1 is, instead, routed to EL2. This means that an application can execute at EL0 without using any functionality at EL1.
D1.12 Synchronous exception types, routing and priorities

--- Note ---

- When EL2 is using AArch64 state, the HCR_EL2.TGE control applies regardless of whether EL0 is using AArch32 state or AArch64 state.
- Implementations typically use the following Exception level and software hierarchy:
  
  **EL2**  
  Hypervisor.

  **EL1**  
  Operating system.

  **EL0**  
  Application.

  In such an implementation, setting HCR_EL2.TGE to 1 means that an application can run at EL0 under the direct control of a hypervisor executing at EL2, with no operating system involvement.

---

**D1.12.2 Routing debug exceptions to EL2**

When EL2 is enabled in the current Security state and the value of MDCR_EL2.TDE is 1, debug exceptions are routed to EL2. For more information, see *Routing debug exceptions* on page D2-2423.

When the value of MDCR_EL2.TDE is 1, each of the MDCR_EL2.TDRA, TDOSA, TDA bits is treated as 1 for all purposes other than direct reads of the MDCR_EL2.

**D1.12.3 Routing synchronous External aborts**

When the value of SCR_EL3.EA is 1, synchronous external aborts are taken to EL3.

When the RAS Extension is implemented, EL2 is enabled in the current Security state, and the value of HCR_EL2.TEA is 1, synchronous external aborts from EL0 and EL1 that are not routed to EL3 are routed to EL2.

**D1.12.4 Synchronous exception prioritization for exceptions taken to AArch64 state**

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. For exceptions taken to an Exception level that is using AArch64, these are prioritized as follows, where 1 is the highest priority.

--- Note ---

The priority numbering in this list correlates with the equivalent AArch32 state list in *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-5747 and the list in *Debug state entry and debug event prioritization* on page H2-7017.

1-3 These priority numbers represent debug events.

4 Software Step exceptions. See *Software Step exceptions* on page D2-2466.

5 This priority number represents debug events.

6 PC alignment fault exceptions. See *PC alignment checking* on page D1-2327.

7 Instruction Abort exceptions. See *AArch64 state prioritization of synchronous aborts from a single stage of address translation* on page D5-2652.

8 Breakpoint exceptions or Address Matching Vector Catch exceptions. See:

  - *Breakpoint exceptions* on page D2-2433.
  - *Vector Catch exceptions* on page D2-2465.

Vector Catch exceptions are only taken from AArch32 state.
Note

An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in "Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-5747." This means that it is outside the scope of the description of this section.

9

Illegal Execution state exceptions. See "Illegal return events from AArch64 state on page D1-2345."

10

Software Breakpoint exceptions caused by the execution of a Breakpoint instruction:

- For exceptions taken from AArch64 state, BRK.
- For exceptions taken from AArch32 state, BKPT.

11

Branch Target exceptions. See "About PSTATE.BTYPE on page D5-2602."

12

Exceptions taken from EL1 to EL2 because of one of the following configuration settings:

- HSTR_EL2.Tn.
- HCR_EL2.TIDCP.
- If FEAT_NV is implemented, HCR_EL2.NV or HCR_EL2.NV1.

Note

If FEAT_NV2 is implemented and HCR_EL2.\{NV, NV1, NV2\} are set such that register accesses to EL1 are transformed into memory accesses, then HCR_EL2.\{NV, NV1\} do not generate exceptions to EL2.

13

Exceptions that occur as a result of attempting to execute an instruction that is UNDEFINED for one or more of the following reasons:

- Attempting to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
- Attempting to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
- Debug state execution of an instruction encoding that is not accessible in Debug state.
- Non-debug state execution of an instruction encoding that is not accessible in Non-debug state.
- Execution of an HVC instruction, when HVC instructions are disabled by SCR_EL3.HCE or HCR_EL2.HCD.
- Execution of an MSR or MRS instruction to SP_EL0 when the value of SP Sel is 0.
- Execution of an HLT instruction when HLT instructions are disabled by EDSCR.HDE or halting is prohibited.
- In Debug state:
  - Execution of a DCPS1 instruction in Non-secure EL0 when HCR_EL2.TGE is 1.
  - Execution of a DCPS2 instruction in EL1 or EL0 when EL2 is disabled in the current Security state or is not implemented.
  - Execution of a DCPS3 instruction when EDSCR.SDD is 1 or when EL3 is not implemented.
  - When the value of EDSCR.SDD is 1, execution in EL2, EL1, or EL0 of an instruction that is configured by EL3 control registers to trap to EL3. It is IMPLEMENTATION DEFINED whether this type of exception is prioritized at this level or has the priority of the original trap exception.
- When executing in AArch32 state, execution of an instruction that is UNDEFINED as a result of any of:
  - Being in an IT block when SCTLR_EL1.ITD is 1.
  - Executing a SETEND instruction executed when SCTLR_EL1.SED is 1.
— Executing a CP15DMB, CP15DSB, or CP15ISB barrier instruction when SCTL_EL1.CP15BEN is 0.

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are SCTL. {ITD, SED, CP15BEN}, with additional controls HSCTLR. {ITD, SED, CP15BEN}.

See Disabling or enabling EL0 use of AArch32 deprecated functionality on page D1-2371

• When executing in AArch32 state, execution of an instruction that is UNDEFINED because at least one of FPCR. {Stride, Len} is nonzero, when programming these bits to nonzero values is supported. See Floating-point exceptions and exception traps on page G1-5816.

Note

— This case applies only when EL0 is using AArch32 and EL1 is using AArch64. The exception generated by the attempted execution at EL0 of the UNDEFINED instruction is taken to EL1 using AArch64.

— When EL1 is using AArch32, the corresponding controls are FPSCR. {Stride, Len}, and any exception generated by the attempted execution at EL0 or EL1 of an instruction that is UNDEFINED because of a nonzero {Stride, Len} value is taken to EL1 using AArch32.

14

Exceptions taken to EL1, or taken to EL2 because the value of HCR_EL2.TGE is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 4-13.

Note

When EL2 is using AArch32, the equivalent control for routing exceptions to EL2 is HCR.TGE.

15

Exceptions taken from EL0 to EL2 because of one of the following configuration settings:

• HSTR_EL2.Tn.
• HCR_EL2.TIDCP.

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are HSTR.Tn and HCR.TIDCP.

16

Exceptions taken to EL2 because of configuration settings in CPTR_EL2.

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, the equivalent controls are in HCPTR.

17

Exceptions taken to EL2 because of one of the following configuration settings:

• Any setting in HCR_EL2 other than the {TIDCP, NV} fields.
• Any setting in CNTHCTL_EL2.
• Any setting in MDCR_EL2.
• Any of the fine-grained traps in HAFGRTR_EL2, HDFGRTR_EL2, HDFGWTR_EL2, HFGITR_EL2, HFGRTR_EL2, HFGWTR_EL2.

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, equivalent controls are:

• Settings in HCR, other than the TIDCP bit.
For exceptions taken to AArch32 state there is no control equivalent to HCR_EL2.NV.
- Any setting in CNTHCTL or HDCR.
- If EL1 is using AArch64 state, any of the fine-grained traps in HAFGRTR_EL2, HDFGRTR_EL2, HDFGWTR_EL2, HFGITR_EL2, HFGRT_EL2, HFGWTR_EL2.

18

Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 4-17.

19

Exceptions caused by the SMC instruction being UNDEFINED because the value of SCR_EL3.SMD is 1.

20

Exceptions caused by the execution of an Exception generating instruction not covered by priority 10:
- For exceptions taken from AArch64 state, Branches, Exception generating, and System instructions on page C3-200 defines these and the priority 10 instructions.
- When executing in AArch32 state, the exception-generating instructions are SVC, HVC, and SMC.

21

Exceptions taken to EL3 because of configuration settings in the CPTR_EL3.

Note

When in Debug state and the value of EDSCR.SDD is 1, instructions executed at EL2, EL1 or EL0 that are configured by EL3 control registers to trap to EL3 are treated as UNDEFINED and generate an exception taken to EL2 or EL1. It is IMPLEMENTATION DEFINED whether these exceptions are prioritized as an UNDEFINED instruction or have the priority of the original trap exception.

22

Exceptions taken to EL3 from Secure EL1 using AArch32, because of execution of the instructions listed in Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2385.

23

Exceptions taken to EL3 from EL0, EL1, or EL2 because of configuration settings in the MDCR_EL3.

Note

When in Debug state and the value of EDSCR.SDD is 1, instructions executed at EL2, EL1 or EL0 that are configured by EL3 control registers to trap to EL3 are treated as UNDEFINED and generate an exception taken to EL2 or EL1. It is IMPLEMENTATION DEFINED whether these exceptions are prioritized as an UNDEFINED instruction or have the priority of the original trap exception.

24

Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities 4-23.

Note

When in Debug state and the value of EDSCR.SDD is 1, instructions executed at EL2, EL1 or EL0 that are configured by EL3 control registers to trap to EL3 are treated as UNDEFINED and generate an exception taken to EL2 or EL1. It is IMPLEMENTATION DEFINED whether these exceptions are prioritized as an UNDEFINED instruction or have the priority of the original trap exception.

25

If FEAT_FPAC is implemented, exceptions generated from a pointer authentication instruction authorization failure. See Faulting on pointer authentication on page D5-2533.

26

Trapped floating-point exceptions, if supported. See Floating-point exceptions and exception traps on page D1-2354.

27

This priority number represents debug events.

28

SP alignment faults. See SP alignment checking on page D1-2327.
Data Abort exceptions other than a Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk or the update of a page table entry. That is, any Data Abort exception that is not covered by item 31. See AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D5-2652. It is IMPLEMENTATION DEFINED whether synchronous External aborts are prioritized here or as item 31.

Watchpoint exceptions. See Watchpoint exceptions on page D2-2451.

Data Abort exception:

- Generated by a synchronous External abort that was not generated by a translation table walk or the update of a page table entry, see External aborts on page D4-2519.
- If FEAT_MTE is implemented and enabled, Tag Check Faults are prioritized as Data Abort. For more information, see PE handling of Tag Check Fault on page D6-2690.
- It is IMPLEMENTATION DEFINED whether synchronous External aborts are prioritized here or as item 29.

For items 29-31, if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

--- Note ---

Exceptions generated by a translation table walk are reported and prioritized as either an Instruction Abort exception, priority 7 in this list, or a Data Abort exception, priority 29 in this list. See also AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D5-2652.

---

**D1.12.5 Effect of Data Aborts and Watchpoints**

If an instruction that stores to memory generates a Data Abort or Watchpoint, the value of each memory location that instruction stores to is either:

- Unchanged for any location for which one of the following applies:
  - An Alignment fault is generated.
  - An MMU fault is generated.
  - A Watchpoint exception or Watchpoint debug event is generated.
  - An External abort is generated, if that External abort is taken synchronously.

--- Note ---

If an External abort is taken asynchronously, using the SError interrupt, it is outside the scope of the architecture to define the effect of the store on the memory location, because it depends on the system-specific nature of the External abort. However, in general, Arm recommends that such memory locations are not updated.

---

- UNKNOWN for any location for which no exception and no debug event is generated.

For External aborts and Watchpoint exceptions, the size of a memory location is defined as being the size for which a memory access is single-copy atomic.

--- Note ---

For the definition of a single-copy atomic access, see Properties of single-copy atomic accesses on page B2-120.

---

An External abort might signal a data corruption to the PE. For example a memory location might have been corrupted. The error that caused the External abort might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.
For Data Aborts from load or store instructions executed in AArch64 state, if the:

**Data Abort is taken synchronously**

- If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
- If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
- If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.

**Data Abort is taken asynchronously, using the SError interrupt**

If the instruction was a load, the destination registers of the load take an UNKNOWN value if the SError interrupt is taken at a point in the instruction stream after the load.

---

**D1.12.6 Floating-point exceptions and exception traps**

Execution of a floating-point instruction, or an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a floating-point exception.

**Note**

In AArch64 state, a floating-point instruction performs only a single floating-point operation. However, an Advanced SIMD instruction that operates on floating-point values can perform multiple floating-point operations. Therefore, this section describes the handling of a floating-point exception on an operation, rather than on an instruction.

The Armv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED:

- For an implementation that does provide this capability, FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are the control bits that enable synchronous exception generation for each of the different floating-point exceptions.
- For an implementation that does not provide this capability, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits are RAZ/WI.

**Note**

- An Input Denormal floating-point exception is generated when a single-precision or double-precision floating-point value is flushed-to-zero because the value of FPCR.FZ is 1. However, no Input Denormal exception is generated when a half-precision floating-point value is flushed-to-zero because the value of FPCR.FZ16 is 1.
- The Armv8-A architecture does not support asynchronous reporting of floating-point exceptions.

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that an exception can never be taken to a lower Exception level.

The exception is reported in the ESR_ELx for the Exception level to which it is taken.
In an implementation that includes synchronous exception generation for floating-point exceptions in AArch64 state:

- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception bits in the event of such an exception. For more information, see [Combinations of floating-point exceptions](#).

- When the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the ESR_ELx reports only the exceptions that occur in a single element that the instruction uses. The architecture does not specify which element is reported.

The AArch64.FPTrappedException() and FPProcessException() pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch64 state.

### Combinations of floating-point exceptions

Many pseudocode functions perform floating-point operations, including FixedToFP(), FPAdd(), FPCmpare(), FCmpareEQ(), FCmpareGE(), FCmpareGT(), FPDiv(), FPMax(), FPMin(), FMul(), FMulAdd(), FPrecipEstimate(), FPrecipStepFused(), FPRSqrtEstimate(), FPRSqrtStepFused(), FPSqrt(), FPSqr(), FSub(), and FPToFixed(). All of these operations can generate floating-point exceptions.

**Note**

FPAbs() and FPNeg() are not classified as floating-point operations because:

- They cannot generate floating-point exceptions.
- The floating-point operation behavior described in the following sections does not apply to them:
  - [Flush-to-zero on page A1-55](#).
  - [NaN handling and the Default NaN on page A1-56](#).

More than one floating-point exception can occur on the same operation. The only combinations of floating-point exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other floating-point exceptions.

The priority order of these floating-point exceptions is that the Inexact exception is treated as lowest priority, and the Input Denormal exception is treated as highest priority.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, a floating-point exception on one operation is treated as higher priority than a floating-point exception on another operation if the occurrence of the second floating-point exception depends on the result of the first operation. Otherwise, it is [CONstrained UnPREDictable](#) which floating-point exception is treated as higher priority, where the exception prioritized might differ between different instances of the same two floating-point exceptions being generated on the same operation during execution of the instruction.

When none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative bit in the FPSR to be set to 1.

When a floating-point exception is trapped:

- It is IMPLEMENTATION DEFINED whether the FPSR is restored when the trapped floating-point exception is taken. If the FPSR is not restored then, then it is CONstrained UnPREDictable which untrapped floating-point exception, if any, are indicated by the corresponding FPSR cumulative exception bits having the value 1.

- In the ESR_ELx for the Exception level to which the trapped exception is taken, the value of the floating-point exception trapped bit for the highest priority trapped floating-point exception must be 1.
In this ESR_ELx:

— The value of the floating-point exception trapped bit for any other untrapped floating-point exception generated by the same operation must be 0. This applies to both higher priority and lower priority untrapped floating point exceptions.

— The value of the floating-point exception trapped bit for any lower priority trapped floating-point exception generated by the same operation might be 1, but the architecture does not require this.

For trapped floating-point exceptions from Advanced SIMD instructions, the architecture does not define the floating-point exception prioritization between different elements of the instruction. The architectural requirements for floating-point exception prioritization apply only to multiple floating-point exceptions generated on the same element of an Advanced SIMD operation.

**Note**

An implementation might provide information about a lower priority or untrapped floating-point exceptions in an IMPLEMENTATION DEFINED way, for example using an IMPLEMENTATION DEFINED register.
D1.13 Asynchronous exception types, routing, masking and priorities

In the Armv8-A architecture, asynchronous exceptions that are taken to AArch64 state are also known as interrupts.

There are two types of interrupts:

**Physical interrupts**
- Are signals sent to the PE from outside the PE. They are:
  - SError. System Error.
  - IRQ.
  - FIQ.

**Virtual interrupts**
- Are interrupts that software executing at EL2 can enable and make pending. A virtual interrupt is taken from EL0 or EL1 to EL1.
- Virtual interrupts have names that correspond to the physical interrupts:
  - vSError.
  - vIRQ.
  - vFIQ.

---

**Note**

- For information about how virtual interrupts might be used, see *Virtual interrupt usage model* on page D1-2320.
- The SError interrupt replaces the Armv7 asynchronous abort. The new name better describes the nature of the exception, and means that, in AArch64 state, it is categorized as a unique exception class, with EC encoding 0x2F.

An External abort generated by the memory system might be taken asynchronously using the SError interrupt. These SError interrupts always behave as edge-triggered interrupts. An implementation might include other sources of SError interrupt. It is IMPLEMENTATION DEFINED whether these other sources are edge-triggered or level-sensitive. See also *External aborts on page D4-2519.*

Each physical interrupt type can be assigned a target Exception level of EL1, EL2 or EL3, as shown in *Asynchronous exception routing on page D1-2358.*

When an interrupt occurs:

- On taking an SError or a vSError interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is updated to describe an SError interrupt.
  - When the RAS Extension is implemented, the exception syndrome for the vSError interrupt is taken from the values in the VSESR_EL2 register. See *Exception classes and the ESR_ELx syndrome registers on page D1-2336,* and the *ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.*
- On taking an IRQ, vIRQ, FIQ or vFIQ interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is not updated.

The remainder of this section contains the following:

- *Asynchronous exception routing on page D1-2358.*
- *Asynchronous exception masking on page D1-2361.*
- *Virtual interrupts on page D1-2363.*
- *Prioritization and recognition of interrupts on page D1-2365.*
- *Taking an interrupt or other exception during a multi-access load or store on page D1-2366.*
### D1.13.1 Asynchronous exception routing

The following tables show the routing of physical interrupts when the highest implemented Exception level is using AArch64:

- For implementations that include both EL2 and EL3, see Table D1-8.
- For implementations that include EL3 but not EL2, see Table D1-9 on page D1-2359.
- For implementations that include EL2 but not EL3, see Table D1-10 on page D1-2360.

When the highest implemented Exception level is using AArch32, see Table G1-19 on page G1-5776.

In the tables:

**SCR**
- This is the *Effective value* of a field in SCR.

**FIQ IRQ EA**
- The *Effective value* of the field that handles the asynchronous exception type in SCR, if the highest EL is using AArch32, or SCR\_EL3, if the highest EL is using AArch64.

**HCR**
- This is the *Effective value* of a field in HCR, if EL2 is using AArch32 or HCR\_EL2 if EL2 is using AArch64.

  - When the value of the TGE is 1, the virtual exceptions are disabled.

  - When the *Effective value* of HCR.\{E2H, TGE\} is:
    - \{0, 1\} The *Effective value* of each of the HCR.\{AMO, IMO, FMO\} fields is 1.
    - \{1, 1\} The *Effective value* of each of the HCR.\{AMO, IMO, FMO\} fields is 0.

**FMO IMO AMO**
- The *Effective value* of the mask override field for the asynchronous exception type in HCR, if EL2 is using AArch32 or HCR\_EL2 if EL2 is using AArch64.

**EL2**
- The exception is taken to EL2 using AArch64.

**EL3**
- The exception is taken to EL3 using AArch64.

**C**
- The interrupt is not taken and remains pending, regardless of the PSTATE.\{A, I, F\} interrupt masks.

**FIQ IRQ Abt**
- The exception is taken to the FIQ mode, the IRQ mode or the Abort mode according to the type of asynchronous exception.

**Hyp**
- The exception is taken to AArch32 Hyp mode.

**Mon**
- The exception is taken to AArch32 Monitor mode.

**n/a**
- Not applicable. The field does not exist in the register in this configuration or the Exception level is not accessible in this configuration.

D1.13.2 Asynchronous exception masking

When an interrupt is masked, it means that it cannot be taken. Instead, it remains pending.

When executing in AArch64 state, interrupts are masked implicitly when the target Exception level of the interrupt is lower than the current Exception level.

In addition, interrupts can be masked when the target Exception level is the current Exception level. The controls for this are:

- **SError**: PSTATE.A
- **IRQ**: PSTATE.I
- **FIQ**: PSTATE.F

When the target Exception level is higher than the current Exception level:

- If the target Exception level is EL3, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL2, and either HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL2, HCR_EL2.E2H is 1, and HCR_EL2.TGE is 1, the interrupt can be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL1, the interrupt can be masked by the PSTATE.{A, I, F} bits.

**Note**

- The ability to execute in EL0 with interrupts to EL1 masked is required by some user level driver code.
- The PSTATE.{A, I, F} bits can mask both physical interrupts and virtual interrupts.
- The Armv8-A architecture does not support Non-maskable FIQ (NMFI) operations. This means that it does not provide a configuration option to override the masking of FIQs by PSTATE.F.

On taking any exception to an Exception level using AArch64, all of PSTATE.{A, I, F} are set to 1, masking all interrupts that target that Exception level.

The following tables show the masking of physical interrupts when the highest implemented Exception level is using AArch64:

- For implementations that include both EL2 and EL3, see Table D1-11 on page D1-2362.
- For implementations that include EL3 but not EL2, see Table D1-12 on page D1-2363.
- For implementations that include EL2 but not EL3, see Table D1-13 on page D1-2363.

For the masking of interrupts when the highest implemented Exception level is using AArch32, see Table G1-20 on page G1-5777.

For the masking of virtual interrupts, see Virtual interrupts on page D1-2363.

In the tables:

- **SCR**: This is the Effective value of a field in SCR.
- **FIQ IRQ EA**: The Effective value of the field that handles the asynchronous exception type in SCR, if the highest EL is using AArch32, or SCR_EL3, if the highest EL is using AArch64.
- **HCR**: This is the Effective value of a field in HCR.
- **FMO IMO AMO**: The Effective value of the mask override field for the asynchronous exception type in HCR, if EL2 is using AArch32 or HCR_EL2 if EL2 is using AArch64.
- **A**: When the interrupt is asserted it is taken regardless of the value of the PSTATE.{A, I, F} interrupt masks.
When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is not taken. If the value of the mask is 0 the interrupt is taken.

A/B

When FEAT_DoubleFault is implemented, the interrupt is an SError interrupt, and SCR_EL3.NMEA is 1, then the interrupt behaves as A. Otherwise, the interrupt behaves as B.

C

When the interrupt is asserted it is not taken, regardless of the value of the PSTATE.{A, I, F} interrupt masks.

n/a

Not applicable. The PE cannot be executing at this Exception level for the specified state of HCR and SCR_EL3.

a. When the implementation does not include FEAT_SEL2, the SCR_EL3.EEL2 field is not implemented and the Effective value of EEL2 is 0.

b. When the implementation does not include FEAT_VHE, the HCR_EL2.E2H field is not implemented and the Effective value of E2H is 0.
### D1.13.3 Virtual interrupts

When the value of HCR_EL2.TGE is 0, setting an HCR_EL2.{FMO, IMO, AMO} routing control bit to 1 enables the corresponding virtual interrupt. When the value of HCR_EL2.TGE is 1 all virtual interrupts are disabled.

When execution is at EL2 or EL3, all types of virtual interrupt are always masked. If EL2 is not enabled in the current Security state, all types of virtual interrupts are always masked.

Virtual interrupts can only be taken from EL0 or EL1 to EL1. When a virtual interrupt type is enabled, that type of interrupt can be generated by:

- Software setting the corresponding virtual interrupt pending bit, HCR_EL2.{VSE, VI, VF}, to 1.
- For a vIRQ or a vFIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the ARM Generic Interrupt Controller Architecture Specification.

**Note**

For a usage model for virtual interrupts, see *Virtual interrupt usage model on page D1-2320*.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the ISR_EL1.

Each virtual interrupt type can be masked when execution is in EL1 or EL0, by using the same Process State mask bits that mask the physical interrupts, PSTATE.{A, I, F}.

---

Table D1-14 summarizes the bits that enable virtual interrupts and the bits that cause virtual interrupts to be pending.

### Table D1-14 HCR_EL2 interrupt control bits

<table>
<thead>
<tr>
<th>Virtual interrupt type</th>
<th>Enable controla</th>
<th>Cause a virtual interrupt to be pending</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSError</td>
<td>HCR_EL2.AMO</td>
<td>HCR_EL2.VSE</td>
</tr>
<tr>
<td>vIRQ</td>
<td>HCR_EL2.IMO</td>
<td>HCR_EL2.VI</td>
</tr>
<tr>
<td>vFIQ</td>
<td>HCR_EL2.FMO</td>
<td>HCR_EL2.VF</td>
</tr>
</tbody>
</table>

a. Applies only when the value of HCR_EL2.TGE is 0, otherwise the virtual interrupts are disabled.

On taking a vIRQ or a vFIQ interrupt, the corresponding virtual interrupt pending bit in the HCR_EL2 retains its state.

On taking a vSError interrupt, HCR_EL2.VSE is cleared to 0.

Note

This means that if the virtual interrupt pending bits are used, the vIRQ or vFIQ exception handler must cause software executing at EL2 or EL3 to set their corresponding virtual interrupt pending bits to 0.

Taking a vSError interrupt to an Exception level using AArch64 updates ESR_EL1 with the encoding for an SError interrupt. For the encoding, see *Exception classes and the ESR_ELx syndrome registers on page D1-2336*. When the RAS Extension is implemented, the exception syndrome for the vSError interrupt is taken from the values in the VSESR_EL2 register, see the *ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*. Taking a vIRQ or a vFIQ interrupt to an Exception level using AArch64 does not update the ESR_EL1.

The following table shows the masking of virtual interrupts when the highest implemented Exception level is using AArch64. In the table:

- **B** When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is taken. If the value of the mask is 0 the interrupt is taken.
- **C** When the interrupt is asserted it is not taken, regardless of the value of the Process state mask.
- **n/a** Not applicable. The PE cannot be executing at this Exception level for the specified state of HCR and SCR_EL3.
- **HCR** In Table D1-15, including in the table footnote:
  - When EL2 is using AArch64 HCR refers to the AArch64 register HCR_EL2.
  - When EL2 is using AArch32 HCR refers to the AArch32 register HCR.

When the value of HCR.TGE is 1, the virtual exceptions are disabled.

When the *Effective value* of HCR.\{E2H, TGE\} is:

- \{0, 1\} The *Effective value* of each of the HCR.\{AMO, IMO, FMO\} fields is 1.
- \{1, 1\} The *Effective value* of each of the HCR.\{AMO, IMO, FMO\} fields is 0.

</tbody>
</table>
D1.13.4 Prioritization and recognition of interrupts

The prioritization of interrupts, including virtual interrupts, is IMPLEMENTATION DEFINED.

Note

As indicated at the start of Asynchronous exception types, routing, masking and priorities on page D1-2357, in AArch64 state all possible asynchronous exceptions are defined as interrupts.

Any interrupt that is pending before a Context synchronization event in the following list, is taken before the first instruction after the context synchronizing event, provided that the pending interrupt is not masked:

- Execution of an ISB instruction.
- Exception entry, if FEAT_ExS is not implemented, or if FEAT_ExS is implemented and the appropriate SCTLR_ELx.EIS bit is set.
- Exception return, if FEAT_ExS is not implemented or if FEAT_ExS is implemented and the appropriate SCTLR_ELx.EOS bit is set.
- Exit from Debug state.

Note

If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define whether the PE takes the interrupt or the synchronous exception first.

- The ISR_EL1 identifies any pending interrupts.
- Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronizing events does not include the DCPS and DRPS instructions.

An error synchronization event defines additional requirements for taking an SError interrupt, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

In the absence of a specific requirement to take an interrupt, the architecture only requires that unmasked pending interrupts are taken in finite time.

If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits the interrupt to be taken, but does not require this to happen. If the interrupt is taken then it must be taken before the first Context synchronization event after the interrupt was changed to not pending.
D1.13.5 Taking an interrupt or other exception during a multi-access load or store

In AArch64 state, interrupts can be taken during a sequence of memory accesses caused by a single load or store instruction. This is true regardless of the memory type being accessed.

If an interrupt, or another exception, is taken from AArch64 during the execution of an instruction that performs a sequence of memory accesses, rather than a single single-copy atomic access, then:

• For a load, any register being loaded by the instruction other than ones used in the generation of the address by the instruction, can contain an UNKNOWN value. Registers used in the generation of the address are restored to their initial value.

• For a store, any data location being stored to by the instruction can contain an UNKNOWN value.

• For either a load or a store, if the instruction specifies writeback of the base address, then that register is restored to its initial value.

__Note__

• This interrupt behavior is in contrast to behavior in AArch32 state, when interrupts cannot be taken during a sequence of memory accesses caused by a single load or store instruction.

• In both Execution states, synchronous data abort exceptions can be taken during the execution of an instruction that performs a sequence of memory accesses.

• Software must avoid using multiple-register load and store instructions for accesses to Device memory, particularly to Device memory with the non-Gathering attribute, because an exception taken during the load or store can result in repeated accesses.
D1.14 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch64 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an instruction enable, an instruction disable, or a trap control.

Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Exception level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

Trap controls

A trap control determines whether one or more particular instructions, whenever executed at a particular Exception level, are trapped.

A trapped instruction generates a Trap exception.

For trap controls provided by:

- **EL1** Trap exceptions are taken to EL1, unless routed from EL0 to EL2 because HCR_EL2.TGE is 1, as described in Routing exceptions from EL0 to EL2 on page D1-2348. For descriptions of these controls, see EL1 configurable controls on page D1-2368.
- **EL2** Trap exceptions are taken to EL2. For descriptions of these controls, see EL2 configurable controls on page D1-2372.
- **EL3** Trap exceptions are taken to EL3. For descriptions of these controls, see EL3 configurable controls on page D1-2383.

--- Note ---

The definitions of traps and enables and disables overlap, and the classification of some controls is historical. In AArch64 state, the most significant characteristic of an exception report is the ESR_ELx.EC value with which it is reported. Describing a register control field as an instruction enable, an instruction disable, or a trap control, gives no indication of how an exception that is generated as a consequence of the value of that field is handled or reported.

An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if both of the following apply:

- The instruction generating the exception does not also generate a higher priority exception. Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2349 defines the prioritization of different exceptions on the same instruction.
- The instruction is not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state it is executed in. UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions can generate exceptions as a result of these controls, but the architecture does not require them to do so.

Exceptions generated as a result of these controls are synchronous exceptions.

Exceptions are reported in the ESR_ELx, with an EC value that indicates the Exception class, and:

- Many cases, including all traps, are reported with a non-zero EC value and an associated syndrome.
- Some cases where an instruction is UNDEFINED are reported with an EC value 0x00, the value for an exception for an unknown or uncategorized reason, and in these cases no syndrome is provided. ISS encoding for exceptions with an unknown reason on page D13-2967 identifies the cases that are reported with EC value 0x00.

Table D1-6 on page D1-2337 lists the EC values that are used for exceptions that result from traps, enables, and disables.

--- Note ---

- A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, SCTLR_EL1.DZE is a trap control even though DZE means DC ZVA Enable.
• In addition to the controls described in this section, a routing control, HCR_EL2.TGE, can be used to route exceptions from EL0 to EL2. See Routing exceptions from EL0 to EL2 on page D1-2348.

• An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

This section is organized as follows:

• Traps on instructions.
• EL1 configurable controls.
• EL2 configurable controls on page D1-2372.
• EL3 configurable controls on page D1-2383.

D1.14.1 Traps on instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means the preferred exception return of the exception is the instruction that is trapped.

If a conditional instruction is trapped, in AArch32 state, the Armv8-A architecture permits, but does not require the trap to apply to conditional AArch32 instructions that fail their Condition code check. For more information, see:

• Conditional execution of undefined instructions on page G1-5780.
• EL2 configurable controls on page G1-5827.
• EL3 configurable controls on page G1-5846.
• Limitations of the instruction pseudocode on page K14-8132.

If the instruction is a register access instruction:

• No access is made before the exception is taken.
• Side-effects that are normally associated with the access do not occur before the exception is taken.

D1.14.2 EL1 configurable controls

These controls are in _EL0 and _EL1 System registers. The resulting exceptions might be taken from either Execution state. SPSR_EL1.M[4] indicates which Execution state the exception was taken from.

If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 instead of EL1, see Routing exceptions from EL0 to EL2 on page D1-2348.

Table D1-16 shows the _EL0 and _EL1 System registers that contain these controls.

### Traps to EL1 of EL0 accesses to Activity Monitors registers

AMUSERENR_EL0.EN traps EL0 accesses to the Activity Monitors registers to EL1.
Traps to EL1 of EL0 accesses to the Generic Timer registers

CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} trap EL0 accesses to the Generic Timer registers to EL1, as follows:

- CNTKCTL_EL1.EL0PTEN traps EL0 accesses to the physical timer registers.
- CNTKCTL_EL1.EL0VTEN traps EL0 accesses to the virtual timer registers.
- CNTKCTL_EL1.EL0PCTEN traps EL0 accesses to the frequency register and physical counter register.
- CNTKCTL_EL1.EL0VCTEN traps EL0 accesses to the frequency register and virtual counter register.

Accesses to the frequency register, CNTFRQ_EL0 or CNTFRQ, are only trapped if CNTKCTL_EL1.EL0PCTEN and CNTKCTL_EL1.EL0VCTEN are both 0.

Traps to EL1 of EL0 and EL1 System register accesses to the trace registers

CPACR_EL1.TTA traps EL0 and EL1 System register accesses to the trace registers to EL1.

--- Note ---

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the Armv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and the resulting exception is higher priority than a CPACR_EL1.TTA Trap exception.
- The Armv8-A architecture does not provide traps on trace register accesses through the optional Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Traps on instructions on page D1-2368.

Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality

When EL1 is using AArch64, CPACR_EL1.FPEN traps EL0 and EL1 accesses of the following registers to EL1:

- FPCR, FPSR, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See The SIMD and floating-point registers, V0-V31 on page D1-2322.
- FPSCR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point System registers on page G1-5814.

The value of CPACR_EL1.FPEN determines whether the trap applies to accesses from both EL0 and EL1 using AArch64, or only to accesses from EL0 accesses from both Execution states.

Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers

MDSCR_EL1.TDCC traps EL0 accesses to the DCC registers to EL1.

Traps of AArch32 accesses to DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

Traps of AArch64 accesses to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0 are ignored in Debug state.

Traps to EL1 of EL0 accesses to Performance Monitors registers

PMUSERENR_EL0.{ER, CR, SW, EN} trap EL0 accesses to the Performance Monitors registers to EL1.

For those Performance Monitors registers that more than one PMUSERENR_EL0.{ER, CR, SW, EN} control applies to, accesses are only trapped if all controls that apply are set to 0.

The accesses that these trap controls trap might be reads, writes, or both.

PMUSERENR_EL0.EN traps EL0 access only if the corresponding EL1 accesses is permitted. For example, the PMSWINC_EL0 and PMSWINC registers are WO at EL1, and therefore are not trapped.
Enabling use of the Pointer authentication instructions, EL1&0 translation regime

This control is implemented when FEAT_PAuth is implemented.

Each of the SCTLR_EL1.{EnDA, EnDB, EnIA, EnIB} fields enables the pointer authentication functionality for the corresponding Pointer authentication instructions for the EL1&0 translation regime. For more information, see System register control of pointer authentication on page D5-2533.

--- Note ---
These controls cause the pointer authentication instructions to execute as NOPs. They never cause an exception to be generated.

Traps to EL1 of EL0 execution of cache maintenance instructions

SCTLR_EL1.UCI traps EL0 execution using AArch64 of cache maintenance instructions to EL1.

Traps to EL1 of EL0 execution of \texttt{WFE} and \texttt{WFI} instructions

SCTLR_EL1.{nTWE, nTWI} trap EL0 execution of \texttt{WFE} and \texttt{WFI} instructions to EL1 if the instruction would otherwise have caused the PE to enter a low-power state.

--- Note ---
Since a \texttt{WFE} or \texttt{WFI} can complete at any time, even without a Wakeup event, the traps on \texttt{WFE} of \texttt{WFI} are not guaranteed to be taken, even if the \texttt{WFE} or \texttt{WFI} is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- \textit{Wait for Event mechanism and Send event} on page D1-2391.
- \textit{Wait For Interrupt} on page D1-2394.

Traps to EL1 of EL0 accesses to the CTR_EL0

SCTLR_EL1.UCT traps EL0 accesses using AArch64 to the CTR_EL0 to EL1.

Traps to EL1 of EL0 execution of \texttt{DC ZVA} instructions

SCTLR_EL1.DZE traps EL0 execution of \texttt{DC ZVA} instructions to EL1. If the trap is enabled, reading the DCZID_EL0 returns a value that indicates that \texttt{DC ZVA} instructions are not implemented.

Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks

SCTLR_EL1.UMA traps EL0 execution of MSR and MRS instructions that access the PSTATE.{D, A, I, F} masks to EL1. If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2.

Disabling or enabling EL0 use of AArch32 deprecated functionality

Table D1-19 on page D1-2372 shows the deprecated AArch32 functionality that might have disable controls in the SCTLR_EL1:

- The SED control is always implemented.
- Whether each of the ITD, CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.
These SCTLR_EL1 controls apply only to execution at EL0 using AArch32. When an instruction is disabled by one of these controls, it is UNDEFINED at EL0 using AArch32. Table D1-19 shows how the exceptions are reported in ESR_EL1:

Table D1-19 EL1 controls for disabling and enabling EL0 use of AArch32 deprecated functionality

<table>
<thead>
<tr>
<th>Deprecated AArch32 functionality</th>
<th>Instruction enable or disable in the SCTLR_EL1</th>
<th>Disabled instructions</th>
<th>Syndrome reporting in ESR_EL1a</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETEND instructions</td>
<td>SEDb</td>
<td>SETEND instructions</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td>Some uses of IT instructions</td>
<td>ITDc</td>
<td>See the SCTLR_EL1.IT description</td>
<td></td>
</tr>
<tr>
<td>Accesses to the CP15DMB, CP15DSB, and CP15ISB barrier instructions</td>
<td>CP15BEND</td>
<td>MCR accesses to the CP15DMB, CP15DSB, and CP15ISB instructions</td>
<td></td>
</tr>
</tbody>
</table>

- a. If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, the exception is routed to EL2 and reported in ESR_EL2 using the EC value shown in the table.
- b. SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
- c. IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
- d. System register (coproc == 0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

---

**Note**

- The uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB barrier instructions, are deprecated for performance reasons.
- The SCTLR provides similar controls that apply when EL1 is using AArch32, and the HSCTLR provides similar controls that apply when EL2 is using AArch32.

---

**Disabling Address tagging for instruction accesses, EL1&0 translation regime**

This control is implemented when FEAT_PAuth is implemented.

When a TCR_EL1.{TBI0, TBI1} field enables the use of address tagging for the EL1&0 translation regime, the corresponding TCR_EL1.{TBID0, TBID1} field determines whether address tagging is used for both data and instruction addresses, or only for data addresses. For more information, see *Address tagging in AArch64 state* on page D5-2528.

---

**Note**

These controls determine the scope of address tagging. They never cause an exception to be generated.

---

**D1.14.3 EL2 configurable controls**

These controls are in _EL2 System registers. The resulting exceptions might be taken from either Execution state. SPSR_EL2.M[4] indicates which Execution state the exception was taken from.

These controls are ignored in Secure state.

FEAT_FGT provides fine-grained traps for architected system registers. Where implementations have IMPLEMENTATION DEFINED registers accessible from EL1 or EL0, Arm recommends that EL2 accessible fine-grained traps are provided for these registers using a control register held in IMPLEMENTATION DEFINED space.
Table D1-20 shows the _EL2 System registers that contain these controls.

Table D1-20 _EL2 registers that contain instruction disables and trap controls

Also see the following for more general information about traps to EL2:

- *Traps on instructions on page D1-2368.*
- For traps from an Exception level using AArch32:
  - *Instructions that fail their Condition code check on page G1-5829.*
  - *Trapping to EL2 of instructions that are UNPREDICTABLE on page G1-5829.*

Traps to EL2 of EL0 and EL1 accesses to the Generic Timer registers

CNTHCTL_EL2, {EL1PCEN, EL1PCTEN} trap EL0 and EL1 accesses to the Generic Timer registers to EL2 if enabled for the current Security state, as follows:

- CNTHCTL_EL2.EL1PCEN traps EL0 and EL1 accesses to the physical timer registers.
- CNTHCTL_EL2.EL1PCTEN traps EL0 and EL1 accesses to the physical counter register.

Trapping to EL2 of EL1 accesses to the CPACR_EL1 or CPACR

CPTR_EL2.TCPAC traps EL1 accesses to the CPACR_EL1 or CPACR to EL2:

Note

- The CPACR_EL1 or CPACR is not accessible at EL0.
- In Armv7 and earlier versions of the Arm architecture, one function of the CPACR is as an ID register that identifies what coprocessor or conceptual coprocessor functionality is implemented. Legacy software might use this identification mechanism, and a hypervisor can use this trap to emulate this mechanism. For more information about this coprocessor model, see *Background to the System register interface on page G1-5810.*

Traps to EL2 of EL1 and EL0 accesses to Activity Monitors registers

CPTR_EL2.TAM traps EL1 and EL0 accesses to the Activity Monitor registers to EL2.
Traps to EL2 of System register accesses to the trace registers

**CPTR_EL2.TTA** traps System register accesses to the trace registers to EL2.

--- **Note** ---

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the Armv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than a **CPTR_EL2.TTA** Trap exception.

- EL2 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see *Traps on instructions* on page D1-2368.

General trapping to EL2 of accesses to the SIMD and floating-point registers

**CPTR_EL2.TFP** traps accesses to the following SIMD and floating-point registers to EL2:

- **FPCR, FPSR, FPEXC32_EL2**, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See *The SIMD and floating-point registers, V0-V31* on page D1-2322.

- **FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC**, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See *Advanced SIMD and floating-point System registers* on page G1-5814. Permitted VMSR accesses to the FPSID are ignored, but for the purposes of this trap the architecture defines a VMSR access to the FPSID from EL1 or higher as an access to a SIMD and floating-point register.

Fine-grained traps to EL2 of EL0 and EL1 read accesses to Activity Monitors registers

The fields in **HAFGRTR_EL2** trap read accesses to individual or pairs of Activity Monitors registers to EL2 if enabled in the current Security state. The values of the register are treated as 0 for all purposes other than direct reads of the register when **HCR_EL2.{E2H, TGE}** is \{1,1\}.

EL1 accesses are trapped from AArch64. When EL1 is using AArch64 and the functionality is accessible from EL0, EL0 accesses are trapped from AArch64 or AArch32.

If the Activity monitors extension is not implemented, **HAFGRTR_EL2** is not implemented. If an Activity monitor auxiliary counter is not implemented, the corresponding field in **HAFGRTR_EL2** is RES0.

Traps to EL2 of EL1 accesses to the RAS error record registers

**HCR_EL2.TERR** traps EL1 accesses to the RAS ER* registers to EL2 if enabled in the current Security state.

**HCR_EL2.FIEN** traps EL1 accesses to the RAS ER* registers to EL2 if enabled in the current Security state.

Trap to EL2 of EL1 accesses to **AT S1E*<sup>+</sup> instructions**

This control is implemented when **FEAT_NV** is implemented.

**HCR_EL2.AT** traps to EL2, if enabled in the current Security state, from EL1 accesses to some Address translation instructions. Because nested virtualization is supported only in AArch64 state this control only traps from AArch64 state.

For more information, see *Effect of HCR_EL2.{NV, NV1}* on page D5-2638.

Traps to EL2 for Nested virtualization

These controls are implemented when **FEAT_NV** is implemented.
Note

When FEAT_NV2 is implemented and HCR_EL2.NV2 is 1, the redirection of register accesses to memory accesses has priority over the trapping of register accesses by HCR_EL2.{NV, NV1}, see Enhanced support for nested virtualization on page D5-2640.

HCR_EL2.NV traps the following to EL2, if enabled in the current Security state, from EL1:

- Some System register, System instruction, and Special-purpose register accesses that are UNDEFINED at EL1 when FEAT_NV is not implemented.
- Only accesses that are not UNDEFINED at EL2 are trapped.

Note

This means that, for a register that is RO at EL2, and UNDEFINED at Non-secure EL1 when FEAT_NV is not implemented, when FEAT_NV is implemented and this trap is enabled:

- Read accesses to the register from EL1 are trapped to EL2.
- Write accesses to the register from EL1 remain UNDEFINED.

- The execution of some instructions that are UNDEFINED at EL1 when FEAT_NV is not implemented.

Because nested virtualization is supported only in AArch64 state this control only traps from AArch64 state.

Note

In addition, when the value of HCR_EL2.NV is 1, a read of CurrentEL returns the value 0b10 for bits[3:2].

HCR_EL2.NV1 traps to EL2, if enabled in the current Security state, from EL1 accesses to some System registers and Special-purpose registers. Because nested virtualization is supported only in AArch64 state this control only traps from AArch64 state.

For more information, see Effect of HCR_EL2.{NV, NV1} on page D5-2638.

Trap to EL2 of EL0 accesses to Pointer authentication instructions

This control is implemented when FEAT_PAuth is implemented.

HCR_EL2.API traps, to EL2 if enabled in the current Security state, accesses to any of the Pointer authentication instructions for which pointer authentication is enabled, for instructions executed either:

- At EL1.
- If the Effective value of HCR_EL2.{TGE, E2H} is not {1, 1}, at EL0.

Because pointer authentication is supported only in AArch64 state, this control only traps from AArch64 state.

For more information, including the description of when pointer authentication is enabled for an instruction, see System register control of pointer authentication on page D5-2533.

Trap to EL2 of EL1 accesses to Pointer authentication key registers

This control is implemented when FEAT_PAuth is implemented.

HCR_EL2.APK traps, to EL2 if enabled in the current Security state, accesses to the Pointer authentication key registers from EL1 to EL2. Because pointer authentication is supported only in AArch64 state this control only traps from AArch64 state.

For more information, see System register control of pointer authentication on page D5-2533.

Traps to EL2 of EL1 accesses to virtual memory control registers

HCR_EL2.{TRVM, TVM} trap EL1 accesses to the virtual memory control registers to EL2, if enabled in the current Security state.
EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the Non-secure memory system. A hypervisor might use this trap as part of its virtualization of memory management.

Disabling Non-secure state execution of \texttt{HVC} instructions

\texttt{HCR\_EL2.HCD} disables execution of \texttt{HVC} instructions at EL2 and EL1, and any resulting exception is taken from the current Exception level to the current Exception level.

Note

\texttt{HVC} instructions are always \texttt{UNDEFINED} at EL0.

\texttt{HCR\_EL2.HCD} is only implemented if EL3 is not implemented. Otherwise, it is \texttt{RES0}.

Traps to EL2 of EL0 and EL1 execution of \texttt{DC ZVA} instructions

\texttt{HCR\_EL2.TDZ} traps EL0 and EL1 execution of \texttt{DC ZVA} instructions to EL2 if enabled in the current Security state, and reading the \texttt{DCZID\_EL0} returns a value that indicates that \texttt{DC ZVA} instructions are not implemented.

Traps to EL2 of EL1 execution of TLB maintenance instructions

In the Armv8-A architecture, the System instruction encoding space includes TLB maintenance instructions.

\texttt{HCR\_EL2.TTLB} traps EL1 execution of TLB maintenance instructions to EL2 if enabled in the current Security state:

Note

These instructions are always \texttt{UNDEFINED} at EL0.

For more information about these instructions, see:

- \texttt{TLB maintenance instructions} on page D5-2664, for the AArch64 state instructions.
- \texttt{The scope of TLB maintenance instructions} on page G5-6044, for the AArch32 state instructions.

Traps to EL2 of EL0 and EL1 execution of cache maintenance instructions

\texttt{HCR\_EL2.{TSW, TPC, TPU}} trap cache maintenance instructions to EL2, if enabled in the current Security state. Execution is trapped from EL1, or from EL0 if permitted by \texttt{SCTLR\_EL1.UCI}.

\texttt{HCR\_EL2.TSW} traps data or unified cache maintenance by set/way instructions.

Note

These instructions are always \texttt{UNDEFINED} at EL0.

\texttt{HCR\_EL2.TPC} traps data or unified cache maintenance to point of coherency instructions.

Note

\texttt{DC IVAC} is always \texttt{UNDEFINED} at EL0 using AArch64.

\texttt{DCIMVAC}, \texttt{DCCIMVAC}, and \texttt{DCCMVAC} are always \texttt{UNDEFINED} at EL0 using AArch32.

\texttt{HCR\_EL2.TPU} traps cache maintenance to point of unification instructions.
Note

IC IALLUIS and IC IALLU are always UNDEFINED at EL0 using AArch64.
ICIMVAU, ICIALLU, ICIALLUI, and DCCMVAU are always UNDEFINED at EL0 using AArch32.

For more information about these instructions, see:
- Cache maintenance instructions, and data cache zero operation on page C5-377 for the AArch64 instructions.
- Cache maintenance system instructions on page K15-8185 for the AArch32 instructions.

Traps to EL2 of EL1 accesses to the Auxiliary Control Register

HCR_EL2.TACR traps EL1 accesses to the Auxiliary Control Registers to EL2 if enabled in the current Security state:

Note

- The ACTLR_EL1, ACTLR, and ACTLR2 are not accessible at EL0.
- The Auxiliary Control Registers are IMPLEMENTATION DEFINED registers that might implement global control bits for the PE.

Traps to EL2 of EL0 and EL1 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the Armv8-A architecture are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of System registers for control of these features.

HCR_EL2.TIDCP traps the execution of System register access instructions that access any of the encodings described in Reserved encodings for IMPLEMENTATION DEFINED registers on page D12-2860 and any of the following AArch32 encodings:
- CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}.
- CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}.
- CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}.

Execution at EL1 is trapped to EL2 if enabled in the current Security state. Execution at EL1 is an IMPLEMENTATION DEFINED choice between either a trap to EL2, or UNDEFINED with any resulting exception taken to EL1.

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

Note

- Arm expects the trapping of EL0 accesses to these functions to EL2 to be unusual, and used only when the hypervisor is virtualizing EL0 operation. Arm strongly recommends that unless the hypervisor must virtualize EL0 operation, a EL0 access to any of these functions is UNDEFINED, as it would be if the implementation did not include EL2. The PE then takes any resulting exception to EL1.
- The trapping of accesses to these registers from EL1 is higher priority than an exception resulting from the register access being UNDEFINED.

Traps to EL2 of EL1 execution of SMC instructions

HCR_EL2.TSC traps EL1 execution of SMC instructions to EL2 if enabled in the current Security state. the value of SCR_EL3.SMD is ignored.

If EL3 is not implemented, HCR_EL2.TSC is RES0.

For more information about SMC instructions, see SMC on page C6-1202.
Note

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are UNDEFINED at EL0.
- HCR_EL2.TSC traps execution of the SMC instruction. It is not a routing control for the SMC exception. Trap exceptions and SMC exceptions have different preferred return addresses.

Traps to EL2 of EL0 and EL1 accesses to the ID registers

Other than the MIDR_EL1, MPIDR_EL1, and PMCR_EL0.N, the ID registers are divided into groups, with a trap control in the HCR_EL2 for each group.

HCR_EL2.TID0 traps accesses to primary device identification registers at EL1 and EL0 to EL2 if enabled in the current Security state. HCR_EL2.TID1 traps accesses to implementation identification registers at EL1 to EL2 if enabled in the current Security state. HCR_EL2.TID2 traps accesses to cache identification registers at EL1 and EL0 to EL2 if enabled in the current Security state. HCR_EL2.TID3 traps accesses to detailed feature identification registers at EL1 to EL2 if enabled in the current Security state.

Note

In AArch32 state, the detailed feature identification registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See The CPUID identification scheme on page G8-6135.

For the MIDR_EL1 and MPIDR_EL1, and for PMCR_EL0.N, the architecture provides read/write aliases. The original register becomes accessible only from EL2 or Secure state, and an EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

Table D1-23 ID register substitution

<table>
<thead>
<tr>
<th>Register</th>
<th>Original</th>
<th>Alias, EL2 using AArch64</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main ID</td>
<td>MIDR_EL1</td>
<td>VPIDR_EL2</td>
</tr>
<tr>
<td>Multiprocessor Affinity</td>
<td>MPIDR_EL1</td>
<td>VMPIDR_EL2</td>
</tr>
<tr>
<td>Performance Monitors Control Register</td>
<td>PMCR_EL0.N</td>
<td>MDCR_EL2.HPMN</td>
</tr>
</tbody>
</table>

Note

- If the OPTIONAL Performance Monitors Extension is not implemented, MDCR_EL2.HPMN is RES0 and PMCR_EL0 is reserved.
- MDCR_EL2.HPMN also affects whether a Performance Monitors counter can be accessed from EL0 or EL1. See the register description of MDCR_EL2 for more information.
- PMCR_EL0 contains other fields that identify the implementation. For more information about trapping accesses to the PMCR_EL0, see Traps to EL2 of EL0 and EL1 accesses to Performance Monitors registers on page D1-2383.

Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions

HCR_EL2.[TWE, TWI] trap EL0 and EL1 execution of WFE and WFI instructions to EL2 if the instruction would otherwise have caused the PE to enter a low-power state.
--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:
- Wait for Event mechanism and Send event on page D1-2391.
- Wait For Interrupt on page D1-2394.

**Fine-grained traps to EL2 of EL0 and EL1 accesses to the debug, trace, and PMU registers**

The fields in HDFGRTR_EL2 and HDFGWTR_EL2 trap read and write accesses to individual and groups of related debug and trace registers to EL2 if enabled in the current Security state. The values of the registers are treated as 0 for all purposes other than direct reads of the register when HCR_EL2.{E2H, TGE} is {1,1}.

Most RW registers have fine-grained traps for read and write accesses. However, PMCR_EL0 has a trap for write accesses only. For more details, see HDFGRTR_EL2 and HDFGWTR_EL2.

If a fine-grained trap selects a breakpoint or watchpoint that is not implemented, the access is UNDEFINED. Accesses to unimplemented registers and unimplemented event counters are UNDEFINED.

When FEAT_FGT is implemented, access to an implemented Performance Monitors counter <n> when n is greater than, or equal to MDCR_EL2.HPMN is always trapped to EL2, and the value of the corresponding fine-grained trap field in HDFGRTR_EL2 or HDFGWTR_EL2 is ignored. If FEAT_FGT is not implemented, access to an implemented Performance Monitors counter <n> when n is greater than or equal to MDCR_EL2.HPMN has CONSTRAINED UNPREDICTABLE behavior.

**Fine-grained traps to EL2 of EL0 and EL1 accesses to System registers**

The fields in HFGRTR_EL2 and HFGWTR_EL2 trap read or write accesses to individual or small groups of system registers to EL2 if enabled in the current Security state. The values of the register are treated as 0 for all purposes other than direct reads of the register when HCR_EL2.{E2H, TGE} is {1,1}.

EL1 accesses are trapped from AArch64. When EL1 is using AArch64 and the functionality is accessible from EL0, EL0 accesses are trapped from AArch64 or AArch32.

If a register is not implemented, the corresponding field is RES0.

**Fine-grained Traps to EL2 of EL0 and EL1 accesses to instructions**

The fields in HFGITR_EL2 trap specific system instructions to EL2 if enabled in the current Security state. The values of the register are treated as 0 for all purposes other than direct reads of the register when HCR_EL2.{E2H, TGE} is {1,1}.

If an instruction is not implemented and behaves as an unallocated instruction, the corresponding field in HFGITR_EL2 is RES0.

For cache maintenance instructions to a PoC, PoU, PoP, or PoDP, if no caches are defined to be affected in the implementation before that point in the memory system, it is IMPLEMENTATION DEFINED whether the instruction is trapped when the corresponding trap enable field is set.

**General trapping to EL2 of EL0 and EL1 accesses to System registers, from AArch32 state only**

HISTR_EL2.{T0-T3, T5-T13, T15} trap accesses to the AArch32 System registers in the coproc==0b1111 encoding space, by the register number, {c0-c3, c5-c13, c15} used for:
- The Cn argument used when accessing the register using an MCR or MRC instruction.
- The Cn argument used when accessing the register using an MCRR or MRRC instruction.
These traps are from AArch32 state only. They are from both:

- EL1 using AArch32.
- EL0 using AArch32.

--- Note ---

HSTR_EL2[4, 14] is reserved, RES0. Although the Generic Timer AArch32 System registers are implemented in the coproc==0b1111 encoding space and accessed using a CRn or CRm value of c14, EL2 does not provide a trap on accesses to the Generic Timer System registers.

--- System registers in the (coproc==0b1111) encoding space with IMPLEMENTATION DEFINED access permission from EL0 ---

For an AArch32 System register in the (coproc==0b1111) encoding space, which is accessed using a CRn or CRm value that can be trapped by a HSTR_EL2.Tn control, if an access to the register from EL0 is UNDEFINED when the value of the corresponding HSTR_EL2.Tn trap control is 0, then when that HSTR_EL2.Tn trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure EL0 using AArch32:

- Generates a Trap exception that is taken to EL2.
- Is UNDEFINED and generates an exception that is taken to Non-secure EL1.

If the instruction is treated as UNDEFINED and generates an exception that is taken to Non-secure EL1, and Non-secure EL1 is using AArch64, the exception is reported in ESR_EL1 as an exception for an unknown reason, using EC value 0x00.

--- Note ---

Arm expects that trapping to EL2 of Non-secure EL0 accesses to AArch32 System register in the (coproc==0b1111) encoding space will be unusual, and used only when the hypervisor must virtualize EL0 operation. Arm recommends that, whenever possible, Non-secure EL0 accesses to the System registers behave as they would if the implementation did not include EL2. This means that, if the architecture does not support the Non-secure EL0 access, then the register access instruction is treated as UNDEFINED and generates an exception that is taken to Non-secure EL1.

--- Traps to EL2 of System register accesses to the trace filter control registers ---

MDCR_EL2.TTRF traps System register accesses to the trace filter control registers to EL2, if enabled in the current Security state.

--- Traps to EL2 of EL0 and EL1 System register accesses to debug registers ---

MDCR_EL2.{TDRA, TDOSA, TDA} trap System register accesses to the debug registers to EL2 if enabled in the current Security state, as follows:

- MDCR_EL2.TDRA traps EL0 and EL1 accesses to the Debug ROM registers to EL2 if enabled in the current Security state. This trap applies to Non-secure EL0 only if it is using AArch32. If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDRA is 1 other than for the purpose of a direct read.
- MDCR_EL2.TDOSA traps EL1 accesses to powerdown debug registers to EL2 if enabled in the current Security state. These registers are not accessible at EL0. If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDOSA is 1 other than for the purpose of a direct read.
- MDCR_EL2.TDA traps EL0 and EL1 accesses to those debug System registers that are not trapped by MDCR_EL2.TDRA and MDCR_EL2.TDOSA. The MDCR_EL2.TDA traps are to EL2 if enabled in the current Security state. If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDA is 1 other than for the purpose of a direct read.

--- Note ---

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.
System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2. See Traps on instructions on page D1-2368.

**Traps to EL2 of EL0 and EL1 accesses to the Debug Communications Channel registers**

If the PE is not in Debug state, MDCR_EL2.TDCC traps EL0 and EL1 accesses to DCC registers to EL2 if enabled for the current Security state.

If the PE is in Debug state, MDCR_EL2.TDCC does not trap accesses to DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0, DBGDTRRXint, and DBGDTRTXint that would otherwise be trapped. See MDCR_EL2.TDCC for more information.

**Traps to EL2 of EL0 and EL1 accesses to Performance Monitors registers**

MDCR_EL2.{TPM, TPMCR} trap EL0 and EL1 accesses to the Performance Monitors registers to EL2 if enabled in the current Security state:

--- Note ---

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

MDCR_EL2.HPMN affects whether a counter can be accessed from Non-secure EL0 or EL1. See the register description of MDCR_EL2 for more information.

--- Note ---

Enabling use of the Pointer authentication instructions, EL2 translation regime

This control is implemented when FEAT_PAuth is implemented.

Each of the SCTLR_EL2.{EnDA, EnDB, EnIA, EnIB} fields enables the pointer authentication functionality for the corresponding Pointer authentication instructions for the EL2 or EL2&0 translation regime. For more information, see System register control of pointer authentication on page D5-2533.

--- Note ---

These controls cause the pointer authentication instructions to execute as NOPs. They never cause an exception to be generated.

--- Note ---

Disabling Address tagging for instruction accesses, EL2 translation regime

This control is implemented when FEAT_PAuth is implemented.

When a TCR_EL2.TBI or TCR_EL2.{TBI0, TBI1} field enables the use of address tagging for the EL2 translation regime, the corresponding TCR_EL2.TBID or TCR_EL2.{TBID0, TBID1} field determines whether address tagging is used for both data and instruction addresses, or only for data addresses. For more information, see Address tagging in AArch64 state on page D5-2528.

--- Note ---

These controls determine the scope of address tagging. They never cause an exception to be generated.

--- D1.14.4 EL3 configurable controls ---

These controls are in EL3 System registers. The resulting exceptions might be taken from either Execution state. SPSR_EL3.M[4] indicates which Execution state the exception was taken from.
Table D1-24 shows the _EL3 System registers that contain these controls.

**Table D1-24 _EL3 registers that contain instruction enables and disables, and trap controls**

Also see the following for more general information about traps to EL3:

- Traps on instructions on page D1-2368.
- Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32.

Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32

If EL1 is using AArch32, all of the following are trapped to EL3:

- Secure EL1 reads and writes to any of the SCR, NSACR, MVBAR or SDCR.
- Any attempt at Secure EL1 to execute any of the following:
  - ATS12NSO** instructions.
  - SRS instructions that use the R13_mon banked register.
  - MSR or MSR instructions that access any of the SPSR_mon, R13_mon or R14_mon banked registers.

In addition, if EL1 is using AArch32:

- Secure EL1 write accesses to the CNTFRQ register are UNDEFINED. They are not trapped to EL3.
- Any attempt at Secure EL1 to change the PE mode to Monitor mode, by using a CPS or an MSR instruction, or by performing an exception return, is treated as an illegal change of the CPSR.M field. See Illegal changes to PSTATE.M on page G1-5739.

--- Note ---

- Reads of the NSACR from either Non-secure EL1 using AArch32 or Non-secure EL2 using AArch32 return the value 0x000000C0. See Restricted access System registers on page G5-6093.
- These operations are not available at EL0.

Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR

CPTR_EL3.TCPAC traps all of the following to EL3:

- EL2 accesses to the CPTR_EL2 or HCPTR.
- EL2 and EL1 accesses to the CPACR_EL1 or CPACR.
When CPTR_EL3.TCPAC is:

For EL1, this trap control applies to accesses from both Security states.

Traps to EL3 of EL2, EL1, and EL0 accesses to Activity Monitors registers

CPTR_EL3.TAM traps EL2, EL1, and EL0 accesses to the Activity Monitor registers to EL3.

Traps to EL3 of System register accesses to the trace registers

CPTR_EL3.TTA traps System register accesses to the trace registers, from all Exception levels, to EL3:

<table>
<thead>
<tr>
<th>Note</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>• The ETMv4 architecture does not permit EL0 to access the trace registers. If the Armv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than a CPTR_EL3.TTA Trap exception.</td>
<td></td>
</tr>
<tr>
<td>• EL3 does not provide traps on trace register accesses through the Memory-mapped interface.</td>
<td></td>
</tr>
</tbody>
</table>

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Traps on instructions on page D1-2368.

For EL0 and EL1, this trap control applies to accesses from both Security states.

Traps to EL3 of all accesses to the SIMD and floating-point registers

CPTR_EL3.TFP traps all accesses to the following SIMD and floating-point registers, from all Exception levels, to EL3:

<table>
<thead>
<tr>
<th>Note</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>FPCR, FPSR, FPEXC32_EL2, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See The SIMD and floating-point registers, V0-V31 on page D1-2322.</td>
<td></td>
</tr>
<tr>
<td>FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point System registers on page G1-5814. Permitted VMSR accesses to the FPSID are ignored, but for the purposes of this trap the architecture defines a VMSR access to the FPSID from EL1 or higher is an access to a SIMD and floating-point register.</td>
<td></td>
</tr>
</tbody>
</table>

For EL0 and EL1, this trap control applies to accesses from both Security states.

<table>
<thead>
<tr>
<th>Note</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>FPEXC32_EL2 is not accessible from EL0 using AArch64.</td>
<td></td>
</tr>
<tr>
<td>FPSID, MVFR0, MVFR1, and FPEXC are not accessible from EL0 using AArch32.</td>
<td></td>
</tr>
</tbody>
</table>

Traps to EL3 of EL2, EL1, and EL0 accesses to Debug Communication Channel registers

MDCR_EL3.TDCC traps EL2, EL1, and EL0 accesses to DCC registers to EL3.

If the PE is in Debug state, MDCR_EL3.TDCC does not trap accesses to DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0, DBGDTRRXint, and DBGDTRTXint that would otherwise be trapped. See MDCR_EL3.TDCC for more information.

Traps to EL3 of all System register accesses to the filter trace control registers

MDCR_EL3.TTRF traps System register accesses to the trace registers, from all Exception levels, to EL3:

For EL0 and EL1, this trap control applies to accesses from both Security states.
Traps to EL3 of EL2, EL1, and EL0 System register accesses to debug registers

MDCR_EL3.TDOSA traps EL2, EL1, and EL0 System register accesses to the powerdown debug registers to EL3, from both Security states. For EL1, this trap control applies to accesses from both Security states.

MDCR_EL3.TDA traps EL2, EL1, and EL0 System register accesses to the debug registers that are not trapped by MDCR_EL3.TDOSA, to EL3, from both Security states.

——— Note ————
EL3 does not provide traps on debug register accesses through the Memory-mapped or External debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL3, no side-effects occur before the exception is taken to EL3. See Traps on instructions on page D1-2368.

Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers

MDCR_EL3.TPM traps EL2, EL1, and EL0 accesses to the Performance Monitors registers to EL3:
For EL0 and EL1, this trap control applies to accesses from both Security states.

Traps to EL3 of EL2 accesses to fine-grained trap registers

If SCR_EL3.FGTEn is set to 0, EL2 accesses to the following fine-grained trap registers are trapped to EL3:
• HFRGRTR_EL2, HFGWTR_EL2 for System register traps.
• HFGITR_EL2 for System instruction traps.
• HDFGRTR_EL2, HDFGWTR_EL2 for debug and trace register traps.
• HAFGRTR_EL2 for activity monitor register traps.

Traps to EL3 of EL1 and EL2 accesses to the RAS error record registers

SCR_EL3.FIEN traps EL1 and EL2 accesses to the RAS ERXP* registers to EL3.
SCR_EL3.TERR traps EL1 and EL2 read accesses to the RAS ER* registers that are not trapped by SCR_EL3.FIEN, to EL3.

Trap to EL3 accesses to Pointer authentication instructions

This control is implemented when FEAT_PAuth is implemented.
SCR_EL3.API traps, to EL3, accesses to any of the Pointer authentication instructions for which pointer authentication is enabled, for instructions executed at an Exception level lower than EL3, in either Security state.
Because pointer authentication is supported only in AArch64 state this control only traps from AArch64 state.
For more information, including the description of when pointer authentication is enabled for an instruction, see System register control of pointer authentication on page D5-2533.

Trap to EL3 accesses to Pointer authentication key registers

This control is implemented when FEAT_PAuth is implemented.
SCR_EL3.APK traps, to EL3, accesses to the Pointer authentication key registers from EL2 or from Secure or Non-secure EL1. Because pointer authentication is supported only in AArch64 state this control only traps from AArch64 state.
For more information, see System register control of pointer authentication on page D5-2533.

Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions

SCR_EL3.{TWE, TWI} trap EL2, EL1, and EL0 execution of WFE and WFI instructions to EL3.
Note

Since a `WFE` or `WFI` can complete at any time, even without a Wakeup event, the traps on `WFE` of `WFI` are not guaranteed to be taken, even if the `WFE` or `WFI` is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:
- *Wait for Event mechanism and Send event* on page D1-2391.
- *Wait For Interrupt* on page D1-2394.

Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers

`SCR_EL3.ST` traps Secure EL1 accesses to the Counter-timer Physical Secure timer registers to EL3.

Note

- Accesses to the Counter-timer Physical Secure timer registers are always enabled at EL3.
- These registers are not accessible at EL0.

Enabling EL3, EL2, and Non-secure EL1 execution of `HVC` instructions

`SCR_EL3.HCE` enables `HVC` instruction execution at EL1 and above. Otherwise, `HVC` instructions are UNDEFINED at EL1, EL2, and EL3, and any resulting exception is taken from the current Exception level to the current Exception level.

For EL1, this enable control applies to `HVC` instructions in Non-secure state only.

If EL2 is not implemented, this bit is RES0.

Note

`HVC` instructions are always UNDEFINED at EL0.

Disabling EL3, EL2, and EL1 execution of `SMC` instructions

`SCR_EL3.SMD` disables `SMC` instruction execution at EL1 and above. `SMC` instructions are UNDEFINED at EL1 and above, and any resulting exception is taken from the current Exception level to the current Exception level.

For EL1, this disable control applies to `SMC` instructions in both Security states.

Note

`SMC` instructions are always UNDEFINED at EL0.

If `HCR_EL2.TSC` or `HCR.TSC` traps attempted EL1 execution of `SMC` instructions to EL2, that trap has priority over this disable.

Enabling use of the Pointer authentication instructions, EL3 translation regime

This control is implemented when `FEAT_PAuth` is implemented.

Each of the `SCTLR_EL3.{EnDA, EnDB, EnIA, EnIB}` fields enables the pointer authentication functionality for the corresponding Pointer authentication instructions for the EL3 translation regime. For more information, see *System register control of pointer authentication* on page D5-2533.
Note

These controls cause the pointer authentication instructions to execute as NOPs. They never cause an exception to be generated.

Disabling Address tagging for instruction accesses, EL3 translation regime

This control is implemented when FEAT_PAuth is implemented.

When the TCR_EL3.TBI field enables the use of address tagging for the EL3 translation regime, the TCR_EL3.TBID field determines whether address tagging is used for both data and instruction addresses, or only for data addresses. For more information, see Address tagging in AArch64 state on page D5-2528.

Note

This control determines the scope of address tagging. It never causes an exception to be generated.
D1.15 System calls

A system call is generated by the execution of an SVC, HVC, or SMC instruction:

- By default, the execution of an SVC instruction generates a Supervisor Call, a synchronous exception that targets EL1. This provides a mechanism for software executing at EL0 to make a call to an operating system or other software executing at EL1.

- In an implementation that includes EL2, the execution of an HVC instruction generates a Hypervisor Call, a synchronous exception that targets EL2 by default.
  
  The HVC instruction is UNDEFINED:
  
  — At EL0.
  
  — At EL1 in Secure state.

  Note

  Software executing at EL0 cannot directly generate a Hypervisor Call.

- In an implementation that includes EL3, by default the execution of an SMC instruction generates a Secure Monitor Call, a synchronous exception that targets EL3.

  The SMC instruction is UNDEFINED at EL0, meaning software executing at EL0 cannot directly generate a Secure Monitor Call.

The default behavior applies when the instruction is not UNDEFINED and both of the following are true:

- The instruction is executed at an Exception level that is the same as or lower than the target Exception level.
- The instruction is not trapped to a different Exception level.

If an SVC or HVC instruction is executed at an Exception level that is higher than the target Exception then it generates a synchronous exception that is taken to the current Exception level.

EL2 and EL3 can disable Hypervisor Call exceptions, see:

- Disabling Non-secure state execution of HVC instructions on page D1-2378.
- Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions on page D1-2388.

EL2 can trap use of the SMC instruction, see Traps to EL2 of EL1 execution of SMC instructions on page D1-2379.

EL3 can disable Secure Monitor Call exceptions, see Disabling EL3, EL2, and EL1 execution of SMC instructions on page D1-2388.

D1.15.1 Pseudocode description of system calls

The AArch64.CallSupervisor() pseudocode function performs an SVC call in AArch64 state.

The AArch64.CallHypervisor() pseudocode function performs an HVC call in AArch64 state.

The AArch64.CallSecureMonitor() pseudocode function performs an SMC call in AArch64 state.

The AArch64.CallSupervisor(), AArch64.CallHypervisor(), and AArch64.CallSecureMonitor() functions are described in Chapter J1 Armv8 Pseudocode.
D1.16 Mechanisms for entering a low-power state

The Arm architecture provides mechanisms that software can use to indicate that the PE can enter a low-power state, if it supports that state. The following sections describe those mechanisms:

- **Wait for Event mechanism and Send event**.
- **Wait For Interrupt on page D1-2394**.

D1.16.1 Wait for Event mechanism and Send event

A PE can use the **Wait for Event** (WFE) mechanism to enter a low-power state, depending on the value of the Event Register for that PE. To enter the low-power state, the PE executes a Wait For Event instruction, WFE, and if the Event Register is clear, the PE can enter the low-power state.

If the PE does enter the low-power state, it remains in that low-power state until it receives a **WFE wake-up event**.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFE instruction must not cause a loss of memory coherency.

WFE mechanism behavior depends on the interaction of all of the following, that are described in the subsections that follow:

- The Event Register for the PE. See subsection *The Event Register* on page D1-2392.
- The Wait For Event instruction, WFE. See subsection *The Wait For Event instruction* on page D1-2392.
- **WFE wake-up events**. See subsection *WFE wake-up events in AArch64 state* on page D1-2393.
- The Send Event instructions, SEV and SEVL that can cause WFE wake-up events. See subsection *The Send Event instructions* on page D1-2393.

--- Note ---

Because the Wait for Event mechanism is associated with suspending execution on a PE for the purpose of power saving, Arm recommends that the Event Register is set only infrequently. However, software must only use the setting of the Event Register as a hint, and must not assume that any particular message is sent as a result of the setting of the Event Register.

---

Example D1-2 describes how a spinlock implementation might use the WFE mechanism to save energy.

--- Example D1-2 Spinlock as an example of using Wait For Event and Send Event ---

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device, it might need to add data received from the device to a queue. If another PE is removing data from the same queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the second PE has released the lock. The first PE cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in *Synchronization and semaphores* on page B2-166.
- If the PE obtains the lock it performs its memory operation and then releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. When the lock becomes available, the PE again attempts to obtain it.
A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multiprocessor system the execution of spin-locks by multiple waiting PEs can degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock:

- A PE that fails to obtain a lock executes a WFE instruction to request entry to a low-power state, at the time when the Exclusives monitor is set holding the address of the location holding the lock.
- When a PE releases a lock, the write to the lock location causes the Exclusives monitor of any PE monitoring the lock location to be cleared. This clearing of the Exclusives monitors generates a WFE wake-up event for each of those PEs. Then, these PEs can attempt to obtain the lock again.

For large systems, more advanced locking systems, such as ticket locks, can avoid unfairness caused by having multiple PEs simultaneously reading the lock. In such systems, the WFE mechanism can be used in a similar way to monitor the next ticket value.

---

### The Event Register

The Event Register is a single bit register for each PE. When set, an Event Register indicates that an event has occurred since the register was last cleared, that might require some action by the PE. Therefore, when the Event Register is set, the PE must not suspend operation on executing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by any of the following:

- A Send Event instruction, SEV, executed by any PE in the system.
- A Send Event Local instruction, SEVL, executed by the PE.
- An exception return.
- The clearing of the global monitor for the PE.
- An event from a Generic Timer event stream, see [Event streams on page D11-2839](#).
- An event sent by some IMPLEMENTATION DEFINED mechanism.

The Event Register is cleared only by a Wait For Event instruction.

---

**Note**

Software cannot read or write the value of the Event Register directly.

---

### The Wait For Event instruction

The action of the Wait For Event instruction, WFE, depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately.
- If the Event Register is clear the PE can suspend execution and enter a low-power state. It remains in that state until the PE detects a WFE wake-up event, or earlier if the implementation chooses, or until a reset. When the PE detects a WFE wake-up event, or earlier if chosen, the WFE instruction completes. If the wake-up event sets the Event Register, it is IMPLEMENTATION DEFINED whether on restarting execution, the Event Register is cleared.

---

**Note**

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake-ups.
Trapping of WFE

The WFE instruction is available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-2371.
- Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions on page D1-2380.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-2387.

If FEAT_TWED is implemented, the delay for taking a WFE trap is configurable.

The delay on the trap does not effect the priority of the traps. In particular, if execution is subject to a trap at EL1 as a result of SCTLR_EL1.nTWE==0 and HCR_EL2.TWE==1, the only trap that will be taken is a trap to EL1, even if the delay at EL1 is longer than the delay at EL2.

WFE wake-up events in AArch64 state

The following are WFE wake-up events:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by EDSCR.INTdis and:
  - Is marked as A in the tables in Asynchronous exception masking on page D1-2361, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
  - Is marked as B in the tables in Asynchronous exception masking on page D1-2361, if the value of the corresponding PSTATE.{A, I, F} mask bit is 0.

  —— Note ——
  Any physical SError interrupt, IRQ interrupt, or FIQ interrupt that is marked as A/B behaves as A or B. See A/B on page D1-2362.

  —— Note ——
  In EL1 or EL0, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by EDSCR.INTdis and is marked as B in Table D1-15 on page D1-2364 in Virtual interrupts on page D1-2363, if the value of the corresponding PSTATE.{A, I, F} mask bit is 0.

- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed see Halting allowed and halting prohibited on page H2-7015.
  
  See also External Debug Request debug event on page H3-7071.

- An event sent by the timer event stream for the PE. See Event streams on page D11-2839.
  
- An event caused by the clearing of the global monitor for the PE.
  
- An event sent by some IMPLEMENTATION DEFINED mechanism.

Not all of these wake-up events set the Event Register.

  —— Note ——
  The disabling of interrupts, and WFE wake-up events, by EDSCR.INTdis is possible only when external debug is enabled.

  —— Note ——

The Send Event instructions

The Send Event instructions are:

SEV, Send Event
This causes an event to be signaled to all PEs in the multiprocessor system.

SEVL, Send Event Local
This must set the local Event Register.
D1.16 Mechanisms for entering a low-power state

Note

It might signal an event to other PEs by some IMPLEMENTATION DEFINED mechanism, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, Arm recommends that software includes a DSB instruction before any SEV instruction.

Note

A DSB instruction ensures that no instructions, including any SEV instructions, that appear in program order after the DSB instruction, can execute until the DSB instruction has completed. See Data Synchronization Barrier (DSB) on page B2-138.

The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

The receipt of a signaled SEV or SEVL event by a PE sets the Event Register on that PE.

The SEV and SEVL instructions are available at all Exception levels.

Pseudocode description of the Wait For Event mechanism

This section identifies pseudocode functions that describe the behavior of the Wait For Event mechanism.

The ClearEventRegister() pseudocode function clears the Event Register of the current PE.

The IsEventRegisterSet() pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear.

The WaitForEvent() pseudocode function optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes ClearEventRegister() to be called.

The SendEvent() pseudocode function sets the Event Register of every PE in the multiprocessor system.

The SendEventLocal() pseudocode function sets the event register for the local PE.

D1.16.2 Wait For Interrupt

Software can use the Wait for Interrupt (WFI) instruction to cause the PE to enter a low-power state. The PE then remains in that low-power state until it receives a WFI wake-up event, or until some other IMPLEMENTATION DEFINED reason causes it to leave the low-power state. The architecture permits a PE to leave the low-power state for any reason, but requires that it must leave the low-power state on receipt of any architected WFI wake-up event.

Note

Because the architecture permits a PE to leave the low-power state for any reason, it is permissible for a PE to treat WFI as a NOP, but this is not recommended for lowest power operation.

When the PE leaves a low-power state that was entered as a result of a WFI instruction, that WFI instruction completes.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFI instruction must not cause a loss of memory coherency.

Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-2371.
- Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions on page D1-2380.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-2387.
WFI wake-up events

The following are WFI wake-up events:

- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as A, Bor A/B in the tables in Asynchronous exception masking on page D1-2361, regardless of the value of the corresponding PSTATE. {A, I, F} mask bit.

- In EL1 or EL0, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as B in Table D1-15 on page D1-2364 in Virtual interrupts on page D1-2363, regardless of the value of the corresponding PSTATE. {A, I, F} mask bit.

- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed see Halting allowed and halting prohibited on page H2-7015.

  See also External Debug Request debug event on page H3-7071.

- An event sent by some IMPLEMENTATION DEFINED mechanism.

**Note**

- WFI wake-up events are never disabled by EDSCR.INTdis, and are never masked by the PSTATE. {A, I, F} mask bits. If wake-up is invoked by an interrupt that is disabled or masked the interrupt is not taken.

- Because debug events are WFI wake-up events, Arm recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures that the intervention of debug while waiting does not significantly change the function of the program being debugged.

- Some implementations of the WFI mechanism drain down any pending memory activity before suspending execution. This increases power saving, by increasing the area over which clocks can be stopped. The architecture does not require this operation, therefore software must not rely on the WFI mechanism operating in this way.

Using WFI to indicate an idle state on bus interfaces

Software can use the WFI mechanism to force quiescence on a PE, and, combined with preventing any possible WFI wakeup events, this can be used to complete an entry into a powerdown state.

Because mechanisms for entering powerdown states are inherently IMPLEMENTATION DEFINED, whether an implementation uses the WFI mechanism is IMPLEMENTATION DEFINED. If it does, the WFI instruction forces the suspension of execution, and of all associated bus activity.

The control logic that does this also tracks the activity on the bus interfaces of the PE, so that when the PE has completed all current operations and any associated bus activity has completed, it can signal to an external power controller that there is no ongoing bus activity.

However, the PE must continue to process memory-mapped and external debug interface accesses to debug registers when in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

If the OS Double Lock control is implemented and OSDLR_EL1.DLK is 1, the PE must not signal this idle state to the control logic unless it can also guarantee that the debug interface is idle. For more information about the OS Double Lock, see Debug behavior when the OS Double Lock is locked on page H6-7127.

**Note**

In a PE that implements separate Core and Debug power domains, the debug interface referred to in this section is the interface between the Core and Debug power domains, since the signal to the power controller indicates that the Core power domain is idle. For more information about the power domains, see Power domains and debug on page H6-7117.
The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

**Pseudocode description of Wait For Interrupt**

The `WaitForInterrupt()` pseudocode function optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.
D1.17  Self-hosted debug

The Armv8-A architecture supports both of the following:

Self-hosted debug

The PE itself hosts a debugger. The debugger programs the PE to generate *debug exceptions*. Debug exceptions are accommodated in the Armv8-A Exception model.

External debug

The PE is controlled by an external debugger. The debugger programs the PE to generate *debug events*, that cause the PE to enter *Debug state*. In Debug state, the PE is halted.

This section describes self-hosted debug. It includes:

- Debug exceptions.
- The PSTATE debug mask bit, D.

For external debug, see Part H *External Debug*.

D1.17.1  Debug exceptions

Debug exceptions occur during normal program flow, if a debugger has programmed the PE to generate them.

For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions.

The possible debug exceptions are:

- Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

Chapter D2 *AArch64 Self-hosted Debug* describes these in detail for AArch64.

For the PE to generate a debug exception requires that:

- The debug exception is enabled. The debug exception enable controls on page D2-2422 gives the controls for the different debug exceptions.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level on page D2-2425.

Debug exceptions are synchronous exceptions, and are accommodated in the Armv8 Exception model.

---

**Note**

Breakpoints and Watchpoints can cause entry to Debug state instead of causing debug exceptions. See Chapter H1 *About External Debug*.

---

D1.17.2  The PSTATE debug mask bit, D

As with all other exceptions, when a debug exception is taken, software must take care to avoid generating another instance of an exception within the exception handler, to avoid recursive entry into the exception handler and loss of return state.

To help avoid this, the Armv8 architecture provides a debug exception mask bit, PSTATE.D, that can mask Watchpoint, Breakpoint, and Software Step exceptions when the target Exception level is the current Exception level.
PSTATE.D is set to 1 on taking an exception. This means that while handling an exception in AArch64 state, Watchpoint, Breakpoint, and Software Step exceptions are masked. This prevents recursive entry at the Exception level that debug exceptions are targeted to.

When execution is in AArch64 state, debug exceptions are also masked implicitly when the target Exception level is lower than the current Exception level.

When the target Exception level is higher than the current Exception level, debug exceptions cannot be masked by PSTATE.D.

Because debug exceptions are synchronous, the architecture requires that debug exceptions are not generated when PSTATE.D is 1. By preventing debug exception generation, debug exceptions cannot be taken at a subsequent time when the Process state D mask bit is cleared to 0.

Note
This differs from the behavior for interrupts, where the PSTATE.{A, I, F} mask has the effect of preventing the interrupt from being taken, but instead the interrupt remains pending.
D1.18 Event monitors

The Armv8-A architecture supports the following non-invasive architectural components that allow for event monitoring:

Performance Monitors

The Performance Monitors have a wide feature set, flexible selection of counted events, and are read/write in operation. See The Performance Monitors Extension.

Activity Monitors

The Activity Monitors have a narrow feature set, limited selection of counted events, and are read-only in operation. See The Activity Monitors Extension.

D1.18.1 The Performance Monitors Extension

The System registers provide access to a Performance Monitors Unit (PMU), defined as the OPTIONAL Performance Monitors Extension to the architecture, a non-invasive debug resource that provides information about the operation of the PE. The PMU provides:

• A 64-bit cycle counter.
• An IMPLEMENTATION DEFINED number of event counters. If FEAT_PMUv3p5 is implemented, the event counters are 64-bit unsigned counters, otherwise the event counters are 32-bit event counters.

Each event counter can be configured to count occurrences of a specified event. The events that can be counted are:

— Architectural and microarchitectural events that are likely to be consistent across many microarchitectures. The PMU architecture uses event numbers to identify an event, and the PMU specification defines which event number must be used for each of these architectural and microarchitectural events.
— Implementation-specific events. The PMU specification reserves event numbers for implementation-specific events. See Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events.

For more information, see Chapter D7 The Performance Monitors Extension.

D1.18.2 The Activity Monitors Extension

When the OPTIONAL Activity Monitors Extension is implemented, the System registers provide access to controls and counters for the Activity Monitors Unit (AMU). For more information, see Chapter D8 The Activity Monitors Extension.
D1.19 Interprocessing

Interprocessing is the term used to describe moving between the AArch64 and AArch32 Execution states.

The Execution state can change only on a change of Exception level. This means that the Execution state can change only on taking an exception to a higher Exception level, or returning from an exception to a lower Exception level.

On taking an exception to a higher Exception level, the Execution state either:
• Remains unchanged.
• Changes from AArch32 state to AArch64 state.

On returning from an exception to a lower Exception level, the Execution state either:
• Remains unchanged.
• Changes from AArch64 state to AArch32 state.

Note
If, on taking or returning from an exception, the Exception level remains the same, the Execution state cannot change.

For the description of:
• Exception entry to an Exception level using AArch64, see Exception entry on page D1-2333.
• Exception return from an Exception level using AArch64 state, see Exception return on page D1-2344.
• Exception return to AArch32 state, see Exception return to an Exception level using AArch32 on page G1-5765.

Note
The description in Handling exceptions that are taken to an Exception level using AArch32 on page G1-5743 is outside the scope of interprocessing, because such exceptions must have been taken from an Exception level that is using AArch32, and therefore there is no change of Execution state.

The following sections describe the behavior associated with interprocessing.
• Register mappings between AArch32 state and AArch64 state.
• State of the general-purpose registers on taking an exception to AArch64 state on page D1-2410.
• SPSR, ELR, and AArch64 SP relationships on changing Execution state on page D1-2412.

D1.19.1 Register mappings between AArch32 state and AArch64 state

This section defines the architectural mappings between AArch32 state registers and AArch64 state registers.

The mappings describe:
• For exceptions taken from AArch32 state to AArch64 state, where the AArch32 register content is found.
• For exception returns from AArch64 state to AArch32 state, how the AArch32 register content is derived.

The general model is:
• The AArch32 register contents are situated in the bottom 32 bits of the AArch64 registers.
• In AArch32 state, the upper 32 bits of AArch64 registers are inaccessible and are ignored.

Note
System software that executes in AArch64 state, such as an OS or Hypervisor, can use these mappings for context save and restore, or to interpret and modify the AArch32 registers of an application or virtual machine.

For more information, see the following subsections:
• Mapping of the general-purpose registers between the Execution states on page D1-2401.
• Mapping of the SIMD and floating-point registers between the Execution states on page D1-2402.
Mapping of the general-purpose registers between the Execution states

Table D1-27 shows how each of the AArch32 general-purpose registers, R0-R12, SP, and LR, including the banked copies of these registers, maps to an AArch64 general-purpose register. A register in the AArch64 register column of the table provides the AArch64 view of the corresponding register in the AArch32 register column.

--- Note ---
For some exceptions, the exception syndrome given in the ESR_ELx identifies one or more register numbers from the issued instruction that generated the exception. Where the exception is taken from an Exception level using AArch32, these register numbers give the AArch64 view of the register. For example, if an exception is taken from AArch32 Abort mode, and the faulting instruction specified R14, the ESR_ELx.ISS field would report this using the EC value 0b10100, because register X20 provides the AArch64 view of LR_abt, which is the copy of R14 used in Abort mode.

<td>Q15</td>
</tr>
</tbody>
</table>

The AArch64 registers V16-V31 are not accessible from AArch32 state.

The mapping between the V, D, and S registers in AArch64 state is not the same as the mapping between the Q, D, and S registers in AArch32 state:

- In AArch64 state, there are:
  - 32 64-bit D registers, D0-D31.
  - 32 32-bit S registers, S0-S31.

A smaller register occupies the least-significant bytes of the corresponding larger register. For example, S5 is the least-significant word of D5 and V5. Figure D1-3 on page D1-2403 shows this mapping.
In AArch32 state, there are:

- 16 128-bit Q registers, Q0-Q15.
- 32 64-bit D registers, D0-D31.
- 32 32-bit S registers, S0-S31.

Smaller registers are packed into larger registers. Figure D1-4 shows this mapping.

In AArch32 state:

- There are no S registers that correspond to Q8-Q15.
- D16-D31 pack into Q8-Q15. For example, D16 and D17 pack into Q8.

**Note**

A consequence of this mapping is that if software executing in AArch64 state interprets D or S registers from AArch32 state, it must unpack the D or S registers from the V registers before it uses them.

**Mapping of the System registers between the Execution states**

Armv8 architecturally defines the relationship between the AArch64 System registers and the AArch32 System registers, to allow supervisory code such as a hypervisor, that is executing in AArch64 state, to save, restore, and interpret the System registers belonging to a lower Exception level that is using AArch32.

Any modifications made to AArch32 System registers affects only those parts of those AArch64 registers that are mapped to the AArch32 System registers. Bits[63:32] of AArch64 registers, where they are not mapped to AArch32 registers, are unchanged by AArch32 state execution.

**Note**

This model is different to the model for the general-purpose registers described in *Mapping of the general-purpose registers between the Execution states* on page D1-2401. In this model, there are several cases where two AArch32 System registers are packed into a single AArch64 System register.

When EL3 is implemented and is using AArch32, some System registers are banked between the two Security states. When a register is banked in this way, there is an instance of the register in Secure state, and another instance of the register in Non-secure state. In Table D1-29 on page D1-2404 these banked registers are identified by footnote. This banking is not supported when EL3 is using AArch64 or if EL3 is not implemented. This means that when EL3 is implemented and is using AArch64, exactly the same registers are accessed in the following states:

- Secure EL1 with EL1 using AArch32.
- Non-secure EL1 with EL1 using AArch32.
This means that, architecturally, it is not possible to determine whether an AArch64 register is mapped onto the Secure instance of the corresponding AArch32 register, or onto the Non-secure instance of that register. When EL3 is using AArch64, the interrupt asserted by the AArch64 CNTP_* timer is the same interrupt as is asserted by the Non-secure AArch32 CNTP_* timer when EL3 is using AArch32.

Note
Although the architecture does not require this, because it is not architecturally visible, Arm expects that implementations will map many of the AArch64 registers for use by EL3 to the Secure instances of the banked AArch32 registers, and will map many of the AArch64 registers for use by EL1 to the Non-secure instances of the banked AArch32 registers. However, if EL2 and EL3 are implemented and both support use of AArch32, this is not possible for the following registers:

- **IFAR** This is because when EL3 is using AArch32, HIFAR is an alias of the Secure IFAR.
- **DFAR** This is because when EL3 is using AArch32, HDFAR is an alias of the Secure DFAR.

Table D1-29 shows the mappings between the writable AArch64 System registers and the AArch32 System registers.

There are a small number of AArch32 System registers that are not mapped to any AArch64 System registers. The AArch64 registers listed in Table D1-30 can be used to access these from a higher Exception level that is using AArch64. The registers shown in the table are UNDEFINED if EL1 cannot use AArch32.

### D1.19.2 State of the general-purpose registers on taking an exception to AArch64 state

When an exception is taken from AArch32 state to AArch64 state, the state of a general-purpose register depends on whether, immediately before the exception, the register was accessible from AArch32 state, as follows:

**If the general-purpose register was accessible from AArch32 state**

The upper 32 bits either become zero, or hold the value that the same architectural register held before any AArch32 execution. The choice between these two options is IMPLEMENTATION DEFINED, and might vary dynamically within an implementation. Correspondingly, software must regard the value as being a CONSTRAINED UNPREDICTABLE choice between these two values.

This behavior applies regardless of whether any execution occurred at the Exception level that was using AArch32. That is, this behavior applies even if AArch32 state was entered by an exception return from AArch64 state, and another exception was immediately taken to AArch64 state without any instruction execution in AArch32 state.

Which general-purpose registers have their upper 32 bits affected in this way depends on both:

- The AArch64 state target Exception level.
- The values of both:
  - SCR_EL3.RW.
  - HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES0.

Table D1-32 shows which general-purpose registers can have their upper 32 bits set to zero.

</tr>
<tr>
<td>1</td>
<td>1</td>
<td>X0-X14</td>
</tr>
</tbody>
</table>

a. HCR.RW is a notional bit that is RES0.
b. The RW bit values are not valid for the targeted Exception level.
c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.
Note

If EL2 is not implemented, or the SCR_EL3.NS or SCR.NS bit prevents its use, then as described in The effects of supporting fewer than four Exception levels on page D1-2415, the behavior is consistent with HCR_EL2.RW taking the value of SCR_EL3.RW.

If the general-purpose register was not accessible from AArch32 state

The general rule is that the register retains the state it had before any AArch32 execution.

There is one exception to this rule, that is when taking an exception to EL3 using AArch64 when either EL2 is not implemented or EL1 is in Secure state. In these cases, the X15 register must be treated as if it is accessible when the value of SCR_EL3.RW is 0, and therefore the upper bits of X15 might either be set to zero or retain their previous value.

Which general-purpose registers retain their state depends on both:

- The AArch64 state target Exception level.
- The values of both:
  - SCR_EL3.RW.
  - HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES0.

Table D1-33 shows which general-purpose registers can retain their state.

Table D1-33 General-purpose registers that can retain their state on taking an exception to AArch64 from AArch32

a. HCR.RW is a notional bit that is RES0.
b. The RW bit values are not valid for the targeted Exception level.
c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

Note

If EL2 is not implemented, or the SCR_EL3.NS bit prevents its use, then as described in The effects of supporting fewer than four Exception levels on page D1-2415, the behavior is consistent with HCR_EL2.RW taking the value of SCR_EL3.RW.
D1.19.3   SPSR, ELR, and AArch64 SP relationships on changing Execution state

Table D1-34 shows the SPSR and ELR registers that are architecturally mapped between AArch32 state and AArch64 state.

<td>ELR_EL2</td>
</tr>
</tbody>
</table>

On exception entry to EL3 using AArch64 state from an Exception level using AArch32 state, when EL2 has been using AArch32 state, the upper 32-bits of ELR_EL2 are either set to zero or they retain the value before the AArch32 state execution. The implementation determines the choice between these two options, and the choice might vary dynamically within an implementation. Therefore, software must regard the upper 32-bits as being UNKNOWN.

On exception entry to an Exception level using AArch64 state from an Exception level using AArch32 state, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during execution in AArch32 state at that Exception level, retain the state that they had before the execution in AArch32 state.

The following AArch32 registers are used only during execution in AArch32 state. However, they retain their state when there is execution at EL1 with EL1 using AArch64 state:

- SPSR_abt.
- SPSR_und.
- SPSR_irq.
- SPSR_fiq.

Note

- These registers are accessible during execution in AArch64 state at Exception levels higher than EL1, for context switching.
- If EL1 does not support execution in AArch32 state then these registers are RES0.

On exception entry to an Exception level using AArch64 from an Exception level using AArch32, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during AArch32 execution at that Exception level retain the state that they had before AArch32 execution. This applies to the following registers:

- SP_EL0.
- SP_EL1.
- SP_EL2.
- ELR_EL1.
D1.20 The effect of implementation choices on the programmers’ model

Three of the implementation choices in Armv8 are:
• The number of Exception levels implemented.
• Which Exception levels support AArch32 and which Exception levels support AArch64.
• Whether SIMD and floating-point support is implemented.

The following subsections give more information about how these choices affect the programmers’ model:
• Implication of Exception levels implemented.
• Support for Exception levels and Execution states on page D1-2414.
• Implementations not including Advanced SIMD and floating-point instructions on page D1-2414.
• The effects of supporting fewer than four Exception levels on page D1-2415.

D1.20.1 Implication of Exception levels implemented

All implementations must include EL0 and EL1.

EL2 and EL3 are optional. The architecture permits all combinations of EL2 and EL3.

See also Implementations not including Advanced SIMD and floating-point instructions on page D1-2414 and The effects of supporting fewer than four Exception levels on page D1-2415.

For an implementation that includes all of the Exception levels Figure D1-5 shows the implemented Exception levels and the possible Execution states at lower Exception levels when EL3 is using AArch64. Figure D1-5 applies regardless of whether EL3 also supports use of AArch32.

Figure D1-5 Armv8-A security model when EL3 is using AArch64

† AArch64 permitted only if EL1 is using AArch64
‡ AArch64 permitted only if EL2 is using AArch64
The possible combinations of Exception levels are as follows:

- EL0, EL1, and EL2. The implementation supports only a single Security state. This might be either Secure state or Non-secure state.

- EL0, EL1, and EL3. The implementation does not support Virtualization. The Exception levels and Execution states depend on whether EL3 is using AArch64 state or AArch32 state, as follows:
  - If EL3 is using AArch64, the Exception levels and Execution states are as shown in Figure D1-5 on page D1-2413 with EL2 removed and no virtualization of EL1 and EL0.
  - If EL3 is using AArch32, the Exception levels and Execution states are as shown in Figure G1-1 on page G1-5720 with EL2 removed and no virtualization of EL1 and EL0.

- EL0 and EL1 only. The implementation supports only a single Security state. This might be either Secure state or Non-secure state, see *Behavior when only EL1 and EL0 are implemented* on page D1-2416.

- EL0, EL1, EL2, and EL3, as described in this section.

For more information, see *The effects of supporting fewer than four Exception levels* on page D1-2415.

### D1.20.2 Support for Exception levels and Execution states

Subject to the interprocessing rules defined in *Interprocessing* on page D1-2400, an implementation of the Arm architecture could support:

- AArch64 state only.
- AArch64 and AArch32 states.
- AArch32 state only.

This means the Armv8-A architecture can, potentially, support implementations with very large number of combinations of Execution state and Exception level. Arm intends to license only a subset of the possible combinations.

In an implementation that:

- Supports AArch64 state, all Exception levels are included.
- Has Secure and Non-secure states, EL3 should be implemented.
- Includes all Exception levels, EL3 cannot be included in AArch32 state.

### D1.20.3 Implementations not including Advanced SIMD and floating-point instructions

In general, Armv8-A requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementations targeting specialized markets that do not require support for floating-point or use of Advanced SIMD, Arm might produce or license an Armv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation:

**In AArch64 state**

- The CPACR_EL1.FPEN field is RES0.
- The CPTR_EL2.TFP bit is RES1.
- The CPTR_EL3.TFP bit is RES1.
- Each of the ID_AA64PFR0_EL1.{AdvSIMD, FP} fields is 0b1111.
- The FPEXC32_EL2, FPCR, and FPSR registers are not implemented, and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
  - All Advanced SIMD and floating-point instructions are UNDEFINED.
  - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.
- If at least one Exception level supports execution in AArch32 state, the MVFR0_EL1, MVFR1_EL1 and MVFR2_EL1 registers are RAZ. When no Exception level supports execution in AArch32 state these registers are UNKNOWN.
In AArch32 state

See AArch32 implications of not including support for Advanced SIMD and floating-point on page G1-5812.

D1.20.4 The effects of supporting fewer than four Exception levels

The effect of implementation choices on the programmers’ model on page D1-2413 defines the permitted combinations of Exception levels in an Armv8-A implementation.

In every implementation that supports the highest Exception level using either AArch64 state or AArch32 state, an IMPLEMENTATION DEFINED mechanism determines whether the highest implemented Exception level uses AArch64 state or AArch32 state from a Cold reset. Typically, this mechanism is a configuration input. When the highest level is configured to be AArch64 state, then after a Cold reset execution starts at the reset vector in that Exception level.

The unimplemented Exception levels have no effect on execution:

- No interrupts are routed to these Exception levels.
- No traps that target these Exception levels are active.
- All systems calls to unimplemented Exception levels from lower Exception levels are treated as UNDEFINED.
- There is no support for address translation from these Exception levels.
- Any exception return that targets an unimplemented Exception level is treated as an illegal exception return as described in Illegal return events from AArch64 state on page D1-2345.
- Every accessible register associated with an unimplemented Exception level is RES0 unless the register is associated with the Exception level only to provide the ability to transfer execution to a lower Exception level.

Note

If, for example, EL3 is not implemented and EL2 is the highest implemented Exception level, then because none of the EL3 registers are accessible from EL2, the content of those registers is not architecturally visible.

The following subsections give more information about each of the permitted combinations of Exception levels that do not include all Exception levels.

Behavior when EL3 is not implemented

If EL3 is not implemented:

- If EL2 is implemented and Secure EL2 is not implemented, the Effective value of SCR_EL3.NS is 0b1.
- If Secure EL2 is implemented, the Effective value of SCR_EL3.EEL2 is 0b1 and the Effective value of SCR_EL3.NS is 0b0.
- If EL2 is not implemented, it is IMPLEMENTATION DEFINED whether the Effective value of SCR_EL3.NS is 0b1 or 0b0.

Behavior when EL2 is not implemented

If EL2 is not implemented and EL3 is implemented:

- If EL1 can use AArch32 then the following registers are not RES0:
  — DACR32_EL2.
  — IFSR32_EL2.
  — FPEXC32_EL2.
  — DBGVCR32_EL2.

- The VMPIDR_EL2 and VPIDR_EL2 behave as follows:
  — Reads of VMPIDR_EL2 return the value of MPIDR_EL1, writes to VMPIDR_EL2 are ignored.
  — Reads of VPIDR_EL2 return the value of MIDR_EL1, writes to VPIDR_EL2 are ignored.
The behavior is consistent with the HCR_EL2.RW bit taking the value of the SCR_EL3.RW bit for all purposes other than reading the HCR_EL2.

Virtual interrupts are disabled.

The following address translation and TLB invalidation instructions are UNDEFINED:
- AT S1E2R and AT S1E2W.
- TLBI VAE2, TLBI VALE2, TLBI VAE2IS, TLBI VALE2IS, TLBI VAE2OS, TLBI VALE2OS, TLBI VAE2IS, TLBI VALE2IS, TLBI VAE2OS, TLBI VALE2OS.

Note

No other TLB or address translation instructions become UNDEFINED with this combination of Exception levels.

The SCR_EL3.HCE bit is RES0.

If EL2 is not implemented, regardless of whether EL3 is implemented:
- The Effective value of CNTHCTL_EL2[1:0] is 0b11.
- The Effective value of MDCR_EL2.HPMN is the value of PMCR_EL0.N.

Behavior when only EL1 and EL0 are implemented

If EL3 and EL2 are not implemented, it is IMPLEMENTATION DEFINED whether the Effective value of the SCR_EL3.NS bit is 0b1 or 0b0.

This means that if the PE is part of a system that supports two Security states:
- When the Effective value of the SCR_EL3.NS bit is 0b1, the PE can only access Non-secure memory.
- When the Effective value of the SCR_EL3.NS bit is 0b0, the PE can access both Secure memory and Non-secure memory.

If the Effective value of the SCR_EL3.NS bit is 0b0, then:
- The Effective value of MDCR_EL3.{EPMAD, EDAD} is {0b1, 0b1}.
- The Effective value of MDCR_EL3.{SPME, NSPB} is {0b1, 0b01}.
- The Effective value of MDCR_EL3.SPD32 is 0b11.

If EL3 is not implemented, regardless of whether EL2 is implemented, the Effective value of MDCR_EL3.STE is the inverse of the Effective value of SCR_EL3.NS.

Note

- The behavior described in this subsection still applies if EL1 is configured to use AArch32.
- The implementation can provide a configuration input that determines, from reset, the Effective value of the SCR_EL3.NS bit.
Chapter D2
AArch64 Self-hosted Debug

When the PE is using self-hosted debug, it generates debug exceptions. This chapter describes the AArch64 self-hosted debug exception model. It is organized as follows:

Introductory information
- About self-hosted debug on page D2-2418.
- The debug exception enable controls on page D2-2422.

The debug Exception model
- Routing debug exceptions on page D2-2423.
- Enabling debug exceptions from the current Exception level on page D2-2425.
- The effect of powerdown on debug exceptions on page D2-2427.
- Summary of the routing and enabling of debug exceptions on page D2-2428.
- Pseudocode description of debug exceptions on page D2-2430.

The debug exceptions
- Breakpoint Instruction exceptions on page D2-2431.
- Breakpoint exceptions on page D2-2433.
- Watchpoint exceptions on page D2-2451.
- Vector Catch exceptions on page D2-2465.
- Software Step exceptions on page D2-2466.

Synchronization requirements

The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a Context synchronization event guarantees the effects of the changes:
- Synchronization and debug exceptions on page D2-2479.
D2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of debug exceptions, that are taken using the exception model described in Chapter D1 The AArch64 System Level Programmers’ Model. This section introduces some terms that are used in describing self-hosted debug, and then introduces the debug exceptions. See:

- Definition of a debugger in the context of self-hosted debug.
- Context ID and Process ID.
- About debug exceptions.

D2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, debugger means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the Debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

D2.1.2 Context ID and Process ID

A CONTEXTIDR_ELx identifies the current Context ID, that is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

In AArch64 state, the CONTEXTIDR_ELx has a single field, PROCID, that is defined as the Process Identifier (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical.

D2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger enables one or more debug exceptions. The debug exceptions that can be generated in stage 1 of an AArch64 translation regime are:

- Breakpoint Instruction exceptions on page D2-2419.
- Breakpoint exceptions on page D2-2419, generated by hardware breakpoints.
- Watchpoint exceptions on page D2-2419, generated by hardware watchpoints.
- Software Step exceptions on page D2-2420.

In addition, debug exceptions generated in an AArch32 translation regime might be routed to EL2 using AArch64. See Routing debug exceptions on page D2-2423. Chapter G2 describes the debug exceptions that can be generated in an AArch32 translation regime.

Vector Catch exceptions are exceptions that cannot be generated in an AArch64 translation regime but can be generated in stage 1 of an AArch32 translation regime and routed to EL2 using AArch64. Vector Catch exceptions on page D2-2465 describes the behavior for this case.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.
   See Enabling debug exceptions from the current Exception level on page D2-2425. Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

2. A debugger has enabled that particular debug exception.
   All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See The debug exception enable controls on page D2-2422.

Note

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.
For the definition of halting is allowed, see Halting allowed and halting prohibited on page H2-7015.

The following list summarizes each of the debug exceptions:

**Breakpoint Instruction exceptions**

*Breakpoint instructions* generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

**PE behavior**

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Exception level.
- The current Security state.

For more information, see Breakpoint Instruction exceptions on page D2-2431.

**Breakpoint exceptions**

The Armv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address `0x1000` is committed for execution.

The Armv8-A architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch64 translation regime:

- Address.
  - Comparisons are made with the virtual address of each instruction in the program flow.
- Context:
  - Context ID Match. Matches with the Context ID held in the CONTEXTIDR_EL1.
  - VMID Match. Matches with the VMID value held in the VTTBR_EL2.
  - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see Breakpoint exceptions on page D2-2433.

**Watchpoint exceptions**

The Armv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range `0x1000 - 0x101F`. 
A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a Linked Context type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see *Watchpoint exceptions on page D2-2451*.

**Vector Catch exceptions**

These are not generated in an AArch64 translation regime. They can only be generated in an AArch32 translation regime. See *Vector Catch exceptions on page D2-2465*.

**Software Step exceptions**

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can debug software executing at a lower Exception level, by making it single-step instructions.

After the software being debugged has single-stepped an instruction, the PE takes a Software Step exception.

**PE behavior**

Software step can only be used by a debugger executing in an Exception level that is using AArch64. However, the instruction stepped might be executed in either Execution state, and therefore Software Step exceptions can be taken from either Execution state.

If debug exceptions are enabled, Software Step exceptions can be generated.

If debug exceptions are disabled, software step is inactive.

For more information, see *Software Step exceptions on page D2-2466*.

Table D2-1 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

<table>
<thead>
<tr>
<th>Debug exception</th>
<th>PE behavior if debug exceptions are:</th>
<th>Pseudocode</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td>Breakpoint Instruction exceptions</td>
<td>Takes the exception</td>
<td>Takes the exception</td>
</tr>
<tr>
<td>Breakpoint exceptions</td>
<td>Takes the exception(^a)</td>
<td>Ignored</td>
</tr>
</tbody>
</table>
### Table D2-1 PE behavior and pseudocode for each of the debug exceptions (continued)

<table>
<thead>
<tr>
<th>Debug exception</th>
<th>PE behavior if debug exceptions are:</th>
<th>Pseudocode</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td>Watchpoint exceptions</td>
<td>Takes the exception&lt;sup&gt;a&lt;/sup&gt;</td>
<td>Ignored</td>
</tr>
<tr>
<td>Vector Catch exceptions</td>
<td>Takes the exception</td>
<td>Ignored</td>
</tr>
<tr>
<td>Software Step exceptions</td>
<td>Takes the exception</td>
<td>Not applicable&lt;sup&gt;b&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

<sup>a</sup> If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Chapter H2 Debug State.

<sup>b</sup> Software Step is inactive if debug exceptions are disabled. No Software Step exceptions can be generated.
D2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

**Breakpoint Instruction exceptions**

None. Breakpoint Instruction exceptions are always enabled.

**Breakpoint exceptions**

MDSCR\_EL1.MDE, plus an enable control for each breakpoint, DBGBCR\(<n>_EL1.E.

**Watchpoint exceptions**

MDSCR\_EL1.MDE, plus an enable control for each watchpoint, DBGWCR\(<n>_EL1.E.

**Vector Catch exceptions**

MDSCR\_EL1.MDE.

**Software Step exceptions**

MDSCR\_EL1.SS.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level* on page D2-2425.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
D2.3 Routing debug exceptions

Debug exceptions are enabled and routed according to the following controls:

- MDCR_EL2.TDE.
- HCR_EL2.TGE.
- MDCR_EL3.SDD.
- The Security state when the exception is taken.
- The Exception level where the exception is taken.

Breakpoint Instructions are enabled in some situations where other Debug exceptions are disabled.

If the OS Lock is locked, or if DoubleLockStatus() == TRUE, a Debug exception cannot be taken.

--- Note ---

If EL2 is not implemented, the Effective value of HCR_EL2.TGE is 0 and the Effective value of MDCR_EL2.TDE is 0. Throughout this section, references to the values of these fields are to the Effective values of the fields.

If EL3 is not implemented, and the implementation is a Secure state only implementation, the Effective value of MDCR_EL3.SDD is 0.

The routing of debug exceptions is as follows:

Table D2-2 shows when debug exceptions are enabled from the current Security state.

<table>
<thead>
<tr>
<th>Current Security state</th>
<th>Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>Secure</td>
<td>Enabled</td>
<td>Disabled if MDCR_EL3.SDD is 1. See Disabling debug exceptions from Secure state on page D2-2425. Otherwise enabled.</td>
</tr>
</tbody>
</table>

Debug exceptions taken when EL2 is implemented and enabled in the current Security state

The routing of debug exceptions taken depends on the values of MDCR_EL2.TDE and HCR_EL2.TGE:

If the Effective value of {MDCR_EL2.TDE, HCR_EL2.TGE} is not {0, 0}

Debug exceptions are routed to EL2, EL_D is EL2.

Otherwise

Debug exceptions behave as follows:
- Debug exceptions taken from EL1 and EL0 are routed to EL1. EL_D is EL1
- Breakpoint Instruction exceptions taken from EL2 are routed to EL2.
- All other debug exceptions are disabled from EL2 using AArch64.

When EL3 is implemented

Breakpoint Instruction exceptions taken from EL3 are routed to EL3.
All other debug exceptions are disabled from EL3 using AArch64.

Otherwise

Debug exceptions are routed to EL1.

This means that, for all debug exceptions, the debug target Exception level, EL_D, is either EL1 or EL2. When executing in the same exception level as EL_D, see Enabling debug exceptions from the current Exception level on page D2-2425.
Table D2-3, Table D2-4, and Table D2-5 show the routing of debug exceptions. In these tables:

<table>
<thead>
<tr>

</tbody>
</table>

**D2.3.1 Pseudocode description of routing debug exceptions**

DebuggerTarget() returns the current debug target Exception level.

DebuggerTargetFrom() returns the debug target Exception level for the specified Security state.

These functions are described in Chapter J1 Armv8 Pseudocode.
D2.4 Enabling debug exceptions from the current Exception level

A debug exception can only be taken if all of the following are true:

• The OS Lock is unlocked.
• DoubleLockStatus() == FALSE.
• The debug exception is enabled from the current Exception level.
• The debug exception is enabled from the current Security state.

Table D2-6 shows when debug exceptions are enabled from the current Exception level. In the table, EL_D is the Exception level that Table D2-3 on page D2-2424 defines.

Table D2-6 Whether debug exceptions are enabled from the current Exception level

<table>
<thead>
<tr>
<th>Current Exception level</th>
<th>Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any Exception level that is higher than EL_D&lt;sup&gt;a&lt;/sup&gt;</td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td>EL_D</td>
<td>Enabled</td>
<td>Disabled if either of the following is true:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The Local (kernel) Debug Enable bit, MDSCR_EL1.KDE, is 0.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The Debug exception mask bit, PSTATE.D, is 1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Otherwise enabled.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This means that a debugger must explicitly enable these debug exceptions from EL_D by setting MDSCR_EL1.KDE to 1 and PSTATE.D to 0.</td>
</tr>
<tr>
<td>Any Exception level that is lower than EL_D</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

<sup>a</sup> This includes EL3. EL3 is always higher than EL_D.

---

Note

PSTATE.D is set to 1 at reset and on exception entry.

D2.4.1 Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can set the Secure Debug Disable bit, MDCR_EL3.SDD, to 1 to disable all debug exceptions taken from AArch64 Secure state other than Breakpoint Instruction exceptions.

The Armv8-A architecture does not support disabling debug in Non-secure state.

---

Note

• If the boot software executed when reset is deasserted sets MDCR_EL3.SDD to 1, software operating at EL3 never has to switch the debug registers between Secure state and Non-secure state.
• The PE cannot take a debug exception unless it is enabled from the current Exception level. See Table D2-6.
• If either the OS Lock or the OS Double Lock is locked, debug exceptions other than Breakpoint Instruction exceptions are disabled.
• If EL3 and EL2 are not implemented, and the implementation is a Secure state only implementation, the PE behaves as if MDCR_EL3.SDD is 0.
D2.4.2 Pseudocode description of enabling debug exceptions

AArch64.GenerateDebugExceptions() determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the current Exception level and Security state.

AArch64.GenerateDebugExceptionsFrom() determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the specified Exception level and Security state.

These functions are described in Chapter J1 Armv8 Pseudocode.
D2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-7123 describes the powerdown save routine and the restore routine.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

If the OS Lock is unlocked, and DoubleLockStatus() == FALSE, debug exceptions other than Breakpoint Instruction exceptions are enabled.

If OS Lock is locked, or if DoubleLockStatus() == TRUE, debug exceptions other than Breakpoint Instruction exceptions are disabled.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.
### D2.6 Summary of the routing and enabling of debug exceptions

Behavior is as follows:

**Breakpoint Instruction exceptions**

These are always enabled, regardless of the current Exception level and Security state. A Breakpoint Instruction exception taken from EL3 is always routed to EL3. A Breakpoint Instruction exception taken from EL2 is routed to EL2. A Breakpoint Instruction exception taken from EL0 or EL1 is always routed to EL1.

**All other debug exceptions**

Table D2-7 shows the valid combinations of MDCR_EL3.SDD, MDCR_EL2.TDE, MDSCR_EL1.KDE, and PSTATE.D, and for each combination shows where these exceptions are enabled from and where they are taken to.

In the table:
- **Lock** Means the value of (OSLSR_EL1.OSLK == '1' || DoubleLockStatus()).
- **NS** Means the Effective value of SCR_EL3.NS.
- **SDD** Means the Effective value of MDCR_EL3.SDD. See Disabling debug exceptions from Secure state on page D2-2425.
- **EEL2** Means the Effective value of SCR_EL3.EEL2. If FEAT_SEL2 is not implemented, this is 0.
- **TGE** Means the value of HCR_EL2.TGE. If EL2 is not implemented, the PE behaves as if this is 0.
- **TDE** Means the value of MDCR_EL2.TDE. If EL2 is not implemented, the PE behaves as if this is 0.
- **KDE** Means the value of MDSCR_EL1.KDE.
- **D** Means the value of PSTATE.D.
- **n/a** Means not applicable. The PE cannot be executing at this Exception level.
- **-** Means that debug exceptions are disabled from that Exception level.

D2.7 Pseudocode description of debug exceptions

AArch64.DebugFault() returns a FaultRecord object that indicates that a memory access has generated a debug exception:

The AArch64.Abort() function processes FaultRecord objects, as described in Abort exceptions on page D4-2524, and generates a debug exception.

AArch64.Abort() calls one of the following:
• AArch64.BreakpointException().
• AArch64.WatchpointException().
• AArch64.VectorCatchException().
• AArch64.SoftwareStepException().

These functions are defined in Chapter J1 Armv8 Pseudocode.
D2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

• In an Exception level that is using AArch64.
• At EL0 using AArch32 when EL1 is using AArch64.

For software executing in an Exception level that is using AArch64, a Breakpoint Instruction exception results from the execution of an A64 BRK instruction. However, within the AArch64 EL1&0 translation regime, executing a T32 or A32 BKPT instruction at EL0 using AArch32 generates a Breakpoint Instruction exception.

For more information about the T32 and A32 BKPT instructions, see:

• Breakpoint instruction in the A32 and T32 instruction sets on page G2-5867.
• BKPT instructions as the first instruction in an IT block on page G2-5868.

The following subsections describe Breakpoint Instruction exceptions in an AArch64 translation regime:

• About Breakpoint Instruction exceptions.
• Breakpoint instructions.
• Exception syndrome information and preferred return address on page D2-2432.
• Pseudocode description of Breakpoint Instruction exceptions on page D2-2432.

D2.8.1 About Breakpoint Instruction exceptions

A breakpoint is an event that results from the execution of an instruction, which is based on either:

• The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
• The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint Instruction exceptions, that this section describes, are software breakpoints. Breakpoint exceptions on page D2-2433 describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

• The current Exception level.
• The current Security state.
• Whether the debug target Exception level, EL_D, is using AArch64 or AArch32.

Note

• The debug target Exception level, EL_D, is the Exception level that debug exceptions are targeting. Routing debug exceptions on page D2-2423 describes how EL_D is derived.
• Debuggers using breakpoint instructions must be aware of the Armv8 rules for concurrent modification and execution of instructions. See Concurrent modification and execution of instructions on page B2-120.

D2.8.2 Breakpoint instructions

The breakpoint instruction in the A64 instruction set is BRK #<immediate>. It is unconditional.

For details of the instruction encoding, see BRK on page C6-837.

The breakpoint instruction in the A32 and T32 instruction sets is BKPT #<immediate>.

For more information about the A32 and T32 breakpoint instruction, see Breakpoint instruction in the A32 and T32 instruction sets on page G2-5867.
D2.8.3 Exception syndrome information and preferred return address

See the following:

- Exception syndrome information.
- Preferred return address.

Exception syndrome information

On taking a Breakpoint Instruction exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- ESR_EL1.
- ESR_EL2.
- ESR_EL3.

--- Note ---

Breakpoint Instruction exceptions are the only debug exception that can be taken to EL3 using AArch64.

Table D2-8 shows the information that the PE records.

<table>
<thead>
<tr>
<th>ESR_ELx field</th>
<th>Information recorded in ESR_EL1, ESR_EL2, or ESR_EL3.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception Class, EC</td>
<td>Whether the breakpoint instruction was executed in AArch64 state or AArch32 state. The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0x3C for an A64 BRK instruction.</td>
</tr>
<tr>
<td></td>
<td>• 0x38 for an A32 or T32 BKPT instruction.</td>
</tr>
<tr>
<td>Instruction Length, IL</td>
<td>The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0 for a 16-bit T32 BKPT instruction.</td>
</tr>
<tr>
<td></td>
<td>• 1 for an A64 BRK instruction, or an A32 BKPT instruction.</td>
</tr>
<tr>
<td>Instruction Specific Syndrome, ISS</td>
<td>ISS[24:16]</td>
</tr>
<tr>
<td></td>
<td>ISS[15:0]</td>
</tr>
</tbody>
</table>

--- Note ---

- If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Breakpoint Instruction exception is routed to EL2, ESR_EL2.EC is set to the same value as if the exception was taken to EL1.
- For information about how debug exceptions can be routed to EL2, see Routing debug exceptions on page D2-2423.

Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

D2.8.4 Pseudocode description of Breakpoint Instruction exceptions

AArch64.SoftwareBreakpoint() generates a Breakpoint Instruction exception that is taken to AArch64 state.

This function is defined in Chapter J1 Armv8 Pseudocode.
D2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:
• In an Exception level that is using AArch64.
• At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:
• About Breakpoint exceptions.
• Breakpoint types and linking of breakpoints on page D2-2434.
• Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2442.
• Breakpoint instruction address comparisons on page D2-2444.
• Breakpoint context comparisons on page D2-2446.
• Breakpoint usage constraints on page D2-2447.
• Preferred return address on page D2-2450.
• Pseudocode description of Breakpoint exceptions taken from AArch64 state on page D2-2450.

D2.9.1 About Breakpoint exceptions

A breakpoint is an event that results from the execution of an instruction, which is based on either:
• The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
• The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint exceptions are generated by Breakpoint debug events. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in Breakpoint Instruction exceptions on page D2-2431.

An implementation can include between 2-16 hardware breakpoints. ID_AA64DFR0_EL1.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:
• The Breakpoint Control Register, DBGBCR<n>_EL1. This contains controls for the breakpoint, for example an enable control.
• The Breakpoint Value Register, DBGBVR<n>_EL1. This holds the value used for breakpoint matching, that is one of:
  — An instruction virtual address.
  — A Context ID.
  — A VMID value.
  — A concatenation of both a Context ID value and a VMID value.

These registers are numbered, so that:
• DBGBCR_1_EL1 and DBGBVR1_EL1 are for breakpoint number one.
• DBGBCR2_EL1 and DBGBVR2_EL1 are for breakpoint number two.
• …
• …
• DBGBCR<n>_EL1 and DBGBVR<n>_EL1 are for breakpoint number n.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:
• The breakpoint is enabled. That is, the breakpoint enable control for it, DBGBCR<n>_EL1.E, is 1.
• The conditions specified in the DBGCR<\text{n}>_EL1 are met.
• The comparison with the value held in the DBGVR<\text{n}>_EL1 is successful.
• If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
• The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:
• Whether the instruction passes its Condition code check.
• The instruction type.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state.
Otherwise, if debug exceptions are:
• Enabled, Breakpoint debug events generate Breakpoint exceptions.
• Disabled, Breakpoint debug events are ignored.

—— Note ———
The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.
However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls on page D2-2422 describes the enable controls for Breakpoint debug events.

D2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:
• A context-aware breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  — An instruction address match.
  — A Context ID match, with the value held in the CONTEXTIDR_EL1.
  — A VMID match, with the VMID value held in the VTTBR_EL2.
  — Both a Context ID match and a VMID match.
• A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match.

ID_AA64DFR0_EL1.CTX_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an Address breakpoint. Breakpoints that are programmed to match on anything else are categorized as Context breakpoints.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:
• Used in isolation. In this case, the breakpoint is called an Unlinked breakpoint.
• Enabled for linking to another breakpoint. In this case, the breakpoint is called a Linked breakpoint.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match occurs. For example, a debugger might:
1. Program breakpoint number one to be a Linked Address Match breakpoint.
2. Program breakpoint number five to be a Linked Context ID Match breakpoint.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The Breakpoint Type field for a breakpoint, DBGBCR<n>_EL1.BT, controls the breakpoint type and whether the breakpoint is enabled for linking. If BT[0] is 1, the breakpoint is enabled for linking.

If AArch32 state is implemented, Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See Specifying the halfword-aligned address that an Address breakpoint matches on page D2-2444.

Note
Stage 1 of an AArch32 translation regimes supports two additional breakpoint types, Unlinked and Linked Address Mismatch breakpoints, BT == 0b0100 and BT == 0b101. For information about these, see Chapter G2 AArch32 Self-hosted Debug. These types are reserved in stage 1 of an AArch64 translation regime. See Reserved BT values on page D2-2447.

Rules for linking breakpoints
The rules for breakpoint linking are as follows:

• Only Linked breakpoint types can be linked.

• Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGBCR<n>_EL1.LBN, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  — DBGBCR<n>_EL1.{SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2442.
  — DBGBCR<n>_EL1.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.

• Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.

• Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.

• If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See Other usage constraints for Address breakpoints on page D2-2449.

• If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.

• Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

Note
Multiple Linked watchpoints can also link to a single Linked Context breakpoint. Watchpoint exceptions on page D2-2451 describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

• Multiple Linked Address Match breakpoints.
• Multiple Linked watchpoints.

Note
If FEAT_NV2 is implemented, the hypervisor must use the 0b1101, Linked CONTEXTIDR_EL2 Match breakpoint type to guarantee a linked match, see Interaction with self-hosted and External debug on page D5-2644.
It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

**Figure D2-1** shows an example of permitted breakpoint and watchpoint linking.

<table>
<thead>
<tr>
<th>Breakpoint or watchpoint number</th>
<th>Breakpoints</th>
<th>Watchpoints</th>

</tbody>
</table>

**Figure D2-1 The role of linking in Breakpoint and Watchpoint exception generation**

In **Figure D2-1**, each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

**Breakpoint types defined by DBGBCRn_EL1.BT**

The following list provides more detail about each breakpoint type:

- **Unlinked Address Match breakpoint**
  
  Generation of a Breakpoint exception depends on both:
  - **DBGBCR<n>_EL1.{SSC, HMC, PMC}**. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See *Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2442*.
  - A successful address match, as described in *Breakpoint instruction address comparisons on page D2-2444*.

  **DBGBCR<n>_EL1.LBN** for this breakpoint is ignored.
0b0001, Linked Address Match breakpoint
Generation of a Breakpoint exception depends on all of the following:
• \( \text{DBGBCR}^{\langle n\rangle}_\text{EL1}.\{\text{SSC, HMC, PMC}\} \) for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2442.
• A successful address match defined by this breakpoint, as described in Breakpoint instruction address comparisons on page D2-2444.
• A successful context match defined by the Linked Context breakpoint that this breakpoint links to.
\( \text{DBGBCR}^{\langle n\rangle}_\text{EL1}.\text{LBN} \) for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, Unlinked Context ID Match breakpoint
BT == 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.
For context-aware breakpoints, generation of a Breakpoint exception depends on both:
• \( \text{DBGBCR}^{\langle n\rangle}_\text{EL1}.\{\text{SSC, HMC, PMC}\} \). These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2442.
• A successful Context ID match, as described in Breakpoint context comparisons on page D2-2446.
The value of \( \text{DBGBVR}^{\langle n\rangle}_\text{EL1}.\text{ContextID} \) is compared with the current Context ID.
\( \text{CONTEXTIDR}_\text{EL2} \) holds the current Context ID when all of:
• The implementation includes FEAT_VHE.
• EL2 is implemented and enabled in the current Security state.
• EL2 using AArch64 and \( \text{HCR}_{\text{EL2}.E2H} \) is set to 1.
• The PE is executing at EL0 and \( \text{HCR}_{\text{EL2}.TGE} \) is 1, or the PE is executing at EL2.
Otherwise, \( \text{CONTEXTIDR}_\text{EL1} \) holds the current Context ID.
\( \text{DBGBCR}^{\langle n\rangle}_\text{EL1}.\{\text{LBN, BAS}\} \) for this breakpoint are ignored

0b0011, Linked Context ID Match breakpoint
BT == 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.
For context-aware breakpoints, one of the following applies:
• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-2444.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2446.
• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2456.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2446.
The value of \( \text{DBGBVR}^{\langle n\rangle}_\text{EL1}.\text{ContextID} \) is compared with the current Context ID.
\( \text{CONTEXTIDR}_\text{EL2} \) holds the current Context ID when all of:
• The implementation includes FEAT_VHE.
• EL2 is implemented and enabled in the current Security state.
• EL2 using AArch64 and \( \text{HCR}_{\text{EL2}.E2H} \) is set to 1.
• The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.
Otherwise, CONTEXTIDR_EL1 holds the current Context ID.
DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

**0b0100, Unlinked Address Mismatch breakpoint**

BT == 0b0100 is a reserved value in stage 1 of an AArch64 translation regime. See Reserved BT values on page D2-2447.

*0b0100, Unlinked Address Mismatch breakpoint on page G2-5875 describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.*

**0b0101, Linked Address Mismatch breakpoint**

BT == 0b0101 is a reserved value in stage 1 of an AArch64 translation regime. See Reserved BT values on page D2-2447.

*0b0101, Linked Address Mismatch breakpoint on page G2-5875 describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.*

**0b0110, Unlinked CONTEXTIDR_EL1 Match breakpoint**

BT == 0b0110 is a reserved value if either:

• The breakpoint is not a context-aware breakpoint.
• The implementation does not include FEAT_VHE.

In an implementation that includes FEAT_VHE, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

• DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
• A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2446.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGBVR<n>_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

Note: ___________
The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

**0b0111, Linked CONTEXTIDR_EL1 Match breakpoint**

BT == 0b0111 is a reserved value if either:

• The breakpoint is not a context-aware breakpoint.
• The implementation does not include FEAT_VHE.

In an implementation that includes FEAT_VHE, for context-aware breakpoints, one of the following applies:

• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.

• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-2444.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2446.

• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2456.
— A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2446.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGVR<\n>_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

Note
The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGCR<\n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1000, Unlinked VMID Match breakpoint
BT == 0b1000 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:
• DBGCR<\n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2442.
• A successful VMID match, as described in Breakpoint context comparisons on page D2-2446.

DBGCR<\n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1001, Linked VMID Match breakpoint
BT == 0b1000 is a reserved value if either:
• The breakpoint is not a context-matching breakpoint.
• EL2 is not implemented.

For context-aware breakpoints, one of the following applies:
• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.

• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See Breakpoint instruction address comparisons on page D2-2444.
  — A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2446.

• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2456.
  — A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2446.

DBGCR<\n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint
BT == 0b1010 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:
• DBGCR<\n>_EL1.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates a Breakpoint exception for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2442.
• A successful Context ID match, as described in Breakpoint context comparisons on page D2-2446.
• A successful VMID match.

The value of DBGBVR<\(n\)>_EL1.ContextID is compared with CONTEXTIDR_EL1. Breakpoint context comparisons on page D2-2446 describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<\(n\)>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1011, Linked Context ID and VMID Match breakpoint

BT == 0b1011 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, one of the following applies:
• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
• Generation of a Breakpoint exception depends on all of the following:
  — A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-2444.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2446.
  — A successful VMID match defined by this breakpoint.

• Generation of a Watchpoint exception depends on all of the following:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2456.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2446.
  — A successful VMID match defined by this breakpoint.

The value of DBGBVR<\(n\)>_EL1.ContextID is compared with CONTEXTIDR_EL1. Breakpoint context comparisons on page D2-2446 describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

DBGBCR<\(n\)>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1100, Unlinked CONTEXTIDR_EL2 Match breakpoint

BT == 0b1100 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on both:
• DBGBCR<\(n\)>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
• A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons on page D2-2446.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<\(n\)>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGBCR<\(n\)>_EL1.{LBN, BAS} for this breakpoint are ignored.
0b1101, Linked CONTEXTIDR_EL2 Match breakpoint

BT == 0b1101 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-2444.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons on page D2-2446.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2456.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons on page D2-2446.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1110, Unlinked Full Context ID Match breakpoint

BT == 0b1110 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons on page D2-2446.

The Context ID check is made against the values in both CONTEXTIDR_EL1 and CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1[31:0] is compared with the Context ID value held in CONTEXTIDR_EL1, and the value of DBGBVR<n>_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR_EL2. Both comparisons must match for the Context ID check.

Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1111, Linked Full Context ID Match breakpoint

BT == 0b1111 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
• FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, one of the following applies:

• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.

• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons on page D2-2444.*
  — A successful Context ID match, as described in *Breakpoint context comparisons on page D2-2446.*

• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons on page D2-2456.*
  — A successful Context ID match, as described in *Breakpoint context comparisons on page D2-2446.*

The Context ID check is made against the values in both CONTEXTIDR_EL1 and CONTEXTIDR_EL2. The value of DBGVR<\(n\) EL1>[31:0] is compared with the Context ID value held in CONTEXTIDR_EL1, and the value of DBGVR<\(n\) EL1>[63:32] is compared with the Context ID value held in CONTEXTIDR_EL2. Both comparisons must match for the Context ID check.

__Note__
The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

__Note__
DBGCR<\(n\) EL1>.[LBN, SSC, HMC, BAS, PMC] for this breakpoint are ignored.

---

**D2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions**

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at EL0 in Secure state.

DBGCR<\(n\) EL1>.{SSC, HMC, PMC} defines the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

**Security State Control, SSC**

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

__Note__
This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

**Higher Mode Control, HMC, and Privileged Mode Control, PMC**

HMC and PMC together control which Exception levels the breakpoint generates Breakpoint exceptions in.
Table D2-9 shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Exception levels breakpoints generate Breakpoint exceptions in.

In the table:

- **Y**: Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row can generate Breakpoint exceptions in that Exception level and Security state.

- **-**: Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row cannot generate Breakpoint exceptions in that Exception level and Security state.

For information about which combinations of HMC, SSC and PMC are reserved if an Exception level or Security state are not implemented or enabled, see **Reserved DBGBCR<n>_EL1.[SSC, HMC, PMC] values** on page D2-2448.

</table>
a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at EL3 using AArch64.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See Reserved DBGBCR<n>_EL1.(SSC, HMC, PMC) values on page D2-2448.

**D2.9.4 Breakpoint instruction address comparisons**

In this subsection, the term $\text{AddrTop}$ represents the most significant bit of a virtual address used by breakpoint data address comparisons. $\text{AddrTop}$ is:

- 55, if address tagging is used for the address. See Address tagging in AArch64 state on page D5-2528.
- 63, otherwise.

--- Note ---

When stage 1 translation is enabled, in AArch64 state, a virtual address has a maximum address width of either 48 bits or, when FEAT_LVA is implemented and the 64KB translation granule is used, 52 bits. Software can configure a smaller address width for a virtual address, see Input address size on page D5-2543. Attempting to translate an address that is larger than the configured input address size generates a Translation fault.

When stage 1 translation is disabled, using an address that ia larger than the implemented PA size generates an Address size fault. The implemented PA size is IMPLEMENTATION DEFINED up to 52 bits, see Physical address size on page D5-2542.

These faults have a higher priority than breakpoints.

---

An address comparison is successful if bits $\text{AddrTop}:2$ of the current instruction virtual address are equal to DBGBVR$n>\_EL1[\text{AddrTop}:2]$.

--- Note ---

DBGBVR$n>\_EL1$ is a 64-bit register. The most significant bits of this register are sign-extension bits. DBGBVR$n>\_EL1[1:0]$ are RES0 and are ignored.

---

If EL1 is using AArch64 and EL0 is using AArch32, A32 and T32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, the instruction addresses are zero-extended before comparison with the breakpoint.

**Specifying the halfword-aligned address that an Address breakpoint matches on**

For Address Match breakpoints, if the implementation supports AArch32 state, a debugger must program the Byte Address Selection field, DBGBCR$n>\_EL1.BAS$.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0011</td>
<td>DBGBCR$n&gt;_EL1</td>
<td>Use for T32 instructions.</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBCR$n&gt;_EL1 + 2</td>
<td>Use for T32 instructions.</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBCR$n&gt;_EL1</td>
<td>Use for A64 and A32 instructions.</td>
</tr>
</tbody>
</table>

If the implementation is an AArch64-only implementation, all instructions are word-aligned and DBGBCR$n>\_EL1.BAS$ is RES1.
Figure D2-2 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with DBGBCR<n>_EL1.BAS programmed as either 0b0011 or 0b1111 generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

**Note**

To breakpoint on an A64 instruction, Arm recommends that the debugger programs DBGBCR<n>_EL1.BAS as 0b1111.

In the figure:

- **Yes** Means that the breakpoint generates a Breakpoint exception.
- **No** Means that the breakpoint does not generate a Breakpoint exception.
- **UNP** Means that it is CONstrained UNPREDICTable whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page D2-2449.

### Figure D2-2 Summary of BAS field meanings for Address Match breakpoints

<table>
<thead>
<tr>
<th>Instruction set</th>
<th>Size</th>
<th>Location of instruction(^a)</th>
<th>BAS[3:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>0</td>

<tr>
<td>Row 6</td>
<td>A32</td>
<td>32-bit</td>
<td></td>
</tr>
<tr>
<td>Row 7</td>
<td>A64</td>
<td>32-bit</td>
<td></td>
</tr>
</tbody>
</table>

\(^a\) 0 means the word-aligned address held in the DBGBVR<n>_EL1[maxAddressSize:2]:00. The other locations a
- -2 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) – 2).
- -1 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) – 1).
- ... 
- ... 
- +5 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) + 5).

The solid areas show the location of the instruction.
D2.9.5 Breakpoint context comparisons

The breakpoint type defined by DBGBCR<\textit{n}>.EL1.BT determines what context comparison is required, if any. Table D2-11 shows the BT values that require a comparison, and the match required for the comparison to be successful.

Table D2-11 Breakpoint Context ID and VMID comparison tests

<table>
<thead>
<tr>
<th>DBGBCR&lt;\textit{n}&gt;.BT</th>
<th>Test required for successful context comparison</th>
</tr>
</thead>
</table>
| 0b001x                | • When FEAT_VHE is implemented, EL2 is using AArch64, the \textit{Effective value} of HCR_EL2.E2H is 1, and either the PE is executing at EL0 with HCR_EL2.TGE set to 1, or the PE is executing at EL2, CONTEXTIDR_EL2 must match the DBGBR<n>_EL1.ContextID value.  
  • Otherwise, CONTEXTIDR_EL1 must match the DBGBR<n>_EL1.ContextID value. |
| 0b011x                | CONTEXTIDR_EL1 must match the DBGBR<n>_EL1.ContextID value. |
| 0b100x                | VTTBR_EL2.VMID must match the DBGBR<n>_EL1.VMID value. |
| 0b101x                | CONTEXTIDR_EL1 must match the DBGBR<n>_EL1.ContextID value and VTTBR_EL2.VMID must match the DBGBR<n>_EL1.VMID value. |
| 0b110x                | CONTEXTIDR_EL2 must match the DBGBR<n>_EL1.ContextID2 value, DBGBR<n>_EL1[63:32]. |
| 0b111x                | Both:  
  • CONTEXTIDR_EL1 must match the DBGBR<n>_EL1.ContextID value, DBGBR<n>_EL1[31:0].  
  • CONTEXTIDR_EL2 must match the DBGBR<n>_EL1.ContextID2 value, DBGBR<n>_EL1[63:32]. |

No Context ID or VMID comparison is required for other valid DBGBCR<\textit{n}>.BT values.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of CONTEXTIDR_EL1 and any of:
  - The PE is executing at EL3 using AArch64.
  - The PE is executing at EL2.
  - FEAT_VHE is implemented, EL2 is using AArch64, EL2 is enabled in the current Security state, and HCR_EL2.[E2H, TGE] \(\{1, 1\}\).

- The comparison uses the value of CONTEXTIDR_EL2 and any of:
  - Neither FEAT_VHE is implemented, nor FEAT_Debugv8p2 is implemented.
  - If the PE is in Secure state, and either FEAT_SEL2 is not implemented, or Secure EL2 is disabled.
  - EL2 is using AArch32.
  - EL2 is not implemented.

- The comparison uses the current VMID value and any of:
  - EL2 is not implemented.
  - If the PE is in Secure state, and either FEAT_SEL2 is not implemented, or Secure EL2 is disabled.
  - The PE is executing at EL2.
  - FEAT_VHE is implemented, EL2 is using AArch64, EL2 is enabled in the current Security state, and HCR_EL2.[E2H, TGE] \(\{1, 1\}\).

**Note**

- For all Context breakpoints, DBGBCR<\textit{n}>.EL1.BAS is \textit{RES1} and is ignored.
- For Linked Context breakpoints, DBGBCR<\textit{n}>.EL1.[LBN, SSC, HMC, PMC] are \textit{RES0} and are ignored.
### D2.9.6 Breakpoint usage constraints

See the following sections:

- *Reserved DBGBCR<n>_EL1.BT values.*
- *Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values* on page D2-2448.
- *Reserved DBGBCR<n>_EL1.BAS values* on page D2-2448.
- *Reserved DBGBCR<n>_EL1.LBN values* on page D2-2449.
- *Other usage constraints for Address breakpoints* on page D2-2449.
- *Other usage constraints for Context breakpoints* on page D2-2449.

#### Reserved DBGBCR<n>_EL1.BT values

Table D2-12 shows when particular DBGBCR<n>_EL1.BT values are reserved.

<table>
<thead>
<tr>
<th>BT value</th>
<th>Breakpoint type</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b001x</td>
<td>Context ID Match</td>
<td>If the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b010x</td>
<td>Address Mismatch</td>

</tr>
<tr>
<td>0b101x</td>
<td>Context ID and VMID Match</td>
<td>If EL2 is not implemented, or the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b110x</td>
<td>CONTEXTIDR_EL2 Match</td>
<td>If FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, or if the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b111x</td>
<td>Full Context ID Match</td>
<td></td>
</tr>
</tbody>
</table>

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct or external read of DBGBCR<n>_EL1.
- For a direct or external read of DBGBCR<n>_EL1, if the reserved BT value:
  - Has no function for any execution conditions, the value read back is **UNKNOWN**.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.
Reserved DBGBCR<\n>_EL1.{SSC, HMC, PMC} values

Table D2-13 shows when particular combinations of DBGBCR<\n>_EL1.{SSC, HMC, PMC} are reserved in stage 1 of an AArch64 translation regime.

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10, except for the combination with HMC set to 1, SSC set to 0b01, and PMC set to 0b00</td>
<td>When EL3 is not implemented and EL2 is implemented</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b01, and PMC set to 0b00, or combinations when SSC is set to 0b11</td>
<td>When both of EL2 and EL3 are not implemented</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00</td>
<td>When EL2 is not implemented</td>
</tr>
<tr>
<td>The combinations with SSC set to 0b11 except the combination with HMC set to 1, SSC set to 0b11 and PMC set to 0b00</td>
<td>When Secure EL2 is not implemented</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b01 and PMC set to 0b00</td>
<td>When Secure EL2 is not implemented</td>
</tr>
<tr>
<td>Combinations not included in Table D2-9 on page D2-2443</td>
<td>Always</td>
</tr>
</tbody>
</table>

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is disabled.
