  - The applicable one of the ERR\(<n>\)CTLR.{WUE,RUE,UE} bits is implemented and was set to 0b1 when an Uncorrected error was detected.
  - The applicable one of the ERR\(<n>\)CTLR.{WUE,RUE,UE} bits is not implemented and the node always reports errors.

It is IMPLEMENTATION DEFINED whether this bit can be set to 0b1 by a Deferred error.
If this bit is nonzero, then Arm recommends that software write \( 0b1 \) to this bit to clear this bit to zero, when any of:

- Clearing \( \text{ERR}<n>\text{STATUS.V} \) to \( 0b0 \).
- Clearing \( \text{ERR}<n>\text{STATUS.UE} \) to \( 0b0 \), if this bit is never set to \( 0b1 \) by a Deferred error.
- Clearing \( \text{ERR}<n>\text{STATUS.UE,DE} \) to \( \{0,0\} \), if this bit can be set to \( 0b1 \) by a Deferred error.

This bit is not valid and reads \text{UNKNOWN} \ if any of the following are true:

- \( \text{ERR}<n>\text{STATUS.V} = 0b0 \).
- \( \text{ERR}<n>\text{STATUS.UE} = 0b0 \) and this bit is never set to \( 0b1 \) by a Deferred error.
- \( \text{ERR}<n>\text{STATUS.UE,DE} = \{0,0\} \) and this bit can be set to \( 0b1 \) by a Deferred error.

This bit ignores writes if \( \text{ERR}<n>\text{STATUS.UE,DE} \neq \{0,0\} \), and the highest priority of these is not being cleared to zero in the same write.

This bit is read/write-one-to-clear.

Note

An External Abort signaled by the node might be masked and not generate any exception.

On an Error recovery reset, the value of this field is unchanged.

On a Cold reset, this field resets to an architecturally \text{UNKNOWN} \ value.

**OF, bit [27]**

Overflow.

Indicates that multiple errors have been detected. This bit is set to \( 0b1 \) when one of the following occurs:

- An Uncorrected error is detected and \( \text{ERR}<n>\text{STATUS.UE} = 0b1 \).
- A Deferred error is detected, \( \text{ERR}<n>\text{STATUS.UE} = 0b0 \) and \( \text{ERR}<n>\text{STATUS.DE} = 0b1 \).
- A Corrected error is detected, no Corrected error counter is implemented, \( \text{ERR}<n>\text{STATUS.UE} = 0b0 \), \( \text{ERR}<n>\text{STATUS.DE} = 0b0 \), and \( \text{ERR}<n>\text{STATUS.CE} \neq 0b00 \). \( \text{ERR}<n>\text{STATUS.CE} \) might be updated for the new Corrected error.
- A Corrected error counter is implemented, \( \text{ERR}<n>\text{STATUS.UE} = 0b0 \), \( \text{ERR}<n>\text{STATUS.DE} = 0b0 \), and the counter overflows.

It is IMPLEMENTATION DEFINED whether this bit is set to \( 0b1 \) when one of the following occurs:

- A Deferred error is detected and \( \text{ERR}<n>\text{STATUS.UE} = 0b1 \).
- A Corrected error is detected, no Corrected error counter is implemented, and either or both the \( \text{ERR}<n>\text{STATUS.UE} \) or \( \text{ERR}<n>\text{STATUS.DE} \) bits are set to \( 0b1 \).
- A Corrected error counter is implemented, either or both the \( \text{ERR}<n>\text{STATUS.UE} \) or \( \text{ERR}<n>\text{STATUS.DE} \) bits are set to \( 0b1 \), and the counter overflows.

It is IMPLEMENTATION DEFINED whether this bit is cleared to \( 0b0 \) when one of the following occurs:

- An Uncorrected error is detected and \( \text{ERR}<n>\text{STATUS.UE} = 0b0 \).
- A Deferred error is detected, \( \text{ERR}<n>\text{STATUS.UE} = 0b0 \) and \( \text{ERR}<n>\text{STATUS.DE} = 0b0 \).
- A Corrected error is detected, \( \text{ERR}<n>\text{STATUS.UE} = 0b0 \), \( \text{ERR}<n>\text{STATUS.DE} = 0b0 \) and \( \text{ERR}<n>\text{STATUS.CE} = 0b00 \).

The IMPLEMENTATION DEFINED clearing of this bit might also depend on the value of the other error status bits.

If a Corrected error counter is implemented:

- A direct write that modifies the counter overflow flag indirectly might set this bit to an \text{UNKNOWN} \ value.
A direct write to this bit that clears this bit to 0b0 might indirectly set the counter overflow flag to an unknown value.

### Note

This bit might have been set to 0b1 when an error syndrome was discarded and later cleared to 0b0 when a higher priority syndrome was recorded.

### Note

This bit is not valid and reads unknown if ERR<\texttt{n}>STATUS.V == 0b0.

### Note

This bit is read/write-one-to-clear.

### Note

On an Error recovery reset, the value of this field is unchanged.

### Note

On a Cold reset, this field resets to an architecturally unknown value.

### MV, bit [26]

When error record \texttt{<n>} includes an additional information for an error:

- **Miscellaneous Registers Valid.**
  - 0b0: ERR<\texttt{n}>MISC<\texttt{m}> not valid.
  - 0b1: The implementation defined contents of the ERR<\texttt{n}>MISC<\texttt{m}> registers contains additional information for an error recorded by this record.

This bit ignores writes if ERR<\texttt{n}>STATUS.{CE,DE,UE} \neq {0b0,0,0}, and the highest priority of these is not being cleared to zero in the same write.

This bit is read/write-one-to-clear.

### Note

If the ERR<\texttt{n}>MISC<\texttt{m}> registers can contain additional information for a previously recorded error, then the contents must be self-describing to software or a user. For example, certain fields might relate only to Corrected errors, and other fields only to the most recent error that was not discarded.

On an Error recovery reset, the value of this field is unchanged.

On a Cold reset, this field resets to 0.

### Otherwise:

Reserved, RES0.

### CE, bits [25:24]

Corrected Error.
- 0b00: No errors were corrected.
- 0b01: At least one transient error was corrected.
- 0b10: At least one error was corrected.
- 0b11: At least one persistent error was corrected.
The mechanism by which a node detects whether a correctable error is transient or persistent is IMPLEMENTATION DEFINED. If no such mechanism is implemented, then the node sets this field to 0b10 when an error is corrected.

When clearing ERR<n>STATUS.V to 0b0, if this field is nonzero, then Arm recommends that software write ones to this field to clear this field to zero.

This field is not valid and reads UNKNOWN if ERR<n>STATUS.V == 0b0. This field ignores writes if ERR<n>STATUS.OF == 0b1 and is not being cleared to 0b0 in the same write.

This field is read/write-ones-to-clear. Writing a value other than all-zeros or all-ones sets this field to an UNKNOWN value.

On an Error recovery reset, the value of this field is unchanged.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

DE, bit [23]

Deferred Error.

0b0 No errors were deferred.
0b1 At least one error was not corrected and deferred.

Support for deferring errors is IMPLEMENTATION DEFINED.

When clearing ERR<n>STATUS.V to 0b0, if this bit is nonzero, then Arm recommends that software write 0b1 to this bit to clear this bit to zero.

This bit is not valid and reads UNKNOWN if ERR<n>STATUS.V == 0b0. This bit ignores writes if ERR<n>STATUS.OF == 0b1 and is not being cleared to 0b0 in the same write.

This bit is read/write-one-to-clear.

On an Error recovery reset, the value of this field is unchanged.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

PN, bit [22]

Poison.

0b0 Uncorrected error or Deferred error recorded because a corrupt value was detected, for example, by an error detection code (EDC), or Corrected error recorded.
0b1 Uncorrected error or Deferred error recorded because a poison value was detected.

If this bit is nonzero, then Arm recommends that software write 0b1 to this bit to clear this bit to zero, when any of:
- Clearing ERR<n>STATUS.V to 0b0.
- Clearing both ERR<n>STATUS.{DE, UE} to 0b0.

This bit is not valid and reads UNKNOWN if any of the following are true:
- ERR<n>STATUS.V == 0b0.
- ERR<n>STATUS.{DE,UE} == {0,0}.

This bit ignores writes if ERR<n>STATUS.{CE,DE,UE} != {0b0,0,0}, and the highest priority of these is not being cleared to zero in the same write.

This bit is read/write-one-to-clear.

On an Error recovery reset, the value of this field is unchanged.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

UET, bits [21:20]

Uncorrected Error Type. Describes the state of the component after detecting or consuming an Uncorrected error.

0b00 Uncorrected error, Uncontainable error (UC).
0b01 Uncorrected error, Unrecoverable error (UEU).
0b10 Uncorrected error, Latent or Restartable error (UEO).
0b11 Uncorrected error, Signaled or Recoverable error (UER).

If this field is nonzero, then Arm recommends that software write ones to this field to clear this field to zero, when any of:

- Clearing ERR<\n>STATUS.V to 0b0.
- Clearing ERR<\n>STATUS.UE to 0b0.

This field is not valid and reads UNKNOWN if any of the following are true:

- ERR<\n>STATUS.V == 0b0.
- ERR<\n>STATUS.UE == 0b0.

This field ignores writes if ERR<\n>STATUS.{CE,DE,UE} != {0b00,0,0}, and the highest priority of these is not being cleared to zero in the same write.

This field is read/write-ones-to-clear. Writing a value other than all-zeros or all-ones sets this field to an UNKNOWN value.

--- Note ---

Software might use the information in the error record registers to determine what recovery is necessary.

---

On an Error recovery reset, the value of this field is unchanged.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [19:16]

Reserved, RES0.

IERR, bits [15:8]

IMPLEMENTATION DEFINED error code. Used with any primary error code ERR<\n>STATUS.SERR value. Further IMPLEMENTATION DEFINED information can be placed in the ERR<\n>MISC<m> registers.

The implemented set of valid values that this field can take is IMPLEMENTATION DEFINED. If any value not in this set is written to this register, then the value read back from this field is UNKNOWN.

--- Note ---

This means that one or more bits of this field might be implemented as fixed read-as-zero or read-as-one values.

---

This field is not valid and reads UNKNOWN if all of the following are true:

- Any of the following are true:
  - The RAS Common Fault Injection Model Extension is implemented by the node that owns this error record and ERR<\n>PFGF.SYN == 0b0.
  - The RAS Common Fault Injection Model Extension is not implemented by the node that owns this error record.
- ERR<\n>STATUS.V == 0b0.

This field ignores writes if ERR<\n>STATUS.{CE,DE,UE} != {0b00,0,0}, and the highest priority of these is not being cleared to zero in the same write.

On an Error recovery reset, the value of this field is unchanged.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

SERR, bits [7:0]

Architecturally-defined primary error code. The primary error code might be used by a fault handling agent to triage an error without requiring device-specific code. For example, to count and threshold corrected errors in software, or generate a short log entry.

0x00 No error.
0x01 IMPLEMENTATION DEFINED error.
0x02  Data value from (non-associative) internal memory. For example, ECC from on-chip SRAM or buffer.
0x03  IMPLEMENTATION DEFINED pin. For example, nSEI pin.
0x04  Assertion failure. For example, consistency failure.
0x05  Error detected on internal data path. For example, parity on ALU result.
0x06  Data value from associative memory. For example, ECC error on cache data.
0x07  Address/control value from associative memory. For example, ECC error on cache tag.
0x08  Data value from a TLB. For example, ECC error on TLB data.
0x09  Address/control value from a TLB. For example, ECC error on TLB tag.
0x0A  Data value from producer. For example, parity error on write data bus.
0x0B  Address/control value from producer. For example, parity error on address bus.
0x0C  Data value from (non-associative) external memory. For example, ECC error in SDRAM.
0x0D  Illegal address (software fault). For example, access to unpopulated memory.
0x0E  Illegal access (software fault). For example, byte write to word register.
0x0F  Illegal state (software fault). For example, device not ready.
0x10  Internal data register. For example, parity on a SIMD&FP register. For a PE, all general-purpose, stack pointer, SIMD&FP, and SVE registers are data registers.
0x11  Internal control register. For example, Parity on a System register. For a PE, all registers other than general-purpose, stack pointer, SIMD&FP, and SVE registers are control registers.
0x12  Error response from Completer of access. For example, error response from cache write-back.
0x13  External timeout. For example, timeout on interaction with another node.
0x14  Internal timeout. For example, timeout on interface within the node.
0x15  Deferred error from Completer not supported at Requester. For example, poisoned data received from the Completer of an access by a Requester that cannot defer the error further.
0x16  Deferred error from Requester not supported at Completer. For example, poisoned data received from the Requester of an access by a Completer that cannot defer the error further.
0x17  Deferred error from Completer passed through. For example, poisoned data received from the Completer of an access and returned to the Requester.
0x18  Deferred error from Requester passed through. For example, poisoned data received from the Requester of an access and deferred to the Completer.
0x19  Error recorded by PCIe error logs. Indicates that the node has recorded an error in a PCIe error log. This might be the PCIe device status register, AER, DVSEC, or other mechanisms defined by PCIe.

All other values are reserved.

The implemented set of valid values that this field can take is IMPLEMENTATION DEFINED. If any value not in this set is written to this register, then the value read back from this field is UNKNOWN.

--- Note ---

This means that one or more bits of this field might be implemented as fixed read-as-zero or read-as-one values.
This field is not valid and reads UNKNOWN if all of the following are true:

• Any of the following are true:
  — The RAS Common Fault Injection Model Extension is implemented by the node that owns this error record and ERR<\n>PFGF.SYN == 0b0.
  — The RAS Common Fault Injection Model Extension is not implemented by the node that owns this error record.

• ERR<\n>STATUS.V == 0b0.

This field ignores writes if ERR<\n>STATUS.[CE,DE,UE] != \{0b00,0,0\}, and the highest priority of these is not being cleared to zero in the same write.

On an Error recovery reset, the value of this field is unchanged.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the ERR<\n>STATUS:**

The \{AV, V, UE, OF, MV, CE, DE, PN, UET, CI\} fields are write-one-to-clear, meaning writes of zero are ignored, and a write of one or all-ones to the field clears the field to zero. The \{IERR, SERR\} fields are read/write fields, although the set of implemented valid values is IMPLEMENTATION DEFINED. See also ERR<\n>PFGF.SYN.

After reading ERR<\n>STATUS, software must clear the valid bits in the register to allow new errors to be recorded. However, between reading the register and clearing the valid bits, a new error might have overwritten the register. To prevent this error being lost by software, the register prevents updates to fields that might have been updated by a new error.

When RAS System Architecture v1.0 is implemented:

• Writes to the \{UE, DE, CE\} fields are ignored if the OF bit is set and is not being cleared.

• Writes to the V bit are ignored if any of the \{UE, DE, CE\} fields are nonzero and are not being cleared.

• Writes to the \{AV, MV\} bits and \{ER, PN, UET, IERR, SERR\} syndrome fields are ignored if the highest priority error status field is nonzero and not being cleared. The error status fields in priority order from highest to lowest, are UE, DE, and CE.

When RAS System Architecture v1.1 is implemented, a write to the register is ignored if all of:

• Any of \{V, UE, OF, CE, DE\} fields are nonzero before the write.

• The write does not clear the nonzero \{V, UE, OF, CE, DE\} fields to zero by writing ones to the applicable field or fields.

Some of the fields in ERR<\n>STATUS are also defined as UNKNOWN where certain combinations of the \{V, DE, UE\} status fields are zero. The rules for writes to ERR<\n>STATUS allow a node to implement such a field as a fixed read-only value.

For example, when RAS System Architecture v1.1 is implemented, a write to ERR<\n>STATUS when ERR<\n>STATUS.V is 1 results in either ERR<\n>STATUS.V field being cleared to zero, or ERR<\n>STATUS.V not changing. Since all fields in ERR<\n>STATUS, other than \{AV, V, MV\}, usually read as UNKNOWN values when ERR<\n>STATUS.V is zero, this means those fields can be implemented as read-only if applicable.

To ensure correct and portable operation, when software is clearing the valid bits in the register to allow new errors to be recorded, Arm recommends that software:

• Determine which fields to clear to zero by reading ERR<\n>STATUS.

• Write ones to all the write-one-to-clear fields that are nonzero.

• Write zero to all the read/write fields.

• Write zero to all the write-one-to-clear fields that are zero.

Otherwise, these fields might not have the correct value when a new fault is recorded.
An exception is when the node supports writing to these fields as part of fault injection. See also ERR\(<n>\)PFGF.SYN.

ERR\(<n>\)STATUS can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAS</td>
<td>0x010 + (64 * n)</td>
<td>ERR(&lt;n&gt;)STATUS</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Accesses to this register are RW.
I5.8.33 ERRPIDR0, Peripheral Identification Register 0

The ERRPIDR0 characteristics are:

**Purpose**

Provides discovery information about the component.

For more information, see *About the Peripheral identification scheme* on page K2-7999.

**Configurations**

Implementation of this register is OPTIONAL.

ERRPIDR0 is implemented only as part of a memory-mapped group of error records.

**Attributes**

ERRPIDR0 is a 32-bit register.

**Field descriptions**

The ERRPIDR0 bit assignments are:

```
   31  8  7  0

   RES0  PART_0
```

**Bits [31:8]**

Reserved, RES0.

**PART_0, bits [7:0]**

Part number, bits [7:0].

The part number is selected by the designer of the component. The designer chooses whether to use a 12-bit or a 16-bit part number:

- If a 12-bit part number is used, it is stored in ERRPIDR1.PART_1 and ERRPIDR0.PART_0. There are 8 bits, ERRPIDR2.REVISION and ERRPIDR3.REVAND, available to define the revision of the component.
- If a 16-bit part number is used, it is stored in ERRPIDR2.PART_2, ERRPIDR1.PART_1 and ERRPIDR0.PART_0. There are 4 bits, ERRPIDR3.REVISION, available to define the revision of the component.

This field reads as an IMPLEMENTATION DEFINED value.

**Accessing the ERRPIDR0:**

ERRPIDR0 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAS</td>
<td>0xFE0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Accesses to this register are RO.
I5.8.34 ERRPIDR1, Peripheral Identification Register 1

The ERRPIDR1 characteristics are:

**Purpose**

Provides discovery information about the component.

For more information, see About the Peripheral identification scheme on page K2-7999.

**Configurations**

Implementation of this register is OPTIONAL.

ERRPIDR1 is implemented only as part of a memory-mapped group of error records.

**Attributes**

ERRPIDR1 is a 32-bit register.

**Field descriptions**

The ERRPIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>DES_0</td>
<td>PART_1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**DES_0, bits [7:4]**

Designer, JEP106 identification code, bits [3:0]. ERRPIDR1.DES_0 and ERRPIDR2.DES_1 together form the JEDEC-assigned JEP106 identification code for the designer of the component. The parity bit in the JEP106 identification code is not included. The code identifies the designer of the component, which might not be the same as the implementer of the device containing the component. To obtain a number, or to see the assignment of these codes, contact JEDEC http://www.jedec.org.

This field reads as an IMPLEMENTATION DEFINED value.

**Note**

For a component designed by Arm Limited, the JEP106 identification code is 0x38.

**PART_1, bits [3:0]**

Part number, bits [11:8].

The part number is selected by the designer of the component. The designer chooses whether to use a 12-bit or a 16-bit part number:

- If a 12-bit part number is used, it is stored in ERRPIDR1.PART_1 and ERRPIDR0.PART_0. There are 8 bits, ERRPIDR2.REVISION and ERRPIDR3.REV AND, available to define the revision of the component.
- If a 16-bit part number is used, it is stored in ERRPIDR2.PART_2, ERRPIDR1.PART_1 and ERRPIDR0.PART_0. There are 4 bits, ERRPIDR3.REVISION, available to define the revision of the component.

This field reads as an IMPLEMENTATION DEFINED value.
**Accessing the ERRPIDR1:**

ERRPIDR1 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAS</td>
<td>0xFE4</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Accesses to this register are RO.
### ERRPIDR2, Peripheral Identification Register 2

The ERRPIDR2 characteristics are:

#### Purpose

Provides discovery information about the component.

For more information, see *About the Peripheral identification scheme on page K2-7999.*

#### Configurations

Implementation of this register is OPTIONAL.

ERRPIDR2 is implemented only as part of a memory-mapped group of error records.

#### Attributes

ERRPIDR2 is a 32-bit register.

#### Field descriptions

The ERRPIDR2 bit assignments are:

**When the component uses a 12-bit part number:**

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>Reserved (RES0)</td>
<td>0</td>
</tr>
<tr>
<td>7-4</td>
<td>Revision (REVISION)</td>
<td>0b0000</td>
</tr>
<tr>
<td>3-0</td>
<td>Designer (DES_1)</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>JEDEC</td>
<td>0 or 1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits [31:8]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**REVISION, bits [7:4]**

Component major revision. ERRPIDR2.REVISION and ERRPIDR3.REVAND together form the revision number of the component, with ERRPIDR2.REVISION being the most significant part and ERRPIDR3.REVAND the least significant part. When a component is changed, ERRPIDR2.REVISION or ERRPIDR3.REVAND are increased to ensure that software can differentiate the different revisions of the component. If ERRPIDR2.REVISION is increased then ERRPIDR3.REVAND should be set to 0b0000.

This field reads as an IMPLEMENTATION DEFINED value.

**JEDEC, bit [3]**

JEDEC-assigned JEP106 implementer code is used.

Reads as 0b1.

**DES_1, bits [2:0]**

Designer, JEP106 identification code, bits [6:4]. ERRPIDR1.DES_0 and ERRPIDR2.DES_1 together form the JEDEC-assigned JEP106 identification code for the designer of the component. The parity bit in the JEP106 identification code is not included. The code identifies the designer of the component, which might not be the same as the implementer of the device containing the component. To obtain a number, or to see the assignment of these codes, contact JEDEC http://www.jedec.org.

This field reads as an IMPLEMENTATION DEFINED value.

---

**Note**

For a component designed by Arm Limited, the JEP106 identification code is 0x3B.
When the component uses a 16-bit part number:

| Bits [31:8] | Reserved, RES0. |
| PART_2, bits [7:4] | Part number, bits [15:12]. The part number is selected by the designer of the component. The designer chooses whether to use a 12-bit or a 16-bit part number: |
| - If a 12-bit part number is used, it is stored in ERRPIDR1.PART_1 and ERRPIDR0.PART_0. There are 8 bits, ERRPIDR2.REVISION and ERRPIDR3.REVISION, available to define the revision of the component. |
| - If a 16-bit part number is used, it is stored in ERRPIDR2.PART_2, ERRPIDR1.PART_1 and ERRPIDR0.PART_0. There are 4 bits, ERRPIDR3.REVISION, available to define the revision of the component. |
| This field reads as an IMPLEMENTATION DEFINED value. |

JEDEC, bit [3]
JEDEC-assigned JEP106 implementer code is used.
Reads as 0b1.

DES_1, bits [2:0]
Designer, JEP106 identification code, bits [6:4]. ERRPIDR1.DES_0 and ERRPIDR2.DES_1 together form the JEDEC-assigned JEP106 identification code for the designer of the component. The parity bit in the JEP106 identification code is not included. The code identifies the designer of the component, which might not be the same as the implementer of the device containing the component. To obtain a number, or to see the assignment of these codes, contact JEDEC http://www.jedec.org.
This field reads as an IMPLEMENTATION DEFINED value.

Note
For a component designed by Arm Limited, the JEP106 identification code is 0x3B.

Accessing the ERRPIDR2:
ERRPIDR2 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAS</td>
<td>0xFE8</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Accesses to this register are RO.
I5.8.36 ERRPIDR3, Peripheral Identification Register 3

The ERRPIDR3 characteristics are:

**Purpose**

Provides discovery information about the component.

For more information, see *About the Peripheral identification scheme* on page K2-7999.

**Configurations**

Implementation of this register is OPTIONAL.

ERRPIDR3 is implemented only as part of a memory-mapped group of error records.

**Attributes**

ERRPIDR3 is a 32-bit register.

**Field descriptions**

The ERRPIDR3 bit assignments are:

**When the component uses a 12-bit part number:**

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>REVAND</td>
<td>CMOD</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**REVAND, bits [7:4]**

Component minor revision. ERRPIDR2.REVISION and ERRPIDR3.REVAND together form the revision number of the component, with ERRPIDR2.REVISION being the most significant part and ERRPIDR3.REVAND the least significant part. When a component is changed, ERRPIDR2.REVISION or ERRPIDR3.REVAND are increased to ensure that software can differentiate the different revisions of the component. If ERRPIDR2.REVISION is increased then ERRPIDR3.REVAND should be set to 0b0000.

This field reads as an IMPLEMENTATION DEFINED value.

**CMOD, bits [3:0]**

Customer Modified.

Indicates the component has been modified.

A value of 0b0000 means the component is not modified from the original design.

Any other value means the component has been modified in an IMPLEMENTATION DEFINED way.

For any two components with the same Unique Component Identifier:

- If the value of the CMOD fields of both components equals zero, the components are identical.
- If the CMOD fields of both components have the same non-zero value, it does not necessarily mean that they have the same modifications.
- If the value of the CMOD field of either of the two components is non-zero, they might not be identical, even though they have the same Unique Component Identifier.

This field reads as an IMPLEMENTATION DEFINED value.
When the component uses a 16-bit part number:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>8</td>
<td>Reserved, REVISION</td>
</tr>
<tr>
<td>4</td>
<td>Reserved, CMOD</td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Component revision. When a component is changed, ERRPIDR3.REVISION is increased to ensure that software can differentiate the different revisions of the component.

This field reads as an IMPLEMENTATION DEFINED value.

CMOD, bits [3:0]

Customer Modified.

Indicates the component has been modified.

A value of 0b0000 means the component is not modified from the original design.

Any other value means the component has been modified in an IMPLEMENTATION DEFINED way.

For any two components with the same Unique Component Identifier:

- If the value of the CMOD fields of both components equals zero, the components are identical.
- If the CMOD fields of both components have the same non-zero value, it does not necessarily mean that they have the same modifications.
- If the value of the CMOD field of either of the two components is non-zero, they might not be identical, even though they have the same Unique Component Identifier.

This field reads as an IMPLEMENTATION DEFINED value.

Accessing the ERRPIDR3:

ERRPIDR3 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAS</td>
<td>0xFEC</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Accesses to this register are RO.
I5.8.37 ERRPIDR4, Peripheral Identification Register 4

The ERRPIDR4 characteristics are:

**Purpose**

Provides discovery information about the component.

For more information, see *About the Peripheral identification scheme on page K2-7999*.

**Configurations**

Implementation of this register is OPTIONAL.

ERRPIDR4 is implemented only as part of a memory-mapped group of error records.

**Attributes**

ERRPIDR4 is a 32-bit register.

**Field descriptions**

The ERRPIDR4 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SIZE</td>
<td>DES_2</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**SIZE, bits [7:4]**

Size of the component.

The distance from the start of the address space used by this component to the end of the component identification registers.

A value of 0b0000 means one of the following is true:

- The component uses a single 4KB block.
- The component uses an IMPLEMENTATION DEFINED number of 4KB blocks.

Any other value means the component occupies \(2^{ERRPIDR4\cdot SIZE}\) 4KB blocks.

Using this field to indicate the size of the component is deprecated. This field might not correctly indicate the size of the component. Arm recommends that software determine the size of the component from the Unique Component Identifier fields, and other IMPLEMENTATION DEFINED registers in the component.

This field reads as an IMPLEMENTATION DEFINED value.

**DES_2, bits [3:0]**

Designer, JEP106 continuation code. This is the JEDEC-assigned JEP106 bank identifier for the designer of the component, minus 1. The code identifies the designer of the component, which might not be the same as the implementer of the device containing the component. To obtain a number, or to see the assignment of these codes, contact JEDEC http://www.jedec.org.

This field reads as an IMPLEMENTATION DEFINED value.

---

**Note**

For a component designed by Arm Limited, the JEP106 bank is 5, meaning this field has the value 0x4.
Accessing the ERRPIDR4:

ERRPIDR4 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAS</td>
<td>0xFD0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Accesses to this register are RO.
Part J

Architectural Pseudocode
Chapter J1
Armv8 Pseudocode

This chapter contains pseudocode that describes many features of the Armv8 architecture. It contains the following sections:

- *Pseudocode for AArch64 operation* on page J1-7612.
- *Pseudocode for AArch32 operation* on page J1-7733.
- *Shared pseudocode* on page J1-7812.
Pseudocode for AArch64 operation

This section holds the pseudocode for execution in AArch64 state. Functions that are listed in this section are identified as AArch64.FunctionName. Some of these functions have an equivalent AArch32 function, AArch32.FunctionName. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example aarch64/debug/breakpoint.

The top-level sections of the AArch64 pseudocode hierarchy are:

- aarch64/debug
- aarch64/exceptions
- aarch64/functions
- aarch64/instrs
- aarch64/translation

J1.1.1 aarch64/debug

This section includes the following pseudocode functions:

- aarch64/debug/breakpoint/AArch64.BreakpointMatch
- aarch64/debug/breakpoint/AArch64.BreakpointValueMatch on page J1-7613.
- aarch64/debug/breakpoint/AArch64.StateMatch on page J1-7614.
- aarch64/debug/enables/AArch64.GenerateDebugExceptions on page J1-7615.
- aarch64/debug/enables/AArch64.GenerateDebugExceptionsFrom on page J1-7615.
- aarch64/debug/pmuv/AArch64.CheckForPMUOverflow on page J1-7616.
- aarch64/debug/pmuv/AArch64.CountEvents on page J1-7616.
- aarch64/debug/statisticalprofiling/CheckProfilingBufferAccess on page J1-7617.
- aarch64/debug/statisticalprofiling/CheckStatisticalProfilingAccess on page J1-7617.
- aarch64/debug/statisticalprofiling/CollectContextIDR1 on page J1-7618.
- aarch64/debug/statisticalprofiling/CollectContextIDR2 on page J1-7618.
- aarch64/debug/statisticalprofiling/CollectPhysicalAddress on page J1-7618.
- aarch64/debug/statisticalprofiling/CollectRecord on page J1-7618.
- aarch64/debug/statisticalprofiling/CollectTimeStamp on page J1-7619.
- aarch64/debug/statisticalprofiling/OpType on page J1-7619.
- aarch64/debug/statisticalprofiling/ProfilingBufferEnabled on page J1-7620.
- aarch64/debug/statisticalprofiling/ProfilingBufferOwner on page J1-7620.
- aarch64/debug/statisticalprofiling/ProfilingSynchronizationBarrier on page J1-7620.
- aarch64/debug/statisticalprofiling/SysRegAccess on page J1-7620.
- aarch64/debug/statisticalprofiling/TimeStamp on page J1-7620.
- aarch64/debug/takeexceptiondbg/AAArch64.TakeExceptionInDebugState on page J1-7621.
- aarch64/debug/watchpoint/AAArch64.WatchpointByteMatch on page J1-7621.
- aarch64/debug/watchpoint/AAArch64.WatchpointMatch on page J1-7622.

J1.2 Pseudocode for AArch32 operation

This section holds the pseudocode for execution in AArch32 state. Functions that are listed in this section are identified as AArch32.FunctionName. Some of these functions have an equivalent AArch64 function, AArch64.FunctionName. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example aarch32/debug/breakpoint.

Note

Many AArch32 pseudocode functions have not been updated to show the constraints on the Armv7 UNPREDICTABLE behaviors that are described in Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors. Where AArch32 pseudocode shows something to be UNPREDICTABLE, check Appendix K1 for possible constraints on the permitted behavior.

The top-level sections of the AArch32 pseudocode hierarchy are:

- aarch32/debug
- aarch32/exceptions on page J1-7741.
- aarch32/functions on page J1-7761.
- aarch32/translation on page J1-7789.

J1.2.1 aarch32/debug

This section includes the following pseudocode functions:

- aarch32/debug/VCRMatch/AArch32.VCRMatch.
- aarch32/debug/pmu/AArch32.CheckForPMUOverflow on page J1-7738.
- aarch32/debug/takeexceptiondbg/AArch32.EnterHypModeInDebugState on page J1-7739.
- aarch32/debug/takeexceptiondbg/AArch32.EnterModeInDebugState on page J1-7739.

J1.3 Shared pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a FunctionName, without an AArch64. or AArch32. prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example shared/debug/DebugTarget.

The top-level sections of the shared pseudocode hierarchy are:

- shared/debug
- shared/exceptions on page J1-7832.
- shared/functions on page J1-7834.
- shared/trace on page J1-7928.
- shared/translation on page J1-7930.

Architectural Constraints on UNPREDICTABLE Behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the Armv8 architecture. It contains the following sections:

• AArch32 CONSTRAINED UNPREDICTABLE behaviors on page K1-7940.
• AArch64 CONSTRAINED UNPREDICTABLE behaviors on page K1-7965.
K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

Armv8 defines architecturally-required constraints on many behaviors that are UNPREDICTABLE in Armv7. The following sections define those constraints:

- Overview of the constraints on Armv7 UNPREDICTABLE behaviors on page K1-7941.
- Using R13 on page K1-7941.
- Using R15 on page K1-7941.
- Branching into an IT block on page K1-7942.
- Branching to an unaligned PC on page K1-7942.
- Loads and Stores to unaligned locations on page K1-7942.
- CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT on page K1-7942.
- Unallocated System register access instructions on page K1-7944.
- SBZ or SBO fields T32 and A32 in instructions on page K1-7944.
- UNPREDICTABLE cases in immediate constants in T32 data-processing instructions on page K1-7944.
- UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions on page K1-7945.
- CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7945.
- CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization on page K1-7946
- Translation Table Base Address alignment on page K1-7946.
- Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-7946.
- Mapping of non-idempotent memory locations using the Normal memory type on page K1-7947.
- The Performance Monitors Extension on page K1-7947.
- The Activity Monitors Extension on page K1-7949.
- Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED on page K1-7950.
- Out of range VA on page K1-7950.
- Instruction fetches from Device memory on page K1-7950.
- Multi-access instructions that load the PC from Device memory on page K1-7950.
- Programming CSSEL.R.Level for a cache level that is not implemented on page K1-7950.
- Crossing a page boundary with different memory types or Shareability attributes on page K1-7951.
- Crossing a 4KB boundary with a Device access on page K1-7951.
- UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-7952.
- CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings on page K1-7952.
- Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-7953.
- CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set on page K1-7953.
K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

- CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions on page K1-7956.
- CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR on page K1-7960.
- CONSTRAINED UNPREDICTABLE behavior of EL2 features on page K1-7960.
- Reserved values in System and memory-mapped registers and translation table entries on page K1-7963.
- CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-7964.

K1.1.1 Overview of the constraints on Armv7 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch32 state, where previous versions of the architecture define behavior as UNPREDICTABLE, the Armv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

--- Note ---
Software designed to be compatible with the Armv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases.

K1.1.2 Using R13

In prior versions of the architecture, the use of R13 as a named register specifier was described as UNPREDICTABLE in the pseudocode. In the Armv8-A architecture, the use of R13 as a named register specifier is not UNPREDICTABLE, unless this is specifically stated, and R13 can be used in the regular form. Bits[1:0] of R13 are not treated as RES0, but can hold any values programmed into them.

K1.1.3 Using R15

All uses of R15 as a named register specifier for a source register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this Manual must do one of the following:
- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Read or return an UNKNOWN value for the source register specified as R15.

All uses of R15 as a named register specifier for a destination register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual must do one of the following:
- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Ignore the write.
- Branch to an UNKNOWN location in either A32 or T32 state.

The choice between these behaviors might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a writeback of the base register, are treated as having R15 as both a source register and a destination register.

For instructions that have two destination registers, for example LDRD, MRRC, and many of the multiply instructions, if Rt, Rt2, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN, if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of PSTATE.{N, Z, C, V}, PSTATE.Q, and PSTATE.GE when the register specifier is not R15, any flags affected by an instruction that is CONSTRAINED UNPREDICTABLE when the register specifier is R15 become UNKNOWN,
In addition, for MRC instructions that use R15 as the destination register descriptor, and therefore target APSR_{nzcv} where these are described as being CONSTRAINED UNPREDICTABLE, PSTATE.{N, Z, C, V} becomes UNKNOWN.

K1.1.4 Branching into an IT block

Branching into an IT block leads to CONSTRAINED UNPREDICTABLE behavior. Execution starts from the address determined by the branch, but each instruction in the IT block is:

- Executed as if it were not in an IT block. This means that it is executed unconditionally.
- Executed as if it had passed its Condition code check within an IT block.
- Executed as a NOP. That is, it behaves as if it had failed the Condition code check.

K1.1.5 Branching to an unaligned PC

In A32 state, when branching to an address that is not word aligned and is defined to be CONSTRAINED UNPREDICTABLE, one of the following behaviors must occur:

- The unaligned location is forced to be aligned.
- The unaligned address generates an exception on the first instruction using the unaligned PC value.
  
  If that instruction is executed at EL0 and either of the following applies, the exception is taken to EL2:
  - EL2 is using AArch32 and the value of HCR.TGE is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

  If the instruction is executed at EL0 when the applicable TGE bit is 0 the exception is taken to EL1.

  If the instruction is executed at an Exception level that is higher than EL0 the exception is taken to the Exception level at which the instruction was executed.

  In all cases, the exception is generated only if the first instruction using the unaligned PC value is architecturally executed.

  If the exception that results from a branch to an unaligned PC value:

  - Is taken to an Exception level that is using AArch64, it is reported as a PC alignment fault exception, see ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D13-2979.
  - Is taken to an Exception level that is using AArch32, it is reported as a Prefetch Abort exception, see Prefetch Abort exception reporting a PC alignment fault exception on page G1-5786.

  Note

  Because bit\[0\] is used for interworking, it is impossible to specify a branch to A32 state when the bottom bit of the target address is 1. Therefore the bottom bit of IFAR, HIFAR, or FAR_ELx is 0 for all these cases.

K1.1.6 Loads and Stores to unaligned locations

Some unaligned loads and stores in the Armv7 architecture are described as UNPREDICTABLE. These are defined in the Armv8-A architecture to do one of the following:

- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

K1.1.7 CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception results.
• The instructions are executed as if they had passed the Condition code check.
• The instructions execute as NOPs. This means that they behave as if they had failed the Condition code check.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the PSTATE.IT state machine must be treated in one of the following ways:

• PSTATE.IT is cleared to 0.
• PSTATE.IT advances for either a sequential or a nonsequential change of the PC in the same way as it does for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

——— Note ————
This does not apply to an instruction that is the last instruction in an IT block.

The instructions addressed by the updated PC must do one of the following:

• Execute as if they had passed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
• Execute as NOPs. That is, they behave as if they had failed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
• Execute as if they were unconditional, or, if the instructions are part of another IT block, in accordance with the behavior described in Branching into an IT block on page K1-7942.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

For exception returns or Debug state exits that cause PSTATE.IT to be set to a reserved value in T32 state or that return to A32 state with a nonzero value in PSTATE.IT, the PSTATE.IT bits are forced to ‘00000000’. The reserved values are:

\[
\begin{align*}
PSTATE.IT[7:4] & = '0000' \land PSTATE.IT[3:0] = '0000' \\
PSTATE.IT[2:0] & = '000' \quad \text{when SCTLR/SCTLR_EL1.ITD} = '1'
\end{align*}
\]

Exception returns or Debug state exits that set PSTATE.IT to a non-reserved value in T32 state can occur when the flow of execution returns to a point:

• Outside an IT block, but with the PSTATE.IT bits set to a value other than ‘00000000’.
• Inside an IT block, but with a different value of the PSTATE.IT bits than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit must do one of the following:

• Execute as if they passed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
• Execute as NOPs. That is, they behave as if they failed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
• Execute as if they were unconditional, or as if the instruction were part of another IT block, in accordance with the behavior in Branching into an IT block on page K1-7942.

The remaining iterations of the PSTATE.IT state machine must behave in one of the following ways:

• The PSTATE.IT state machine advances as if it were in an IT block.
• The PSTATE.IT bits are ignored.
• The PSTATE.IT bits are forced to ‘00000000’.
K1.1.8  **Unallocated System register access instructions**

In Armv8-A, accesses to unallocated System register encodings are UNDEFINED. This includes:

- Reads using encodings that are defined as WO.
- Writes using encodings that are defined as RO.
- MCR or MRC accesses to using a set of \{coproc, CRn, opc1, CRm, opc2\} values that the Armv7 architecture defined as UNPREDICTABLE.
- Accesses to System registers in the \(\text{coproc} = 0b111x\) encoding space that the Armv7 architecture defined as UNPREDICTABLE when particular functionality was not implemented, when an Armv8 implementation does not include the Exception level that provides that functionality.

K1.1.9  **SBZ or SBO fields T32 and A32 in instructions**

Many of the A32 and T32 instructions have (0) or (1) in the instruction decode to indicate should-be-zero, SBZ, or should-be-one, SBO. If the instruction bit pattern of an instruction is executed with these fields not having the should be values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the should-be value.
- Any destination registers of the instruction become UNKNOWN.

The exceptions to this rule are:

- `LDM, LDMIA, LDMFD` on page F5-4436.
- `LDMDB, LDMEA` on page F5-4446.
- `LDR (literal)` on page F5-4455.
- `LDRB (literal)` on page F5-4465.
- `LDRD (immediate)` on page F5-4473.
- `LDRD (register)` on page F5-4479.
- `LDRD (literal)` on page F5-4505.
- `LDRSH (literal)` on page F5-4516.
- `POP` on page F5-4623.
- `PUSH` on page F5-4630.
- `SDIV` on page F5-4710.
- `STM, STMIA, STMEA` on page F5-4803.
- `STMDB, STMFD` on page F5-4811.
- `UDIV` on page F5-4925.

K1.1.10  **UNPREDICTABLE cases in immediate constants in T32 data-processing instructions**

The description of immediate constants in T32 data processing modifies immediate constants in T32 instructions on page F2-4135 include constant values that were UNPREDICTABLE in Armv7. Instruction encodings on page F2-4116 describes 32-bit T32 instructions as \{hw1, hw2\}, where hw1 is the left-hand halfword in the 32-bit encoding diagram for the instruction. The UNPREDICTABLE cases are those where both:

- \(\text{hw2}[7:0] == 0b00000000\).
- \(\text{hw1}[10] == 0\) and either:
  - \(\text{hw2}[14:12] == 0b001\).
  - \(\text{hw2}[14:12] == 0b010\).
  - \(\text{hw2}[14:12] == 0b011\).
In Armv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce the value 0b0000000.

K1.1.11 UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions

The description of immediate constants in Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-4137 include constant values that were UNPREDICTABLE in Armv7. The UNPREDICTABLE cases are those where:

- The bits that the encoding diagram shows as abcd are all 0.
  In the A32 encoding these are bits[24, 18:6, 3:0]. In the T32 encoding they are bits \{hw1[12, 2:0], hw2[3:0]\}.
- The bits that the encoding diagram shows as cmode[3:1] are one of \{0b001, 0b010, 0b011, 0b101, 0b110\}.
  In the A32 encoding these are bits[11:9]. In the T32 encoding they are bits hw2[11:9].

In Armv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce an immediate constant value of zero.

K1.1.12 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The Arm architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to CONSTRAINED UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes FEAT_TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.
- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

**Note**

If the Effective value of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that Effective value must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits within a TLB might generate an exception, reporting the exception using the TLB Conflict fault code, see TLB conflict aborts on page G5-6033.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.
K1.1.13  **CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization**

The Arm architecture requires that changes to System registers must be synchronized before they take effect. This can lead to CONSTRAINED UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

K1.1.14  **Translation Table Base Address alignment**

A misaligned Translation Table Base Address can occur if:

- The VMSAv8-32 Short-descriptor translation table format is enabled and TTBR0[13-N:7], which is defined to be RES0, contains one or more nonzero values.
- The VMSAv8-32 Long-descriptor translation table format is enabled, and TTBR0[x-1:3], TTBR1[x-1:3], HTTBR[x-1:3], or VTTBR[x-1:3], which are defined to be RES0, contain one or more nonzero values.

In the event of a misaligned Translation Table Base Address, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all bits were zero:
  - The value that is read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using that register might be corrupted in those bits that are nonzero.

K1.1.15  **Handling of System register control fields for Advanced SIMD and floating-point operation**

For historical reasons described in *Background to the System register interface on page G1-5810*, each of the CPACR, HCPTR, and NSACR has a pair of control fields that were defined to have identical functionality for controlling Advanced SIMD and floating-point operation. These fields are:

- CPACR.{cp10, cp11}.
- HCPTR.{TCP10, TCP11}.
- NSACR.{cp10, cp11}.

The architecture requires that both fields in one of these pairs are programmed to the same value. If this is not done, then the CONSTRAINED UNPREDICTABLE behavior is that behavior is the same as if the cp11, or TCP11, control field was equal to the cp10, or TCP10, field in all respects other than the value read back by a direct read of the register. After a register write that writes different values to the two fields of a pair, a direct read of the register might return an UNKNOWN value for the cp11 or TCP11 field.

--- Note ---
This means that, when different values are written to the {cp10, cp11} fields in a single register, the architecture permits but does not require that a read of that register returns the value written to the cp11 field.

---

**CONSTRAINED UNPREDICTABLE CPACR and NSACR settings**

If CPACR.cp<n> contains the encoding ‘10’, then one of the following behaviors must occur:

- The encoding maps onto any of the allocated values, but otherwise does not cause UNPREDICTABLE behavior.
• The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.

Note

In Armv7, CPACR had a D32DIS bit, and NSACR had an NSD32DIS bit. There is no CPACR.D32DIS or NSACR.NSD32DIS in Armv8-A, and the corresponding bits in the two registers are RES0.

K1.1.16 Mapping of non-idempotent memory locations using the Normal memory type

If non-idempotent memory locations are mapped using the Normal memory type, the state of the non-idempotent memory location may become corrupted in the following circumstances:

• Speculative read accesses may cause accesses to the non-idempotent memory locations that would not occur as part of a simple sequential execution.
• Writes to non-idempotent memory locations might be merged or split. In this case, the number and size of writes seen by the memory location might not be the number and size that occur as part of a simple sequential execution.

K1.1.17 The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch32 state:

• CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR.
• CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n> on page K1-7948.
• CONSTRAINED UNPREDICTABLE behavior caused by HDCR.HPMN on page K1-7949.

CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR

If FEAT.FGT is implemented, and EL2 is implemented in the current Security state, and EL1 is using AArch64, permitted access to PMXEVCNTR and PMXEVTYPER are not CONSTRAINED UNPREDICTABLE.

Otherwise, if PMSELR.SEL is greater than the number of counters accessible at this Exception level, accesses to PMXEVTYPER or PMXEVCNTR can cause CONSTRAINED UNPREDICTABLE behavior. This occurs when one of the following is true:

• If PMSELR.SEL is not equal to 31, and PMSELR.SEL is greater than or equal to PMCR.N, and the PE is executing in EL2 or EL3.
• If FEAT_SEL2 is disabled or is not implemented, PMSELR.SEL is not 31, and PMSELR.SEL is greater than or equal to PMCR.N, and the PE is executing in Secure EL1 or Secure EL0.
• If PMSELR.SEL is not 31, and PMSELR.SEL is greater than or equal to HDCR.HPMN, and the PE is executing in EL1 or EL0.

In these UNPREDICTABLE cases, one of the following behaviors must occur:

• Accesses to PMXEVTYPER or PMXEVCNTR from that mode are UNDEFINED.
• Accesses to PMXEVTYPER or PMXEVCNTR from that mode behave as RAZ/WI.
• Accesses to PMXEVTYPER or PMXEVCNTR from that mode execute as NOPs.
• Accesses to PMXEVTYPER or PMXEVCNTR from that mode behave as if PMSELR.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
• Accesses to PMXEVTYPER or PMXEVCNTR behave as if PMSELR.SEL is 31.
• If EL2 is implemented and enabled in the current Security state, and PMSELR.SEL is less than the number of implemented counters but greater than the number of accessible counters at this Exception level, access to PMXEVTPYER or PMXEVCNTR from EL1 or permitted access from EL0 is trapped to EL2.

If PMSELR.SEL is equal to 31, then one of the following behaviors must occur:

• Accesses to PMXEVCNTR are UNDEFINED.
• Accesses to PMXEVCNTR behave as RAZ/WI.
• Accesses to PMXEVCNTR execute as NOPs.
• Accesses to PMXEVCNTR behave as if PMSELR.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
• If EL2 is implemented and enabled in the current Security state, for an access to PMXEVCNTR from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2.

Note
If EL2 is implemented and enabled in the current Security state, HDCR.HPMN, or MDCR_EL2.HPMN, identifies the number of accessible counters at EL0 or EL1. Otherwise, the number of accessible counters is the number of implemented counters.

Accesses from EL0 to PMXEVCNTR are permitted when:
• EL1 is using AArch32 and the values of PMUSERENR.{ER, EN} are both 1.
• EL1 is using AArch64 and the values of PMUSERENR_EL0.{ER, EN} are both 1.

Accesses from EL0 to PMXEVTPYPER are permitted when:
• EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
• EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

CONSTRANDED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n>

If FEAT_FGT is implemented, and EL2 is implemented in the current Security state, and EL1 is using AArch64, permitted access to PMEVCNTR<n> and PMEVTYPER<n> are not CONSTRANDED UNPREDICTABLE.

Otherwise, if <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVCNTR<n> and PMEVTYPER<n> are CONSTRANDED UNPREDICTABLE, and the following behaviors are permitted:

• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.
• If EL2 is implemented and enabled in the current Security state, for an access to PMEVCNTR<n> or PMEVTYPER<n> from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2.

Accesses from EL0 are permitted to PMEVCNTR<n> when:
— EL1 is using AArch32 and the values of PMUSERENR.{ER, EN} are both 1.
— EL1 is using AArch64 and the values of PMUSERENR_EL0.{ER, EN} are both 1.

Accesses from EL0 are permitted to PMEVTYPER<n> when:
— EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
— EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note
If EL2 is implemented and enabled in the current Security state, at EL0 and EL1, HDCR.HPMN, or MDCR_EL2.HPMN, identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.
CONSTRANDED UNPREDICATABLE behavior caused by HDCR.HPMN

If HDCR.HPMN is set to 0 or to a value greater than PMCR.N, then the CONSTRANDED UNPREDICATABLE behavior is:

- The value returned by a direct read of HDCR.HPMN is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if HDCR.HPMN is set to an UNKNOWN non-zero value less than PMCR.N.
  - All counters are reserved for EL2 and EL3 use, meaning no counters are accessible from EL1 and EL0.

K1.1.18 The Activity Monitors Extension

The following subsections describe CONSTRANDED UNPREDICATABLE behaviors when accessing the Activity Monitors registers in AArch32 state:

- **CONSTRANDED UNPREDICATABLE accesses to AMEVCNTR0<n> and AMEVTYPER0<n>**

  - If <n> is greater than the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n> and AMEVTYPER0<n> are CONSTRANDED UNPREDICATABLE, and the following behaviors are permitted:
    - Accesses to the register are UNDEFINED.
    - Accesses to the register behave as RAZ/WI.
    - Accesses to the register execute as a NOP.

  **Note**

  AMCGCR.CG0NC identifies the number of architected activity monitor event counters.

- **CONSTRANDED UNPREDICATABLE accesses to AMEVCNTR1<n> and AMEVTYPER1<n>**

  - If <n> is greater than the number of auxiliary activity monitor event counters, reads and writes of AMEVCNTR1<n> and AMEVTYPER1<n> are CONSTRANDED UNPREDICATABLE, and the following behaviors are permitted:
    - Accesses to the register are UNDEFINED.
    - Accesses to the register behave as RAZ/WI.
    - Accesses to the register execute as a NOP.

  **Note**

  AMCGCR.CG1NC identifies the number of auxiliary activity monitor event counters.

- **CONSTRANDED UNPREDICATABLE accesses to AMCNTENCLR1 and AMCNTENSET1**

  - If the number of auxiliary activity monitor event counters that are implemented is zero, reads and writes of AMCNTENCLR1 and AMCNTENSET1 are CONSTRANDED UNPREDICATABLE, and the following behaviors are permitted:
    - Accesses to the register are UNDEFINED.
    - Accesses to the register behave as RAZ/WI.
    - Accesses to the register execute as a NOP.
The number of auxiliary activity monitor event counters that are implemented is zero exactly when \texttt{AMCFGR.NCG} == 0b0000.

**K1.1.19 Syndrome register handling for CONSTRANDED UNPREDICTABLE instructions treated as UNDEFINED**

When a CONSTRANDED UNPREDICTABLE instruction is treated as UNDEFINED, this generates an exception:
- If this exception is taken to an Exception level that is using AArch64 then \texttt{ESR ELx} is UNKNOWN.
- If this exception is taken to EL2 and EL2 is using AArch32, then the HSR is unknown.

**Note**
The value written to ESR or HSR must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but resulted from a situation that is not CONSTRANDED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

**K1.1.20 Out of range VA**

If the PE executes an instruction for which the instruction address, size, and alignment mean it contains the bytes \texttt{0xFFFF FFFF} and \texttt{0x0000 0000}, then the bytes that wrap around and appear to be from \texttt{0x0000 0000} onwards come from an UNKNOWN address.

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses bytes \texttt{0xFFFF FFFF} and \texttt{0x0000 0000}, then the bytes that wrap around and appear to be from \texttt{0x0000 0000} onwards come from an UNKNOWN address.

**K1.1.21 Instruction fetches from Device memory**

Instruction fetches from Device memory are CONSTRANDED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location when address translation is enabled.

If a branch causes the program counter to point to a location in memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:
- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

**K1.1.22 Multi-access instructions that load the PC from Device memory**

Multi-access instructions that load the PC from Device memory when address translation is enabled are UNPREDICTABLE in AArch32 state. In the Armv8-A architecture in AArch32 state an implementation must perform one of the following behaviors:
- It loads the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It generates a permission fault.

**K1.1.23 Programming CSSEL.R.Level for a cache level that is not implemented**

If \texttt{CSSEL.R.Level} is programmed to a cache level that is not implemented, then a read of \texttt{CSSEL.R} returns an UNKNOWN value in \texttt{CSSEL.R.Level}.
If CSSEL.R.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR an implementation must perform one of the following behaviors:

- The CCSIDR read is treated as a \texttt{NOP}.
- The CCSIDR read is \texttt{UNDEFINED}.
- The CCSIDR read returns an \texttt{UNKNOWN} value.

When \texttt{FEAT\_CIDX} is implemented, CCSIDR2 is implemented. If CSSEL.R.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR2 an implementation must perform one of the following behaviors:

- The CCSIDR2 read is treated as a \texttt{NOP}.
- The CCSIDR2 read is \texttt{UNDEFINED}.
- The CCSIDR2 read returns an \texttt{UNKNOWN} value.

### K1.1.24 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in \texttt{CONSTRAINED UNPREDICTABLE} behavior. In this case, the implementation must perform one of the following behaviors:

- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an alignment fault caused by the memory type.

For the Non-secure PL1&0 translation regime:

- If the stage 1 translation causes the mismatch, the resulting exception is taken to PL1.
- If the stage 2 translation causes the mismatch, the resulting exception is taken to PL2.
- If both stages of translation cause the mismatch, the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a \texttt{NOP}.

### K1.1.25 Crossing a 4KB boundary with a Device access

A memory access from a load or store instruction to Device memory that crosses a 4KB boundary results in \texttt{CONSTRAINED UNPREDICTABLE} behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses, except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault caused by the memory type.

For the Non-secure PL1&0 translation regime:

- If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to PL1.
- If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to PL2.
- If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a \texttt{NOP}.

---

**Note**

The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.
K1.1.26 UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-4069 defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. These cases were UNPREDICTABLE in Armv7. In summary, these cases are:

• The target virtual address of a StoreExcl instruction is different from the virtual address of the preceding LoadExcl instruction in the same thread of execution.

• The transaction size of a StoreExcl instruction is different from the transaction size of the preceding LoadExcl instruction in the same thread of execution.

• The memory attributes for a StoreExcl instruction are different from the memory attributes for the preceding LoadExcl instruction in the same thread of execution, either:
  — Because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction.
  — Because the LoadExcl instruction and the StoreExcl instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-4069 for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

Note

Additional CONSTRAINED UNPREDICTABLE cases can apply to Load-Exclusive and Store-Exclusive instructions, see CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set on page K1-7953.

K1.1.27 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings

The A32 and T32 instruction sets include encodings that result in CONSTRAINED UNPREDICTABLE behavior when they are decoded.

CONSTRAINED UNPREDICTABLE behavior of CRC32 instruction encodings

In the A32 and T32 instruction sets, there are encodings of the CRC32 and CRC32C instructions that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in the following places in the A32 and T32 instruction sets:

• Cyclic Redundancy Check on page F4-4226 for the A32 instruction set, with sz = 11.

• Data-processing (two source registers) on page F3-4212 for the T32 instruction set, with op1 = 10x and op2 = 11.

The CONSTRAINED UNPREDICTABLE behavior for these encodings is described in CRC32 on page F5-4377 and CRC32C on page F5-4380.

CONSTRAINED UNPREDICTABLE behavior of other A32 instruction encodings

In the A32 instruction set, there are encodings that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in:

• Miscellaneous on page F4-4261.

• Memory hints and barriers on page F4-4272.

• Barriers on page F4-4273.
The CONSTRAINED UNPREDICTABLE behavior is that an implementation must treat the encodings in one of the following ways:

- The instruction encoding is UNDEFINED.
- The instruction encoding executes as NOP.

**K1.1.28 Out of range values of the Set/Way/Index fields in cache maintenance instructions**

In the cache maintenance by set/way instructions DCCISW, DCCSW, and DCISW, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

**Note**

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the A64 cache maintenance by set/way instructions DCISW, DCISW, and DCISW.

**K1.1.29 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set**

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 System instructions.

**Note**

If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

**SRS (T32)**

For a description of this instruction and the encoding, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-4767.

**CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

**SRS (A32)**

For a description of this instruction and the encoding, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-4767.
**CON Strained UNPREDICTAB Le behav ior**

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOW N address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOW N.

**SUBS PC, LR and related instructions (T32)**

For a description of this instruction and the encoding, see the exception return form of SUB, SUBS (immediate) on page F5-4869.

**CON Strained UNPREDICTABLE behav ior**

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.

--- Note ---

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

---

For encoding T5:

- If hwI[3:0] are not 0b1110, and the instruction is executed when not in Hyp mode, System mode, or User mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if hwI[3:0] are 0b1110.
  - The program counter is set using the value in the register specified by hwI[3:0].

**SUBS PC. LR and related instructions (A32)**

For a description of this instruction and the encoding, see the exception return forms of MOV, MOVS (register) on page F5-4555 and SUB, SUBS (immediate) on page F5-4869.

**CON Strained UNPREDICTABLE behav ior**

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.
Note

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.
K1.1.30 CONSTRANDED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions

This section lists the CONSTRANDED UNPREDICTABLE behavior for the different A32 and T32 Advanced SIMD and floating-point instructions listed in Alphabetical list of Advanced SIMD and floating-point instructions on page F6-4994.

--- Note ---

- The pseudocode used in this section to describe cases that can result in CONSTRANDED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
- If an instruction can result in CONSTRANDED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRANDED UNPREDICTABLE behavior.

VCVT (between floating-point and fixed-point)

For a description of this instruction and the encoding, see VCVT (between floating-point and fixed-point, floating-point) on page F6-5153.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRANDED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRANDED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRANDED UNPREDICTABLE.

VLD1 (multiple single elements)

For a description of this instruction and the encoding, see VLD1 (multiple single elements) on page F6-5251.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRANDED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRANDED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRANDED UNPREDICTABLE.

VLD1 (single element to all lanes)

For a description of this instruction and the encoding, see VLD1 (single element to all lanes) on page F6-5248.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRANDED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRANDED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRANDED UNPREDICTABLE.

VLD2 (multiple 2-element structures)

For a description of this instruction and the encoding, see VLD2 (multiple 2-element structures) on page F6-5268.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRANDED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRANDED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRANDED UNPREDICTABLE.

VLD2 (single 2-element structure to one lane)

For a description of this instruction and the encoding, see VLD2 (single 2-element structure to one lane) on page F6-5259.
If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD2 (single 2-element structure to all lanes)**

For a description of this instruction and the encoding, see *VLD2 (single 2-element structure to all lanes)* on page F6-5265.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD3 (multiple 3-element structures)**

For a description of this instruction and the encoding, see *VLD3 (multiple 3-element structures)* on page F6-5282.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD3 (single 3-element structure to one lane)**

For a description of this instruction and the encoding, see *VLD3 (single 3-element structure to one lane)* on page F6-5273.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD3 (single 3-element structure to all lanes)**

For a description of this instruction and the encoding, see *VLD3 (single 3-element structure to all lanes)* on page F6-5279.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD4 (multiple 4-element structures)**

For a description of this instruction and the encoding, see *VLD4 (multiple 4-element structures)* on page F6-5294.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD4 (single 4-element structure to one lane)**

For a description of this instruction and the encoding, see *VLD4 (single 4-element structure to one lane)* on page F6-5285.
If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD4 (single 4-element structure to all lanes)**

For a description of this instruction and the encoding, see *VLD4 (single 4-element structure to all lanes)* on page F6-5291.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLDM**

For a description of this instruction and the encoding, see *VLDM, VLDMDB, VLDMIA* on page F6-5297.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VMOV (between two general-purpose registers and two single-precision registers)**

For a description of this instruction and the encoding, see *VMOV (between two general-purpose registers and two single-precision registers)* on page F6-5375.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VMOV (between two general-purpose registers and a doubleword floating-point register)**

For a description of this instruction and the encoding, see *VMOV (between two general-purpose registers and a doubleword floating-point register)* on page F6-5354.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST1 (multiple single elements)**

For a description of this instruction and the encoding, see *VST1 (multiple single elements)* on page F6-5619.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST2 (multiple 2-element structures)**

For a description of this instruction and the encoding, see *VST2 (multiple 2-element structures)* on page F6-5633.
If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST2 (single 2-element structure from one lane)**

For a description of this instruction and the encoding, see *VST2 (single 2-element structure from one lane)* on page F6-5627.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST3 (multiple 3-element structures)**

For a description of this instruction and the encoding, see *VST3 (multiple 3-element structures)* on page F6-5644.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST3 (single 3-element structure from one lane)**

For a description of this instruction and the encoding, see *VST3 (single 3-element structure from one lane)* on page F6-5638.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST4 (multiple 4-element structures)**

For a description of this instruction and the encoding, see *VST4 (multiple 4-element structures)* on page F6-5653.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST4 (single 4-element structure from one lane)**

For a description of this instruction and the encoding, see *VST4 (single 4-element structure from one lane)* on page F6-5647.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VSTM**

For a description of this instruction and the encoding, see *VSTM, VSTMDB, VSTMIA* on page F6-5656.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.
K1.1.31 CONSTRUCTED UNPREDICTABLE behaviors associated with the VTCR

The following subsections describe the CONSTRUCTED UNPREDICTABLE behavior associated with programming the VTCR:

- Misprogramming VTCR.S.
- Misprogramming VTCR.{SL0, T0SZ}.

Misprogramming VTCR.S

VTCR.S must be programmed to the value of T0SZ[3], or the effect is CONSTRUCTED UNPREDICTABLE. For the Armv8-A architecture, if VTCR.S is not programmed correctly, then the VTCR.T0SZ value is treated as an UNKNOWN value.

Note

The CONSTRUCTED UNPREDICTABLE behavior described in Misprogramming VTCR.{SL0, T0SZ} means the UNKNOWN VTCR.T0SZ value might generate a Translation fault.

Misprogramming VTCR.{SL0, T0SZ}

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level, as programmed in the VTCR.SL0 field, or the VTCR.SL0 field is programmed to a reserved value, then at the time of a translation walk that uses the stage 2 translation, a stage 2 level 1 Translation Fault is generated.

K1.1.32 CONSTRUCTED UNPREDICTABLE behavior of EL2 features

The following sections describe CONSTRUCTED UNPREDICTABLE behavior that can occur in an implementation that includes EL2 where EL2 can use AArch32:

- ERET in User mode or System mode.
- Accessing Hyp mode from outside Hyp mode.
- Modifying PSTATE.M when in Hyp mode on page K1-7961
- Use of Hyp mode in Secure state on page K1-7961.
- Execution of Load/Store unprivileged instructions in Hyp mode on page K1-7961.
- Exception return to Hyp mode on page K1-7961.
- Accessing registers that cannot be accessed using MSR/MRS instructions on page K1-7961.
- Memory type handling on page K1-7962.
- Hyp mode TLB maintenance instructions on page K1-7962.
- Hyp mode VA to PA address translation instructions on page K1-7962.
- Stage 1 default memory type on page K1-7962.
- Trapping of general exceptions to Hyp mode on page K1-7962.
- Prevention of rootkits using Hyp mode or Secure state on page K1-7963.
- HVC on page K1-7963.
- MSR (banked register) and MRS (banked register) on page K1-7963.

ERET in User mode or System mode

If ERET is executed in User mode or System mode, it behaves as described in SUBS PC, LR and related instructions (T32) on page K1-7954.

Accessing Hyp mode from outside Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the Armv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

S85 using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in SRS (T32) on page K1-7953 and SRS (A32) on page K1-7953.
Modifying PSTATE.M when in Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the Armv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in SRS (T32) on page K1-7953 and SRS (A32) on page K1-7953.

Use of Hyp mode in Secure state

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the Armv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in SRS (T32) on page K1-7953 and SRS (A32) on page K1-7953.

Execution of Load/Store unprivileged instructions in Hyp mode

If LDRT, LDRSHT, LDRHT, LDRSBT, LDRBT, STRT, STRHT or STRBT are executed in Hyp mode, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the equivalent, corresponding LDR, LDRSH, LDRH, LDRSB, LDRB, STR, STRH or STRB instruction in Hyp mode.

Exception return to Hyp mode

Exception returns to Hyp mode when SCR.NS == 0 or from a Non-secure PL1 mode invokes the Armv8 illegal exception return.

Accessing registers that cannot be accessed using MSR/MRS instructions

The following MSR and MRS instructions can lead to CONSTRAINED UNPREDICTABLE behavior:

MSR <Rm>_<mode>, <Rn>
MSR SPSR_<mode>, <Rn>
MSR ELR_hyp, <Rn>
MRS <Rn>, <Rm>_<mode>
MRS <Rn>, SPSR_<mode>
MRS <Rn>, ELR_hyp

If these instructions are executed in either Secure or Non-secure User mode, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.

If the MSR and MRS instructions attempt to access a register that cannot be legally accessed, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• For MSR instructions, the destination general-purpose register becomes UNKNOWN.
• For MRS instructions, if the register specified could be accessed from the current mode by other mechanisms, then this register is UNKNOWN. Otherwise the instruction executes as a NOP.
Memory type handling

If the attributes for a memory location after combining stage 1 and stage 2 of a translation regime is Normal Inner Non-cacheable, Outer Non-cacheable, then the shareability attributes after combining the two stages of translation is Outer Shareable.

Hyp mode TLB maintenance instructions

If a TLBIMVAH, TLBIMVALH, TLBIMVAHIS, TLBIMVALHIS, TLBIALLH, TLBIALLHIS, TLBIALLNSNH, TLBIALLNSNHIS, TLBIIPAS2, TLBIIPAS2L, TLBIIPAS2IS, or TLBIIPAS2LIS instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction is executes as if it had been executed in Monitor mode.

For more information about these instructions see The scope of TLB maintenance instructions on page G5-6044.

Hyp mode VA to PA address translation instructions

If an ATS1HR or ATS1HW instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction is executes as if it had been executed in Monitor mode.

For more information about these instructions see Address translation instruction naming and operation summary on page G5-6083.

Stage 1 default memory type

If HCR.DC == 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with:

• SCTLR.M == 0, regardless of the actual value of SCTLR.M, other than for the value returned by an explicit read of SCTLR.M.
• HCR.VM == 1, regardless of the actual value of HCR.VM, other than for an explicit read of this bit.

Trapping of general exceptions to Hyp mode

Attempting to perform an exception return to a Non-secure PL1 mode when HCR.TGE == 1 invokes an illegal exception return.

Attempting to change from Monitor mode to a Non-secure PL1 mode when HCR.TGE == 1 by executing a CPS or MSR instruction generates an Illegal Execution state exception, by not changing the mode, and setting PSTATE.IL to 1.

When EL3 is using AArch32, attempting to change from a Secure PL1 mode to a Non-secure PL1 mode when HCR.TGE is set, by changing SCR.NS from 0 to 1, results in no change of SCR.NS.

Because taking an exception into Non-secure PL1 modes leads to a CONSTRAINED UNPREDICTABLE situation, the following additional properties apply when HCR.TGE == 1:

• All exceptions that would be routed to EL1 are routed to EL2.
• Non-secure SCTLR.M is treated as being 0, regardless of its actual value, other than for an explicit read of this bit.
• HCR.FMO, HCR.IMO, and HCR.AMO are treated as being 1, regardless of their actual value, other than for an explicit read of these bits.
• All virtual interrupts are disabled.
• Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.

**Prevention of rootkits using Hyp mode or Secure state**

If an HVC instruction is executed in Hyp mode when SCR.HCE == 0, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.

If an SMC instruction is executed in a Secure privileged mode when SCR.SCD == 1, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.

**HVC**

For a description of this instruction and the encoding, see *HVC on page F5-4413*.

For the A1 encoding, if cond field !=1110, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction executes unconditionally.
• The instruction executes conditionally.

**MSR (banked register) and MRS (banked register)**

*Encoding and use of banked register transfer instructions on page F5-4989* identifies cases where attempted execution of an MRS (banked register) or MSR (banked register) was UNPREDICTABLE in Armv7 and becomes CONSTRAINED UNPREDICTABLE in Armv8. This includes cases where:
• The target register specified by the {R, SYSn} fields of the instruction encoding is not accessible from the PE mode in which the instruction was executed, see *Usage restrictions on the banked register transfer instructions on page F5-4990*.
• The instruction was executed specifying unallocated {R, SYSn} field values, see *Encoding the register argument in the banked register transfer instructions on page F5-4991*.

If one of these encodings for an MSR (banked register) or MRS (banked register) instruction is executed, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• An allocated MSR (banked register) or MRS (banked register) instruction is executed.

**K1.1.33 Reserved values in System and memory-mapped registers and translation table entries**

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within the AArch32 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:
• The encoding maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
• The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
• The encoding causes the field to have no functional effect.
Note

These constraints are identical to those for the equivalent AArch64 definitions, as given in Reserved values in System and memory-mapped registers and translation table entries on page K1-7981.

K1.1.34 CONSTRAINTED UNPREDICTABLE behavior in Debug state

Behavior in Debug state on page H2-7024 of this manual describes the CONSTRAINTED UNPREDICTABLE behaviors that are specifically associated with Debug state.
K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors

It contains the following sections:

- Overview of the constraints on AArch64 UNPREDICTABLE behaviors.
- SBZ or SBO fields in A64 instructions.
- CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7966.
- CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization on page K1-7966.
- Translation table base address alignment on page K1-7967.
- The Performance Monitors Extension on page K1-7967.
- The Activity Monitors Extension on page K1-7969.
- Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED on page K1-7969.
- Out of range virtual address on page K1-7970.
- Mapping of non-idempotent memory locations using the Normal memory type on page K1-7970.
- Instruction fetches from Device memory on page K1-7970.
- Programming the CSSELR_EL1.Level for a cache level that is not implemented on page K1-7970.
- Crossing a page boundary with different memory types or Shareability attributes on page K1-7971.
- Crossing a peripheral boundary with a Device access on page K1-7971.
- CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-7972.
- CONSTRAINED UNPREDICTABLE behavior for A64 instructions on page K1-7972.
- Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-7981.
- Reserved values in System and memory-mapped registers and translation table entries on page K1-7981.
- CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-7981.

K1.2.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the Armv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

______ Note _______

Software designed to be compatible with the Armv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

K1.2.2 SBZ or SBO fields in A64 instructions

Some A64 instructions have (0) or (1) in the instruction decode to indicate should-be-zero, SBZ, or should-be-one, SBO, as described in Fixed values in AArch64 instruction and System register descriptions on page C2-195. Except for specific cases identified in CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-7972, if the instruction bit pattern of an instruction is executed with these fields not having the should be values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the should-be value.
- Any destination registers of the instruction become UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.
K1.2.3  CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The Arm architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes FEAT_TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

--- Note ---

If the Effective value of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that Effective value must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits in a TLB might generate an exception, reporting the exception using the TLB conflict fault code, see TLB conflict aborts on page D5-2660.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

K1.2.4  CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The Arm architecture requires that changes to System registers must be synchronized before they take effect. This can lead to UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.
K1.2.5 Translation table base address alignment

In the translation table base registers TTBR0_EL1, TTBR1_EL1, TTBR0_EL2, TTBR1_EL2, VTTBR_EL2, and TTBR0_EL3, register bits[48:x] hold the translation table base address, where x depends on the translation table granule size and the size of the addressed translation table, as described in Memory translation granule size on page D5-2548. Register bits[(x-1):0], unless redefined for another purpose, correspond to bits[(x-1):0] of the translation table base address and therefore are RES0.

Note

- When FEAT_LPA is implemented and the 64KB granule size is used, register bits[5:2] are redefined to hold bits[51:48] of the translation table base address.
- When FEAT_TTCNP is implemented register bit[0] is redefined as the CnP bit.

For these registers, if one or more RES0 bits in register bits [(x-1):0] does not have a value of 0, this can result in a misaligned translation table base address. In this case, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all the bits had a value of 0:
  - The value read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using those registers might be corrupted in those bits that are nonzero.

For more information, see the appropriate TTBR.BADDR field description.

K1.2.6 The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch64 state:

- CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER_EL0 or PMXEVTYPER_EL0.
- CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n>_EL0 and PMEVTYPER<n>_EL0 on page K1-7968.
- CONSTRAINED UNPREDICTABLE behavior caused by MDCR_EL2.HPMN on page K1-7969.

CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER_EL0 or PMXEVTYPER_EL0

If FEAT_FGT is implemented, and EL2 is implemented in the current Security state, and EL1 is using AArch64, permitted access to PMXEVTYPER_EL0 and PMXEVCNTR_EL0 are not CONSTRAINED UNPREDICTABLE.

Otherwise, if PMSELR_EL0.SEL is greater than the number of counters accessible at this Exception level, accesses to PMXEVTYPER_EL0 and PMXEVCNTR_EL0 can cause CONSTRAINED UNPREDICTABLE behavior. This occurs when one of the following is true:

- If PMSELR_EL0.SEL is not equal to 31, and PMSELR_EL0.SEL is greater than or equal to PMCR_EL0.N, and the PE is executing in EL2 or EL3.
- If FEAT_SEL2 is disabled or is not implemented, PMSELR_EL0.SEL is not 31, and PMSELR_EL0.SEL is greater than or equal to PMCR_EL0.N, and the PE is executing in Secure EL1 or Secure EL0.
- If PMSELR_EL0.SEL is not 31, and PMSELR_EL0.SEL is greater than or equal to MDCR_EL2.HPMN, and the PE is executing in EL0 or EL1.

In these cases, one of the following behaviors must occur:

- Accesses to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state are UNDEFINED.
- Accesses to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state behave as RAZ/WI.
• Accesses to PMXEVTPYER_EL0 or PMXEVCNTR_EL0 from that state execute as NOPS.

• Accesses to PMXEVTPYER_EL0 or PMXEVCNTR_EL0 from that state behave as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.

• Accesses to PMXEVTPYER_EL0 or PMXEVCNTR_EL0 from that state behave as if PMSELR_EL0.SEL is 31.

• If EL2 is implemented and enabled in the current Security state, and PMSELR_EL0.SEL is less than the number of implemented counters but greater than or equal to the number of accessible counters at this Exception level, access to PMXEVTPYER_EL0 or PMXEVCNTR_EL0 from EL1 or a permitted access from EL0 is trapped to EL2.

**Note**

If EL2 is implemented and enabled in the current Security state, MDCCR_EL2.HPMN identifies the number of accessible counters at EL0 or EL1. Otherwise, the number of accessible counters is the number of implemented counters.

Accesses from EL0 to PMXEVCNTR_EL0 are permitted when:
- EL1 is using AArch32 and the values of PMUSERENR.ER, EN are both 1.
- EL1 is using AArch64 and the values of PMUSERENR_EL0.ER, EN are both 1.

Accesses from EL0 to PMXEVTPYER_EL0 are permitted when:
- EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
- EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

If PMSELR_EL0.SEL is equal to 31, then one of the following behaviors must occur:

• Accesses to PMXEVCNTR_EL0 are UNDEFINED.

• Accesses to PMXEVCNTR_EL0 behave as RAZ/WI.

• Accesses to PMXEVCNTR_EL0 execute as NOPS.

• Accesses to PMXEVCNTR_EL0 behave as if PMSELR_EL0.SEL contains an unknown value that is less than the number of counters accessible at the current Exception level and Security state.

**CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n>_EL0 and PMEVTYPER<n>_EL0**

If FEAT_FGT is implemented, and EL2 is implemented in the current Security state, and EL1 is using AArch64, permitted access to PMEVCNTR<n>_EL0 and PMEVTYPER<n>_EL0 are not CONSTRAINED UNPREDICTABLE.

Otherwise, if <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVCNTR<n>_EL0 and PMEVTYPER<n>_EL0 are CONSTRAINED UNPREDICTABLE, the following behaviors are permitted:

• Accesses to the register are UNDEFINED.

• Accesses to the register behave as RAZ/WI.

• Accesses to the register execute as a NOP.

• If EL2 is implemented and enabled in the current Security state, for an access to PMEVCNTR<n>_EL0 or PMEVTYPER<n>_EL0 from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2.

Accesses from EL0 to PMEVCNTR<n>_EL0 are permitted when:
- EL1 is using AArch32 and the value of PMUSERENR.ER, EN are both 1.
- EL1 is using AArch64 and the value of PMUSERENR_EL0.ER, EN are both 1.
Accesses from EL0 to PMEVTPER<\text{n}>_EL0 are permitted when:

— EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
— EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

**CONSTRANGED UNPREDICTABLE behavior caused by MDCR_EL2.HPMN**

If MDCR_EL2.HPMN is set to 0, or to a value larger than PMCR_EL0.N, then the following CONSTRANGED UNPREDICTABLE behavior applies:

- The value returned by a direct read of MDCR_EL2.HPMN is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if MDCR_EL2.HPMN is set to an UNKNOWN non-zero value less than PMCR_EL0.N.
  - All counters are reserved for EL2 and EL3 use, meaning no counters are accessible from EL1 and EL0.

**K1.2.7 The Activity Monitors Extension**

If \(<\text{n}>\) is greater than the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<\text{n}>_EL0 and AMEVTYPER0<\text{n}>_EL0 are CONSTRANGED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

---

**Note**

AMEVCNTR0_EL0.CG0NC identifies the number of architected activity monitor event counters.

---

If \(<\text{n}>\) is greater than the number of auxiliary activity monitor event counters, reads and writes of AMEVCNTR1<\text{n}>_EL0 and AMEVTYPER1<\text{n}>_EL0 are CONSTRANGED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

---

**Note**

AMEVCNTR1_EL0.CG1NC identifies the number of auxiliary activity monitor event counters.

---

If the number of auxiliary activity monitor event counters that are implemented is zero, reads and writes of AMCNTENCLR1_EL0 and AMCNTENSET0_EL0 are CONSTRANGED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

---

**Note**

The number of auxiliary activity monitor event counters that are implemented is zero exactly when AMCFGR_EL0.NCG == 0b0000.

---

**K1.2.8 Syndrome register handling for CONSTRANGED UNPREDICTABLE instructions treated as UNDEFINED**

When a CONSTRANGED UNPREDICTABLE instruction is treated as UNDEFINED, ESR_ELx is UNKNOWN.
Note

The value written to ESR_ELx must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but was the result of a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.2.9 Out of range virtual address

If the PE executes a load or store instruction with tagged addressing disabled in the current translation regime, and where the computed virtual address, total access size, and alignment mean that it accesses the bytes at $0xFFFF FFFF$ and $0x0000 0000 0000 0000$, then the bytes that appear to be from $0x0000 0000 0000 0000$ onwards are accessed at an UNKNOWN address.

If the PE executes a load or store instruction with tagged addressing enabled in the current translation regime, and where the computed address, total access size, and alignment mean that it accesses the bytes at $0xFFFF FFFF$ and $0x0000 0000 0000 0000$, then the bytes that appear to be from $0x0000 0000 0000 0000$ onwards are accessed at an unknown address and the tags associated with address also become unknown.

Note

Because of program counter alignment constraints, it is impossible for a PE to fetch an A64 instruction that includes both the byte at virtual address $0xFFFF FFFF$ and the byte at virtual address $0x0000 0000 0000 0000$.

K1.2.10 Mapping of non-idempotent memory locations using the Normal memory type

If non-idempotent memory locations are mapped using the Normal memory type, the state of the non-idempotent memory location may become corrupted north following circumstances:

- Speculative read accesses may cause accesses to the non-idempotent memory locations that would not occur as part of a simple sequential execution.
- Writes to non-idempotent memory locations might be merged or split. In this case, the number and size of writes seen by the memory location might not be the number and size that occur as part of a simple sequential execution.

K1.2.11 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when address translation is enabled.

If a branch causes the program counter to point to an area of memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

K1.2.12 Programming the CSSEL_EL1.Level for a cache level that is not implemented

If the CSSEL_EL1.Level is programmed to a cache level that is not implemented, then a read of CSSEL_EL1 returns an UNKNOWN value in CSSEL_EL1.Level.

If CSSEL_EL1.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR_EL1 an implementation must perform one of the following behaviors:

- The CCSIDR_EL1 read is treated as a NOP.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.
When **FEAT_CCIDX** is implemented, **CCSIDR2_EL1** is implemented. If **CSSELR_EL1.Level** is programmed to a cache level that is not implemented, then on a read of **CCSIDR2_EL1** an implementation must perform one of the following behaviors:

- The **CCSIDR2_EL1** read is treated as a **NOP**.
- The **CCSIDR2_EL1** read is **UNDEFINED**.
- The **CCSIDR2_EL1** read returns an **UNKNOWN** value.

### K1.2.13 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in **CONSTRAINED UNPREDICTABLE** behavior. In this case, the implementation must perform one of the following behaviors:

- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.

- The instruction generates an Alignment fault caused by the memory type.

  For the EL1&0 translation regime, when EL2 is enabled in the current Security state:
  - If the stage 1 translation generated the mismatch, the resulting exception is taken to EL1.
  - If the stage 2 translation generated the mismatch, the resulting exception is taken to EL2.
  - If both stages of translation generate the mismatch, the exception can be taken to either EL1 or EL2.

- The instruction executes as a **NOP**.

### K1.2.14 Crossing a peripheral boundary with a Device access

Performing memory accesses from one load or store instruction to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes **CONSTRAINED UNPREDICTABLE** behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses.

- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.

- The instruction generates an alignment fault caused by the memory type.

  For the EL1&0 translation regime, when EL2 is enabled in the current Security state:
  - If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to EL1.
  - If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to EL2.
  - If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either EL1 or EL2.

- The instruction executes as a **NOP**.

---

**Note**

The boundary referred to is between two Device memory regions that are both:

- Of the size of the smallest implemented translation granule.
- Aligned to the size of the smallest implemented translation granule.
K1.2.15 CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-173 defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. In summary, these cases are:

- The target virtual address of a StoreExcl instruction is different from the virtual address of the preceding LoadExcl instruction in the same thread of execution.
- The transaction size of a StoreExcl instruction is different from the transaction size of the preceding LoadExcl instruction in the same thread of execution.
- The StoreExcl instruction accesses a different number of registers than the preceding LoadExcl instruction in the same thread of execution.
- The memory attributes for a StoreExcl instruction are different from the memory attributes for the preceding LoadExcl instruction in the same thread of execution, either:
  - Because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction.
  - Because the LoadExcl instruction and the StoreExcl instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-173 for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

K1.2.16 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in Chapter C6 A64 Base Instruction Descriptions and Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions.

LDAXP

For a description of this instruction and the encoding, see LDAXP on page C6-963.

CONSTRAINED UNPREDICTABLE behavior

If t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

LDNP

For a description of this instruction and the encoding, see LDNP on page C6-989.

CONSTRAINED UNPREDICTABLE behavior

If t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

**LDNP (SIMD&FP)**

For a description of this instruction and the encoding, see *LDNP (SIMD&FP)* on page C6-991.

**CONSTRAINED UNPREDICTABLE behavior**

If t == t2, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

**LDP**

For a description of this instruction and the encoding, see *LDP* on page C7-1829.

**CONSTRAINED UNPREDICTABLE behavior**

If t == t2, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

**Note**

Pre-indexed addressing and post-indexed addressing imply writeback.

**LDP (SIMD&FP)**

For a description of this instruction and the encoding, see *LDP (SIMD&FP)* on page C7-1831.

**CONSTRAINED UNPREDICTABLE behavior**

If t == t2, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

LDPSW

For a description of this instruction and the encoding, see LDPSW on page C6-994.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and (t == n || t2 == n) && n != 31, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

If t == t2, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

Note
Pre-indexed addressing and post-indexed addressing imply writeback.

LDR (immediate)

For a description of this instruction and the encoding, see LDR (immediate) on page C6-997.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and n == t && n != 31, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

Note
Pre-indexed addressing and post-indexed addressing imply writeback.

LDRB (immediate)

For a description of this instruction and the encoding, see LDRB (immediate) on page C6-1006.
**CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the load using the specified addressing mode, and the base register is set to an **UNKNOWN** value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

---

**Note**

Pre-indexed addressing and post-indexed addressing imply writeback.

---

**LDRH (immediate)**

For a description of this instruction and the encoding, see *LDRH (immediate)* on page C6-1011.

**CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the load using the specified addressing mode, and the base register is set to an **UNKNOWN** value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

---

**Note**

Pre-indexed addressing and post-indexed addressing imply writeback.

---

**LDRSB (immediate)**

For a description of this instruction and the encoding, see *LDRSB (immediate)* on page C6-1016.

**CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the load using the specified addressing mode, and the base register is set to an **UNKNOWN** value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

---

**Note**

Pre-indexed addressing and post-indexed addressing imply writeback.
LDRSH (immediate)

For a description of this instruction and the encoding, see LDRSH (immediate) on page C6-1021.

CONSTRANDED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \&\& n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

Note
Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSW (immediate)

For a description of this instruction and the encoding, see LDRSW (immediate) on page C6-1026.

CONSTRANDED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \&\& n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

Note
Pre-indexed addressing and post-indexed addressing imply writeback.

LDXP

For a description of this instruction and the encoding, see LDXP on page C6-1088.

CONSTRANDED UNPREDICTABLE behavior

If \( t = t2 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

STP

For a description of this instruction and the encoding, see STP on page C6-1258.
CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and (t == n || t2 == n) && n != 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

Note
Pre-indexed addressing and post-indexed addressing imply writeback.

STLXP

For a description of this instruction and the encoding, see STLXP on page C6-1247.

CONSTRAINED UNPREDICTABLE behavior

If s == t || (s == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

If s == n && n != 31 then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

STLXR

For a description of this instruction and the encoding, see STLXR on page C6-1250.

CONSTRAINED UNPREDICTABLE behavior

If s == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

If s == n && n != 31 then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

STLXRB

For a description of this instruction and the encoding, see STLXRB on page C6-1252.
CONSTRANDED UNPREDICTABLE behavior

If \( s = t \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a \texttt{NOP}.
- The instruction performs the store to the specified address, but the value stored is \texttt{UNKNOWN}.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \texttt{HCR_EL2.TIDCP} is 1, the instruction is trapped to EL2 with EC value \texttt{0x0}.

If \( s = n \land n \neq 31 \) then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a \texttt{NOP}.
- The instruction performs the store to an \texttt{UNKNOWN} address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \texttt{HCR_EL2.TIDCP} is 1, the instruction is trapped to EL2 with EC value \texttt{0x0}.

STLXRH

For a description of this instruction and the encoding, see \textit{STLXRH} on page C6-1254.

CONSTRANDED UNPREDICTABLE behavior

If \( s = t \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a \texttt{NOP}.
- The instruction performs the store to the specified address, but the value stored is \texttt{UNKNOWN}.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \texttt{HCR_EL2.TIDCP} is 1, the instruction is trapped to EL2 with EC value \texttt{0x0}.

If \( s = n \land n \neq 31 \) then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a \texttt{NOP}.
- The instruction performs the store to an \texttt{UNKNOWN} address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \texttt{HCR_EL2.TIDCP} is 1, the instruction is trapped to EL2 with EC value \texttt{0x0}.

STR (immediate)

For a description of this instruction and the encoding, see \textit{STR (immediate)} on page C6-1261.

CONSTRANDED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a \texttt{NOP}.
- The instruction performs a store using the specified addressing mode but the value stored is \texttt{UNKNOWN}.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \texttt{HCR_EL2.TIDCP} is 1, the instruction is trapped to EL2 with EC value \texttt{0x0}.

\begin{center} Note \end{center}

Pre-indexed addressing and post-indexed addressing imply writeback.

STRB (immediate)

For a description of this instruction and the encoding, see \textit{STRB (immediate)} on page C6-1266.
CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

Note
Pre-indexed addressing and post-indexed addressing imply writeback.

STRH (immediate)

For a description of this instruction and the encoding, see STRH (immediate) on page C6-1271.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

Note
Pre-indexed addressing and post-indexed addressing imply writeback.

STXP

For a description of this instruction and the encoding, see STXP on page C6-1316.

CONSTRAINED UNPREDICTABLE behavior

If \( s = t \lor (s = t2) \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

If \( s = n \land n \neq 31 \) then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0.

STXR

For a description of this instruction and the encoding, see STXR on page C6-1319.
**CONSTRAINED UNPREDICTABLE behavior**

If \( s == t \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to the specified address, but the value stored is **UNKNOWN**.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \( \text{HCR}_{EL2}.TIDCP \) is 1, the instruction is trapped to EL2 with EC value \( 0x0 \).

If \( s == n && n != 31 \) then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to an **UNKNOWN** address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \( \text{HCR}_{EL2}.TIDCP \) is 1, the instruction is trapped to EL2 with EC value \( 0x0 \).

---

**STXRB**

For a description of this instruction and the encoding, see *STXRB* on page C6-1321.

---

**CONSTRAINED UNPREDICTABLE behavior**

If \( s == t \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to the specified address, but the value stored is **UNKNOWN**.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \( \text{HCR}_{EL2}.TIDCP \) is 1, the instruction is trapped to EL2 with EC value \( 0x0 \).

If \( s == n && n != 31 \) then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to an **UNKNOWN** address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \( \text{HCR}_{EL2}.TIDCP \) is 1, the instruction is trapped to EL2 with EC value \( 0x0 \).

---

**STXRH**

For a description of this instruction and the encoding, see *STXRH* on page C6-1323.

---

**CONSTRAINED UNPREDICTABLE behavior**

If \( s == t \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to the specified address, but the value stored is **UNKNOWN**.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \( \text{HCR}_{EL2}.TIDCP \) is 1, the instruction is trapped to EL2 with EC value \( 0x0 \).

If \( s == n && n != 31 \) then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to an **UNKNOWN** address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \( \text{HCR}_{EL2}.TIDCP \) is 1, the instruction is trapped to EL2 with EC value \( 0x0 \).
K1.2.17 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions DC CISW, DC CSW, and DC ISW, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Note: This CONSTRAINED UNPREDICTABLE behavior applies, also, to the AArch32 cache maintenance by set/way instructions DCCISW, DCCSW, and DCISW.

K1.2.18 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated in this manual, all unallocated or reserved values of fields with allocated values within AArch64 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The unallocated value maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The unallocated value causes effects that could be achieved by a combination of more than one of the allocated values.
- The unallocated value causes the field to have no functional effect.

Note: These constraints are identical to those for the equivalent AArch32 definitions, as given in Reserved values in System and memory-mapped registers and translation table entries on page K1-7963.

K1.2.19 CONSTRAINED UNPREDICTABLE behavior in Debug state

Behavior in Debug state on page H2-7024 of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.
Architectural Constraints on UNPREDICTABLE Behaviors
K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors
Appendix K2
Recommended External Debug Interface

This appendix describes the recommended external debug interface. It contains the following sections:

- *About the recommended external debug interface* on page K2-7984.
- *PMUEVENT bus* on page K2-7988.
- *Recommended authentication interface* on page K2-7989.
- *Management registers and CoreSight compliance* on page K2-7991.

___ Note ___

This recommended external debug interface specification is not part of the Arm architecture specification. Implementers and users of the Armv8 architecture must not consider this appendix as a requirement of the architecture. It is included as an appendix to this manual only:

- As reference material for users of Arm products that implement this interface.
- As an example of how an external debug interface might be implemented.

The inclusion of this appendix is no indication of whether any Arm products might, or might not, implement this external debug interface. For details of the implemented external debug interface you must always see the appropriate product documentation.
# K2.1 About the recommended external debug interface

See the *Note* on the first page of this appendix for information about the architectural status of this recommended debug interface.

This specification provides a recommended external debug interface for Armv8 to define a standard set of connections for validation environments. In general, the connection between components, such as between the PE and Trace extension, is not described here, although the table does include the signals for the CTI connection. Table K2-1 shows the signals in the recommended interface.

- a. This is the port where the PE completes debug APB transactions. Arm recommends a single port for all integrated debug components.
- b. The value of \( n \) depends on the size of the address space occupied by the Debug port.
- c. This is the port where the PE outputs trace.

Figure K2-1 shows the recommended debug interface.

![Recommended debug interface diagram](image)

**Figure K2-1** Recommended external debug interface, including the APB4 Completer port.
K2.1.1 EDBGRQ and DBGACK

**EDBGRQ**

EDBGRQ is an IMPLEMENTATION DEFINED means of generating the External Debug Request debug event described in *External Debug Request debug event* on page H3-7071.

The PE asserts **DBGACK** when the PE is in Debug state. The PE might also include variants of this signal:

**DBGTRIGGER**

Asserted by the PE when it commits to entering Debug state.

**DBGCPUDONE**

Asserted by the PE when it has completed all Non-debug state memory accesses and Debug state entry is complete. **DBGCPUDONE** indicates that memory accesses issued by the PE result from operations originating from debugger commands.

In previous architecture versions, these signals provide an interface between the PE and cross-trigger logic. In Armv8, the architectural Cross-Trigger Interface provides this functionality for external debuggers.

K2.1.2 Secure and Non-secure views of the debug registers

If **FEAT_Debugv8p4** is implemented, the external debug interface has views of Secure and Non-secure debug registers. The DAP is must ensure that accesses are made only when permitted. The Arm debug interface describes a standard APB-AP programmers model for APB4 which signals Secure and Non-secure accesses on the **PPROTDBG[1]** signal, and is recommended for new designs.

If **FEAT_Debugv8p4** is implemented, and an APB-AP implements an APB3 Requester port, which does not support Secure and Non-secure views, Arm recommends that the following is implemented:

- If **SPIDEN** is HIGH and **DBGEN** is HIGH, all external debug accesses area treated as Secure.
- If either **SPIDEN** is LOW or **DBGEN** is LOW, all external debug accesses are treated as Non-secure.

If the PE APB Completer port is APB4, this might be implemented by, for example, fixing **PPROTDBG[1]** to the inverse of (**SPIDEN & DBGEN**) when bridging from APB3 to APB4.
K2.2 PMUEVENT bus

The PMUEVENT bus exports Performance Monitor events from the PE to an on-chip agent. Arm recommends that it has the following characteristics:

- The bus is synchronous.
- The width of the bus is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED which events are exported on the bus.
- Each exported event occupies a contiguous sub-field of the bus. Arm recommends that the sub-fields of the bus are occupied in the same order as the event numbers.
- If the event can only occur once per cycle, it occupies a single bit. If the event can occur more than once per cycle, it is IMPLEMENTATION DEFINED how the event is encoded. The encoding depends on constraints such as the designated use of the event bus and the number of pins available. For example, the event can be encoded:
  - As a count, using a plain binary number. This is the most useful encoding when exporting to an external counter. It is not a useful encoding for exporting to a Trace extension external input.
  - As a count, using thermometer encoding. This is the most useful encoding when exporting to a Trace extension.
  - Using a single bit encoding to indicate whether the event count is zero or nonzero. This is useful for exporting to an activity monitor where the number of pins is constrained.

If a Trace extension is implemented, the PMUEVENT bus is normally connected to the Trace extension using the external inputs. TRCEXTINSELR multiplexes a wide PMUEVENT bus to a narrow set of inputs. An external PMUEVENT bus might also be provided. For more information, contact Arm.
K2.3 Recommended authentication interface

An implementation of the Armv8 architecture must support debug authentication described in Required debug authentication on page H1-7012.

The details of the debug authentication interface are IMPLEMENTATION DEFINED, but Arm recommends the use of the CoreSight interface, which includes the following signals for external debug authentication:

- **DBGEN**.
- **SPIDEN**.

If FEAT_Debugv8p4 is not implemented, Arm also recommends using the following signals:

- **NIDEN**.
- **SPNIDEN**.

Arm recommends an interface in which **DBGEN** and **SPIDEN** are also used for self-hosted Secure debug authentication if either:

- EL3 is using AArch32 and SDCR.SPD == 0b00.
- Secure EL1 is using AArch32 and MDCR_EL3.SPD32 == 0b00.

If EL3 is not implemented and the PE is in Non-secure state, **SPIDEN** and **SPNIDEN** are not implemented, and the PE behaves as if these signals were tied LOW.

If EL3 is not implemented and the PE is in Secure state, **SPIDEN** is usually connected to **DBGEN** and **SPNIDEN** is connected to **NIDEN**, but this is not required. The recommended interface is defined as if all four signals are implemented.

How the authentication signals are driven is IMPLEMENTATION DEFINED. For example, the signals might be hard-wired, connected to fuses, or to an authentication module. The architecture permits PEs within a cluster to have independent authentication interfaces, but this is not required. Arm recommends that any Trace extension has the same authentication interface as the PE it is connected to.

If FEAT_Debugv8p4 and CoreSight ETR are both implemented, the ETR has an independent **DBGEN** signal that must be tied HIGH to enable self-hosted use of trace.

Table K2-2 shows the debug authentication pseudocode functions and the recommended implementations.

### Table K2-2 Recommended implementation of debug enable pseudocode functions

<table>
<thead>
<tr>
<th>Pseudocode function</th>
<th>Description</th>
<th>Implementation</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()</td>
<td>Secure invasive self-hosted debug enabled in AArch32 state (legacy)</td>
<td>(DBGEN AND SPIDEN)</td>
</tr>
<tr>
<td>ExternalSecureNoninvasiveDebugEnabled()a</td>
<td>Secure non-invasive debug enabled</td>
<td>(DBGEN OR NIDENb) AND (SPIDEN OR SPNIDENC)</td>
</tr>
<tr>
<td>ExternalSecureInvasiveDebugEnabled()</td>
<td>Secure invasive debug enabled</td>
<td>(DBGEN AND SPIDEN)</td>
</tr>
<tr>
<td>ExternalNoninvasiveDebugEnabled()d</td>
<td>Non-secure non-invasive debug enabled</td>
<td>(DBGEN OR NIDENb)</td>
</tr>
<tr>
<td>ExternalInvasiveDebugEnabled()</td>
<td>Non-secure invasive debug enabled</td>
<td>DBGEN</td>
</tr>
</tbody>
</table>

a. If FEAT_Debugv8p4 is implemented, **ExternalSecureNoninvasiveDebugEnabled()** == **ExternalSecureInvasiveDebugEnabled()**.
b. If FEAT_Debugv8p4 is implemented, the **NIDEN** signal is not implemented.
c. If FEAT_Debugv8p4 is implemented, the **SPNIDEN** signal is not implemented.
d. If FEAT_Debugv8p4 is implemented, **ExternalNoninvasiveDebugEnabled()** == TRUE.
The `Debug_authentication()` pseudocode function on `shared/debug` on page J1-7812 defines the authentication signals DBGEN, SPIDEN, NIDEN and SPNIDEN.
K2.4 Management registers and CoreSight compliance

The CoreSight architecture requires the implementation of a set of management registers that occupy the memory map from 0xF00 upwards in each of the debug components.

CoreSight compliance and complete implementation of the management registers is OPTIONAL, but Arm recommends that the registers are implemented.

The CoreSight architecture specification recommends that any integration test registers are implemented starting from 0xEFC downwards. Each of the debug components has an IMPLEMENTATION DEFINED region from 0xE80 to 0xEFC for this purpose.

K2.4.1 CoreSight interface register map

Table K2-3 shows the external management register maps for the following registers:

ED These are the external debug register.

CTI These are the Cross-trigger interface registers.

PMU These are the Performance Monitors registers.

K2.4.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

Table K2-4 on page K2-7993, Table K2-5 on page K2-7994, Table K2-6 on page K2-7995, Table K2-7 on page K2-7996, and Table K2-8 on page K2-7997 show the response to accesses by the external debug interface to the CoreSight management registers.

</tr>
</tbody>
</table>

a. This register must always be implemented, regardless of whether the component is CoreSight compliant.
b. If implemented, the number of CLAIM bits is IMPLEMENTATION DEFINED and can be discovered by reading CLAIMSET.
c. If the CTI implements CTIv1, this register is not implemented. See the register description for details.
d. The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.
e. PMDEVID is implemented only from Armv8.2 or if FEAT_PCSRv8p2 is implemented, otherwise its offset is RES0.

K2.4.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

Table K2-4 on page K2-7993, Table K2-5 on page K2-7994, Table K2-6 on page K2-7995, Table K2-7 on page K2-7996, and Table K2-8 on page K2-7997 show the response to accesses by the external debug interface to the CoreSight management registers.

--- Note ---

Access to the CoreSight management registers is not affected by the values of EDAD and EPMAD.

---

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses. See Register access permissions for memory-mapped accesses on page H8-7142.

When HaveSecureExtDebugView() == TRUE, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

The terms in Table K2-4 on page K2-7993, Table K2-5 on page K2-7994, Table K2-6 on page K2-7995, Table K2-7 on page K2-7996, and Table K2-8 on page K2-7997 are defined as follows:

**Domain**

This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

If FEAT_DoPD is implemented, most External debug interface registers are in the Core power domain, as shown in Table K2-4 on page K2-7993 and Table K2-7 on page K2-7996.

If FEAT_DoPD is not implemented, most of the registers are in the Debug Power Domain, as shown in Table K2-5 on page K2-7994 and Table K2-8 on page K2-7997.

**Conditions**

This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column that lists the condition as being true.
The conditions are:

**Off** \( \text{EDPRSR.PU} == 0 \). The Core power domain is completely off, or in low-power state. In these cases, the Core power domain registers cannot be accessed.

**Note**

When the Debug power domain is off, all accesses to the registers in the external Debug power domain return an error.

**DLK** If the OS Double Lock is implemented and \( \text{DoubleLockStatus()} == \text{TRUE} \). The OS Double Lock is locked.

**OSLK** \( \text{OSLSR.OSLK} == 1 \). The OS Lock is locked.

**Default** This provides the default access permissions, if there are no conditions that prevent access to the register.

**SLK** This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See Register access permissions for memory-mapped accesses on page H8-7142. If \text{FEAT_DoPD} is implemented, the Software Lock is not locked, or not implemented, this column is ignored.

The access permissions are:

- **This means that the default access permission applies.** See the Default column, or the SLK column, if applicable.

- **RO** This means that the register or field is read-only.

- **RW** This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.

- **RC** This means that the bit clears to 0 after a read.

- **(SE)** This means that accesses to this register have indirect write side effects. A side effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.

- **WO** This means that the register or field is write-only.

- **WI** This means that the register or field ignores writes.

- **IMP DEF** This means that the access permissions are IMPLEMENTATION DEFINED.

---

K2.4.3 Management register resets

Table K2-9 shows the management register resets. This table does not include:

- Read-only identification registers that have a fixed value from reset. These registers include those with the DEVAFFn, DEVARCH, DEVID[n], DEVTYPE, PIDRn, and CIDRn mnemonics.
- Registers that have the AUTHSTATUS mnemonic. This is a read-only status register that reflects the status outside of the reset domain of the register.
- Registers that have the LAR mnemonic. These are write-only registers that only have an effect on writes.

All other fields in the management registers are reset to an IMPLEMENTATION DEFINED value which can be UNKNOWN. The registers are in the reset domain specified in the table.

Table K2-9 shows a summary of the management register resets.

K2.4.4 About the Peripheral identification scheme

The Peripheral Identification scheme provides the standard information required by all components that conform to the Arm® Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2, that implements the CoreSight identification scheme. They identify a peripheral in a particular namespace. For more information, see the Arm® CoreSight™ Architecture Specification.

Table K2-10 lists the Peripheral ID Registers that make up the Peripheral Identification scheme for each component.

Figure K2-2 shows the register field allocation scheme for the Peripheral ID Registers.

[Diagram of Peripheral ID register format]

Software can consider the eight Peripheral ID Registers as defining a single 64-bit Peripheral ID, as shown in Figure K2-3 on page K2-8000.
Figure K2-3 Mapping between Peripheral ID Registers and a 64-bit Peripheral ID Value

Figure K2-3 shows the fields in the 64-bit Peripheral ID value, and includes the field values for fields that:

- Have fixed values, including the bits that are reserved.
- Have fixed values in an implementation that is designed by Arm.

For more information about the fields and their values see Table K2-11.

<tr>
<td></td>
<td></td>
<td>implementation designer then this field is RES0.</td>
<td></td>
</tr>
</tbody>
</table>
A component is identified uniquely by the combination of the following fields:

- JEP106 continuation code.
- JEP106 identity code.
- Part number.
- Revision.
- Customer Modified.
- RevAnd.

For components with a **Component class** of 0x9, Debug component, indicated by the Component Identification Registers, multiple components can have the same Part number, provided each component has a different CoreSight **Device type**. However, Arm strongly recommends that each device has a unique Part number. For more information:

- About the Component Identification Registers, see *About the Component Identification scheme on page K2-8002.*
- About the CoreSight Device type, see EDDEVTYPE, CTIDEVTYPE, or PMDEVTYPE.
- About CoreSight components and their identification, see the *Arm® Debug Interface Architecture Specification.*

### Allocating revisions and part numbers

Within the Peripheral Identification registers, the allocation of major and minor revisions, part numbers, and customer-modified fields is **IMPLEMENTATION DEFINED**, with the following set of restrictions so that:

- The **REVISION** field must increase monotonically with revisions.

  __________
  **Note**
  __________

  Arm recommends that the **REVISION** field is updated for each update to the RTL, regardless of whether this is a major or minor update.

- The **REV AND** field should increase monotonically with revisions.

  __________
  **Note**
  __________

  Arm recommends that the **REV AND** field is used only for post-release changes. For example, those due to engineering change order (ECO) fixes related to the debug component of the processor.

- The **PART** field must have a degree of uniqueness:

  — Two component designs can have the same part number so long as they are sub-components of the same part and the programmers’ model for the part has the means to disambiguate sub-components.
  — Otherwise, two component designs must have unique part numbers.

---

**Table K2-11 Fields in the Peripheral Identification Registers (continued)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Description</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Revision</td>
<td>4 bits</td>
<td>Revision number for the implementation.</td>
<td>EDPIDR2, CTIPIDR2, PMPIDR2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Starts at 0x0 and increments by 1 at both major and minor revisions.</td>
<td></td>
</tr>
<tr>
<td>Uses JEP106</td>
<td>1 bit</td>
<td>This bit is set to 1 when a JEP106 identification code is used.</td>
<td>EDPIDR2, CTIPIDR2, PMPIDR2</td>
</tr>
<tr>
<td>ID code</td>
<td></td>
<td>This bit must be 1 on all Armv8 implementations.</td>
<td></td>
</tr>
<tr>
<td>Part number</td>
<td>12 bits</td>
<td>Part number for the implementation. Each organization designing to the Arm Debug architecture specification keeps its own part number list.</td>
<td>EDPIDR0, EDPIDR1, CTIPIDR0, CTIPIDR1, PMPIDR0, PMPIDR1</td>
</tr>
</tbody>
</table>
The DEVARCH (if implemented) or DEVTYPE (otherwise) register provides the means to disambiguate sub-components of the Debug Architecture.

A ROM table has no DEVTYPE or DEVARCH register. However, if it is the only CLASS 0x1 component in a processor cluster, it can still be disambiguated.

Multiple instances of the same component design have the same part number.

### K2.4.5 About the Component Identification scheme

The Component Identification Registers identify the processor as an Arm Debug Interface v5 component. For more information, see the *Arm® Debug Interface Architecture Specification* and the *Arm® CoreSight™ Architecture Specification*.

The Component Identification Registers occupy the last four words of the 4KB block of debug registers.

Figure K2-5 shows the register field allocation scheme for the Component ID Registers.

![Component ID Register format](image)

Software can consider the eight Component ID Registers as defining a single 32-bit Component ID, as shown in Figure K2-6.

![Mapping between Component ID Registers and a 32-bit Component ID Value](image)
Appendix K3
Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

This appendix describes the Arm recommendations for the use of the IMPLEMENTATION DEFINED event numbers. It contains the following sections:

- Arm recommendations for IMPLEMENTATION DEFINED event numbers on page K3-8004.
- Summary of events for exceptions taken to an Exception level using AArch64 on page K3-8019.
K3.1 Arm recommendations for IMPLEMENTATION DEFINED event numbers

These are the Arm recommendations for the use of the IMPLEMENTATION DEFINED event numbers. Arm does not define these events as rigorously as those in the architectural and microarchitectural event lists, and an implementation might:

- Modify the definition of an event to better correspond to the implementation.
- Not use some, or many, of these event numbers.

Table K3-1 lists the PMU IMPLEMENTATION DEFINED event numbers in event number order.

For more information, see *Relationship between REFILL events and associated access events* on page K3-8017. 

The Glossary defines the term *Taken locally*. See also *Exception levels* on page D1-2312 for more information.

0x0040, L1D_CACHE_RD, Attributable Level 1 data cache access, read
This event is similar to Level 1 data cache access, L1D_CACHE, but the counter counts only memory-read operations that access at least the Level 1 data or unified cache.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted.

See also:
- Attributability on page D7-2701.
- Meaningful ratios between common microarchitectural events on page D7-2763.

0x0041, L1D_CACHE_WR, Attributable Level 1 data cache access, write
This event is similar to Level 1 data cache access, L1D_CACHE, but the counter counts only memory-write operations that access at least the Level 1 data or unified cache.

The counter counts DC ZVA as a store instruction.

0x0042, L1D_CACHE_REFILL_RD, Attributable Level 1 data cache refill, read
This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read operations that cause a refill of at least the Level 1 data or unified cache.

See also Relationship between REFILL events and associated access events. on page K3-8017.

0x0043, L1D_CACHE_REFILL_WR, Attributable Level 1 data cache refill, write
This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-write operations that cause a refill of at least the Level 1 data or unified cache.

The counter counts DC ZVA as a store instruction.

See also Relationship between REFILL events and associated access events. on page K3-8017.

0x0044, L1D_CACHE_REFILL_INNER, Attributable Level 1 data cache refill, inner
This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read and memory-write operations that generate refills satisfied by transfer from another cache inside of the immediate cluster.

Note
The boundary between inner and outer is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

0x0045, L1D_CACHE_REFILL_OUTER, Attributable Level 1 data cache refill, outer
This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read and memory-write operations that generate refills satisfied from outside of the immediate cluster.

0x0046, L1D_CACHE_WB_VICTIM, Attributable Level 1 data cache Write-Back, victim
This event is similar to Level 1 data cache Write-Back, L1D_CACHE_WB, but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

If FEAT_PMUv3p4 is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x0047, L1D_CACHE_WB_CLEAN, Level 1 data cache Write-Back, cleaning and coherency
This event is similar to Attributable Level 1 data cache Write-Back, L1D_CACHE_WB, but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.
If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

--- Note ---

The transfer of a dirty cache line from the Level 1 data cache of this PE to the Level 1 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

0x0048, L1D_CACHE_INV AL, Attributable Level 1 data cache invalidate
The counter counts each invalidation of a cache line in the Level 1 data or unified cache.
The counter does not count events if a cache refill invalidates a line.
If FEAT_PMUv3p4 is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x004C, L1D_TLB_REFILL_RD, Attributable Level 1 data TLB refill, read
This event is similar to Level 1 data TLB refill, L1D_TLB_REFILL, but the counter counts only memory-read operations that cause a data TLB refill of a least the Level 1 data or unified TLB.
See also Relationship between REFILL events and associated access events. on page K3-8017.

0x004D, L1D_TLB_REFILL_WR, Attributable Level 1 data TLB refill, write
This event is similar to Level 1 data TLB refill, L1D_TLB_REFILL, but the counter counts only memory-write operations that cause a data TLB refill of a least the Level 1 data or unified TLB.
The counter counts DC ZVA as a store instruction.
See also Relationship between REFILL events and associated access events. on page K3-8017.

0x004E, L1D_TLB_RD, Attributable Level 1 data or unified TLB access, read
This event is similar to Level 1 data or unified TLB access, L1D_TLB, but the counter counts only memory-read operations that cause a TLB access to at least the Level 1 data or unified TLB.

0x004F, L1D_TLB_WR, Attributable Level 1 data or unified TLB access, write
This event is similar to Level 1 data or unified TLB access, L1D_TLB, but the counter counts only memory-write operations that cause a TLB access to at least the Level 1 data or unified TLB.

0x0050, L2D_CACHE_RD, Attributable Level 2 data cache access, read
This event is similar to Attributable Level 2 data cache access, L2D_CACHE, but the counter counts only memory-read operations that access at least the Level 2 data or unified cache.

0x0051, L2D_CACHE_WR, Attributable Level 2 data cache access, write
This event is similar to Attributable Level 2 data cache access, L2D_CACHE, but the counter counts only memory-write operations that access at least the Level 2 data or unified cache.
The counter counts DC ZVA as a store instruction.

0x0052, L2D_CACHE_REFILL_RD, Attributable Level 2 data cache refill, read
This event is similar to Attributable Level 2 data cache refill, L2D_CACHE_REFILL, but the counter counts only memory-read operations that cause a refill of at least the Level 2 data or unified cache.
See also Relationship between REFILL events and associated access events. on page K3-8017.
0x0053, L2D_CACHE_REFILL_WR, Attributable Level 2 data cache refill, write

This event is similar to Attributable Level 2 data cache refill, L2D_CACHE_REFILL, but the counter counts only memory-write operations that cause a refill of at least the Level 2 data or unified cache.

The counter counts DC ZVA as a store instruction.

See also Relationship between REFILL events and associated access events. on page K3-8017.

0x0056, L2D_CACHE_WB_VICTIM, Attributable Level 2 data cache Write-Back, victim

This event is similar to Attributable Level 2 data cache Write-Back, L2D_CACHE_WB, but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

If FEAT_PMUv3p4 is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x0057, L2D_CACHE_WB_CLEAN, Level 2 data cache Write-Back, cleaning and coherency

This event is similar to Attributable Level 2 data cache Write-Back, L2D_CACHE_WB, but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted as IMPLEMENTATION DEFINED.

Note

The transfer of a dirty cache line from the Level 2 data cache of this PE to the Level 2 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x0058, L2D_CACHE_INV, Attributable Level 2 data cache invalidate

The counter counts each invalidation of a cache line in the Level 2 data or unified cache.

The counter does not count events if a cache refill invalidates a line.

If FEAT_PMUv3p4 is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting events that directly affect this PE.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x005C, L2D_TLB_REFILL_RD, Attributable Level 2 data or unified TLB refill, read

This event is similar to Attributable Level 2 data or unified TLB refill, L2D_TLB_REFILL, but the counter counts only Attributable memory read operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also Relationship between REFILL events and associated access events. on page K3-8017.
Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events
K3.1 Arm recommendations for IMPLEMENTATION DEFINED event numbers

0x005D, L2D_TLB_REFILL_WR, Attributable Level 2 data or unified TLB refill, write
This event is similar to Attributable Level 2 data or unified TLB refill, L2D_TLB_REFILL, but the counter counts only Attributable memory write operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also Relationship between REFILL events and associated access events on page K3-8017.

0x005E, L2D_TLB_RD, Attributable Level 2 data or unified TLB access, read
This event is similar to Attributable Level 2 data or unified TLB access, L2D_TLB, but the counter counts only Attributable memory read operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x005F, L2D_TLB_WR, Attributable Level 2 data or unified TLB access, write
This event is similar to Attributable Level 2 data or unified TLB access, L2D_TLB, but the counter counts only Attributable memory write operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x0060, BUS_ACCESS_RD, Bus access, read
This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read operations that access outside the boundary of the PE and its closely-coupled caches.

0x0061, BUS_ACCESS_WR, Bus access, write
This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-write operations that access outside the boundary of the PE and its closely-coupled caches.

0x0062, BUS_ACCESS_SHARED, Bus access, Normal, Cacheable, Shareable
This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Normal, Cacheable, Shareable accesses outside the boundary of the PE and its closely-coupled caches.

Note
It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

0x0063, BUS_ACCESS_NOT_SHARED, Bus access, not Normal, Cacheable, Shareable
This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make accesses outside the boundary of the PE and its closely-coupled caches that are not Normal, Cacheable, Shareable. For example, the counter counts accesses marked as:

- Normal, Cacheable, Non-shareable.
- Normal, Non-cacheable.
- Device.

Note
It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.
If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

0x0064, BUS_ACCESS_NORMAL, Bus access, normal
This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Normal accesses outside the boundary of the PE and its closely-coupled caches. For example, the counter counts Normal, Cacheable and Normal, Non-cacheable accesses but does not count Device accesses.

0x0065, BUS_ACCESS_PERIPH, Bus access, peripheral
This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Device accesses outside the boundary of the PE and its closely-coupled caches.

0x0066, MEM_ACCESS_RD, Data memory access, read
This event is similar to Data memory access, MEM_ACCESS, but the counter counts only memory-read operations and SVE memory-read operations that the PE made.

0x0067, MEM_ACCESS_WR, Data memory access, write
This event is similar to Data memory access, MEM_ACCESS, but the counter counts only memory-write operations and SVE memory-write operations made by the PE.

0x0068, UNALIGNED_LDR_SPEC, Unaligned access, read
This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-read operations and unaligned memory-read SVE operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x0069, UNALIGNED_STR_SPEC, Unaligned access, write
This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-write operations and unaligned SVE memory-write operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x006A, UNALIGNED_LDST_SPEC, Unaligned access
This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-read operations, unaligned memory-write operations, unaligned memory-read SVE operations, and unaligned memory-write SVE operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x006C, LDREX_SPEC, Exclusive operation speculatively executed, Load-Exclusive
The counter counts Load-Exclusive instructions speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x006D, STREX_PASS_SPEC, Exclusive operation speculatively executed, Store-Exclusive pass
The counter counts Store-Exclusive instructions speculatively executed that completed a write. The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.

0x006E, STREX_FAIL_SPEC, Exclusive operation speculatively executed, Store-Exclusive fail
The counter counts Store-Exclusive instructions speculatively executed that fail to complete a write. It is within the IMPLEMENTATION DEFINED definition of speculatively executed whether this includes conditional instructions that fail the condition code check. The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.
0x006F, STREX_SPEC, Exclusive operation speculatively executed, Store-Exclusive
The counter counts Store-Exclusive instructions speculatively executed.
The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.
Arm recommends that this event is implemented if it is not possible to implement the exclusive operation speculatively executed, Store-Exclusive pass, and exclusive operation speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the LDREX_SPEC event.

0x0070, LD_SPEC, Operation speculatively executed, load
This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only operations due to memory-reading instructions and operations due to memory-reading SVE instructions, as defined by the LD_RETIRED event.
The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0071, ST_SPEC, Operation speculatively executed, store
This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only operations due to memory-writing instructions and operations due to memory-writing SVE instructions, as defined by the ST_RETIRED event.
The counter counts DC ZVA as a store operation.
The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0072, LDST_SPEC, Operation speculatively executed, load or store
This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only operations due to memory-reading instructions, operations due to memory-writing instructions, operations due to memory-reading SVE instructions and operations due to memory-writing SVE instructions as defined by the LD_RETIRED and ST_RETIRED events.
The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0073, DP_SPEC, Operation speculatively executed, integer data processing
This event is similar to Operation speculatively executed, INST_SPEC, but counts only operations due to integer data-processing instructions. It counts the following operations that operate on the general-purpose registers:
- In AArch64 state, Data processing - immediate on page C3-224 and Data processing - register on page C3-229.
- In AArch32 state, Data-processing instructions on page F1-4080.
This includes MOV and MVN operations.
This event also counts the following miscellaneous instructions:
- In AArch64 state, System register instructions on page C3-202, System instructions on page C3-203, and Hint instructions on page C3-203.
- In AArch32 state, PSTATE and banked register access instructions on page F1-4088, Banked register access instructions on page F1-4088, Miscellaneous instructions on page F1-4093, other than ISB and preloads, and System register access instructions on page F1-4097, other than LDC and STC instructions.
If the preload instructions PRFM, PLD, PLDh, and PLT, do not count as memory-reading instructions then they must count as integer data-processing instructions.
If ISB8s do not count as software change of the PC then they must count as integer data-processing instructions.
The definition of Speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.
It is IMPLEMENTATION DEFINED whether the following instructions are counted as integer data-processing operations, SIMD operations, or floating-point operations, but Arm recommends that the instructions are all counted as integer data-processing operations:

- For AArch64 state, from the A64 floating-point convert to integer class, operations that move a value between a general-purpose register and a SIMD and floating-point register without type conversion:
  - `FMOV` (general).

- For AArch64 state, from the SIMD Move group, operations that move a values between a general-purpose register and an element or elements in a SIMD and floating-point register:
  - `DUP` (general).
  - `SMOV`.
  - `UMOV`.
  - `INS` (general).

- For AArch32 state:
  - `VDUP` (general-purpose register) and all `VMOV` instructions that transfer data between a general-purpose register and a SIMD and floating-point register.
  - `VMRS`.
  - `VMSR`.

0x0074, **ASE_SPEC, Operation speculatively executed, Advanced SIMD**

This event is similar to Operation speculatively executed, **INST_SPEC**, but the counter counts only operations due to Advanced SIMD data-processing instructions, see:

- For AArch64 state, the SIMD operations listed in *Data processing - SIMD and floating-point* on page C3-237.
- For AArch32 state, *Advanced SIMD data-processing instructions* on page F1-4101.

This includes all operations that operate on the SIMD and floating-point registers, except those that are counted as:

- Integer data-processing operations.
- Floating-point data-processing operations.
- Memory-reading operations.
- Memory-writing operations.
- Cryptographic operations other than `PMULL`, in AArch64 state.
- `VMULL`, in AArch32 state.

Advanced SIMD scalar operations are counted as Advanced SIMD operations, including those which operate on floating-point values. In AArch64 state, `PMULL`, and in AArch32 state, `VMULL` are counted as Advanced SIMD operations.

The definition of Speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the **INST_SPEC** event.

0x0075, **VFP_SPEC, Operation speculatively executed, floating-point**

This event is similar to Operation speculatively executed, **INST_SPEC**, but the counter counts only operations due to floating-point data-processing instructions, see:

- In AArch64 state, only the scalar floating-point operations listed in *Data processing - SIMD and floating-point* on page C3-237.

**Note**

This event does not count the SIMD floating-point operations listed in *Data processing - SIMD and floating-point* on page C3-237.

- In AArch32 state, *Floating-point data-processing instructions* on page F1-4112.
This includes all operations that operate on the SIMD and floating-point registers as floating-point values, except for SIMD scalar operations and those that are counted as one of:

- Integer data processing.
- Memory-reading operations.
- Memory-writing operations.

The following instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point), are counted as floating-point data-processing operations:

- In AArch64 state, `FCVT{<mode>}`, `UCVTF`, and `SCVTF`.
- In AArch32 state, `VCVT<mode>` (floating-point), `VCVT`, `VCVT.T`, and `VCVT.B`.

The definition of Speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

0x0076, `PC_WRITE_SPEC`, Operation speculatively executed, software change of the PC

This event is similar to Operation speculatively executed, `INST_SPEC`, but the counter counts only operations due to software changes of the PC. Defined by the instruction architecturally executed, condition code check pass, software change of the PC event, see `Common event numbers` on page D7-2716.

The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the `INST_SPEC` event.

See also `PC_WRITE_RETIRED`.

0x0077, `CRYPTO_SPEC`, Operation speculatively executed, Cryptographic instruction

This event is similar to Operation speculatively executed, `INST_SPEC`, but the counter counts only operations due to Cryptographic instructions, except `PMULL` and `VMULL`, see `The Cryptographic Extension` on page C3-259.

The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the `INST_SPEC` event.

0x0078, `BR_IMMED_SPEC`, Branch speculatively executed, immediate branch

The counter counts immediate branch instructions speculatively executed. Defined by the instruction architecturally executed, immediate branch event, see `Common event numbers` on page D7-2716.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.

See also `BR_IMMED_RETIRED`.

0x0079, `BR_RETURN_SPEC`, Branch speculatively executed, procedure return

The counter counts procedure return instructions speculatively executed. Defined by the `BR_RETURN_RETIRED` event.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.

See also `BR_RETURN_RETIRED`.

0x007A, `BR_INDIRECT_SPEC`, Branch speculatively executed, indirect branch

The counter counts indirect branch instructions speculatively executed. This includes software change of the PC other than exception-generating instructions and immediate branch instructions.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.

0x007C, `ISB_SPEC`, Barrier speculatively executed, ISB

The counter counts Instruction Synchronization Barrier instructions speculatively executed, including `CP15ISB`.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.
Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

K3.1 Arm recommendations for IMPLEMENTATION DEFINED event numbers

0x007D, DSB_SPEC, Barrier speculatively executed, DSB
The counter counts data synchronization barrier instructions speculatively executed, including CP15DSB, SSBB and PSSBB.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.

0x007E, DMB_SPEC, Barrier speculatively executed, DMB
The counter counts data memory barrier instructions speculatively executed, including CP15DSB. It does not include the implied barrier operations of load/store operations with release consistency semantics.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.

007F, CSDB_SPEC, Barrier speculatively executed, CSDB
If FEAT_PMUv3p5 is implemented, the counter counts control speculation barrier instructions speculatively executed.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.

0x0081, EXC_UNDEF, Exception taken, other synchronous
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only those exceptions Taken locally that are not counted as:
  • Exception taken, Supervisor Call (EXC_SVC).
  • Exception taken, Secure Monitor Call (EXC_SMC).
  • Exception taken, Hypervisor Call (EXC_HVC).
  • Exception taken, Instruction Abort (EXC_PABORT).
  • Exception taken, Data Abort or SError (EXC_DABORT).
  • Exception taken, IRQ (EXC_IRQ).
  • Exception taken, FIQ (EXC_FIQ).

0x0082, EXC_SVC, Exception taken, Supervisor Call
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Supervisor Call exceptions that are Taken locally.

0x0083, EXC_PABORT, Exception taken, Instruction Abort
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Instruction Abort exceptions that are Taken locally.

0x0084, EXC_DABORT, Exception taken, Data Abort or SError
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Data Abort or SError interrupt exceptions. The counter counts only exceptions Taken locally.

0x0086, EXC_IRQ, Exception taken, IRQ
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only IRQ exceptions that are Taken locally, including Virtual IRQ exceptions.

0x0087, EXC_FIQ, Exception taken, FIQ
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only FIQ exceptions that are Taken locally, including Virtual FIQ exceptions.

0x0088, EXC_SMC, Exception taken, Secure Monitor Call
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Secure Monitor Call exceptions. The counter does not increment on SMC instructions trapped as a Hyp Trap exception.

0x008A, EXC_HVC, Exception taken, Hypervisor Call
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Hypervisor Call exceptions. The counter counts for both Hypervisor Call exceptions Taken locally in the hypervisor and those taken as an exception from Non-secure EL1.
0x008B, EXC_TRAP_PABORT, Exception taken, Instruction Abort not Taken locally
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Instruction Abort exceptions not Taken locally.

0x008C, EXC_TRAP_DABORT, Exception taken, Data Abort or SError not Taken locally
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Data Abort or SError interrupt exceptions not Taken locally.

0x008D, EXC_TRAP_OTHER, Exception taken, other traps not Taken locally
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only those traps that are not counted as:
• Exception taken, Secure Monitor Call (EXC_SMC).
• Exception taken, Hypervisor Call (EXC_HVC).
• Exception taken, Instruction Abort not Taken locally (EXC_TRAP_PABORT).
• Exception taken, Data Abort or SError not Taken locally (EXC_TRAP_DABORT).
• Exception taken, IRQ not Taken locally (EXC_TRAP_IRQ).
• Exception taken, FIQ not Taken locally (EXC_TRAP_FIQ).

0x008E, EXC_TRAP_IRQ, Exception taken, IRQ not Taken locally
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only IRQ exceptions not Taken locally.

0x008F, EXC_TRAP_FIQ, Exception taken, FIQ not Taken locally
This event is similar to Exception taken, EXC_TAKEN, but the counter counts only FIQ exceptions not Taken locally.

0x0090, RC_LD_SPEC, Release consistency operation speculatively executed, Load-Acquire
The counter counts memory-read operations with acquire or acquirepc semantics that are speculatively executed.

0x0091, RC_ST_SPEC, Release consistency operation speculatively executed, Store-Release
The counter counts memory-write operations with release semantics that are speculatively executed.

0x00A0, L3D_CACHE_RD, Attributable Level 3 data or unified cache access, read
This event is similar to Attributable Level 3 data or unified cache access, L3D_CACHE, but the counter counts only attributable memory read operations that cause a cache access to at least the Level 3 data or unified cache.

0x00A1, L3D_CACHE_WR, Attributable Level 3 data or unified cache access, write
This event is similar to Attributable Level 3 data or unified cache access, L3D_CACHE, but the counter counts only attributable memory write operations that cause a cache access to at least the Level 3 data or unified cache.

0x00A2, L3D_CACHE_REFILL_RD, Attributable Level 3 data or unified cache refill, read
This event is similar to Attributable Level 3 data or unified cache refill, L3D_CACHE_REFILL, but the counter counts only attributable memory read operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3 cache. See also Relationship between REFILL events and associated access events. on page K3-8017.

0x00A3, L3D_CACHE_REFILL_WR, Attributable Level 3 data or unified cache refill, write
This event is similar to Attributable Level 3 data or unified cache refill, L3D_CACHE_REFILL, but the counter counts only attributable memory write operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3 cache. See also Relationship between REFILL events and associated access events. on page K3-8017.
0x00A6, L3D_CACHE_WB_VICTIM, Attributable Level 3 data or unified cache Write-Back, victim

This event is similar to Attributable Level 3 data cache Write-Back, L3D_CACHE_WB, but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

If FEAT_PMUv3p4 is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x00A7, L3D_CACHE_WB_CLEAN, Level 3 data or unified cache Write-Back, cache clean

This event is similar to Attributable Level 3 data cache Write-Back, L3D_CACHE_WB, but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

--- Note ---
The transfer of a dirty cache line from the Level 3 data cache of this PE to the Level 3 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

--- Note ---
If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x00A8, L3D_CACHE_INV, Attributable Level 3 data or unified cache access, invalidate

The counter counts each invalidation of a cache line in the Level 3 data or unified cache.

The counter does not count events if a cache refill invalidates a line.

If FEAT_PMUv3p4 is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

--- Note ---
Software that uses this event must know whether the Level 3 data cache is shared with other PEs. This event does not follow the general rule of Level 3 data cache events of only counting Attributable events.

K3.1.1 Relationship between REFILL events and associated access events.

CACHE_REFILL and TLB_REFILL events count the refills for accesses that are counted by the corresponding CACHE or TLB event. Table K3-2 shows this correspondence.

<table>

Note

The Glossary defines the term *Taken locally*, that is used in event definitions in this chapter. See also *Exception levels* on page D1-2312 for more information.
Appendix K4
Recommendations for Reporting Memory Attributes on an Interconnect

This appendix describes the Arm recommendations for reporting the memory attributes that are assigned by the PE. It contains the following section:

- *Arm recommendations for reporting memory attributes on an interconnect* on page K4-8022.
K4.1  Arm recommendations for reporting memory attributes on an interconnect

The Arm architecture defines the architectural interface between software and the PE hardware. This means the mechanisms by which different memory type and Cacheability attributes are presented on an interface to an interconnect fabric such as AMBA® AXI are, strictly, outside the scope of the architecture. This appendix describes an approach for the interface between a PE implementation and an interconnect fabric that Arm strongly recommends, but these recommendations do not form part of the Armv8 architecture.

K4.1.1 Effect of microarchitectural choices on memory attributes

Implementations of the Arm architecture permit considerable variability in the presentation of memory attributes on the interconnect fabric, particularly in cases where the PE implementation does not provide optimized support for a memory type. For example, an implementation might treat Write-Through locations as Non-cacheable at some level of cache, because functionally this is consistent with the definition of Write-Through, but for the particular implementation the performance trade-off does not merit the hardware directly providing Write-Through capability. However, in such implementations, the assigned memory attributes are not changed by the microarchitectural choices. The microarchitecture simply implements different ways of handling some memory attributes.

Therefore, Arm strongly recommended that where any or all of the following memory attributes are presented on the interface between a PE and an interconnect fabric, the attributes that are presented are completely consistent with the attributes defined by the translation system:

- The memory type, Normal or Device.
- The Early write acknowledgement attribute.
- The ordering requirements.
- The Shareability.
- The Cacheability, including where practicable, the allocation hints.

Effect when memory accesses are forced to be Non-cacheable

Arm also strongly recommends that the effects of forcing accesses to Normal memory to be Non-cacheable, as described in Enabling and disabling the caching of memory accesses on page D4-2497 for AArch64 and in Enabling and disabling the caching of memory accesses in AArch32 state on page G4-5933 for AArch32, are reflected on the interconnect by the memory type and attributes used for memory transactions generated while the cache is disabled.
Appendix K5
Additional Information for Implementations of the Generic Timer

This appendix gives additional information about implementations of the Generic Timer. It contains the following sections:

• Providing a complete set of features in a system level implementation on page K5-8024.
• Gray-count scheme for timer distribution scheme on page K5-8026.
K5.1 Providing a complete set of features in a system level implementation

As an example system design, using memory-mapped Generic Timer components as described in Chapter 12 System Level Implementation of the Generic Timer, the feature set of a System registers counter and timer, in an implementation that includes Non-secure EL2 and EL3, can be implemented using the following set of timer frames:

- A CNTCTRLBase control frame.
- The following CNTBaseN timer frames:
  - **Frame 0** Accessible by Non-secure accesses, with second view and virtual capability. This provides the Non-secure EL1&0 timers.
  - **Frame 1** Accessible by Non-secure accesses, with no second view and no virtual capability. This provides the Non-secure EL2 timers.
  - **Frame 2** Accessible only by Secure accesses, with a second view but no virtual capability. This provides the Secure PL1&0 timers, meaning:
    - Compared to a PE where EL3 is using AArch32, it provides the only Secure state timer.
    - Compared to a PE where EL3 is using AArch64, it provides the Secure EL1&0 timer.
  - **Frame 3** Accessible only by Secure accesses, with no second view and no virtual capability. This provides the Secure EL3 timers.

--- Note ---

This frame is not required for a memory-mapped timer that provides only the feature set of a PE for which EL3 is using AArch32.

In this implementation, the full set of implemented frames, and accessibility as memory pages in the different translation regimes, is as follows:

**CNTCTRLBase**

The control frame. This frame is accessible in both the Secure and Non-secure memory maps, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

**CNTBase0**

The first view of the Non-secure EL1&0 timers. This frame is accessible only in the Non-secure memory map, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

**CNTEL0Base0**

The second view of CNTBase0, meaning it is the EL0 view of the Non-secure EL1&0 timers. This frame is accessible only in the Non-secure memory map, and:

- In the Secure EL1&0 translation regime, the architecture permits this frame to be accessible at EL1, or at EL1 and EL0, but does not require either of these options.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.

**CNTBase1**

The first and only view of the Non-secure EL2 timers. This frame is accessible only in Non-secure memory map, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- In the Non-secure EL2 translation regime, this frame is accessible.
• In the Non-secure EL1&0 translation regime, this frame is not accessible.

**CNTBase2**
The first view of the Secure EL1&0, or PL1&0 timers.

--- **Note** ---
In AArch64 state, these timers are always called the Secure EL1&0 timers. In AArch32 state they are usually called the Secure PL1&0 timers because, in AArch32 Secure state, whether some of the PE modes map to EL1 or to EL3 depends on whether EL3 is using AArch64 or is using AArch32, see *Security state, Exception levels, and AArch32 execution privilege* on page G1-5722.

This frame is accessible only in the Secure memory map, and:
• When EL3 is using AArch64:
  — In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  — In the Secure EL3 translation regime, this frame is accessible.
• When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
• Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

**CNTEL0Base2**
The second view of CNTBase2, meaning it is the EL0 view of the Secure EL1&0, or PL1&0, timers.

--- **Note** ---
See the Note in the description of the CNTBase2 frame for more information about the naming of these timers.

This frame is accessible only in the Secure memory map, and:
• When EL3 is using AArch64:
  — In the Secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.
  — In the Secure EL3 translation regime, this frame is accessible.
• When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible at PL1 (EL3) and EL0.
• Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

**CNTBase3**
The first and only view of the EL3 timers. This frame is accessible only in the Secure memory map, and:
• When EL3 is using AArch64:
  — In the Secure EL1&0 translation regime, this frame is not accessible.
  — In the Secure EL3 translation regime, this frame is accessible.
• When EL3 is using AArch32, this frame is not accessible.
• Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

--- **Note** ---
*About the Virtual Memory System Architecture (VMSA)* on page D5-2526 describes the VMSAv8-64 translation regimes, and *About VMSAv8-32* on page G5-5962 describes the VMSAv8-32 translation regimes.
K5.2 Gray-count scheme for timer distribution scheme

The distribution of the Counter value using a Gray-code provides a relatively simple mechanism to avoid any danger of the count being sampled with an intermediate value even if the clocking is asynchronous. It has a further advantage that the distribution is relatively low power, since only one bit changes on the main distribution wires for each clock tick.

A suitable Gray-coding scheme can be achieved with the following logic:

\[
\begin{align*}
\text{Gray}[N] &= \text{Count}[N] \\
\text{Gray}[i] &= (\text{XOR}(\text{Gray}[N:i+1])) \text{ XOR Count}[i] \text{ for } N-1 \geq i \geq 0 \\
\text{Count}[i] &= (\text{XOR}(\text{Gray}[N:i])) \text{ for } N \geq i \geq 0
\end{align*}
\]

This is for an \( N+1 \) bit counter, where Count is a conventional binary count value, and Gray is the corresponding Gray count value.

--- Note ---

This scheme has the advantage of being relatively simple to switch, in either direction, between operating with low-frequency and low-precision, and operating with high-frequency and high-precision. To achieve this, the ratio of the frequencies must be \( 2^n \), where \( n \) is an integer. A switch-over can occur only on the \( 2n+1 \) boundary to avoid losing the Gray-coding property on a switch-over.
Appendix K6
Legacy Instruction Syntax for AArch32 Instruction Sets

This appendix describes the legacy instruction syntax in the Arm instruction sets, and their Unified Assembler Language (UAL) equivalents. It contains the following section:

• Legacy Instruction Syntax on page K6-8028.
K6.1 Legacy Instruction Syntax

Early versions of the Arm Architecture defined an assembly language for A32 (ARM) instructions, and a separate assembly language for T32 (Thumb) instructions. UAL is based on the A32 assembly language, with some changes to the instruction syntax. The appendix describes those changes. The pre-UAL mnemonics are compatible with UAL, and might be supported by an assembler.

The original T32 assembly language is not compatible with UAL, and is not described in the manual.

K6.1.1 Pre-UAL instruction syntax for the A32 base instructions

Table K6-1 lists the syntax for the A32 base instructions that have changed after UAL was introduced.

K6.1.3 FCONST

The syntax of FCONST is

FCONST<dest>{<c>} <Fd>, #<imm8>
where:

<dest> Specifies the destination data type. It must be one of:

S Single-precision floating-point.
D Double-precision floating-point.

<c> This is an optional field. It specifies the condition under which the instruction is executed. See Conditional execution on page F2-4121 for the range of available conditions and their encoding. If <c> is omitted, it defaults to always (AL).

<Fd> Specifies the destination register. It must be one of:

<d> 64-bit name of the SIMD&FP destination register.
<s> 32-bit name of the SMID&FP destination register.

<imm8> Specifies the immediate value used to generate the floating-point constant.

FCONST{<c>} <d>, #<imm8> maps to VMOV.F64 <d>, #<fpimm>
FCONST{<c>} <s>, #<imm8> maps to VMOV.F32 <s>, #<fpimm>
Appendix K7
Address Translation Examples

This appendix gives examples of address translations using the translation regimes described in Chapter D5 The AArch64 Virtual Memory System Architecture and Chapter G5 The AArch32 Virtual Memory System Architecture. It contains the following sections:

• AArch64 Address translation examples on page K7-8036.
• AArch32 Address translation examples on page K7-8048.

Note
This chapter gives examples of translation table lookups for the Armv8 address translation stages. It does not define any part of the address translation mechanism. If any information in this appendix appears to contradict the information in Chapter D5 The AArch64 Virtual Memory System Architecture or Chapter G5 The AArch32 Virtual Memory System Architecture then the information in Chapter D5 or Chapter G5 must be taken as the definition of the required behavior.
Figure D5-1 on page D5-2536 shows the VMSAv8 address translation stages that are controlled by an Exception level that is using AArch64. The VMSAv8-64 address translation system on page D5-2534 describes the VMSAv8-64 address translation scheme. This section gives examples of the use of that scheme, for common translation requirements.

System registers relevant to MMU operation on page D5-2541 specifies the relevant registers, including the TCR_ELx and TTBR_ELx, or TTBR_ELxs, for each stage of address translation.

For any stage of translation, a TCR_ELx.TnSZ field indicates the supported input address size. For a stage of address translation controlled from an Exception level using AArch64, the supported input address size is 2^(64-TnSZ).

This section describes:

• Performing the initial lookup, for an address for which the initial lookup is either:
  — At the highest lookup level used for the appropriate translation granule size.
  — Because of the concatenation of translation tables at the initial lookup level, one level down from the highest level used for the translation granule size.

These descriptions take account of the following cases:

— The IA size is smaller than the largest size for the translation level, see Reduced IA width on page D5-2553.
— For a stage 2 translation, translation tables are concatenated, to move the initial lookup level down by one level, see Concatenated translation tables on page D5-2554.

For examples of performing the initial lookup, see Examples of performing the initial lookup.

• The full translation flow for resolving a page of memory. These examples describe resolving the largest IA size supported by the initial lookup level. For these examples, see Full translation flows for VMSAv8-64 address translation on page K7-8042.

K7.1.1 Examples of performing the initial lookup

The address ranges used for the initial translation table lookup depend on the translation granule, as described in:

• Performing the initial lookup using the 4KB translation granule.
• Performing the initial lookup using the 16KB granule on page K7-8038.
• Performing the initial lookup using the 64KB translation granule on page K7-8040.

Performing the initial lookup using the 4KB translation granule

This subsection describes examples of the initial lookup when using the 4KB translation granule that Table D5-13 on page D5-2560 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in The VMSAv8-64 address translation system on page D5-2534.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-13 on page D5-2560 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

• Initial lookup at level 0, 4KB translation granule on page K7-8037.
• Initial lookup at level 1, 4KB translation granule on page K7-8037.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see Overview of stage 2 translations, 4KB granule on page D5-2560.
**Initial lookup at level 0, 4KB translation granule**

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). As Table D5-13 on page D5-2560 shows, a stage 1 or stage 2 initial lookup at level 0 is required when \(39 \leq n \leq 47\). For these lookups:

- \(TTBR_{-ELx}[47:(n-35)]\) specify the translation table base address.
- \(Bits[n:39]\) of the input address are \(bits[(n-36):3]\) of the descriptor offset in the translation table.

--- Note ---

This means that, when the input address width is less than 48 bits:

- The size of the translation table is reduced.
- More low-order bits of the \(TTBR_{-ELx}\) are required to specify the translation table base address.
- Fewer input address bit are used to specify the descriptor offset in the translation table.

For example, if the input address width is 46 bits:

- The translation table size is 1KB.
- \(TTBR_{-ELx}\) bits\([47:10]\) specify the translation table base address.
- Input address bits\([45:39]\) specify \(bits[9:3]\) of the descriptor offset.

Figure K7-1 shows this lookup.

---

**Initial lookup at level 1, 4KB translation granule**

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\).

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D5-13 on page D5-2560 shows, this applies to \(IA[n:0]\), where \(30 \leq n \leq 38\). For these lookups:

- There is a single translation table at this level.
- \(TTBR_{-ELx}[47:(n-26)]\) specify the translation table base address.
- \(Bits[n:30]\) of the input address are \(bits[(n-27):3]\) of the descriptor offset in the translation table.

Figure K7-2 on page K7-8038 shows this lookup.
Address Translation Examples
K7.1 AArch64 Address translation examples

As Table D5-13 on page D5-2560 shows, this applies to IA[n:0], where 39 ≤ n ≤ 42. For these lookups:
• There are 2^{(n-38)} concatenated translation tables at this level.
• These concatenated translation tables must be aligned to 2^{(n-38)}×4KB. This means TTBR_ELx[(n-27):12] must be zero.
• TTBR_ELx[47:(n-26)] specify the base address of the block of concatenated translation tables.
• Bits[n:30] of the input address are bits[(n-27):3] of the descriptor offset from the base address of the block of concatenated translation tables.

---

As Table D5-13 on page D5-2560 shows, this applies to IA[n:0], where 39 ≤ n ≤ 42. For these lookups:
• There are 2^{(n-38)} concatenated translation tables at this level.
• These concatenated translation tables must be aligned to 2^{(n-38)}×4KB. This means TTBR_ELx[(n-27):12] must be zero.
• TTBR_ELx[47:(n-26)] specify the base address of the block of concatenated translation tables.
• Bits[n:30] of the input address are bits[(n-27):3] of the descriptor offset from the base address of the block of concatenated translation tables.

---

Performing the initial lookup using the 16KB granule

This subsection describes examples of the initial lookup when using the 16KB translation granule that Table D5-15 on page D5-2563 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in The VMSAv8-64 address translation system on page D5-2534.
Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-15 on page D5-2563 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:
- **Initial lookup at level 0, 16KB translation granule.**
- **Initial lookup at level 1, 16KB translation granule.**

In all cases, for a stage 2 translation, the **VTCR_EL2.SL0** field must indicate the required initial lookup level, and this level must be consistent with the value of the **VTCR_EL2.T0SZ** field, see **Overview of stage 2 translations, 16KB granule** on page D5-2563.

**Initial lookup at level 0, 16KB translation granule**

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). As Table D5-14 on page D5-2562 shows, the only case where an address translation using the 16KB granule starts at level 0 is a stage 1 translation of a 48-bit input address, \(IA[47:0]\). For this lookup:

- The required translation table has only two entries, meaning its size is 16 bytes, and it must be aligned to 16 bytes.
- \(TTBR_ELx[47:4]\) specify the translation table base address.

Figure K7-4 shows this lookup.

**Initial lookup at level 1, 16KB translation granule**

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables:

As Table D5-15 on page D5-2563 shows, this applies to \(IA[n:0]\), where \(36 \leq n \leq 46\). For these lookups:

- There is a single translation table at this level.
- \(TTBR_ELx[47:(n-32)]\) specify the translation table base address.
- Bits[n:36] of the input address are bits[(n-33):3] of the descriptor offset in the translation table.

Figure K7-5 on page K7-8040 shows this lookup.
**Address Translation Examples**

**K7.1 AArch64 Address translation examples**

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D5-15 on page D5-2563 shows, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address, IA[47:0]. For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to 2×16KB. This means TTBR_ELx[14] must be zero.
- TTBR_ELx[47:15] specify the base address of the block of two concatenated translation tables.
- Bits[47:36] of the input address are bits[14:3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K7-6 shows this lookup.

Supported input address range is IPA[47:0]. The bit marked † must be zero.

* Field has additional properties to the default RES0 definition, see the register description for more information.

† For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor.

**Figure K7-5 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, without concatenation**

**Performing the initial lookup using the 64KB translation granule**

This subsection describes examples of the initial lookup when using the 64KB translation granule that Table D5-17 on page D5-2567 shows as starting at level 1 or at level 2. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 2. This means that it gives specific examples of the mechanisms described in The VMSAv8-64 address translation system on page D5-2534.
Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-17 on page D5-2567 shows as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.

The following subsections describe these examples of the initial lookup:

- Initial lookup at level 1, 64KB translation granule.
- Initial lookup at level 2, 64KB translation granule.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.TOSZ field, see Overview of stage 2 translations, 64KB granule on page D5-2567.

Initial lookup at level 1, 64KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(\text{IA}[n:0]\). As Table D5-17 on page D5-2567 shows, a stage 1 or stage 2 initial lookup at level 1 is required when \(42 \leq n \leq 47\). For these lookups:

- The size of the translation table is \(2^{(n-39)}\) bytes. This means the size of the translation table, at this level, is always less than the granule size. The address of this translation table must align to the size of the table.
- Bits\([n:42]\) of the input address are bits\([n-39:3]\) of the descriptor offset in the translation table.
- Bits\([47:(n-38)]\) of the TTBR_ELx specify the translation table base address.

Figure K7-7 shows this lookup.

Initial lookup at level 2, 64KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(\text{IA}[n:0]\). For a stage 1 or stage 2 initial lookup at level 2, without the use of concatenated translation tables

As Table D5-17 on page D5-2567 shows, this applies to \(\text{IA}[n:0]\), where \(29 \leq n \leq 41\). For these lookups:

- There is a single translation table at this level.
- \(\text{TTBR}_{-}\text{ELx}[47:(n-25)]\) of the specify the translation table base address.
- Bits\([n:29]\) of the input address are bits\([n-26:3]\) of the descriptor offset in the translation table.

Figure K7-8 on page K7-8042 shows this lookup.
Address Translation Examples
K7.1 AArch64 Address translation examples

Figure K7-8 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, without concatenation

For a stage 2 initial lookup at level 2, with concatenated translation tables

As Table D5-17 on page D5-2567 shows, this applies to IA[n:0], where 42 ≤ n ≤ 45. For these lookups:
• There are 2(m-41) concatenated translation tables at this level.
• These concatenated translation tables must be aligned to 2(m-41)×64KB. This means TTBR_ELx[(n-26):16] must be zero.
• TTBR_ELx[47:(n-25)] specify the base address of the block of translation tables.
• Bits[n:42] of the input address are bits[(n-26):16] of the descriptor offset from the base address of the block of translation tables.

Figure K7-9 shows this lookup.

Figure K7-9 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation

K7.1.2 Full translation flows for VMSAv8-64 address translation

In a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR_ELx. Subsequent lookups use a combination of address information from:
• The table descriptor read in the previous lookup.
• The input address.

This section describes example full translation flows, from the initial lookup to the address of a memory page. The example flows:
• Resolve the maximum-sized IA range supported by the initial lookup level.
• Do not have any concatenation of translation tables.
• Cover only the 4KB and the 64KB translation granules.

Examples of performing the initial lookup on page K7-8036 described how either reducing the IA range or concatenating translation tables affects the initial lookup.

Note
Reducing the IA range or concatenating translation tables affects only the initial lookup.

The following sections describe full VMSAv8-64 translation flows, down to an entry for a memory page:
• The address and properties fields shown in the translation flows.
• Full translation flow using the 4KB granule and starting at level 0.
• Full translation flow using the 4KB granule and starting at level 1 on page K7-8045.
• Full translation flow using the 64KB granule and starting at level 1 on page K7-8046.
• Full translation flow using the 64KB granule and starting at level 2 on page K7-8047.

The address and properties fields shown in the translation flows
For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state:
• Any descriptor address is the IPA of the required descriptor.
• The final output address is the IPA of the block or page.

In these cases, an EL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D5-2593.

Full translation flow using the 4KB granule and starting at level 0

Figure K7-10 on page K7-8044 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure, see The address and properties fields shown in the translation flows.
Figure K7-10 Complete stage 1 translation of a 48-bit address using the 4KB translation granule

If the level 1 lookup or level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-10 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.
Full translation flow using the 4KB granule and starting at level 1

Figure K7-11 shows the complete translation flow for a stage 1 translation table walk for a 39-bit input address. This lookup must start with a level 1 lookup. For more information about the fields shown in the figure, see The address and properties fields shown in the translation flows on page K7-8043.

For details of Properties fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K7-11 Complete stage 1 translation of a 39-bit address using the 4KB translation granule**

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-11 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-10 on page K7-8044, shows how the translation for the 42-bit address start the same lookup process one stage later.
Full translation flow using the 64KB granule and starting at level 1

Figure K7-10 on page K7-8044 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure, see The address and properties fields shown in the translation flows on page K7-8043.

For details of Properties fields, see the register or descriptor description.

Figure K7-12 Complete stage 1 translation of a 48-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-12 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

The level 1 lookup resolves only 6 bits of the input address. As described in Performing the initial lookup using the 64KB translation granule on page K7-8040, this means:

- The translation table size for this level is only 512 bytes.
- The required translation table alignment for this level is 512 bytes.
- The Base address field in the TTBR_ELx is extended, at the low-order end, to be bits[47:9].
Full translation flow using the 64KB granule and starting at level 2

Figure K7-11 on page K7-8045 shows the complete translation flow for a stage 1 translation table walk for a 42-bit input address. This lookup must start with a level 2 lookup. For more information about the fields shown in the figure, see The address and properties fields shown in the translation flows on page K7-8043.

Figure K7-13 Complete stage 1 translation of a 42-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-13 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-12 on page K7-8046, shows:

- The translation for the 42-bit address starts the same lookup process one stage later.
- Because the initial lookup resolves 13 bits of address:
  - The translation table size for this level is 64KB.
  - The required translation table alignment for this level is 64KB.
  - The Base address field in the TTBR_ELx is bits[47:16].
K7.2 AArch32 Address translation examples

The following sections give address translation examples for the VMSAv8-32 address translation formats:

- Address translation examples using the VMSAv8-32 Short descriptor translation table format.
- Address translation examples using the VMSAv8-32 Long descriptor translation table format on page K7-8053.

K7.2.1 Address translation examples using the VMSAv8-32 Short descriptor translation table format

VMSAv8-32 Short-descriptor translation table format descriptors on page G5-5980 describes the memory section and page option for a single VMSAv8-32 address translation. The following sections show the full translation flow for each of these options:

- Translation flow for a Supersection.
- Translation flow for a Section on page K7-8049.
- Translation flow for a Large page on page K7-8050.
- Translation flow for a Small page on page K7-8051.

The address and Properties fields shown in the translation flows on page K7-8052 summarizes the information returned by the lookup.

Translation flow for a Supersection

Figure K7-14 on page K7-8049 shows the complete translation flow for a Supersection. For more information about the fields shown in this figure, see The address and Properties fields shown in the translation flows on page K7-8052.
Figure K7-14 VMSAv8-32 Short-descriptor Supersection address translation

Note

Figure K7-14 shows how, when the input address, the VA, addresses a Supersection, the top four bits of the Supersection index bits of the address overlap the bottom four bits of the Table index bits. For more information, see Additional requirements for Short-descriptor format translation tables on page G5-5983.

Translation flow for a Section

Figure K7-15 on page K7-8050 shows the complete translation flow for a Section. For more information about the fields shown in this figure, see The address and Properties fields shown in the translation flows on page K7-8052.
Translation flow for a Large page

Figure K7-15 on page K7-8051 shows the complete translation flow for a Large page. For more information about the fields shown in this figure, see The address and Properties fields shown in the translation flows on page K7-8052.
Figure K7-16 VMSAv8-32 Short-descriptor Large page address translation

For a translation based on TTBR0, N is the value of TTBCR.N
For a translation based on TTBR1, N is 0
For details of Properties fields, see the register or descriptor description

Figure K7-16 shows how, when the input address, the VA, addresses a Large page, the top four bits of the page index bits of the address overlap the bottom four bits of the level 1 table index bits. For more information, see Additional requirements for Short-descriptor format translation tables on page G5-5983.

Translation flow for a Small page

Figure K7-17 shows the complete translation flow for a Small page. For more information about the fields shown in this figure, see The address and Properties fields shown in the translation flows.
The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation tables:
• Any descriptor address is the IPA of the required descriptor.
• The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information, see Information returned by a translation table lookup on page G5-5975, and the description of the register or translation table descriptor.

‡ This field is absent if N is 0
L1 = Level 1, L2 = Level 2
For a translation based on TTBR0, N is the value of TTBCR.N
For a translation based on TTBR1, N is 0
For details of Properties fields, see the register or descriptor description.

Figure K7-17 VMSAv8-32 Short-descriptor Small page address translation
For translations using the Short-descriptor translation table format, *VMSAv8-32 Short-descriptor translation table format descriptors on page G5-5980* describes the descriptors formats.

**K7.2.2 Address translation examples using the VMSAv8-32 Long descriptor translation table format**

As described in *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G5-6003*, in a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

The following sections give examples of full VMSAv8-32 Long-descriptor format address translation flows, down to an entry for a 4KB page:

- *Full translation flow, starting at level 1 lookup.*
- *Full translation flow, starting at level 2 lookup on page K7-8055.*

*The address and Properties fields shown in the translation flows on page K7-8052* summarizes the information returned by the lookup.

**Full translation flow, starting at level 1 lookup**

*Figure K7-18 on page K7-8054* shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a level 1 lookup. For more information about the fields shown in the figure, see *The address and Properties fields shown in the translation flows on page K7-8052.*
Figure K7-18 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 1

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

If bits[47:40] of the TTBR or the descriptor are not zero then the lookup will generate an Address size fault, see Address size fault on page G5-6054.

A stage 2 translation that starts at a level 1 lookup differs from the translation shown in Figure K7-18 only as follows:

- The possible values of \( n \) are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.
**Full translation flow, starting at level 2 lookup**

Figure K7-19 shows the complete translation flow for a stage 1 VMSAv8-32 Long-descriptor translation table walk that starts at a level 2 lookup. For more information about the fields shown in the figure, see *The address and Properties fields shown in the translation flows* on page K7-8052.

For details of *Properties* fields, see the register or descriptor description.

‡ See the lookup description for more information about bits[40:47] of the TTBR and descriptors

---

**Figure K7-19 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 2**

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

If bits[47:40] of the TTBR or the descriptor are not zero then the lookup will generate an Address size fault, see *Address size fault* on page G5-6054.

A stage 2 translation that starts at a level 2 lookup differs from the translation shown in Figure K7-19 only as follows:

- The possible values of \( n \) are 7-16, to support an input address of up to 34 bits.
- The descriptor and output addresses are always PAs.

**The address and Properties fields shown in the translation flows**

For the Non-secure PL1\&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, a PL1\&0 stage 2 translation is performed to translate the IPA to the required PA.
For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information, see Information returned by a translation table lookup on page G5-5975, and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5989 describes the descriptors formats.
Appendix K8
Example OS Save and Restore Sequences

This appendix provides possible OS Save and Restore sequences for a v8A Debug implementation. It contains the following sections:

- Save Debug registers on page K8-8058.
- Restore Debug registers on page K8-8060.
K8.1 Save Debug registers

This section shows how to save the registers that are used by an external debugger.

; On entry, X0 points to a block to save the debug registers in.
; Returns the pointer beyond the block and corrupts X1-X3

SaveDebugRegisters
; (1) Set OS lock.
  MOV  X2,#1               ; Set the OS lock. In AArch64 state, the OS lock
  MSR  OSLAR_EL1,X2        ; is writable via OSLAR.
  ISB                           ; Context synchronization event

; (2) Walk through the registers, saving them
  MRS  X1,OSDTRRX_EL1        ; Read DTRRX
  MRS  X2,OSDTRTX_EL1        ; Read DTRTX

K8.2 Restore Debug registers
Appendix K9
Recommended Upload and Download Processes for External Debug

This appendix contains the following section:
• Using memory access mode in AArch64 state on page K9-8064.

Note
This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might find this information useful.
K9.1 Using memory access mode in AArch64 state

Figure K9-1 and Figure K9-2 on page K9-8065 show the processes for using memory access mode to implement a download (external host to target) and an upload (target to external host).

To transfer \( n \) words of data:
- The download sequence needs \( n+6 \) accesses by the external debug interface.
- The upload sequence needs \( n+8 \) accesses by the external debug interface.

In both cases, in the innermost loop the debugger can make an external access to a DTR without polling EDSCR after each write as underrun and overrun detection prevent failure. Normally external accesses from the debugger are outpaced by the memory accesses of the PE, making underruns and overruns unlikely. If this is not the case, the EDSCR.ERR flag is set to 1. This is checked once at the end of the sequence, although a debugger can check it more often, for example once for each page. If the EDSCR.ERR flag is set to 1 because of overrun or underrun, the debugger can restart. The address to restart from is frozen in X0. EDSCR.ERR might also be set because of a Data abort.

If underruns and overruns are common, the debugger can pace itself accordingly.

---

**Note**

- The base address must be a multiple of 4.
- The order of the writes that set up the address does not matter in Debug state.

---

![Figure K9-1 Fast code download in AArch64 state (external host to target)](image-url)
In Figure K9-1 on page K9-8064, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.
   b. Write address [63:32] to DBGDTRTX_EL0.
   c. Write MRS X0, DBGDTR_EL0 to EDITR. The PE executes this instruction.
   d. Set EDSCR.MA to 1.

2. Loop \( n \) times. From the external debug interface:
   a. Write to DBGDTRRX_EL0. The PE reads the word from DTRRX and stores it to memory. It increments X0 by 4.

3. Epilogue. From the external debug interface:
   a. Clear EDSCR.MA to 0.
   b. Read EDSCR to check for overruns or Data Aborts during download.

---

**Figure K9-2 Fast data upload in AArch64 state (target to external host)**

In Figure K9-2, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.
b. Write address [63:32] to DBGDTRTX_EL0.
c. Write MRS X0, DBGDTR_EL0 to EDITR.
d. Write MSR DBGDTR_EL0, X0 to EDITR. This dummy operation ensures EDSCR.TXfull == 1.
e. Set EDSCR.MA to 1.
f. Read DBGDTRTX_EL0 and discard the value. The PE returns the previous DTR value, loads the first word, and writes it to DTR. It increments X0 by 4.

2. Loop \(n-1\) times. From the external debug interface:
   a. Read DBGDTRTX_EL0. The PE returns the previous DTRTX value, loads a new word, and writes it to DTRTX. It increments X0 by 4.

3. Epilogue. From the external debug interface:
   a. Clear EDSCR.MA to 0.
   b. Read DBGDTRTX_EL0 for the \(n\)th value.
   c. Read EDSCR to check for underruns, overruns or Data Aborts during upload.
Appendix K10
Software Usage Examples

This appendix gives software usage examples, for cases where these are likely to contribute significantly to an understanding of the Arm architecture.

It contains the following sections:

• Use of the Advanced SIMD complex number instructions on page K10-8068.
• Use of the Armv8.2 extensions to the Cryptographic Extension on page K10-8070.
K10.1 Use of the Advanced SIMD complex number instructions

FEAT_FCMA provides instructions to aid floating-point computations of complex numbers. This section illustrates the use of these instructions for complex arithmetic. It is not part of the Arm architecture definition.

This section uses the AArch64 instructions FCADD and FCMLA - usage of the AArch32 instructions VCCADD and VCMUL is similar.

When using the instructions implemented by FEAT_FCMA, a complex numbers is represented in a SIMD&FP register as a pair of adjacent elements, each holding a floating-point number, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number.

K10.1.1 Complex addition

Simple complex addition on a vector of complex numbers is already provided by the vector form of the FADD instruction.

The functionality that FCADD adds is to rotate each complex number in the second vector by 90 degrees or 270 degrees counterclockwise (considering the complex numbers on an Argand diagram) before performing the addition. Mathematically, this is equivalent to multiplying the second complex number by i or -i before addition.

This means, given a complex number z stored in a pair of elements in one vector, and a complex number w stored in the corresponding element pair in another vector:

- FADD calculates $z + w$.
- FCADD calculates $z \pm iw$.

K10.1.2 Complex multiplication

The FCMLA instruction does not provide functionality for complex multiplication directly. However, a pair of FCMLA instructions can provide this function.

The FCMLA instruction operates on corresponding pairs of complex numbers stored in SIMD&FP vector registers, and adds the result to the corresponding complex number in the destination SIMD&FP vector register. This computation is as follows:

1. The second complex number is rotated by 0, 90, 180 or 270 degrees counterclockwise.
2. That complex number is multiplied by either the real or imaginary part of the first complex number:
   - When the rotation is 0 or 180 degrees, the real part is used.
   - When the rotation is 90 or 270 degrees, the imaginary part is used.
3. The resulting complex number is added to the corresponding complex number in the destination register.

Mathematically, considering the complex numbers on an Argand diagram:

- Rotation by 180 degrees is equivalent to negation.
- Rotation by 90 degrees is equivalent to multiplying by i.
- Rotation by 270 degrees is equivalent to multiplying by -i.

This means that, for a first complex number $z$, where $z = a + bi$, and a second complex number $w$, if initially the corresponding complex number in the destination register is zero:

- When the rotation is 0 degrees the result of the multiply-add is $aw$.
- When the rotation is 180 degrees, the result is -$aw$.
- When the rotation is 90 degrees, the result is $biw$.
- When the rotation is 270 degrees, the result is -$biw$. 
This means that, if the destination register is zeroed and an FCMLA instruction is executed with a rotation parameter of 0, and then the same instruction is executed with a rotation parameter of 90:

- The first execution returns aw in the destination register.
- The second execution accumulates biw to this, meaning the result is aw+biw.
- This result is the product of (a+bi)w, which is the product zw.

So, this pair of instructions can be used to implement complex multiplication.

After zeroing V0, the syntax of a pair of instructions to perform this complex number multiplication might be:

```
FCMLA V0.4S, V1.4S, V2.4S, #0
FCMLA V0.4S, V1.4S, V2.4S, #90
```

Other simple pairs of FCMLA instructions perform useful computations. For example, considering a first complex number z and second complex number w, defined as before, and a destination register that has been zeroed before the first FCMLA instruction is executed:

1. The following pair of instructions calculates the complex conjugate of z multiplied by w.
   
   ```
   FCMLA V0.4S, V1.4S, V2.4S, #0
   FCMLA V0.4S, V1.4S, V2.4S, #270
   ```

2. The following pair of instructions calculates the negation of z multiplied by w.

   ```
   FCMLA V0.4S, V1.4S, V2.4S, #180
   FCMLA V0.4S, V1.4S, V2.4S, #270
   ```

3. The following pair of instructions calculates the negation of the complex conjugate of z multiplied by w.

   ```
   FCMLA V0.4S, V1.4S, V2.4S, #180
   FCMLA V0.4S, V1.4S, V2.4S, #90
   ```

--- **Note** ---

For these examples, the following caveats must be considered:

- **FCMLA** performs a fused multiply-add, meaning there is no intermediate rounding. This lack of intermediate rounding can give unexpected results in some cases. Arm expects that these instructions are only used in situations where the effect of the rounding of these results is not material to the calculation.

- When using the FCMLA instructions, the behavior of (∞+∞i) multiplied by (0+i) is (NaN+NaNi), rather than the result expected by ISO C, which is complex ∞.
K10.2 Use of the Armv8.2 extensions to the Cryptographic Extension

K10.2.1 Use of the SHA512 instructions

These instructions are implemented when FEAT_SHA512 is implemented.

The following code sequence shows the use of the SHA512 instructions to calculate a SHA512 hash iteration of 80 rounds. This code is not fully optimized.

```
// X0 contains the pointer to the bottom of the (padded) 16*64 bytes of message to be
// hashed, with space above the that message to hold a further 64 * 64 bytes of working
// data
// X1 contains the pointer to the 0th element of 80 64-bit constants (in ascending addresses) defined in
// the SHA2 specification
// X2 contains a loop variable
// V4,V5,V6, V7 hold VS0 to VS3 respectively
// V8 holds running hash V1
// V9 holds running hash V0

MOVB X2, #0
loop1:
    LD1 {V0.2D}, [X0]          // Data
    LD1 {V1.2D}, [X1]          // K values
    ADD X1, X1, #16

    ADD V7.2D, V7.2D, V2.2D
    SHA512H Q7, Q8, V9.2D
```

K10.2 Use of the Armv8.2 extensions to the Cryptographic Extension

K10.2.2 Use of the SHA3 instructions

These instructions are implemented when FEAT_SHA3 is implemented.

The following code sequence shows the use of the SHA3 instructions to obtain the combined theta, phi, rho and chi operations of a SHA3 iteration. Arm expects the iota operation to be performed using a lookup table.

This code is not fully optimized for multiple iterations.

```assembly
// Input State:
// // x=0  x=1  x=2  x=3  x=4
// y=0  v12  v13  v14  v10  v11
// y=1  v7   v8   v9   v5   v6
// y=2  v2   v3   v4   v0   v1
// y=3  v22  v23  v24  v20  v21
// y=4  v17  v18  v19  v15  v16

Appendix K11
Barrier Litmus Tests

This appendix gives examples of the use of the barrier instructions provided by the Armv8 architecture. It contains the following sections:

- *Introduction* on page K11-8078.
- *Using a mailbox to send an interrupt* on page K11-8090.
- *Cache and TLB maintenance instructions and barriers* on page K11-8091.
- *Armv7 compatible approaches for ordering, using DMB and DSB barriers* on page K11-8103.

--- Note ---

This information is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.
K11.1 Introduction

The exact rules for the insertion of barriers into code sequences is a very complicated subject, and this appendix describes many of the corner cases and behaviors that are possible in an implementation of the Armv8 architecture.

This appendix is to help programmers, hardware design engineers, and validation engineers understand the need for the different kinds of barriers.

K11.1.1 Overview of memory consistency

Early generations of microprocessors were relatively simple processing engines that executed each instruction in program order. In such processors, the effective behavior was that each instruction was executed in its entirety before a subsequent instruction started to be executed. This behavior is sometimes referred to as the Sequential Execution Model (SEM), and in this Manual it is described as Simple sequential execution of the program.

In later processor generations, the needs to increase processor performance, both in terms of the frequency of operation and the number of instructions executed each cycle, mean that such a simple form of execution is abandoned. Many techniques, such as pipelining, write buffering, caching, speculation, and out-of-order execution, are introduced to provide improved performance.

For general purpose PEs, such as Arm, these microarchitectural innovations are largely hidden from the programmer by a number of microarchitectural techniques. These techniques ensure that, within an individual PE, the behavior of the PE largely remains the same as the SEM. There are some exceptions to this where explicit synchronization is required. In the Arm architecture, these are limited to cases such as:

- Synchronization of changes to the instruction stream.
- Synchronization of changes to System registers.

In both these cases, the ISB instruction provides the necessary synchronization.

While the effect of ordering is largely hidden from the programmer within a single PE, the microarchitectural innovations have a profound impact on the ordering of memory accesses. Write buffering, speculation, and cache coherency protocols, in particular, can all mean that the order in which memory accesses occur, as seen by an external observer, differs significantly from the order of accesses that would appear in the SEM. This is usually invisible in a uniprocessor environment, but the effect becomes much more significant when multiple PEs are trying to communicate with memory. In reality, these effects are often only significant at particular synchronization boundaries between the different threads of execution.

The problems that arise from memory ordering considerations are sometimes described as the problem of memory consistency. Processor architectures have adopted one or more memory consistency models, or memory models, that describe the permitted limits of the memory re-ordering that can be performed by an implementation of the architecture. The comparison and categorization of these has generated significant research and comment in academic circles, and Arm recommends the Memory Consistency Models for Shared Memory-Multiprocessors paper as an excellent detailed treatment of this subject.

This appendix does not reproduce such a work, but instead concentrates on some cases that demonstrate the features of the weakly-ordered memory model of the Arm architecture from Armv6. In particular, the examples show how the use of the DMB and DSB memory barrier instructions can provide the necessary safeguards to limit memory ordering effects at the required synchronization points.

K11.1.2 Barrier operation definitions

The following reference, or provide, definitions of terms used in this appendix:

- **DMB** See Data Memory Barrier (DMB) on page B2-135.
- **DSB** See Data Synchronization Barrier (DSB) on page B2-138.
- **ISB** See Instruction Synchronization Barrier (ISB) on page B2-135.
- **Observer, Completion** See Definition of the Armv8 memory model on page B2-123. 
  See Completion and endpoint ordering on page B2-130.
Barrier Litmus Tests

K11.1 Introduction

Program order

The order of instructions as they appear in an assembly language program. This appendix does not attempt to describe or define the legal transformations from a program written in a higher level programming language, such as C or C++, into the machine language that can then be disassembled to give an equivalent assembly language program. Such transformations are a function of the semantics of the higher level language and the capabilities and options on the compiler.

K11.1.3 Conventions

Many of the examples are written in a stylized extension to Arm assembler, to avoid confusing the examples with unnecessary code sequences.

AArch32

The construct \texttt{WAIT([Rx]==1)} describes the following sequence:

\begin{verbatim}
loop
  LDR R12, [Rx]
  CMP R12, #1
  BNE loop
\end{verbatim}

Also, the construct \texttt{WAIT_ACQ([Rx]==1)} describes the following sequence:

\begin{verbatim}
loop
  LDA R12, [Rx] ; load acquire ensures it is ordered before subsequent loads/stores
  CMP R12, #1
  BNE loop
\end{verbatim}

R12 is chosen as an arbitrary temporary register that is not in use. It is named to permit the generation of a false dependency to ensure ordering.

AArch64

The construct \texttt{WAIT([Xx]==1)} describes the following sequence:

\begin{verbatim}
loop
  LDR W12, [Xx]
  CMP W12, #1
  B.NE loop
\end{verbatim}

Also, the construct \texttt{WAIT_ACQ([Xx]==1)} describes the following sequence:

\begin{verbatim}
loop
  LDAR W12, [Xx] ; load acquire ensures it is ordered before subsequent loads/stores
  CMP W12, #1
  B.NE loop
\end{verbatim}

For each example, a code sequence is preceded by an identifier of the observer running it:

- \texttt{P0, P1…P}\textsubscript{x} refer to caching coherent PEs that implement the Armv8 architecture and are in the same shareability domain.
- \texttt{E0, E1…E}\textsubscript{x} refer to non-caching observers that do not participate in the coherency protocol, but execute Armv8 instructions and have a weakly ordered memory model. This does not preclude these observers being different objects, such as DMA engines or other system Requesters.

These observers are unsynchronized other than as required by the documented code sequence.

Note

Throughout this appendix, \textit{Armv8 instruction} and \textit{instruction} refer to instructions from the A64, A32, or T32 instruction set, provided by Armv8 implementations.
Results are expressed in terms of $\langle\text{agent}\rangle:R:\langle\text{register}\rangle$, such as $P0:R5$. The results can be described as:

**Permissible**
This does not imply that the results expressed are required or are the only possible results. In most cases they are results that would not be possible under a sequentially consistent running of the code sequences on the agents involved. In general terms, this means that these results might be unexpected to anyone unfamiliar with memory consistency issues.

**Not permissible**
Results that the architecture expressly forbids.

**Required**
Results that the architecture expressly requires.

The examples omit the required shareability domain arguments of DMB and DSB instructions. The arguments are assumed to be selected appropriately for the shareability domains of the observers.

In AArch32 state, where the barrier function in the litmus test can be achieved by a DMB ST, that is a barrier to stores only, this is shown by the use of DMB [ST]. This indicates that the ST qualifier can be omitted without affecting the result of the test. In some implementations DMB ST is faster than DMB.

For AArch64 code, the shareability domain of the DMB or DSB must be included. This is shown in this manual using the notation DMB $\langle\text{domain}\rangle$ and DSB $\langle\text{domain}\rangle$ respectively.

Except where otherwise stated, other conventions are:

- All memory initializes to 0.
- R0 and W0 contain the value 1.
- R1 - R4 and W1 - W4 contain arbitrary independent addresses that initialize to the same value on all PEs. The addresses held in these registers are shareable and:
  - The addresses held in R1 and R2 are in Write-Back Cacheable Normal memory.
  - The address held in R3 is in Write-Through Cacheable Normal memory.
  - The address held in R4 is in Non-cacheable Normal memory.
- R5 - R8 and W5 - W8 contain:
  - When used with an STR instruction, 0x55, 0x66, 0x77, and 0x88 respectively.
  - When used with an LDR instruction, the value 0.
- R11 and W11 contain a new instruction or new translation table entry, as appropriate, and R10 contains the virtual address and the ASID, for use in this change of translation table entry.
- Memory locations are Normal memory locations unless otherwise stated.

The examples use mnemonics for the cache maintenance and TLB maintenance instructions. The following tables describe the mnemonics:

- *Cache maintenance system instructions* on page K15-8210.
- *TLB maintenance system instructions* on page K15-8211.
K11.2  Load-Acquire, Store-Release and barriers

The Load-Acquire and Store-Release instructions are described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-139.

The following sections show that most of the examples in sections Simple ordering and barrier cases on page K11-8103 and Load-Exclusive, Store-Exclusive and barriers on page K11-8107 can be achieved using the Load-Acquire and Store-Release instructions without the need for additional barriers.

K11.2.1  Message passing

The following sections describe:

- Resolving weakly-ordered message passing by using Acquire and Release.
- Resolving message passing by the use of Store-Release and address dependency on page K11-8082.

Resolving weakly-ordered message passing by using Acquire and Release

The message passing problem described in Weakly-ordered message passing problem on page K11-8103 can be solved by the use of Load-Acquire and Store-Release instructions when accessing the communications flag:

AArch32

P1

```
STR R5, [R1] ; sets new data
STL R0, [R2] ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([[R2]==1]) ; waits on flag
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1] ; sets new data
STLR W0, [X2] ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([[X2]==1]) ; waits on flag
LDR W5, [X1]
```

This ensures the observed order of both the reads and the writes allows transfer of data such that the result P2:R5==0x55 is guaranteed.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT_ACQ([[R2]==1]) ; waits on flag
LDR R5, [R1]
```

AArch64

P3

```
WAIT_ACQ([[X2]==1]) ; waits on flag
LDR W5, [X1]
```
Resolving message passing by the use of Store-Release and address dependency

The lack of ordering of stores discussed in Message passing with multiple observers on page K11-8104 can be resolved by the use of Store-Release for the store of the valid flag by P1, even when the observers are using an address dependency:

**AArch32**

P1

```
STR R5, [R1] ; sets new data
STL R0, [R2] ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
: and so is ordered after the flag has been seen
```

**AArch64**

P1

```
STR W5, [X1] ; sets new data
STLR W0, [X2] ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([X2]==1)
AND W12, W12, WZR ; W12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12] ; the load has an address dependency on W12
: and so is ordered after the flag has been seen
```

This ensures the observed order of the writes allows transfer of data such that P2:R5 and P3:R5 contain the same value of 0x55.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

**AArch32**

P3

```
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
: and so is ordered after the flag has been seen
```

**AArch64**

P3

```
WAIT([X2]==1)
AND W12, W12, WZR ; W12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12] ; the load has an address dependency on W12
: and so is ordered after the flag has been seen
```
### K11.2.2 Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object. A Store-Release can be used to ensure the order of the update of the base address:

**AArch32**

```asm
P1
    STR R5, [R1, #offset] ; sets new data in a field
    STL R1, [R2]         ; updates base address

P2
    LDR R1, [R2]         ; reads base address
    CMP R1, #0           ; checks if it is valid
    BEQ null_trap
    LDR R5, [R1, #offset] ; uses base address to read field
```

**AArch64**

```asm
P1
    STR W5, [X1, #offset] ; sets new data in a field
    STLR X1, [X2]         ; updates base address

P2
    LDR X1, [X2]         ; reads base address
    CMP X1, #0           ; check if it is valid
    B.EQ null_trap
    LDR W5, [X1, #offset] ; uses base address to read field
```

It is required that P2:R5==0x55 if the null_trap is not taken. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not need a barrier to ensure this behavior.

The read of the base address in P2 could be a Load-Acquire, but it is not necessary in this case.
**K11.2.3 WFE and WFI and barriers**

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. An explicit DSB barrier instruction is required if it is necessary to ensure memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in *Posting a store before polling for acknowledgement* on page K11-8106, or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

**AArch32**

P1

```assembly
STR R0, [R2]
DSB
Loop
    WFI
    B Loop
```

**AArch64**

P1

```assembly
STR W0, [X2]
DSB <domain>
Loop
    WFI
    B Loop
```

This requirement is unchanged in Armv8 by the presence of Load-Acquire or Store-Release.
K11.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

The Armv8 architecture adds the acquire and release semantics to Load-Exclusive and Store-Exclusive instructions, which allows them to gain ordering acquire and/or release semantics.

The Load-Exclusive instruction can be specified to have acquire semantics, and the Store-Exclusive instruction can be specified to have release semantics. These can be arbitrarily combined to allow the atomic update created by a successful Load-Exclusive and Store-Exclusive pair to have any of:

• No Ordering semantics (using LDREX and STREX).
• Acquire only semantics (using LDAEX and STREX).
• Release only semantics (using LDREX and STLEX).
• Sequentially consistent semantics (using LDAEX and STLEX).

In addition, the Armv8 specification requires that the clearing of a global monitor will generate an event for the PE associated with the global monitor, which can simplify the use of wFE, by removing the need for a DSB barrier and SEV instruction.

K11.3.1 Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

Note

The inclusion of AArch32 PLDW instructions or AArch64 PFRM PSTL instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

For a critical region, the requirement on taking a lock is usually for acquire semantics, while the clearing of a lock requires release semantics:

AArch32

```
Px
  PLDW[R1] ; preload into cache in unique state
Loop
  LDAEX R5, [R1] ; read lock with acquire
  CMP R5, #0 ; check if 0
  STREXEQ R5, R0, [R1] ; attempt to store new value
  CMPEQ R5, #0 ; test if store succeeded
  BNE Loop ; retry if not
```

; loads and stores in the critical region can now be performed

AArch64

```
Px
  PRFM PSTLKEEP, [X1] ; preload into cache in unique state
Loop
  LDAXR W5, [X1] ; read lock with acquire
  CBNZ W5, Loop ; check if 0
  STXR W5, W0, [X1] ; attempt to store new value
  CBNZ W5, Loop ; test if store succeeded and retry if not
```

; loads and stores in the critical region can now be performed

The acquire associated with the load is sufficient to ensure the required ordering in a lock situation. The Store-Exclusive will fail (and so be retried) if there is a store to the location being monitored between the Load-Exclusive and the Store-Exclusive.
K11.3.2  Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, the lock release needs release semantics:

**AArch32**

```assembly
Px

; loads and stores in the critical region
MOV R0, #0
STL R0, [R1] ; clear the lock with release semantics
```

**AArch64**

```assembly
Px

; loads and stores in the critical region
STLR WZR, [X1] ; clear the lock with release semantics
```

K11.3.3  Ticket locks

When a lock is free, in order to avoid a rush to get the lock by many PEs, the use of ticket locks is common in more advanced systems. When the use is requested, the ticket locks determine the order of the users of the critical sections, in order to avoid starvation that can occur with a simple contention based spin lock.

A ticket lock allocates each thread a ticket number when it first requests the lock, and then compares that number with the current number for the lock. If they are the same, then the critical section can be entered. Otherwise the thread waits until the current number is equal to the ticket number for that thread.

The reading of the current number of the lock needs acquire semantics for the lock to be acquired.

--- Note ---

- The code in this section is little-endian code, as it views the combined current and next values as a single combined quantity. The addresses of the current and next ticket values need to be adjusted for a big-endian system.
- The inclusion of AArch32 `PLDW` instructions or AArch64 `PFRM PST*` instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

---

This is shown in the implementation below:

**AArch32**

```assembly
Px

; R1 holds two 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PLDW[R1] ; preload into cache in unique state
Loop1

LDAEX R5, [R1] ; read current and next
ADD R5, R5, #0x10000 ; increment the next number
STREX R6, R5, [R1] ; and update the value
CMP R6, #0 ; did the exclusive pass
BNE Loop1 ; retry if not

CMP R5, R5, ROR #16 ; is the current ticket ours
BEQ block_start

Loop2

LDAH R6, [R1] ; read current value
```
CMP R6, R5, LSR #16 ; compare it with our allocated ticket
BNE Loop2 ; retry (spin) if it is not the same

block_start

AArch64

Px

; X1 holds 2 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop1
  LDAXR W5, [X1] ; read current and next
  ADD W5, W5, #0x10000 ; increment the next number
  STXR W6, W5, [X1] ; and update the value
  CBNZ W6, Loop1 ; did the exclusive pass - retry if not

  AND W6, W5, #0xFFFF
  CMP W6, W5, LSR #16 ; is the current ticket ours
  B.EQ block_start

Loop2
  LDARH W6, [X1] ; read current value
  CMP W6, W5, LSR #16 ; compare it with our allocated ticket
  B.NE Loop2 ; retry (spin) if it isn’t the same

block_start

Releasing the ticket lock simply involves incrementing the current ticket number, that is still assumed to be in R3, and doing a Store-Release:

AArch32

  ADD R6, R6, #1
  STLH R6, [R1]

AArch64

  ADD W6, W6, #1
  STLRH W6, [X1]

K11.3.4 Use of Wait For Event (WFE) and Send Event (SEV) with locks

The Armv8 architecture can use the Wait For Event mechanism to minimise the energy cost of polling variables by putting the PE into a low power state, suspending execution, until an asynchronous exception or an explicit event is seen by that PE. In Armv8, the event can be generated as a result of clearing the global monitor, so removing the need for a DSB barrier or an explicit send event message.

This can be used with simple locks or with ticket locks.

--- Note ---

The inclusion of AArch32 PLDW instructions or AArch64 PRFM PST* instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

---

Simple lock

The following is an example of lock acquire code using WFE:

AArch32

Px
Barrier Litmus Tests
K11.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

```
PLDW[R1]              ; preload into cache in unique state
Loop
  LDAEX R5, [R1]        ; read lock with acquire
  CMP R5, #0            ; check if 0
  WFE                   ; sleep if the lock is held
  STREXEQ R5, R0, [R1]  ; attempt to store new value
  CMP EQ R5, #0         ; test if store succeeded
  BNE Loop              ; retry if not

AArch64
Px
  SEVL                  ; invalidates the WFE on the first loop iteration
  PRFM PSTLKEEP, [X1]   ; allocate into cache in unique state
Loop
  WFE                   
  LDAXR W5, [X1]        ; read lock with acquire
  CBNZ W5, Loop         ; check if 0
  STXR W5, W0, [X1]     ; attempt to store new value
  CBNZ W5, Loop         ; test if store succeeded and retry if not

; loads and stores in the critical region can now be performed

And the following is an example of lock release code:

AArch32
Px
  ; loads and stores in the critical region
  MOV R0, #0             
  STL R0, [R1]           ; clear the lock

AArch64
Px
  ; loads and stores in the critical region
  STLR WZR, [X1]         ; clear the lock

Ticket lock

In the Ticket lock case, the Load-Exclusive instruction can be used to move the monitor into the exclusive state for
the express purpose of creating an event when the monitor changes state:

AArch32
Px
  ; R1 holds 2 16 bit quantities
  ; the lower halfword holds the current ticket number
  ; the higher halfword holds the next ticket number
  PLDW[R1]              ; preload into cache in unique state
Loop1
  LDAEX R5, [R1]        ; read current and next
  ADD R5, R5, #0x10000   ; increment the next number
  STREX R6, R5, [R1]    ; and update the value
  CMP R6, #0            ; did the exclusive pass
  BNE Loop              ; retry if not
  CMP R5, R5, ROR #16   ; is the current ticket ours
  BEQ block_start
  SEVL
Loop2
  WFE                   ; wait if there has not been a change to the count since last
```

block_start
K11.4 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

**AArch32**

P1

```
STR R5, [R1]          ; message stored to shared memory location
DSB ST
STR R0, [R4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

**AArch64**

P1

```
STR W5, [X1]          ; message stored to shared memory location
DSB ST
STR W0, [X4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR W5, [X1]
```
K11.5 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- Data cache maintenance instructions.
- Instruction cache maintenance instructions on page K11-8095.
- TLB maintenance instructions and barriers on page K11-8098.

K11.5.1 Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- Message passing to non-caching observers.
- Multiprocessing message passing to non-caching observers.
- Invalidating DMA buffers, non-functional example on page K11-8092.
- Invalidating DMA buffers, functional example with single PE on page K11-8093.
- Invalidating DMA buffers, functional example with multiple coherent PEs on page K11-8094.

Message passing to non-caching observers

The Armv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. The Load-Acquire and Store-Release instructions have no effect on cache maintenance instruction. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

AArch32

P1

  STR R5, [R1]          ; updates data (assumed to be in P1 cache)
  DCCMVAC R1            ; cleans cache to point of coherency
  DMB                   ; ensures effects of the clean will be observed before the
                         ; flag is set
  STR R0, [R4]          ; sends flag to external agent (Non-cacheable location)

E1

  WAIT_ACQ ([R4] == 1)  ; waits for the flag (with order)
  LDR R5, [R1]          ; reads the data

AArch64

P1

  STR W5, [X1]          ; updates data (assumed to be in P1 cache)
  DC CVAC, X1           ; cleans cache to point of coherency
  DMB ISH               ; ensures effects of the clean will be observed before the
                         ; flag is set
  STR W0, [X4]          ; sends flag to external agent (Non-cacheable location)

E1

  WAIT_ACQ ([X4] == 1)  ; waits for the flag (with order)
  LDR W5, [X1]          ; reads the data

In this example, it is required that E1:R5==0x55.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions combined with properties of barriers, means that the message passing principle for non-caching observers is:

AArch32

P1
STR R5, [R1]          ; updates data (assumed to be in P1 cache)
STL R0, [R2]          ; sends a flag for P2 (ordered by the store release)

P2
WAIT ([R2] == 1)      ; waits for P1 flag
DMB                   ; ensures cache clean is observed after P1 flag is observed
DCCMVAC R1            ; cleans cache to point of coherency – will clean P1 cache
DMB                   ; ensures effects of the clean will be observed before the
; flag to E1 is set
STR R0, [R4]          ; sends flag to E1

E1
WAIT_ACQ ([R4] == 1)  ; waits for P2 flag (ordered)
LDR R5, [R1]          ; reads data

AArch64

P1
STR WS, [X1]          ; updates data (assumed to be in P1 cache)
STLR W0, [X2]         ; sends a flag for P2 (ordered)

P2
WAIT ([X2] == 1)      ; waits for P1 flag
DMB SY                ; ensure cache clean is observed after P1 flag is observed
DC CVAC, X1           ; cleans cache to point of coherency, will clean P1 cache
DMB SY                ; ensures effects of the clean will be observed before the
; flag to E1 is set
STR W0, [X4]          ; sends flag to E1

E1
WAIT_ACQ ([X4] == 1)  ; waits for P2 flag
LDR WS, [X1]          ; reads data

In this example, it is required that E1::R5==0x55. The clean operation executed by P2 affects the data location in the
P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Note
The cache maintenance instructions are not ordered by the Load-Acquire and Store-Release instructions.

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable
memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute
can be allocated into a cache at any time, for example as a result of speculation. The following example shows this
possibility:

AArch32

P1
DCIMVAC R1            ; ensures cache is not dirty. A clean operation could be used
; but as the DMA will subsequently overwrite this region an
; invalidate operation is sufficient and usually more efficient
DMB                   ; ensures cache invalidation is observed before the next store
; is observed
STR R0, [R3]          ; sends flag to external agent
WAIT_ACQ ([R4]==1)    ; waits for a different flag from an external agent
LDR R5, [R1]          ; reads data
WAIT ([R3] == 1) ; waits for flag
STR R5, [R1] ; stores new data
STL R0, [R4] ; sends a flag

AArch64

P1

DC IVAC, X1 ; ensure cache is not dirty. A clean operation could be used ; but as the DMA will subsequently overwrite this region an
; invalidate operation is sufficient and usually more efficient
DMB SY ; ensures cache invalidation is observed before the next store
; is observed
STR W0, [X3] ; sends flag to external agent
WAIT_ACQ ([X4]==1) ; waits for a different flag from an external agent
LDR W5, [X1]

E1

WAIT ([X3] == 1) ; waits for flag
STR W5, [X1] ; stores new data
STLR W0, [X4] ; sends a flag

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

AArch32

P1

DCIMVAC R1 ; ensures cache is not dirty. A clean operation could be used ; but as the DMA will subsequently overwrite this region an
; invalidate operation is sufficient and usually more efficient
DMB ; ensures cache invalidation is observed before the next store
; is observed
STR R0, [R3] ; sends flag to external agent
WAIT ([R4]==1) ; waits for a different flag from an external agent
DMB ; from external agent is observed
DCIMVAC R1 ; ensures cache discards stale copies before use
LDR R5, [R1]

E1

WAIT ([R3] == 1) ; waits for flag
STR R5, [R1] ; stores new data
STL R0, [R4] ; sends a flag

AArch64

P1

DC IVAC, X1 ; ensure cache is not dirty. A clean operation could be used ; but as the DMA will subsequently overwrite this region an
; invalidate operation is sufficient and usually more efficient
DMB SY ; ensures cache invalidation is observed before the next store
; is observed
STR W0, [X3] ; sends flag to external agent
WAIT ([X4]==1) ; waits for a different flag from an external agent
DMB SY ; from external agent is observed
DC IVAC, X1 ; ensures cache discards stale copies before use
LDR W5, [X1]

E1
WAIT ([X3] == 1)      ; waits for flag
STR W5, [X1]          ; stores new data
STLR W0, [X4]         ; sends a flag

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of 
DMB  instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

AArch32

P0

(Use data from [R1], potentially using [R1] as scratch space)
STL R0, [R2]          ; signals release of [R1]
WAIT_AQO ([R2] == 0)  ; waits for new value from DMA
LDR R5, [R1]

P1

WAIT ([R2] == 1)      ; waits for release of [R1] by P0
DCIMVAC R1            ; ensures caches are not dirty, an invalidate is sufficient
DMB
STR R0, [R3]          ; requests new data for [R1]
WAIT ([R4] == 1)      ; waits for new data
DMB
DCIMVAC R1            ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]          ; signals availability of new [R1]

E1

WAIT ([R3] == 1)      ; waits for new data request
STR R5, [R1]          ; sends new [R1]
DMB [ST]
STR R0, [R2]          ; indicates that new data is available to P1

AArch64

P0

(Use data from [X1], potentially using [X1] as scratch space)
STLR W0, [X2]         ; signals release of [X1]
WAIT_AQO ([X2] == 0)  ; waits for new value from DMA
LDR W5, [X1]

P1

WAIT ([X2] == 1)      ; waits for release of [R1] by P0
DC IVAC, X1           ; ensures caches are not dirty, an invalidate is sufficient
DMB SY
STR W0, [X3]          ; requests new data for [R1]
WAIT ([X4] == 1)      ; waits for new data
DMB SY
DCIMVAC X1            ; ensures caches discard stale copies before use
DMB SY
STR WZR, [X2]         ; signals availability of new [R1]

E1

WAIT ([X3] == 1)      ; waits for new data request
STR W5, [X1]          ; sends new [R1]
STR W0, [X4]          ; indicates new data is available to P1
In this example, the result P0.R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

K11.5.2 Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- Ensuring the visibility of updates to instructions for a uniprocessor.
- Ensuring the visibility of updates to instructions for a multiprocessor.

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

**AArch32**

\[
\begin{align*}
&\text{P1} \\
&\text{STR R11, [R1]} \quad ; \text{R11 contains a new instruction to be stored in program memory} \\
&\text{DCCMVNU R1} \quad ; \text{clean to PoU makes the new instruction visible to the instruction cache} \\
&\text{DSB} \quad ; \text{ensures instruction cache/branch predictor discards stale data} \\
&\text{ICMVMVNU R1} \quad ; \text{ensures completion of the invalidation} \\
&\text{BPIMVNU R1} \quad ; \text{ensures instruction fetch path sees new instruction cache state} \\
&\text{DSB} \quad ; \text{ensures completion of the invalidation} \\
&\text{ISB} \quad ; \text{ensures instruction fetch path sees new instruction cache state} \\
&\text{BX R1} \\
\end{align*}
\]

In AArch64 state, the branch predictor maintenance is not required.

**AArch64**

\[
\begin{align*}
&\text{P1} \\
&\text{STR W11, [X1]} \quad ; \text{W11 contains a new instruction to be stored in program memory} \\
&\text{DC CVNU, X1} \quad ; \text{clean to PoU makes the new instruction visible to instruction cache} \\
&\text{DSB ISH} \quad ; \text{ensures instruction cache/branch predictor discards stale data} \\
&\text{IC IVNU, X1} \quad ; \text{ensures completion of the invalidation} \\
&\text{DSB ISH} \quad ; \text{ensures instruction fetch path sees new instruction cache state} \\
&\text{ISB} \quad ; \text{ensures instruction fetch path sees new instruction cache state} \\
&\text{BR X1} \\
\end{align*}
\]

__Note__

Where the changes to the instructions span multiple cache lines, then the data cache and instruction cache maintenance instructions can be duplicated to cover each of the lines to be cleaned and to be invalidated.

__Note__

Ensuring the visibility of updates to instructions for a multiprocessor

The Armv8 architecture requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:
AArch32

P1

STR R11, [R1] ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB ; ensures completion of the clean on all PEs
ICIMVAU R1 ; ensures instruction cache discards stale data
BPIMVA R ; ensures branch predictor discards stale data
DSB ; ensures completion of the instruction cache and branch predictor
; invalidation on all PEs
STR R0, [R2] ; sets flag to signal completion
ISB ; synchronizes context on this PE
BX R1 ; branches to new code

P2-Px

WAIT ([R2] == 1) ; waits for flag signalling completion
ISB ; synchronizes context on this PE
BX R1 ; branches to new code

AArch64

P1

STR X11, [X1] ; X11 contains a new instruction to be stored in program memory
DC CVAU, X1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB ISH ; ensures completion of the clean on all PEs
IC IVAU, X1 ; ensures instruction cache/branch predictor discards stale data
DSB ISH ; ensures completion of the instruction cache/branch predictor
; invalidation on all PEs
STR W0, [X2] ; sets flag to signal completion
ISB ; synchronizes context on this PE
BR R1 ; branches to new code

P2-Px

WAIT ([X2] == 1) ; waits for flag signalling completion
ISB ; synchronizes context on this PE
BR X1 ; branches to new code

Nonfunctional approach

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance instructions that other PEs issue:

AArch32

P1

STR R11, [R1] ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB ; ensures completion of the clean on all PEs
ICIMVAU R1 ; ensures instruction cache discards stale data
BPIMVA R ; ensures branch predictor discards stale data
DMB ; ensures ordering of the store after the invalidation
; DOES NOT guarantee completion of instruction cache/branch
; predictor on other PEs
STR R0, [R2] ; sets flag to signal completion
DSB ; ensures completion of the invalidation on all PEs
ISB ; synchronizes context on this PE
BX R1 ; branches to new code

P2-Px

WAIT ([R2] == 1) ; waits for flag signalling completion
DSB ; this DSB does not guarantee completion of P1
; ICIMVAU/BPIMVA
ISB
BX R1
AArch64

P1

STR W11, [X1]          ; W11 contains a new instruction to be stored in program memory
DC CVAU, X1           ; clean to PoU makes the new instruction visible to instruction cache
DSB ISH               ; ensures completion of the clean on all PEs
IC IVAU, X1           ; ensures instruction cache/branch predictor discards stale data
DMB ISH               ; ensures ordering of the store after the invalidation
; DOES NOT guarantee completion of instruction cache/branch
; predictor on other PEs
STR W0, [X2]          ; sets flag to signal completion
DSB ISH               ; ensures completion of the invalidation on all PEs
ISB                   ; synchronizes context on this PE
BR X1                 ; branches to new code

P2-Px

WAIT ([X2] == 1)      ; waits for flag signalling completion
DSB ISH               ; this DSB does not guarantee completion of P1
; ICIMVAU/BPIMVA
ISB
BR X1

In this example, P2…Px might not see the updated region of code at R1.
K11.5.3 TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- Ensuring the visibility of updates to translation tables for a uniprocessor.
- Ensuring the visibility of updates to translation tables for a multiprocessor.
- Paging memory in and out on page K11-8099.
- Using break-before-make when updating translation table entries on page K11-8100.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

The Armv8 architecture requires that translation table walks look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

**AArch32**

```
P1
STR R11, [R1] ; updates the translation table entry
DSB ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB ; ensures completion of the BP and TLB invalidation
ISB ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

**AArch64**

```
P1
STR X11, [X1] ; updates the translation table entry
DSB ISH ; ensures visibility of the update to translation table walks
TLBI VAE1, X10 ; assumes we are in the EL1
DSB ISH ; ensures completion of the TLB invalidation
ISB ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. The Armv8 architecture requires a PE that executes a TLB maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.
The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

**Paging memory in and out**

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

**AArch32**

P1

```assembly
STR R11, [R1] ; updates the translation table entry
DSB ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB ; ensures completion of the BP and TLB invalidation
ISB ; Note ISB is not broadcast and must be executed locally
; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed
```

**AArch64**

P1

```assembly
STR X11, [X1] ; updates the translation table entry
DSB ISH ; ensures visibility of the update to translation table walks
TLB VAE1IS, X10
DSB ISH ; ensures completion of the TLB invalidation
ISB ; Note ISB is not broadcast and must be executed locally
; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed
```

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

**AArch32**

P1

```assembly
STR R11, [R1] ; updates the translation table entry
DSB ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
DSB ; invalidates the old entry
ISB ; ensures completion of the invalidation on all PEs
ISB ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ; ensures completion of the memory transfer (this could be part of
; LoadMemoryFromBackingStore)
ICIALLUIS ; also invalidates the branch predictor
DSB ; ensures completion of the instruction cache
; and branch predictor invalidation
STR R9, [R1] ; creates a new translation table entry with a new mapping
DSB ; ensures visibility of the new translation table mapping
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of SaveMemoryPageToBackingStore and LoadMemoryFromBackingStore. LoadMemoryFromBackingStore is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of IC IALLUIS in AArch32 state and IC IALLUIS in AArch64 state to invalidate the entire instruction cache is a simplification that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU in AArch32 state and IC IVAU operations in AArch64 state. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

**Using break-before-make when updating translation table entries**

The Arm Architecture requires that reads to the same location are observed in order, and since application level software relies on this behavior, the operating system needs to maintain this illusion when it is changing a virtual to physical address mapping for a location, as is the case with copy on write or other memory management techniques. This illusion can be maintained provided that the software uses a break-before-make sequence when updating translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation entries involves any of:

- Changing the memory type.
- Changing the cacheability attributes
- Changing the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable.

The architecture requires use of a break-before make sequence in these situations, see *Using break-before-make when updating translation table entries* on page D5-2662 for more information. However, if software did not use a break-before-make approach, an implementation might give a result that would occur if the two reads to the same virtual address did not occur in program order. An example of such an occurrence would be an implementation of copy-on-write, where one PE is performing two reads to the same virtual address at the same time as a second PE, running code associated with the operating system, is copying the data from one physical location that is mapped to by that virtual address, where the page was mapped as read-only, to a different physical location which will be mapped as read-write.

If the operating system changed the address mapping without going through an invalid entry, then it would be possible for a third PE to perform a write to the location that would be seen by the first load by the first PE, and not seen by the second load by the same PE.

The required break-before-make code sequence in this case is:

**AArch32**
P1

; R1, R2 contain an invalid translation table entry (that is, one with bit[0] == 0)
; R3 contains the address of the translation table entry
; R4 contains the Virtual Address and ASID of the VA being remapped
; R5, R6 contain the new valid translation table entry
STRD R1, R2, [R3]          ; stores invalid entry
DSB ISH                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R4               ; invalidates the old entry
DSB ISH                    ; ensures completion of the invalidation on all PEs
ICIALLUIS                  ; also invalidates the branch predictor
STRD R5, R6, [R3]          ; store new mapping
DSB ISH                    ; ensures visibility of the update to translation table walks
ISB                         ; ensures synchronisation of this instruction stream

--- Note ---
This example shows an update to an entry in a translation table that is using the long-descriptor format.

AArch64

P1

; X1 contains an invalid translation table entry (that is, one with bit[0] == 0)
; X2 contains the address of the translation table entry
; X3 contains the Virtual Address and ASID of the VA being remapped
; X4 contains the new valid translation table entry
STR X1, [X2]              ; stores invalid entry
DSB ISH                   ; ensures visibility of the update to translation table walks
TLBIVAEIIS, X3           ; invalidates the old entry
DSB ISH                   ; ensures completion of the invalidation on all PEs
IC IALLUIS                ; also invalidates the branch predictor
STR X4, [X2]              ; store new mapping
DSB ISH                   ; ensures visibility of the update to translation table walks
ISB                       ; ensures synchronisation of this instruction stream

If this sequence is correctly followed, then the architecture guarantees that the loads to a virtual address being remapped will be seen in the correct order.

The instruction cache maintenance is only required if the mapping from input address to output address has been changed as part of the change of the translation table entries, and the memory being moved is executable. In this example, the use of ICIALLUIS in AArch32 state and IC IALLUIS in AArch64 state to invalidate the entire instruction cache is a simplification that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU in AArch32 state, and IC IVAU in AArch64 state. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

K11.5.4 Ordering of Memory-mapped device control with payloads

With a Memory-mapped peripheral, such as a DMA, which can also access memory for its own use, it is common to have control or status registers which are Memory-mapped. These registers need to be accessed in an ordered manner with respect to the data that the Memory-mapped peripheral is handling.

Two simple examples of this are:

• When a processing element is writing a buffer of data, and then writing to a control register in the DMA peripheral to start that peripheral to access the buffer of data.

• When a DMA peripheral has written to a buffer of data in memory, and the processing element is reading a status register to determine that the DMA transfer has completed, and then is reading the data.

For the case of the processing element writing a buffer of data, before starting the DMA peripheral, the ordering requirements between the stores to the data buffer and the stores to the Memory-mapped a to the DMA peripheral can be met by the insertion of a DSB <domain> instruction between these sets of accesses as this ensures the global observation of the stores before the DMA is started. this is shown by the following code:

AArch32
For the case of DMA peripheral writing the data buffer and then setting a status register when those stores are complete (and so globally observed) and then having this status register polled by the processing element before the processing element reads the data buffer, the processing element must insert a DSB <domain> between the load that reads the status register, and the read of the buffer. A DMB, or load-acquire, is not sufficient as this problem is not solely concerned with observation order, since the polling read is actually a read of a status register at a Completer, not the polling a data value that has been written by an observer.

For this case, the code is therefore:

**AArch32**

```
P1
WAIT ([R4] == 1) ; R4 contains the address of the status register,
                   ; and the value '1' indicates completion of the DMA transfer
DSB
LDR R5, [R2] ; reads data from the data buffer
```

**AArch64**

```
P1
WAIT ([X4] == 1) ; X4 contains the address of the status register,
                   ; and the value '1' indicates completion of the DMA transfer
DSB <domain>
LDR W5, [X2] ; reads data from the data buffer
```
K11.6 Armv7 compatible approaches for ordering, using DMB and DSB barriers

The following sections describe the Armv7 compatible approaches for ordering, using DMB and DSB barriers:

- Simple ordering and barrier cases.
- Load-Exclusive, Store-Exclusive and barriers on page K11-8107.
- Using a mailbox to send an interrupt on page K11-8109.
- Cache and TLB maintenance instructions and barriers on page K11-8109.

K11.6.1 Simple ordering and barrier cases

Arm implements a weakly consistent memory model for Normal memory. In general terms, this means that the order of memory accesses observed by other observers might not be the order that appears in the program, for either loads or stores.

This section includes examples of this.

Simple weakly consistent ordering example

P1

```
STR R5, [R1]
LDR R6, [R2]
```

P2

```
STR R6, [R2]
LDR R5, [R1]
```

In the absence of barriers, the result of P1: R6=0, P2: R5=0 is permissible.

Message passing

The following sections describe:

- Weakly-ordered message passing problem.
- Message passing with multiple observers on page K11-8104.

Weakly-ordered message passing problem

P1

```
STR R5, [R1] ; sets new data
STR R0, [R2] ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1) ; waits on flag
LDR R5, [R1]  ; reads new data
```

In the absence of barriers, an end result of P2: R5=0 is permissible.

Resolving by the addition of barriers

The addition of barriers, to ensure the observed order of the reads and the writes, ensures that data is transferred so that the result P2: R5==0x55 is guaranteed, as follows:

P1

```
STR R5, [R1] ; sets new data
DMB [ST] ; ensures all observers observe data before the flag
STR R0, [R2] ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1) ; waits on flag
```
DMB                      ; ensures that the load of data is after the flag has been observed
LDR R5, [R1]

Resolving by the use of barriers and address dependency

There is a rule within the Arm architecture that:

- Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, then these two memory accesses are observed in program order. Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, this is called an *address dependency*. An address dependency exists even if the value returned by the first read has no effect on the virtual address. This might occur if the value returned is masked off before it is used, or if it confirms a predicted address value that it might have changed.

This restriction applies only when the data value returned by a read is used as a data value to calculate the address of a subsequent read or write. It does not apply if the data value returned by a read determines the condition flags values, and the values of the flags are used for condition code evaluation to determine the address of a subsequent read, either through conditional execution or the evaluation of a branch. This is called a *control dependency*.

Where both a control and address dependency exist, the ordering behavior is consistent with the address dependency.

Table K11-1 shows examples of address dependencies, control dependencies, and an address and control dependency.

<table>
<thead>
<tr>
<th>Address dependency</th>
<th>Control dependency</th>
<th>Address and control dependencya</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a) LDR r1, [r0]</td>
<td>(c) LDR r1, [r0]</td>
<td>(d) LDR r1, [r0]</td>
</tr>
<tr>
<td>(b) LDR r2, [r1]</td>
<td>(d) CMP r1, #55</td>
<td>(e) CMP r1, #0</td>
</tr>
<tr>
<td>(d) CMP r1, #0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(e) LDRNE r2, [r3]</td>
<td></td>
<td>LDR r2, [r3, r4]</td>
</tr>
</tbody>
</table>

a. The address dependency takes priority.

This means that the data transfer example of *Weakly-ordered message passing problem* on page K11-8103 can also be satisfied as shown in the following example:

**P1**

```
STR R5, [R1] ; sets new data
DMB [ST] ; ensures all observers observe data before the flag
STR R0, [R2] ; sends flag indicating data ready
```

**P2**

```
WAIT([R2]=#1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
; and so is ordered after the flag has been seen
```

The load of R5 by P2 is ordered with respect to the load from [R2] because there is an address dependency using R12. P1 uses a DMB to ensure that P2 does not observe the write of [R2] before the write of [R1].

**Message passing with multiple observers**

Where the ordering of Normal memory accesses is not resolved by the use of barriers or dependencies, then different observers might observe the accesses in a different order, as shown in the following example:
Barrier Litmus Tests

K11.6 Armv7 compatible approaches for ordering, using DMB and DSB barriers

P1
STR R5, [R1] ; sets new data
STR R0, [R2] ; sends flag indicating data ready

P2
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
                     ; and so is ordered after the flag has been seen

P3
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
                     ; and so is ordered after the flag has been seen

In this case, it is permissible for P2:R5 and P3:R5 to contain different values, because there is no order guaranteed between the two stores performed by P1.

Resolving by the addition of barriers

The addition of a barrier by P1, as shown in the following example, ensures the observed order of the writes, transferring data so that P2:R5 and P3:R5 both contain the value 0x55:

P1
STR R5, [R1] ; sets new data
DMB [ST] ; ensures all observers observe data before the flag
STR R0, [R2] ; sends flag indicating data ready

P2
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
                     ; and so is ordered after the flag has been seen

P3
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
                     ; and so is ordered after the flag has been seen

Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object:

P1
STR R5, [R1, #offset] ; sets new data in a field
DMB [ST] ; ensures all observers observe data before base address is updated
STR R1, [R2] ; updates base address

P2
LDR R1, [R2] ; reads for base address
CMP R1, #0 ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; uses base address to read field

If the null_trap is not taken, it is required that P2:R5==0x55. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not require a barrier to ensure this behavior.
P1 requires a barrier to ensure the observed order of the writes by P1. In general, the impact of requiring a barrier during the construction phase is much less than the impact of requiring a barrier for every read access.

**Posting a store before polling for acknowledgement**

In the case where an observer stores to a location, and then polls for an acknowledge from a different observer, the weak ordering of the memory model can lead to a deadlock, as the following example shows:

```assembly
P1
  STR R0, [R2]
  WAIT ([R3]==1)

P2
  WAIT ([R2]==1)
  STR R0, [R3]
```

In Armv7 implementations that do not include the Multiprocessing Extensions, then this can deadlock because P2 might not observe the store by P1 in finite time. For Armv7 implementations with the Multiprocessing Extensions and for Armv8, this is not an issue as all stores must be observed by all observers within their shareability domain in finite time.

The addition of a DMB instruction prevents this deadlock in Armv7 implementations that do not include the Multiprocessing Extensions:

```assembly
P1
  STR R0, [R2]
  DMB
  WAIT ([R3]==1)

P2
  WAIT ([R2]==1)
  STR R0, [R3]
```

The DMB executed by P1 ensures that P2 observes the store by P1 before it observes the load by P1. This ensures a timely completion.

The following example is a variant of the previous example, where the two observers poll the same memory location:

```assembly
P1
  STR R0, [R2]
  WAIT ([R2]==2)

P2
  WAIT ([R2]==1)
  LDR R0, [R2]
  ADD R0, R0, #1
  STR R0, [R2]
```

In this example, the same deadlock can occur in Armv7 implementations that do not include the Multiprocessing Extensions, because the architecture permits P1 to read the result of its own store to [R2] early, and continue doing so for an indefinite amount of time. The addition of a DMB instruction prevents this deadlock:

```assembly
P1
  STR R0, [R2]
  DMB
  WAIT ([R2]==2)

P2
  WAIT ([R2]==1)
  LDR R0, [R2]
```
ADD R0, R0, #1
STR R0, [R2]

**WFE and WFI and barriers**

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. A DSB barrier instruction is required if it is necessary to ensure that memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanisms that would guarantee the required visibility are the DMB described in *Posting a store before polling for acknowledgement* on page K11-8106, or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

```
P1
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

However, if the example in *Posting a store before polling for acknowledgement* on page K11-8106 is extended to include a WFE, there is no risk of a deadlock. The extended example is:

```
P1
    STR R0, [R2]
    DMB
Loop
    LDR R12, [R3]
    CMP R12, #1
    WFENE
    BNE Loop
```

```
P2
    WAIT ([R2]==1)
    STR R0, [R3]
    DSB
    SEV
```

In this example:

- The DMB by P1 ensures that P2 observes the store by P1 before it observes the load by P1.
- The dependency of the WFE on the result of the load by P1 means that this load must complete before P1 executes the WFE.

For more information about SEV, see *Use of Wait For Event (WFE) and Send Event (SEV) with locks* on page K11-8108.

**K11.6.2 Load-Exclusive, Store-Exclusive and barriers**

The Load-Exclusive and Store-Exclusive instructions, described in *Synchronization and semaphores* on page B2-166, are predictable only with Normal memory. These instructions do not have any implicit barrier functionality. Therefore, any use of these instructions to implement locks of any type requires the addition of explicit barriers.

**Acquiring a lock**

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.
The lack of implicit barriers in the Load-Exclusive and Store-Exclusive instructions means that the mechanism requires a DMB instruction between acquiring a lock and making the first access to the critical region, to ensure that all observers observe the successful claim of the lock before they observe any subsequent loads or stores to the region. This example shows Px acquiring a lock:

```
Px
Loop
  LDREX R5, [R1]       ; reads lock
  CMP R5, #0           ; checks if 0
  STREXEQ R5, R0, [R1] ; attempts to store new value
  CMPEQ R5, #0         ; tests if store succeeded
  BNE Loop             ; retries if not
  DMB                   ; ensures that all subsequent accesses are observed after the
                         ; gaining of the lock is observed
; loads and stores in the critical region can now be performed
```

Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, a DMB usually precedes the lock release, as the following example shows.

```
Px
  ; loads and stores in the critical region
  MOV R0, #0
  DMB                   ; ensures all previous accesses are observed before the lock is cleared
  STR R0, [R1]          ; clears the lock
```

Use of Wait For Event (WFE) and Send Event (SEV) with locks

The Armv8 architecture includes Wait For Event and Send Event instructions, that can be executed to reduce the required number of iterations of a lock-acquire loop, or spinlock, to reduce power. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction that suspends execution on that observer until an asynchronous exception or an explicit event, sent by some other observer using the SEV instruction, is seen by the suspended observer. An observer that holds the lock executes an SEV instruction to send an event after it has released the lock.

The Event signal is a non-memory communication, and therefore the memory update that releases the lock must be observable by all observers before the SEV instruction is executed and the event is sent. This requires the use of DSB instruction, rather than DMB.

Therefore, the following is an example of lock acquire code using WFE:

```
Px
  Loop
    LDREX R5, [R1]       ; reads lock
    CMP R5, #0           ; checks if 0
    WFENE                ; sleeps if the lock is held
    STREXEQ R5, R0, [R1] ; attempts to store new value
    CMPEQ R5, #0         ; tests if store succeeded
    BNE Loop             ; retries if not
    DMB                   ; ensures that all subsequent accesses are observed after the
                            ; gaining of the lock is observed
; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code using SEV:

```
Px
  ; loads and stores in the critical region
  MOV R0, #0
  DMB                   ; ensures all previous accesses are observed before the lock is cleared
```
K11.6.3 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

P1

```
STR R0, [R1]             ; clears the lock
DSB                      ; ensures completion of the store that cleared the lock before
; sending the event
SEV
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

Note

The DSB executed by P1 ensures global observation of the store to [R1]. The interrupt timing ensures that the code executed by P2 is executed after the global observation of the update to [R1], and therefore must see this update. In some implementations, this might be implemented by requiring that interrupts flush non-coherent buffers that hold speculatively loaded data.

K11.6.4 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- Data cache maintenance instructions.
- Instruction cache maintenance instructions on page K11-8112.
- TLB maintenance instructions and barriers on page K11-8113.

Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- Message passing to non-caching observers.
- Multiprocessing message passing to non-caching observers on page K11-8110.
- Invalidating DMA buffers, non-functional example on page K11-8110.
- Invalidating DMA buffers, functional example with single PE on page K11-8111.
- Invalidating DMA buffers, functional example with multiple coherent PEs on page K11-8111.

Message passing to non-caching observers

The Armv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

P1

```
STR R5, [R1]             ; message stored to shared memory location
DSB [ST]                ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```
E1

```assembly
WAIT ([R4] == 1) ; waits for the flag
DMB ; ensures that flag has been seen before reading data
LDR R5, [R1] ; reads the data
```

In this example, it is required that E1:R5==0x55.

### Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions in Armv8, and in Armv7 implementations that include the Multiprocessing Extensions, combined with properties of barriers, means that the message passing principle for non-caching observers is:

P1

```assembly
STR R5, [R1] ; updates data (assumed to be in P1's cache)
DMB [ST] ; ensures new data is observed before the flag to P2 is set
STR R0, [R2] ; sends flag to P2
```

P2

```assembly
WAIT ([R2] == 1) ; waits for flag from P1
DMB ; ensures cache clean is observed after P1 flag is observed
DCCMVAC R1 ; cleans cache to point of coherency - this cleans the cache of P1
DMB ; ensures effects of the clean are observed before the flag to E1 is set
STR R0, [R4] ; sends flag to E1
```

E1

```assembly
WAIT ([R4] == 1) ; waits for flag from P2
DMB ; ensures that flag has been observed before reading the data
LDR R5, [R1] ; reads the data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

### Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

P1

```assembly
DCIMVAC R1 ; ensures caches are not dirty. A clean operation could be
; used but the DMA overwrites this region so an invalidate operation
; is sufficient and usually more efficient
DMB ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3] ; sends flag to external agent
WAIT ([R4]==1) ; waits for a different flag from an external agent
DMB ; observes flag from external agent before reading new data. However [R1]
; could have been brought into cache earlier
LDR R5, [R1]
```

E1

```assembly
WAIT ([R3] == 1) ; waits for flag
STR R5, [R1] ; stores new data
DMB
STR R0, [R4] ; sends a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.
Invalidating DMA buffers, functional example with single PE

P1

    DCIMVAC R1 ; ensures cache is not dirty. A clean operation could be
    ; used but the DMA overwrites this region so an invalidate operation
    ; is sufficient and usually more efficient
    DMB          ; ensures cache invalidation is observed before the next store is observed
    STR R0, [R3]; sends flag to external agent
    WAIT ([R4]==1) ; waits for a different flag from an external agent
    DMB          ; ensures that cache invalidate is observed after the flag
    ; from external agent is observed
    DCIMVAC R1 ; ensures cache discards stale copies before use
    LDR R5, [R1]

E1

    WAIT ([R3] == 1) ; waits for flag
    STR R5, [R1] ; stores new data
    DMB [ST]
    STR R0, [R4] ; sends a flag

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

P0

    (Use data from [R1], potentially using [R1] as scratch space)
    DMB
    STR R0, [R2] ; signals release of [R1]
    WAIT ([R2] == 0) ; waits for new value from DMA
    DMB
    LDR R5, [R1]

P1

    WAIT ([R2] == 1) ; waits for release of [R1] by P0
    DCIMVAC R1 ; ensures caches are not dirty, invalidate is sufficient
    DMB
    STR R0, [R3] ; requests new data for [R1]
    WAIT ([R4] == 1) ; waits for new data
    DMB
    DCIMVAC R1 ; ensures caches discard stale copies before use
    DMB
    MOV R0, #0
    STR R0, [R2] ; signals availability of new [R1]

E1

    WAIT ([R3] == 1) ; waits for new data request
    STR R5, [R1] ; sends new [R1]
    DMB [ST]
    STR R0, [R4] ; indicates new data available to P1

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].
Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- Ensuring the visibility of updates to instructions for a uniprocessor.
- Ensuring the visibility of updates to instructions for a multiprocessor.

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

P1

```
STR R11, [R1]      ; R11 contains a new instruction to store in program memory
DCCMVAU R1         ; clean to PoU makes new instructions visible to instruction cache
DSB                ; ensures completion of the invalidation
ICIMVAU R1         ; ensures instruction cache/branch predictor discard stale data
BPIMVA R1          ; ensures completion of the invalidation
DSB                ; ensures completion of the instruction cache invalidation
ISB                ; ensures instruction cache and branch predictor discard stale data
BX R1              ; ensures instruction fetch path observes new instruction cache state
```

Ensuring the visibility of updates to instructions for a multiprocessor

Armv8, and an Armv7 implementation that includes the Multiprocessing Extensions, requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

P1

```
STR R11, [R1]      ; R11 contains a new instruction to store in program memory
DCCMVAU R1         ; clean to PoU makes new instructions visible to instruction cache
DSB                ; ensures completion of the clean on all processors
ICIMVAU R1         ; ensures instruction cache/branch predictor discards stale data
BPIMVA R1          ; ensures completion of the instruction cache and branch predictor invalidation on all PEs
DSB                ; ensures completion of the instruction cache and branch predictor;
STR R0, [R2]       ; sets flag to signal completion
ISB                ; synchronizes context on this PE
BX R1              ; branches to new code
```

Nonfunctional approach

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance instructions that other PEs issue:

P1

```
STR R11, [R1]      ; R11 contains a new instruction to store in program memory
DCCMVAU R1         ; clean to PoU makes new instructions visible to instruction cache
```
DSB ; ensure completion of the clean on all PEs
ICIMVAU R1 ; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DMB ; ensure ordering of the store after the invalidation
; DOES NOT guarantee completion of instruction cache/branch predictor on other PEs
STR R0, [R2] ; sets flag to signal completion
DSB ; ensures completion of the invalidation on all PEs
ISB ; synchronizes context on this PE
BX R1 ; branches to new code

P2-Px

WAIT ([R2] == 1) ; waits for flag signaling completion
DSB ; this DSB does not guarantee completion of P1's ICIMVAU/BPIMVA
ISB
BX R1

In this example, P2…Px might not see the updated region of code at R1.

TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

• Ensuring the visibility of updates to translation tables for a uniprocessor.
• Ensuring the visibility of updates to translation tables for a multiprocessor on page K11-8114.
• Paging memory in and out on page K11-8114.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

In the Armv8 architecture, and in an Armv7 implementation that includes the Multiprocessing Extensions, translation table walks must look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

P1

STR R11, [R1] ; updates the translation table entry
DSB ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIMAL
DSB ; ensures completion of the BP and TLB invalidation
ISB ; synchronizes context on this PE
; ; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using the old mapping have been completed

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.
**Ensuring the visibility of updates to translation tables for a multiprocessor**

The same code sequence can be used in a multiprocessing system. In the Armv8 architecture, and in an Armv7 implementation that includes the Multiprocessing Extensions, a PE that executes a TLB maintenance instruction must execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

```
P1
  STR R11, [R1] ; updates the translation table entry
  DSB ; ensures visibility of the update to translation table walks
  TLBIMVAIS R10
  BPIALLIS
  DSB ; ensures completion of the BP and TLB invalidation
  ISB ; Note ISB is not broadcast and must be executed locally on other PEs
  ; new translation table entry can be relied upon at this point and all accesses generated by any
  ; observers affected by the broadcast TLBIMVAIS operation using the old mapping have completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

**Paging memory in and out**

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

```
P1
  STR R11, [R1] ; updates the translation table for the region being paged out
  DSB ; ensures visibility of the update to translation table walks
  TLBIMVAIS R10
  ; invalidates the old entry
  DSB ; ensures completion of the invalidation on all processors
  ISB ; ensures visibility of the invalidation
  BL SaveMemoryPageToBackingStore
  BL LoadMemoryFromBackingStore
  DSB ; ensures completion of the memory transfer (this could be part of
  ; LoadMemoryFromBackingStore
  ICIALLUIS ; also invalidates the branch predictor
  DSB ; ensures completion of the instruction cache
  ; and branch predictor invalidation
  STR R9, [R1] ; creates a new translation table entry with a new mapping
  DSB ; ensures visibility of the new translation table mapping
  ISB ; ensures synchronization of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of SaveMemoryPageToBackingStore and LoadMemoryFromBackingStore. LoadMemoryFromBackingStore is required to ensure that the memory updates that it makes are visible to instruction fetches.
In this example, the use of ICIALUIS to invalidate the entire instruction cache is a simplification that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU operations. This invalidation must be done when the mapping used for the ICIMVAU operations is valid but not executable.
Appendix K12
Random Number Generation

This appendix provides further information on the generation of random numbers using FEAT_RNG. It contains the following sections:

- Properties of the generated random number on page K12-8118.
**K12.1 Properties of the generated random number**

When `FEAT_RNG` is implemented, reads to the `RNDR` and `RNDRRS` registers return a 64-bit random number. The random numbers must meet the properties and conform to the standards that are detailed in this section.

The output random number is from a *Deterministic Random Bit Generator* (DRBG), which is seeded from a *True Random Number Generator* (TRNG).

The TRNG provides entropy in the form of random numbers, from the sampled output of an unpredictable physical process.

The TRNG should conform to:
- The NIST SP800-90B standard.
- The NIST SP800-22 standard.
- The FIPS 140-2 standard.
- The BSI AIS-31 standard.

The DRBG produces random numbers from a cryptographically secure algorithm.

The DRBG is seeded from the TRNG.

The DRBG algorithm should conform to the NIST SP800-90A Rev 1 standard.

The DRBG is reseeded after an *IMPLEMENTATION DEFINED* number of random numbers has been generated and read using the `RNDR` register.

The DRBG is reseeded immediately before the random number is generated and read using the `RNDRRS` register.

The entire random number generation should conform to the NIST SP800-90C standard.

--- **Note** ---

Since a TRNG can only generate random bits at a limited rate, the random number bits are commonly collected in an “entropy pool” until needed. An implementation should ensure that lower privileged software cannot impact the performance of higher privileged software by entirely draining this “entropy pool”. The refill time cost of the “entropy pool” should be paid for by the persistent caller.
Appendix K13
Legacy Feature Naming Convention

This appendix maps the legacy feature names for the Armv8.x extensions. It contains the following sections:

• *The Armv8.0 architecture* on page K13-8120.
• *The Armv8.1 architecture extension* on page K13-8121.
• *The Armv8.2 architecture extension* on page K13-8122.
• *The Armv8.3 architecture extension* on page K13-8124.
• *The Armv8.4 architecture extension* on page K13-8125.
• *The Armv8.5 architecture extension* on page K13-8126.
• *The Armv8.6 architecture extension* on page K13-8127.
K13.1 The Armv8.0 architecture

Table K13-1 provides details of the mapping of the legacy names of Armv8.0 features to their current names.

K13.7 The Armv8.6 architecture extension
Appendix K14
Arm Pseudocode Definition

This appendix provides a definition of the pseudocode that is used in this manual, and defines some helper procedures and functions that are used by pseudocode. It contains the following sections:

- About the Arm pseudocode on page K14-8130.
- Pseudocode for instruction descriptions on page K14-8131.
- Data types on page K14-8134.
- Operators on page K14-8139.
- Statements and control structures on page K14-8145.
- Built-in functions on page K14-8150.
- Miscellaneous helper procedures and functions on page K14-8153.
- Arm pseudocode definition index on page K14-8155.

Note
This appendix is not a formal language definition for the pseudocode. It is a guide to help understand the use of Arm pseudocode. This appendix is not complete. Changes are planned for future releases.
K14.1  About the Arm pseudocode

The Arm pseudocode provides precise descriptions of some areas of the Arm architecture. This includes description of the decoding and operation of all valid instructions. Pseudocode for instruction descriptions on page K14-8131 gives general information about this instruction pseudocode, including its limitations.

The following sections describe the Arm pseudocode in detail:

• Data types on page K14-8134.
• Operators on page K14-8139.
• Statements and control structures on page K14-8145.

Built-in functions on page K14-8150 and Miscellaneous helper procedures and functions on page K14-8153 describe some built-in functions and pseudocode helper functions that are used by the pseudocode functions that are described elsewhere in this manual. Arm pseudocode definition index on page K14-8155 contains the indexes to the pseudocode.

K14.1.1  General limitations of Arm pseudocode

The pseudocode statements IMPLEMENTATION_DEFINED, SEE, UNDEFINED, and UNPREDICTABLE indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

• Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
• No subsequent behavior indicated by the pseudocode occurs.

For more information, see Special statements on page K14-8149.
K14.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in General limitations of Arm pseudocode on page K14-8130 and Limitations of the instruction pseudocode on page K14-8132.

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. Instruction encoding diagrams and instruction pseudocode gives more information about the pseudocode provided for each instruction.

K14.2.1 Instruction encoding diagrams and instruction pseudocode

Instruction descriptions in this manual contain:

- An Encoding section, containing one or more encoding diagrams, each followed by some encoding-specific pseudocode that translates the fields of the encoding into inputs for the common pseudocode of the instruction, and picks out any encoding-specific special cases.

- An Operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the EncodingSpecificOperations() function, either at its start or only after a condition code check performed by if ConditionPassed() then.

An encoding diagram specifies each bit of the instruction as one of the following:

- An obligatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.

- A should be 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is CONSTRAINED UNPREDICTABLE. For more information, see SBZ or SBO fields T32 and A32 in instructions on page K1-7944.

- A named single bit or a bit in a named multi-bit field. The cond field in bits[31:28] of many A32/T32 instructions has some special rules associated with it.

An encoding diagram matches an instruction if all obligatory bits are identical in the encoding diagram and the instruction, and one of the following is true:

- The encoding diagram is not for an A32/T32 instruction.

- The encoding diagram is for an A32/T32 instruction that does not have a cond field in bits[31:28].

- The encoding diagram is for an A32/T32 instruction that has a cond field in bits[31:28], and bits[31:28] of the instruction are not 0b1111.

In the context of the instruction pseudocode, the execution model for an instruction is:

1. Find all encoding diagrams that match the instruction. It is possible that no encoding diagram matches. In that case, abandon this execution model and consult the relevant instruction set chapter instead to find out how the instruction is to be treated. The bit pattern of such an instruction is usually reserved and UNDEFINED, though there are some other possibilities. For example, unallocated hint instructions are documented as being reserved and executed as NOPs.

2. If the operation pseudocode for the matching encoding diagrams starts with a condition code check, perform that check. If the condition code check fails, abandon this execution model and treat the instruction as a NOP. If there are multiple matching encoding diagrams, either all or none of their corresponding pieces of common pseudocode start with a condition code check.

3. Perform the encoding-specific pseudocode for each of the matching encoding diagrams independently and in parallel. Each such piece of encoding-specific pseudocode starts with a bitstring variable for each named bit or multi-bit field in its corresponding encoding diagram, named the same as the bit or multi-bit field and initialized with the values of the corresponding bit or bits from the bit pattern of the instruction.
In a few cases, the encoding diagram contains more than one bit or field with the same name. In these cases, the values of the different instances of those bits or fields must be identical. The encoding-specific pseudocode contains a special case using the Consistent() function to specify what happens if they are not identical. Consistent() returns TRUE if all instruction bits or fields with the same name as its argument have the same value, and FALSE otherwise.

If there are multiple matching encoding diagrams, all but one of the corresponding pieces of pseudocode must contain a special case that indicates that it does not apply. Discard the results of all such pieces of pseudocode and their corresponding encoding diagrams.

There is now one remaining piece of pseudocode and its corresponding encoding diagram left to consider. This pseudocode might also contain a special case, most commonly one indicating that it is CONSTRAINED UNPREDICTABLE. If so, abandon this execution model and treat the instruction according to the special case.

4. Check the should be bits of the encoding diagram against the corresponding bits of the bit pattern of the instruction. If any of them do not match, abandon this execution model and treat the instruction as CONSTRAINED UNPREDICTABLE, see SBZ or SBO fields T32 and A32 in instructions on page K1-7944.

5. Perform the rest of the operation pseudocode for the instruction description that contains the encoding diagram. That pseudocode starts with all variables set to the values they were left with by the encoding-specific pseudocode.

The ConditionPassed() call in the common pseudocode, if present, performs step 2, and the EncodingSpecificOperations() call performs steps 3 and 4.

K14.2.2 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

• Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses, see Ordering constraints on page E2-4024.

• Pseudocode does not describe the exact rules when an instruction that generates any of the following fails its condition code check:
  — UNDEFINED instruction.
  — Hyp trap.
  — Monitor trap.
  — Trap to AArch64 exception.

In such cases, the UNDEFINED pseudocode statement or call to the applicable trap function lies inside the if ConditionPassed() then ... structure, either directly or in the EncodingSpecificOperations() function call, and so the pseudocode indicates that the instruction executes as a NOP. For the exact rules, see:
  — Conditional execution of undefined instructions on page G1-5780.
  — EL2 configurable controls on page G1-5827.
  — EL3 configurable controls on page G1-5846.
  — Traps on instructions on page D1-2368.

• Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. Combinations of floating-point exceptions on page E1-4005 describes the exact rules.

—— Note ———

There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.
• An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as `Abort()`, or implicitly, for example if an interrupt is taken during execution of an `LDM` instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in `Handling exceptions that are taken to an Exception level using AArch32` on page G1-5743.
K14.3 Data types

This section describes:
• General data type rules.
• Bitstrings.
• Integers on page K14-8135.
• Reals on page K14-8135.
• Booleans on page K14-8135.
• Enumerations on page K14-8136.
• Structures on page K14-8136.
• Tuples on page K14-8137.
• Arrays on page K14-8138.

K14.3.1 General data type rules

Arm architecture pseudocode is a strongly typed language. Every literal and variable is of one of the following types:
• Bitstring.
• Integer.
• Boolean.
• Real.
• Enumeration.
• Tuple.
• Struct.
• Array.

The type of a literal is determined by its syntax. A variable can be assigned to without an explicit declaration. The variable implicitly has the type of the assigned value. For example, the following assignments implicitly declare the variables x, y and z to have types integer, bitstring of length 1, and Boolean, respectively.

x = 1;
y = '1';
z = TRUE;

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. The following example declares explicitly that a variable named count is an integer.

integer count;

This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

K14.3.2 Bitstrings

This section describes the bitstring data type.

Syntax

bits(N) The type name of a bitstring of length N.
bit A synonym of bits(1).

Description

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 0.
Bitstring constants literals are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants literals of type bit are '0' and '1'. Spaces can be included in bitstrings for clarity.

The bits in a bitstring are numbered from left to right \( N-1 \) to 0. This numbering is used when accessing the bitstring using bitslices. In conversions to and from integers, bit \( N-1 \) is the MSByte and bit 0 is the LSByte. This order matches the order in which bitstrings derived from encoding diagrams are printed.

Every bitstring value has a left-to-right order, with the bits being numbered in standard little-endian order. That is, the leftmost bit of a bitstring of length \( N \) is bit \( (N-1) \) and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings that are derived from encoding diagrams, this order matches the way that they are printed.

Bitstrings are the only concrete data type in pseudocode, corresponding directly to the contents values that are manipulated in registers, memory locations, and instructions. All other data types are abstract.

**K14.3.3 Integers**

This section describes the data type for integer numbers.

**Syntax**

```
integer
```

**Description**

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as integers.

Integer literals are normally written in decimal form, such as 0, 15, -1234. They can also be written in C-style hexadecimal form, such as 0x55 or 0x80000000. Hexadecimal integer literals are treated as positive unless they have a preceding minus sign. For example, 0x80000000 is the integer \(+2^{31}\). If \(-2^{31}\) needs to be written in hexadecimal, it must be written as \(-0x80000000\).

**K14.3.4 Reals**

This section describes the data type for real numbers.

**Syntax**

```
real
```

**Description**

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as reals.

Real constant literals are written in decimal form with a decimal point. This means 0 is an integer constant literal, but 0.0 is a real constant literal.
TRUE: The two values a Boolean variable can take.

**Description**

A Boolean is a logical TRUE or FALSE value.

--- **Note** ---

This is not the same type as bit, which is a bitstring of length 1. A Boolean can only take on one of two values: TRUE or FALSE.

#### K14.3.6 Enumerations

This section describes the enumeration data type.

**Syntax and examples**

```plaintext
enumeration Example {Example_One, Example_Two, Example_Three};

A definition of a new enumeration called Example, which can take on the values Example_One, Example_Two, Example_Three.
```

**Description**

An enumeration is a defined set of named values.

An enumeration must contain at least one named value. A named value must not be shared between enumerations. Enumerations must be defined explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the named values to it. By convention, each named value starts with the name of the enumeration followed by an underscore. The name of the enumeration is its type name, or type, and the named values are its possible values.

#### K14.3.7 Structures

This section describes the structure data type.

**Syntax and examples**

```plaintext
type ShiftSpec is (bits(2) shift, integer amount)

An example definition for a new structure called ShiftSpec that contains an bitstring member called shift and a integer member named amount. Structure definitions must not be terminated with a semicolon.

ShiftSpec abc;

A declaration of a variable named abc of type ShiftSpec.

abc.shift

Syntax to refer to the individual members within the structure variable.
```

**Description**

A structure is a compound data type composed of one or more data items. The data items can be of different data types. This can include compound data types. The data items of a structure are called its members and are named.
In the syntax section, the example defines a structure called ShiftSpec with two members. The first is a bitstring of length 2 named shift and the second is an integer named amount. After declaring a variable of that type named abc, the members of this structure are referred to as abc.shift and abc.amount.

Every definition of a structure creates a different type, even if the number and type of their members are identical. For example:

```plaintext
type ShiftSpec1 is (bits(2) shift, integer amount)
type ShiftSpec2 is (bits(2) shift, integer amount)
```

ShiftSpec1 and ShiftSpec2 are two different types despite having identical definitions. This means that the value in a variable of type ShiftSpec1 cannot be assigned to variable of type ShiftSpec2.

### K14.3.8 Tuples

This section describes the tuple data type.

#### Examples

```plaintext
(bits(32) shifter_result, bit shifter_carry_out)
```

An example of the tuple syntax.

```plaintext
(shift_t, shift_n) = ('00', 0);
```

An example of assigning values to a tuple.

#### Description

A tuple is an ordered set of data items, separated by commas and enclosed in parentheses. The items can be of different types and a tuple must contain at least one data item.

Tuples are often used as the return type for functions that return multiple results. For example, in the syntax section, the example tuple is the return type of the function `Shift_C()`, which performs a standard A32/T32 shift or rotation. Its return type is a tuple containing two data items, with the first of type `bits(32)` and the second of type `bit`.

Each tuple is a separate compound data type. The compound data type is represented as a comma-separated list of ordered data types between parentheses. This means that the example tuple at the start of this section is of type `(bits(32), bit)`. The general principle that types can be implied by an assignment extends to implying the type of the elements in the tuple. For example, in the syntax section, the example assignment implicitly declares:

- `shift_t` to be of type `bits(2)`.
- `shift_n` to be of type `integer`.
- `(shift_t, shift_n)` to be a tuple of type `(bits(2), integer)`. 
K14.3.9 Arrays

This section describes the array data type.

Syntax

array The type name for the array data type.

array data_type array_name[A..B];

Declaration of an array of type data_type, which might be compound data type. It is named array_name and is indexed with an integer range from A to B.

Description

An array is an ordered set of fixed size containing items of a single data type. This can include compound data types. Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then ..., then the upper inclusive end of the range.

For example:

The following example declares an array of 31 bitstrings of length 64, indexed from 0 to 30.

array bits(64) _R[0..30];

Arrays are always explicitly declared, and there is no notation for a constant literal array. Arrays always contain at least one element data item, because:

- Enumerations always contain at least one symbolic constant named value.
- Integer ranges always contain at least one integer.

An array declared with an enumeration type as the index must be accessed using enumeration values of that enumeration type. An array declared with an integer range type as the index must be accessed using integer values from that inclusive range. Accessing such an array with an integer value outside of the range is a coding error.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as _R[i], _MemU[address, size] or _Elem[vector, i, size]. These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing. See Function and procedure calls on page K14-8145.
K14.4 Operators

This section describes:
- Relational operators.
- Boolean operators.
- Bitstring operators on page K14-8140.
- Arithmetic operators on page K14-8140.
- The assignment operator on page K14-8141.
- Precedence rules on page K14-8143.
- Conditional expressions on page K14-8143.
- Operator polymorphism on page K14-8143.

K14.4.1 Relational operators

The following operations yield results of type boolean.

Equality and non-equality

If two variables x and y are of the same type, their values can be tested for equality by using the expression \( x == y \) and for non-equality by using the expression \( x ! = y \). In both cases, the result is of type boolean.

Both x and y must be of type \( \text{bits}(N) \), \text{real}, \text{enumeration}, \text{boolean}, or \text{integer}. Named values from an enumeration can only be compared if they are both from the same enumeration. An exception is that a bitstring can be tested for equality with an integer to allow a \( d==15 \) test.

A special form of comparison is defined with a bitstring literal that can contain bit values ‘0’, ‘1’, and ‘x’. Any bit with value ‘x’ is ignored in determining the result of the comparison. For example, if \( \text{opcode} \) is a 4-bit bitstring, the expression \( \text{opcode} == '1x0x' \) matches the values ‘1000’, ‘1100’, ‘1001’, and ‘1101’. This is known as a bitmask.

Note

This special form is permitted in the implied equality comparisons in the when parts of case ... of ... structures.

Comparisons

If \( x \) and \( y \) are integers or reals, then \( x < y \), \( x <= y \), \( x > y \), and \( x >= y \) are less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results.

Set membership with \( \text{IN} \)

\(<\text{expression}> \text{IN} \{<\text{set}>\} \) produces TRUE if \( \text{expression} \) is a member of \( <\text{set}> \). Otherwise, it is FALSE. \(<\text{set}> \) must be a list of expressions separated by commas.

K14.4.2 Boolean operators

If \( x \) is a Boolean expression, then \( !x \) is its logical inverse.

If \( x \) and \( y \) are Boolean expressions, then \( x \&\& y \) is the result of ANDing them together. As in the C language, if \( x \) is FALSE, the result is determined to be FALSE without evaluating \( y \).

Note

This is known as short circuit evaluation.

If \( x \) and \( y \) are booleans, then \( x | | y \) is the result of ORing them together. As in the C language, if \( x \) is TRUE, the result is determined to be TRUE without evaluating \( y \).
Note

If \(x\) and \(y\) are booleans or Boolean expressions, then the result of \(x \neq y\) is the same as the result of exclusive-ORing \(x\) and \(y\) together. The operator \(\oplus\) only accepts bitstring arguments.

### K14.4.3 Bitstring operators

The following operations can be applied only to bitstrings.

#### Logical operations on bitstrings

If \(x\) is a bitstring, \(\overline{x}\) is the bitstring of the same length obtained by logically inverting every bit of \(x\).

If \(x\) and \(y\) are bitstrings of the same length, \(x \land y\), \(x \lor y\), and \(x \oplus y\) are the bitstrings of that same length obtained by logically ANDing, logically ORing, and exclusive-ORing corresponding bits of \(x\) and \(y\) together.

#### Bitstring concatenation and slicing

If \(x\) and \(y\) are bitstrings of lengths \(N\) and \(M\) respectively, then \(x:y\) is the bitstring of length \(N+M\) constructed by concatenating \(x\) and \(y\) in left-to-right order.

The bitstring slicing operator addresses specific bits in a bitstring. This can be used to create a new bitstring from extracted bits or to set the value of specific bits. Its syntax is \(x<\text{integer_list}>\), where \(x\) is the integer or bitstring being sliced, and \(\text{integer_list}\) is a comma-separated list of integers enclosed in angle brackets. The length of the resulting bitstring is equal to the number of integers in \(\text{integer_list}\). In \(x<\text{integer_list}>\), each of the integers in \(\text{integer_list}\) must be:

- \(\geq 0\).
- \(< \text{Len}(x)\) if \(x\) is a bitstring.

The definition of \(x<\text{integer_list}>\) depends on whether \(\text{integer_list}\) contains more than one integer:

- If \(\text{integer_list}\) contains more than one integer, \(x<i, j, k, ..., n>\) is defined to be the concatenation:
  \[x<i> : x<j> : x<k> : ... : x<n>\].

- If \(\text{integer_list}\) consists of just one integer \(i\), \(x<i>\) is defined to be:
  - If \(x\) is a bitstring, \('0'\) if bit \(i\) of \(x\) is a zero and \('1'\) if bit \(i\) of \(x\) is a one.
  - If \(x\) is an integer, and \(y\) is the unique integer in the range \(0\) to \(2^{(i+1)}-1\) that is congruent to \(x\) modulo \(2^{(i+1)}\). Then \(x<i>\) is \('0'\) if \(y < 2^i\) and \('1'\) if \(y \geq 2^i\).

Loosely, this definition treats an integer as equivalent to a sufficiently long two’s complement representation of it as a bitstring.

The notation for a range expression is \(i:j\) with \(i \geq j\) is shorthand for the integers in the range from \(i\) down to \(j\), with both end values included. For example, \(\text{instr}<31:28>\) represents \(\text{instr}<31, 30, 29, 28>\).

\(x<\text{integer_list}>\) is assignable provided \(x\) is an assignable bitstring and no integer appears more than once in \(\text{integer_list}\). In particular, \(x<i>\) is assignable if \(x\) is an assignable bitstring and \(0 \leq i < \text{Len}(x)\).

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit<31> as \(N\). In such cases, the syntax APSR.<N> is used as a more readable synonym for APSR<31> as named bits can be referred to with the same syntax as referring to members of a struct. A comma-separated list of named bits enclosed in angle brackets following the register name allows multiple bits to be addressed simultaneously. For example, APSR.<N, C, Q> is synonymous with APSR <31, 29, 27>.

### K14.4.4 Arithmetic operators

Most pseudocode arithmetic is performed on integer or real values, with operands obtained by conversions from bitstrings and results converted back to bitstrings. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.
Unary plus and minus

If \( x \) is an integer or real, then \( +x \) is \( x \) unchanged, \( -x \) is \( x \) with its sign reversed. Both are of the same type as \( x \).

Addition and subtraction

If \( x \) and \( y \) are integers or reals, \( x+y \) and \( x-y \) are their sum and difference. Both are of type \( \text{integer} \) if \( x \) and \( y \) are both of type \( \text{integer} \), and \( \text{real} \) otherwise.

There are two cases where the types of \( x \) and \( y \) can be different. A bitstring and an integer can be added together to allow the operation \( PC + 4 \). An integer can be subtracted from a bitstring to allow the operation \( PC - 2 \).

If \( x \) and \( y \) are bitstrings of the same length \( N \), so that \( N = \text{Len}(x) = \text{Len}(y) \), then \( x+y \) and \( x-y \) are the least significant \( N \) bits of the results of converting \( x \) and \( y \) to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

\[
\begin{align*}
  x+y &= (\text{SInt}(x) + \text{SInt}(y))<N-1:0> \\
  &= (\text{UInt}(x) + \text{UInt}(y))<N-1:0> \\
  x-y &= (\text{SInt}(x) - \text{SInt}(y))<N-1:0> \\
  &= (\text{UInt}(x) - \text{UInt}(y))<N-1:0>
\end{align*}
\]

If \( x \) is a bitstring of length \( N \) and \( y \) is an integer, \( x+y \) and \( x-y \) are the bitstrings of length \( N \) defined by \( x+y = x + y<N-1:0> \) and \( x-y = x - y<N-1:0> \). Similarly, if \( x \) is an integer and \( y \) is a bitstring of length \( M \), \( x+y \) and \( x-y \) are the bitstrings of length \( M \) defined by \( x+y = x<M-1:0> + y \) and \( x-y = x<M-1:0> - y \).

Multiplication

If \( x \) and \( y \) are integers or reals, then \( x \times y \) is the product of \( x \) and \( y \). It is of type \( \text{integer} \) if \( x \) and \( y \) are both of type \( \text{integer} \), and \( \text{real} \) otherwise.

Division and modulo

If \( x \) and \( y \) are reals, then \( x/y \) is the result of dividing \( x \) by \( y \), and is always of type \( \text{real} \).

If \( x \) and \( y \) are integers, then \( x \text{ DIV} y \) and \( x \text{ MOD} y \) are defined by:

\[
\begin{align*}
  x \text{ DIV} y &= \text{RoundDown}(x/y) \\
  x \text{ MOD} y &= x - y \times (x \text{ DIV} y)
\end{align*}
\]

It is a pseudocode error to use any of \( x/y \), \( x \text{ DIV} y \), or \( x \text{ MOD} y \) in any context where \( y \) can be zero.

Scaling

If \( x \) and \( n \) are of type \( \text{integer} \), then:

- \( x << n = \text{RoundDown}(x \times 2^n) \).
- \( x >> n = \text{RoundDown}(x \times 2^(-n)) \).

Raising to a power

If \( x \) is an integer or a real and \( n \) is an integer then \( x^n \) is the result of raising \( x \) to the power of \( n \), and:

- If \( x \) is of type \( \text{integer} \) then \( x^n \) is of type \( \text{integer} \).
- If \( x \) is of type \( \text{real} \) then \( x^n \) is of type \( \text{real} \).

K14.4.5 The assignment operator

The assignment operator is the \( = \) character, which assigns the value of the right-hand side to the left-hand side. An assignment statement takes the form:

\[
<\text{assignable_expression}> = <\text{expression}>
\]

This following subsection defines valid expression syntax.
General expression syntax

An expression is one of the following:

• A literal.
• A variable, optionally preceded by a data type name to declare its type.
• The word `UNKNOWN` preceded by a data type name to declare its type.
• The result of applying a language-defined operator to other expressions.
• The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register defined in an Arm architecture specification defines a correspondingly named pseudocode bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as '0' and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

• Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE and do not return UNKNOWN values,
• Be promoted as providing any useful information to software.

--- Note ---

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

---

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.

• Variables.
• The results of applying some operators to other expressions.
  The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
• The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

--- Note ---

If the right-hand side in an assignment is a function returning a tuple, an item in the assignment destination can be written as `-` to indicate that the corresponding item of the assigned tuple value is discarded. For example:

```plaintext
(shifted, -) = LSL_C(operand, amount);
```

The expression on the right-hand side itself can be a tuple. For example:

```plaintext
(x, y) = (function_1(), function_2());
```

Every expression has a data type.

• For a literal, this data type is determined by the syntax of the literal.
• For a variable, there are the following possible sources for the data type
  — An optional preceding data type name.
  — A data type the variable was given earlier in the pseudocode by recursive application of this rule.
A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

- For a language-defined operator, the definition of the operator determines the data type.
- For a function, the definition of the function determines the data type.

### K14.4.6 Precedence rules

The precedence rules for expressions are:

1. Literals, variables and function invocations are evaluated with higher priority than any operators using their results, but see Boolean operators on page K14-8139.
2. Operators on integers follow the normal operator precedence rules of exponentiation before multiply/divide before add/subtract, with sequences of multiply/divides or add/subtracts evaluated left-to-right.
3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if i, j and k are integer variables, \( i > 0 \land j > 0 \land k > 0 \) is acceptable, but \( i > 0 \land j > 0 \lor k > 0 \) is not.

### K14.4.7 Conditional expressions

If \( x \) and \( y \) are two values of the same type and \( t \) is a value of type boolean, then \( \text{if } t \text{ then } x \text{ else } y \) is an expression of the same type as \( x \) and \( y \) that produces \( x \) if \( t \) is TRUE and \( y \) if \( t \) is FALSE.

### K14.4.8 Operator polymorphism

Operators in pseudocode can be polymorphic, with different functionality when applied to different data types. Each resulting form of an operator has a different prototype definition. For example, the operator + has forms that act on various combinations of integers, reals and bitstrings.

Table K14-1 summarizes the operand types valid for each unary operator and the result type. Table K14-2 on page K14-8144 summarizes the operand types valid for each binary operator and the result type.

K14.5 Statements and control structures

This section describes the statements and program structures available in the pseudocode:

- Statements and Indentation
- Function and procedure calls
- Conditional control structures on page K14-8147
- Loop control structures on page K14-8148
- Special statements on page K14-8149
- Comments on page K14-8149

K14.5.1 Statements and Indentation

A simple statement is either an assignment, a function call, or a procedure call. Each statement must be terminated with a semicolon.

Indentation normally indicates the structure in compound statements. The statements contained in structures such as if ... then ... else ... or procedure and function definitions are indented more deeply than the statement structure itself. The end of a compound statement structure and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level. Standard indentation uses four spaces for each level of indent.

K14.5.2 Function and procedure calls

This section describes how functions and procedures are defined and called in the pseudocode.
Procedure and function definitions

A procedure definition has the form:

```plaintext
<procedure name>(<argument prototypes>)
    <statement 1>
    <statement 2>
    ...
    <statement n>
```

where `<argument prototypes>` consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

Note

This first definition line is not terminated by a semicolon. This distinguishes it from a procedure call.

A function definition is similar, but also declares the return type of the function:

```plaintext
<return type> <function name>(<argument prototypes>)
    <statement 1>
    <statement 2>
    ...
    <statement n>
```

Note

A function or procedure name can include a ".". This is a convention used for functions that have similar but different behaviors in AArch32 and AArch64 states.

Array-like functions are similar, but are written with square brackets and have two forms. These two forms exist because reading from and writing to an array element require different functions. They are frequently used in memory operations. An array-like function definition with a return type is equivalent to reading from an array. For example:

```plaintext
<return type> <function name>[<argument prototypes>]
    <statement 1>
    <statement 2>
    ...
    <statement n>
```

Its related function definition with no return type is equivalent to writing to an array. For example:

```plaintext
<function name>[<argument prototypes>] = <value prototype>
    <statement 1>
    <statement 2>
    ...
    <statement n>
```

The value prototype determines what data type can be written to the array. The two related functions must share the same name, but the value prototype and return type can be different.

Procedure calls

A procedure call has the form:

```plaintext
<procedure_name>(<arguments>);
```

Return statements

A procedure return has the form:

```plaintext
return;
```

A function return has the form:
return <expression>;
where <expression> is of the type declared in the function prototype line.

K14.5.3 Conditional control structures

This section describes how conditional control structures are used in the pseudocode.

if ... then ... else ...

In addition to being a ternary operator, a multi-line if ... then ... else ... structure can act as a control structure and has the form:

```
if <boolean_expression> then
    <statement 1>
    <statement 2>
    ...
    <statement n>
elsif <boolean_expression> then
    <statement a>
    <statement b>
    ...
    <statement z>
else
    <statement A>
    <statement B>
    ...
    <statement Z>
```

The block of lines consisting of elsif and its indented statements is optional, and multiple elsif blocks can be used.

The block of lines consisting of else and its indented statements is optional.

Abbreviated one-line forms can be used when the then part, and in the else part if it is present, contain only simple statements such as:

```
if <boolean_expression> then <statement 1>
if <boolean_expression> then <statement 1>; else <statement A>
if <boolean_expression> then <statement 1>; <statement 2>; else <statement A>
```

Note

In these forms, <statement 1>, <statement 2> and <statement A> must be terminated by semicolons. This and the fact that the else part is optional distinguish its use as a control structure from its use as a ternary operator.

case ... of ...

A case ... of ... structure has the form:

```
case <expression> of
    when <literal values1>
        <statement 1>
        <statement 2>
        ...
        <statement n>
    when <literal values2>
        <statement 1>
        <statement 2>
        ...
        <statement n>
    ...
    more "when" groups if required ...
```
otherwise
  <statement A>;
  <statement B>;
  ...
  <statement Z>;

In this structure, <literal values1> and <literal values2> consist of literal values of the same type as <expression>, separated by commas. There can be additional when groups in the structure. Abbreviated one line forms of when and otherwise parts can be used when they contain only simple statements.

If <expression> has a bitstring type, the literal values can also include bitstring literals containing 'x' bits, known as bitmasks. For details, see Equality and non-equality on page K14-8139.

K14.5.4 Loop control structures

This section describes the three loop control structures used in the pseudocode.

**repeat ... until ...**

A repeat .. until .. structure has the form:

```
repeat
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
until <boolean_expression>;
```

It executes the statement block at least once, and the loop repeats until <boolean expression> evaluates to TRUE. Variables explicitly declared inside the loop body have scope local to that loop and might not be accessed outside the loop body.

**while ... do**

A while .. do structure has the form:

```
while <boolean_expression> do
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

It begins executing the statement block only if the Boolean expression is true. The loop then runs until the expression is false.

**for ...**

A for .. structure has the form:

```
for <assignable_expression> = <integer_expr1> to <integer_expr2>
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

The <assignable_expression> is initialized to <integer_expr1> and compared to <integer_expr2>. If <integer_expr1> is less than <integer_expr2>, the loop body is executed and the <assignable_expression> incremented by one. This repeats until <assignable expression> is more than or equal to <integer_expr2>.

There is an alternate form:

```
for <assignable_expression> = <integer_expr1> downto <integer_expr2>
```

where <integer_expr1> is decremented after the loop body executes and continues until <assignable expression> is less than or equal than <integer_expr2>. 
**K14.5.5 Special statements**

This section describes statements with particular architecturally-defined behaviors.

**UNDEFINED**

This subsection describes the statement:

```c
UNDEFINED;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.

**UNPREDICTABLE**

This subsection describes the statement:

```c
UNPREDICTABLE;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

**SEE...**

This subsection describes the statement:

```c
SEE <reference>;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The `<reference>` indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

**IMPLEMENTATION_DEFINED**

This subsection describes the statement:

```c
IMPLEMENTATION_DEFINED {"<text>"};
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION_DEFINED. An optional `<text>` field can give more information.

**K14.5.6 Comments**

The pseudocode supports two styles of comments:

- `//` starts a comment that is terminated by the end of the line.
- `/*` starts a comment that is terminated by `*/`.

`/**` statements might not be nested, and the first `*/` ends the comment.

---

**Note**

Comment lines do not require a terminating semicolon.
K14.6 Built-in functions

This section describes:

• Bitstring manipulation functions.
• Arithmetic functions on page K14-8151.

K14.6.1 Bitstring manipulation functions

The following bitstring manipulation functions are defined:

Bitstring length and most significant bit

If x is a bitstring:

• The bitstring length function \( \text{Len}(x) \) returns the length of x as an integer.

Bitstring concatenation and replication

If x is a bitstring and n is an integer with \( n \geq 0 \):

• \( \text{Replicate}(x, n) \) is the bitstring of length \( n \times \text{Len}(x) \) consisting of n copies of x concatenated together.
• \( \text{Zeros}(n) = \text{Replicate}('0', n) \).
• \( \text{Ones}(n) = \text{Replicate}('1', n) \).

Bitstring count

If x is a bitstring, \( \text{BitCount}(x) \) is an integer result equal to the number of bits of x that are ones.
Testing a bitstring for being all zero or all ones

If x is a bitstring:

- IsZero(x) produces TRUE if all of the bits of x are zeros and FALSE if any of them are ones.
- IsZeroBit(x) produces '1' if all of the bits of x are zeros and '0' if any of them are ones.

IsOnes(x) and IsOnesBit(x) work in the corresponding ways. This means:

IsZero(x) = (BitCount(x) == 0)
IsOnes(x) = (BitCount(x) == Len(x))
IsZeroBit(x) = if IsZero(x) then '1' else '0'
IsOnesBit(x) = if IsOnes(x) then '1' else '0'

Lowest and highest set bits of a bitstring

If x is a bitstring, and N = Len(x):

- LowestSetBit(x) is the minimum bit number of any of the bits of x that are ones. If all of its bits are zeros, LowestSetBit(x) = N.
- HighestSetBit(x) is the maximum bit number of any of the bits of x that are ones. If all of its bits are zeros, HighestSetBit(x) = -1.
- CountLeadingZeroBits(x) is the number of zero bits at the left end of x, in the range 0 to N. This means:
  CountLeadingZeroBits(x) = N - 1 - HighestSetBit(x).
- CountLeadingSignBits(x) is the number of copies of the sign bit of x at the left end of x, excluding the sign bit itself, and is in the range 0 to N-1. This means:
  CountLeadingSignBits(x) = CountLeadingZeroBits(x<N-1:1> EOR x<N-2:0>).

Zero-extension and sign-extension of bitstrings

If x is a bitstring and i is an integer, then ZeroExtend(x, i) is x extended to a length of i bits, by adding sufficient zero bits to its left. That is, if i == Len(x), then ZeroExtend(x, i) = x, and if i > Len(x), then:

ZeroExtend(x, i) = Replicate('0', i-Len(x)) : x

If x is a bitstring and i is an integer, then SignExtend(x, i) is x extended to a length of i bits, by adding sufficient copies of its leftmost bit to its left. That is, if i == Len(x), then SignExtend(x, i) = x, and if i > Len(x), then:

SignExtend(x, i) = Replicate(TopBit(x), i-Len(x)) : x

It is a pseudocode error to use either ZeroExtend(x, i) or SignExtend(x, i) in a context where it is possible that i < Len(x).

Converting bitstrings to integers

If x is a bitstring, SInt() is the integer whose two’s complement representation is x.

UInt() is the integer whose unsigned representation is x.

Int(x, unsigned) returns either SInt(x) or UInt(x) depending on the value of its second argument.

K14.6.2 Arithmetic functions

This section defines built-in arithmetic functions.

Absolute value

If x is either of type real or integer, Abs(x) returns the absolute value of x. The result is the same type as x.
### Rounding and aligning

If \( x \) is a real:
- \( \text{RoundDown}(x) \) produces the largest integer \( n \) such that \( n \leq x \).
- \( \text{RoundUp}(x) \) produces the smallest integer \( n \) such that \( n \geq x \).
- \( \text{RoundTowardsZero}(x) \) produces:
  - \( \text{RoundDown}(x) \) if \( x > 0.0 \).
  - 0 if \( x = 0.0 \).
  - \( \text{RoundUp}(x) \) if \( x < 0.0 \).

If \( x \) and \( y \) are both of type integer, \( \text{Align}(x, y) = y \times (x \text{ DIV } y) \), and is of type integer.

If \( x \) is of type bitstring and \( y \) is of type integer, \( \text{Align}(x, y) = (\text{Align}(\text{UInt}(x), y)) \ll (\text{Len}(x)-1:0) \), and is a bitstring of the same length as \( x \).

It is a pseudocode error to use either form of \( \text{Align}(x, y) \) in any context where \( y \) can be 0. In practice, \( \text{Align}(x, y) \) is only used with \( y \) a constant power of two, and the bitstring form used with \( y = 2^n \) has the effect of producing its argument with its \( n \) low-order bits forced to zero.

### Maximum and minimum

If \( x \) and \( y \) are integers or reals, then \( \text{Max}(x, y) \) and \( \text{Min}(x, y) \) are their maximum and minimum respectively. \( x \) and \( y \) must both be of type integer or of type real. The function returns a value of the same type as its operands.
K14.7 Miscellaneous helper procedures and functions

This section lists the prototypes of miscellaneous helper procedures and functions used by the pseudocode, together with a brief description of the effect of the procedure or function. The pseudocode does not define the operation of these helper procedures and functions.

Note

Chapter J1 *Armv8 Pseudocode* also has an entry for each of these functions, but currently these entries do not say anything about the effect of the function. When this information is added in Chapter J1 this section will be removed from the manual.

K14.7.1 EndOfInstruction()

This procedure terminates processing of the current instruction.

EndOfInstruction();

K14.7.2 Hint_Debug()

This procedure supplies a hint to the debug system.

Hint_Debug(bits(4) option);

K14.7.3 Hint_PreloadData()

This procedure performs a *preload data* hint.

Hint_PreloadData(bits(32) address);

K14.7.4 Hint_PreloadDataForWrite()

This procedure performs a *preload data* hint with a probability that the use will be for a write.

Hint_PreloadDataForWrite(bits(32) address);

K14.7.5 Hint_PreloadInstr()

This procedure performs a *preload instructions* hint.

Hint_PreloadInstr(bits(32) address);

K14.7.6 Hint_Yield()

This procedure performs a *Yield* hint.

Hint_Yield();

K14.7.7 IsExternalAbort()

This function returns TRUE if the abort currently being processed is an External abort and FALSE otherwise. It is used only in exception entry pseudocode.

boolean IsExternalAbort(Fault type)
assert type != Fault_None;
boolean IsExternalAbort(FaultRecord fault);
K14.7.8   IsAsyncAbort()

   This function returns TRUE if the abort currently being processed is an asynchronous abort, and FALSE otherwise. It is used only in exception entry pseudocode.

   boolean IsAsyncAbort(Fault type)
   assert type != Fault_None;

   boolean IsAsyncAbort(FaultRecord fault);

K14.7.9   LSInstructionSyndrome()

   This function returns the extended syndrome information for a fault reported in the HSR.

   bits(11) LSInstructionSyndrome();

K14.7.10  ProcessorID()

   This function returns an integer that uniquely identifies the executing PE in the system.

   integer ProcessorID();

K14.7.11  RemapRegsHaveResetValues()

   This function returns TRUE if the remap registers PRRR and NMRR have their IMPLEMENTATION DEFINED reset values, and FALSE otherwise.

   boolean RemapRegsHaveResetValues();

K14.7.12  ResetControlRegisters()

   This function resets the System registers and memory-mapped control registers that have architecturally-defined reset values to those values. For more information about the affected registers see:

   •  PE state on reset to AArch64 state on page D1-2330.
   •  PE state on reset into AArch32 state on page G1-5801.

   AArch64.ResetControlRegisters(boolean ResetIsCold)
   AArch32.ResetControlRegisters(boolean ResetIsCold)

K14.7.13  ThisInstr()

   This function returns the bitstring encoding of the currently-executing instruction.

   bits(32) ThisInstr();

   ______ Note ________

   Currently, this function is used only on 32-bit instruction encodings.

K14.7.14  ThisInstrLength()

   This function returns the length, in bits, of the current instruction. This means it returns 32 or 16:

   integer ThisInstrLength();
K14.8 Arm pseudocode definition index

This section contains the following tables:

- Table K14-3 which contains the pseudocode data types.
- Table K14-4 which contains the pseudocode operators.
- Table K14-5 on page K14-8156 which contains the pseudocode keywords and control structures.
- Table K14-6 on page K14-8157 which contains the statements with special behaviors.

### Table K14-3 Index of pseudocode data types

<table>
<thead>
<tr>

Appendix K15
Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

• Introduction and register disambiguation on page K15-8160.
• Alphabetical index of AArch64 registers and System instructions on page K15-8165.
• Functional index of AArch64 registers and System instructions on page K15-8179.
• Alphabetical index of AArch32 registers and System instructions on page K15-8194.
• Functional index of AArch32 registers and System instructions on page K15-8204.
• Alphabetical index of memory-mapped registers on page K15-8215.
• Functional index of memory-mapped registers on page K15-8222.
## K15.1 Introduction and register disambiguation

In some sections of this manual, registers are referred to by a *general name*, where the description applies to more than one context. Generally, this is one of the following:

- The description applies to both AArch32 state and AArch64 state, and therefore the register names could apply to either AArch32 System registers or AArch64 System registers.
- The description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception level suffix, 
  \_EL0, 
  \_EL1, 
  \_EL2, or 
  \_EL3.

The following sections disambiguate the general register names:

- *Register name disambiguation by Execution state*.
- *Register name disambiguation by Exception level* on page K15-8164.

### K15.1.1 Register name disambiguation by Execution state

Table K15-1 disambiguates the general names of the registers by Execution state.

K15.3 Functional index of AArch64 registers and System instructions

This section is an index of the AArch64 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- Special-purpose registers.
- VMSA-specific registers on page K15-8180.
- ID registers on page K15-8181.
- Performance monitors registers on page K15-8182.
- Debug registers on page K15-8183.
- RAS registers on page K15-8184.
- Generic timer registers on page K15-8184.
- Cache maintenance system instructions on page K15-8185.
- Address translation system instructions on page K15-8186.
- TLB maintenance system instructions on page K15-8187.
- Prediction restriction System instructions on page K15-8190.
- Base system registers on page K15-8190.

K15.3.1 Special-purpose registers

This section is an index to the registers in the Special-purpose registers functional group.

K15.5 Functional index of AArch32 registers and System instructions

This section is an index of the AArch32 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- Special-purpose registers.
- VMSA-specific registers.
- ID registers on page K15-8205.
- Performance monitors registers on page K15-8206.
- Debug registers on page K15-8207.
- RAS registers on page K15-8208.
- Generic timer registers on page K15-8209.
- Cache maintenance system instructions on page K15-8210.
- Address translation system instructions on page K15-8210.
- TLB maintenance system instructions on page K15-8211.
- Legacy feature registers and system instructions on page K15-8212.
- Base system registers on page K15-8213.

K15.5.1 Special-purpose registers

This section is an index to the registers in the Processor state registers functional group.

K15.7 Functional index of memory-mapped registers

This section is an index of the memory-mapped registers, divided by functional group. Each of the following sections lists the registers for a functional group:

- **ID registers**.
- **Performance monitors registers**.
- **Debug registers on page K15-8224**.
- **RAS registers on page K15-8225**.
- **Cross-trigger interface registers on page K15-8226**.

K15.7.1 ID registers

This section is an index to the registers in the Identification registers functional group.

K15.7 Functional index of memory-mapped registers
Glossary

**A32 instruction**  A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in A32 state. A32 instructions must be word-aligned.

A32 instructions were previously called ARM instructions.

*See also* A32 state, A64 instruction, T32 instruction.

**A32 state**  The AArch32 Instruction set state in which the PE executes A32 instructions.

A32 state was previously called ARM state.

*See also* T32 instruction, T32 state.

**A64 instruction**  A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.

*See also* A32 instruction, T32 instruction.

**AArch32**  The 32-bit Execution state. In AArch32 state, addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

*See also* AArch64, A32 instruction, T32 instruction.

**AArch64**  The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

*See also* AArch32, A64 instruction.

**Abort**  An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.

**Addressing mode**  Means a method for generating the memory address used by a load/store instruction.

**Advanced SIMD**  A feature of the Arm architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.
Aligned
A data item stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.

An aligned access is one where the address of the access is aligned to the size of each element of the access.

Architecturally executed
An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been architecturally executed. Any instruction that, in a simple sequential execution of a program, is treated as a NOP because it fails its condition code check, is an architecturally executed instruction.

In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.

See also Condition code check, Simple sequential execution.

Architecturally mapped
Where this manual describes a register as being architecturally mapped to another register, this indicates that, in an implementation that supports both of the registers, the two registers access the same state.

Architecturally UNKNOWN
An architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of UNKNOWN. Implementations can define the value of the field, but are not required to do so.

See also IMPLEMENTATION DEFINED.

ARM core registers
Some older documentation uses ARM core registers to refer to the following set of registers for execution in AArch32 state:

• The 13 general-purpose registers, R0-R12, that software can use for processing.
• SP, the stack pointer, that can also be referred to as R13.
• LR, the link register, that can also be referred to as R14.
• PC, the program counter, that can also be referred to as R15.

See also General-purpose registers.

ARM instruction
See A32 instruction.

Associativity
See Cache associativity.

Atomicity
Describes either single-copy atomicity or multi-copy atomicity. Atomicity in the Arm architecture defines these forms of atomicity for the Arm architecture.

See also Multi-copy atomicity, Single-copy atomicity.

Banked register
A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.

Base register
A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.

Base register writeback
Describes writing back a modified value to the base register used in an address calculation.

Behaves as if
Where this manual indicates that a PE behaves as if a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.

Big-endian memory
Means that, for example:

• A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.
• A byte at a halfword-aligned address is the most significant byte in the halfword at that address.
See also Endianness, Little-endian memory.

Blocking
Describes an operation that does not permit following instructions to be executed before the operation completes. A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

Branch prediction
Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.
See also Prefetching.

Breakpoint
A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

Byte
An 8-bit data item.

Cache associativity
The number of locations in a cache set to which an address can be assigned. Each location is identified by its way value.

Cache level
The position of a cache in the cache hierarchy. In the Arm architecture, the lower numbered levels are those closest to the PE. For more information, see Terms used in describing the cache maintenance instructions on page D4-2500.

Cache line
The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A memory cache line is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

Cache lockdown
Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.

Cache miss
A memory access that cannot be processed at high speed because the data it addresses is not in the cache.

Cache sets
Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.

Cache way
A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way n consists of the cache line with index n from each cache set.

Coherence order
See Coherent.

Coherent
Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the coherence order for that byte in memory.

Completer
An agent in a computing system that responds to and completes a memory transaction that was initiated by a Requester.
See also Requester.

Condition code check
The process of determining whether a conditional instruction executes normally or is treated as a NOP. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of PSTATE.IT determines whether the instruction is executed normally.

See also Condition code field, Condition flags, Conditional execution.
**Condition code field**
A 4-bit field in an instruction that specifies the condition under which the instruction executes.

*See also* Condition code check.

**Condition flags**
The N, Z, C, and V bits of PSTATE, an SPSR, or FPSCR. See the register descriptions for more information.

*See also* Condition code check, PSTATE.

**Conditional execution**
When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a NOP.

*See also* Condition code check.

**CONSTRAINED UNPREDICTABLE**
Where an instruction can result in UNPREDICTABLE behavior, the Armv8 architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Execution at Non-secure EL1 or EL0 of an instruction that is CONSTRAINED UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term CONSTRAINED UNPREDICTABLE is shown in SMALL CAPITALS.

*See also* UNPREDICTABLE.

**Context switch**
The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

**Context synchronization event**
One of:

- Performing an ISB operation. An ISB operation is performed when an ISB instruction is executed and does not fail its condition code check.
- Exception entry, if FEAT_ExS is not implemented or the exception is taken to AArch32 or if FEAT_ExS is implemented and the appropriate SCTLR_ELx.EIS bit is set.
- Return from an exception, if FEAT_ExS is not implemented, or the exception is returning from AArch32 or if FEAT_ExS is implemented and the appropriate SCTLR_ELx.EOS bit is set.
- Exit from Debug state.
- Executing a DCPS instruction.
- Executing a DRPS instruction.

The effects of a Context synchronization event are:

- All unmasked interrupts that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- If halting is allowed, all Halting debug events that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- No instructions appearing in program order after an instruction that causes a Context synchronization event will have performed any part of their functionality until the Context synchronization event has occurred.
- All direct and indirect writes to System registers that are made before the Context synchronization event affect any instruction, including a direct read, that appears in program order after the instruction causing the Context synchronization event.
- All completed changes to the translation tables for entries that, before the change, were not permitted to be cached in a TLB, affect all instruction fetches that appear in program order after the instruction causing the Context synchronization event.
• All invalidations of TLBs, instruction caches, and, in AArch32 state, branch predictors, that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.

• In AArch32 state, all Non-cacheable writes that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.

• Changes to the Debug external authentication interfaces that are made before the Context synchronization event affect any instruction that appears in program order after the instruction causing the Context synchronization event.

Note

• The architecture requires that instructions that generate Context synchronization events do not appear to be executed speculatively, except that the performance monitor counters are permitted to reveal such speculation.

• Context synchronization events were previously described as context synchronization operations.

Data independent timing (DIT)
The time that it takes to execute a piece of code where the time is not a function of the data being operated on. For more information, see About PSTATE.DIT on page B1-113 and About the DIT bit on page E1-3999.

Debugger
In most of this manual, debugger refers to any agent that is performing debug. However, some chapters or parts of this manual require a more rigorous definition, and define debugger locally. See:

• Definition of a debugger in the context of self-hosted debug on page D2-2418.
• Definition of a debugger in the context of self-hosted debug on page G2-5854.
• Definition and constraints of a debugger in the context of external debug on page H1-7010.

Deprecated
Something that is present in the Arm architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the Arm architecture, but might not be present, or might be deprecated and optional, in future versions of the Arm architecture.

See also OPTIONAL.

Digital signal processing (DSP)
Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

Direct Memory Access (DMA)
An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.

Direct read
A direct read of a System register is a read performed by a System register access instruction.

For more information, see Direct read on page D13-2865.

See also Direct write, Indirect read, Indirect write.

Direct write
A direct write of a System register is a write performed by a System register access instruction.

For more information, see Direct write on page D13-2865.

See also Direct read, Indirect read, Indirect write.

DMA
See Direct Memory Access (DMA).

DNM
See Do-Not-Modify (DNM).

Domain
In the Arm architecture, domain is used in the following contexts.

Shareability domain Defines a set of observers for which the shareability attributes make the data or unified caches transparent for data accesses.

Power domain Defines a block of logic with a single, common, power supply.
Memory regions domain
When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the Domain Access Control Register (DACR). Arm deprecates any use of memory regions domains.

Do-Not-Modify (DNM)
Means the value must not be altered by software. DNM fields read as UNKNOWN values, and must only be written with the value read from the same field on the same PE.

Double-precision value
Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the IEEE Standard for Floating-point Arithmetic.

Doubleword
A 64-bit data item. Doublewords are normally at least word-aligned in Arm systems.

Doubleword-aligned
Means that the address is divisible by 8.

DSP
See Digital signal processing (DSP).

Effective value
A register control field, meaning a field in a register that controls some aspect of the behavior, can be described as having an Effective value:

- In some cases, the description of a control specifies that when control is active it causes a register control field to be treated as having a fixed value for all purposes other than direct reads, or direct reads and direct writes, of the register containing control field. When control is active that fixed value is described as the Effective value of register control field. For example, when the value of HCR.DC is 1, the Effective value of HCR.VM is 1, regardless of its actual value.

- In other cases, in some contexts a register control field is not implemented or is not accessible, but behavior of the PE is as if control field was implemented and accessible, and had a particular value. In this case, that value is the Effective value of register control field.

Note
Where a register control field is introduced in a particular version of the architecture, and is not implemented in an earlier version of the architecture, typically it will have an Effective value in that earlier version of the architecture.

- Otherwise, the Effective value of a register control field is the value of that field.

Endianness
An aspect of the system memory mapping.

See also Big-endian memory and Little-endian memory.

Exception
Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

Exception vector
A fixed address that contains the address of the first instruction of the corresponding exception handler.

Execution stream
The stream of instructions that would have been executed by sequential execution of the program.

Explicit access
A read from memory, or a write to memory, generated by a load or store instruction executed by the PE. Reads and writes generated by hardware translation table accesses are not explicit accesses.

External abort
An abort that is generated by the external memory system.

Fast Context Switch Extension (FCSE)
Modifies the behavior of an Arm memory system to enable multiple programs running on the Arm PE to use identical address ranges, while ensuring that the addresses they present to the rest of the memory system differ. From Armv6, Arm deprecates any use of the FCSE. The FCSE is:

- Optional in an Armv7 implementation that does not include the Multiprocessing Extensions.
- Obsolete from the introduction of the Multiprocessing Extensions.
FCSE  See Fast Context Switch Extension (FCSE).

Flat address mapping  Is where the physical address for every access is equal to its virtual address.

Flush-to-zero mode  A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and intermediate results with zeros, without significantly affecting the accuracy of their final results.

General-purpose registers  The registers that the base instructions use for processing:

- In AArch32 state the general-purpose registers are R0-R14, that can also be described as R0-R12, SP, LR.

  Note  Older documentation defines the AArch32 general-purpose registers as R0-R12, and the Arm core registers as R0-R12, SP, LR, and PC.

- In AArch64 state the general-purpose registers are:
  - W0-W30 when accessed as 32-bit registers.
  - X0-X30 when accessed as 64-bit registers.

See also High registers, Low registers.

Generated by  The memory model is written in terms of reads from memory and writes to memory. These reads and writes:

- Are generated by instructions such as loads, stores, and atomic memory accesses.
- Correspond to the memory accesses, other than translation table walks, that are defined in the instruction pseudocode.

Some instructions generate more than one read or write.

Halfword  A 16-bit data item. Halfwords are normally halfword-aligned in Arm systems.

Halfword-aligned  Means that the address is divisible by 2.

High registers  In AArch32 state, the general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

  Note  In some contexts, high registers refers to R8-R15, meaning R8-R14 and the PC.

See also General-purpose registers, Low registers.

High vectors  An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.

IGNORED  Indicates that the architecture guarantees that the bit or field is not interpreted or modified by hardware.

In body text, the term IGNORED is shown in SMALL CAPITALS.

Immediate and offset fields  Are unsigned unless otherwise stated.

Immediate value  A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many A64, A32, and T32 instructions can be used with an immediate argument.

IMP  An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.
**IMPLEMENTATION DEFINED**
Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.

**Index register**
A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

**Indirect read**
When an instruction uses a System register value to establish operating conditions, that use of the System register is an indirect read of the System register.

For more information, including additional examples of indirect reads, see Indirect read on page D13-2865.

See also Direct read, Direct write, Indirect write.

**Indirect write**
An indirect write of a System register occurs when the contents of a register are updated by some mechanism other than a Direct write to that register. For example, an indirect write to a register might occur as a side-effect of executing an instruction that does not perform a direct write to the register, or because of some operation performed by an external agent.

For more information, see Indirect write on page D13-2865.

See also Direct read, Direct write, Indirect read.

**Inline literals**
These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.

**Intermediate physical address (IPA)**
An implementation of virtualization, the address to which a Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA.

See also Physical address (PA), Virtual address (VA).

**Interworking**
A method of working that permits branches between software using the A32 and T32 instruction sets.

**IPA**
See Intermediate physical address (IPA).

**Level**
See Cache level.

**Level of Coherence (LoC)**
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. For more information, see Terms used in describing the cache maintenance instructions on page D4-2500.

See also Cache level, Point of coherency (PoC).

**Level of Unification, Inner Shareable (LoUIS)**
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. For more information, see Terms used in describing the cache maintenance instructions on page D4-2500.

See also Cache level, Point of unification (PoU).

**Level of Unification, uniprocessor (LoUU)**
For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information, see Terms used in describing the cache maintenance instructions on page D4-2500.

See also Cache level, Point of unification (PoU).

**Line**
See Cache line.

**Little-endian memory**
Means that, for example:

- A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the least significant byte in the halfword at that address.

See also Big-endian memory, Endianness.

**Load/Store architecture**
An architecture where data-processing operations only operate on register contents, not directly on memory contents.

**LoC**
See Level of Coherence (LoC).

**LoUIS**
See Level of Unification, Inner Shareable (LoUIS).

**LoUU**
See Level of Unification, uniprocessor (LoUU).

**Lockdown**
See Cache lockdown.

**Low registers**
In AArch32 state, general-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.

See also General-purpose registers, High registers.

**Memory barrier**
See Memory barriers on page B2-134.

**Memory coherency**
The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.

**Memory Management Unit (MMU)**
Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.

**Memory Protection Unit (MPU)**
A hardware unit whose registers provide simple control of a limited number of protection regions in memory.

**Miss**
See Cache miss.

**MMU**
See Memory Management Unit (MMU).

**MPU**
See Memory Protection Unit (MPU).

**Multi-copy atomicity**
The form of atomicity described in Requirements for multi-copy atomicity on page B2-120.

See also Atomicity, Single-copy atomicity.

**NaN**
Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a quiet NaN, that propagate through most floating-point operations, or a signaling NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the IEEE Standard for Floating-point Arithmetic.

See also Quiet NaN, Signaling NaN.

**Natural eviction**
A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as the execution of a cache maintenance instruction. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.

**Observer**
A PE or mechanism in the system, such as a peripheral device, that can generate reads from or writes to memory.

**Obsolete**
Obsolete indicates something that is no longer supported by Arm. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

**Offset addressing**
Means that the memory address is formed by adding or subtracting an offset to or from the base register value.
OPTIONAL

When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the Arm architecture:

- If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. Arm expects such a feature to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature.
  A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.

- A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the Arm architecture after the initial release of that version of the architecture. Arm recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term OPTIONAL are shown in SMALL CAPITALS.

Note

Do not confuse these Arm-specific uses of OPTIONAL with other uses of optional, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
- Behavior determined by an implementation choice, for example the optional byte order reversal in an Armv7-R implementation, where the SCTLR.IE bit indicates the implemented option.

See also Deprecated.

PA

See Physical address (PA).

PE

See Processing element (PE).

Physical address (PA)

An address that identifies a location in the physical memory map.

See also Intermediate physical address (IPA), Virtual address (VA).

PoC

See Point of coherency (PoC).

PoP

See Point of persistence (PoP).

PoU

See Point of unification (PoU).

Point of coherency (PoC)

For a particular VA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. For more information, see Terms used in describing the cache maintenance instructions on page D4-2500.

Point of persistence (PoP)

The point in a memory system where there is a system guarantee that there is sufficient energy within the system to ensure that a write to memory will be persistent if system power is removed. For more information, see Terms used in describing the cache maintenance instructions on page D4-2500.

Point of unification (PoU)

For a particular PE, the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. For more information, see Terms used in describing the cache maintenance instructions on page D4-2500.

Post-indexed addressing

Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

Prefetching

Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.
In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

---------- Note ----------
The Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

----------

**Pre-indexed addressing**
Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

**Processing element (PE)**

**Protection region**
A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

**Protection Unit**
*See Memory Protection Unit (MPU).*

**Pseudo-instruction**
UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, `MOV <Rd>, <Rm>, LSL #<n>` is a pseudo-instruction that is expected to disassemble as `LSL <Rd>, <Rm>, #<n>`.

**PSTATE**
An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

*See also* Condition flags.

**Quadword**
A 128-bit data item. Quadwords are normally at least word-aligned in Arm systems.

**Quadword-aligned**
Means that the address is divisible by 16.

**Quiet NaN**
A NaN that propagates unchanged through most floating-point operations.

*See also* NaN, Signaling NaN.

**RAO**
*See Read-As-One (RAO).*

**RAZ**
*See Read-As-Zero (RAZ).*

**RAO/SBOP**
In versions of the Arm architecture before Armv8, Read-As-One, Should-Be-One-or-Preserved on writes.

In Armv8, RES1 replaces this description.

*See also* UNK/SBOP, Read-As-One (RAO), RES1, Should-Be-One-or-Preserved (SBOP).

**RAO/WI**
Read-As-One, Writes Ignored.

Hardware must implement the field as Read-as-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

*See also* Read-As-One (RAO).

**RAZ/SBZP**
In versions of the Arm architecture before Armv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.

In Armv8, RES0 replaces this description.

*See also* UNK/SBZP, Read-As-Zero (RAZ), RES0, Should-Be-Zero-or-Preserved (SBZP).
RAZ/WI
Read-As-Zero, Writes Ignored.
Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.
Software can rely on the field reading as all 0s, and on writes being ignored.
This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.
See also Read-As-Zero (RAZ).

Read-allocate cache
A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

Read-As-One (RAO)
Hardware must implement the field as reading as all 1s.
Software:
• Can rely on the field reading as all 1s.
• Must use a SBOP policy to write to the field.
This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.
See also RAO/SBOP, RAO/WI, RES1.

Read-As-Zero (RAZ)
Hardware must implement the field as reading as all 0s.
Software:
• Can rely on the field reading as all 0s
• Must use a SBZP policy to write to the field.
This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.
See also RAZ/SBZP, RAZ/WI, RES0.

Read, modify, write
In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

Requester
An agent in a computing system that is capable of initiating memory transactions.
See also Completer.

RES0
A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.
Within the architecture, there are some cases where a register bit or field:
• Is RES0 in some defined architectural context.
• Has different defined behavior in a different architectural context.

Note
• RES0 is not used in descriptions of instruction encodings.
• Where an AArch32 System register is Architecturally mapped to an AArch64 System register, and a bit or field in that register is RES0 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES0 for fields in read/write registers is:

If a bit is RES0 in all contexts
For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:
1. The bit is hardwired to 0. In this case:
   • Reads of the bit always return 0.
   • Writes to the bit are ignored.
2. The bit can be written. In this case:
   • An indirect write to the register sets the bit to 0.
   • A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
   If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   • A direct write to the bit must update a storage location associated with the bit.
   • The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES0 only in some contexts

For a bit in a read/write register, when the bit is described as RES0:
   • An indirect write to the register sets the bit to 0.
   • A read of the bit must return the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.
   If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   • A direct write to the bit must update a storage location associated with the bit.
   • While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:
   • Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
   • The value of the bit can be written, and a read returns the last value written to the bit.

The RES0 description can apply to bits or fields that are read-only, or are write-only:
   • For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
   • For a write-only bit, RES0 indicates that software must treat the bit as SBZ.

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:
   • Must not rely on the bit reading as 0.
   • Must use an SBZP policy to write to the bit.

This RES0 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES0.

In body text, the term RES0 is shown in SMALL CAPITALS.

See also Read-As-Zero (RAZ), RES1, Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

RES1

A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:
   • Is RES1 in some defined architectural context.
   • Has different defined behavior in a different architectural context.

— Note —
   • RES1 is not used in descriptions of instruction encodings.
• Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES1 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES1 for fields in read/write registers is:

**If a bit is RES1 in all contexts**

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
   • Reads of the bit always return 1.
   • Writes to the bit are ignored.
2. The bit can be written. In this case:
   • An indirect write to the register sets the bit to 1.
   • A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
     If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   • A direct write to the bit must update a storage location associated with the bit.
   • The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

**If a bit is RES1 only in some contexts**

For a bit in a read/write register, when the bit is described as RES1:

• An indirect write to the register sets the bit to 1.
• A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

    [Note]

As indicated in this list, this value might be written by an indirect write to the register.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

• A direct write to the bit must update a storage location associated with the bit.
• While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

• Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
• The value of the bit can be written, and a read returns the last value written to the bit.

The RES1 description can apply to bits or fields that are read-only, or are write-only:

• For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
• For a write-only bit, RES1 indicates that software must treat the bit as SBO.

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

• Must not rely on the bit reading as 1.
• Must use an SBOP policy to write to the bit.
This RES1 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES1.

In body text, the term RES1 is shown in SMALL CAPITALS.

See also Read-As-One (RAO), RES0, Should-Be-One-or-Preserved (SBOP), UNKNOWN.

Reserved

Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
- Bit positions described as reserved are:
  - In an RW or WO register, RES0.
  - In an RO register, UNK.

See also CONSTRAINED UNPREDICTABLE, RES0, RES1, UNDEFINED, UNK, UNPREDICTABLE.

RISC

Reduced Instruction Set Computer.

Rounding error

The value of the rounded result of an arithmetic operation minus the exact result of the operation.

Rounding mode

Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the IEEE Standard for Floating-point Arithmetic, see Floating-point standards, and terminology on page A1-54.

Saturated arithmetic

Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in Arm processors, in which overflowing results wrap around from \(+2^{31}–1\) to \(–2^{31}\) or vice versa.

SBO

See Should-Be-One (SBO).

SBOP

See Should-Be-One-or-Preserved (SBOP).

SBZ

See Should-Be-Zero (SBZ).

SBZP

See Should-Be-Zero-or-Preserved (SBZP).

Security hole

A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The Arm architecture forbids security holes.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Self-modifying code

Code that writes one or more instructions to memory and then executes them. When using self-modifying code, you must use cache maintenance and barrier instructions to ensure synchronization. For more information, see Caches and memory hierarchy on page B2-143.

Set

See Cache sets.

Should-Be-One (SBO)

Hardware must ignore writes to the field.

Arm strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Should-Be-One-or-Preserved (SBOP)

From the introduction of the Armv8 architecture, the description Should-Be-One-or-Preserved (SBOP) is superseded by RES1.
— Note —

The Armv7 Large Physical Address Extension modified the definition of SBOP for register bits that are SBOP in some but not all contexts. The behavior of these bits is covered by the RES1 definition, but not by the generic definition of SBOP given here.

Hardware must ignore writes to the field.

When writing this field, software must either write all 1s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Should-Be-Zero (SBZ)

Hardware must ignore writes to the field.

Arm strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Should-Be-Zero-or-Preserved (SBZP)

From the introduction of the Armv8 architecture, the description Should-Be-Zero-or-Preserved (SBZP) is superseded by RES0.

— Note —

The Armv7 Large Physical Address Extension modified the definition of SBZP for register bits that are SBZP in some but not all contexts. The behavior of these bits is covered by the RES0 definition, but not by the generic definition of SBZP given here.

Hardware must ignore writes to the field.

When writing this field, software must either write all 0s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Signaling NaN

An Invalid Operation floating-point exception occurs whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

See also NaN, Quiet NaN.

Signed immediate and offset fields

Are encoded in two’s complement notation unless otherwise stated.

SIMD

Single-Instruction, Multiple-Data.

The SIMD instructions in AArch32 state are:

- The instructions summarized in Parallel addition and subtraction instructions on page F1-4086.
- The Advanced SIMD instructions summarized in Advanced SIMD and floating-point instructions on page E1-4000, when operating on vectors.
Note

In Armv7, some VFP instructions can operate on vectors. However, Arm deprecates those instruction uses, and strongly recommends that Advanced SIMD instructions are always used for vector operations.

Simple sequential execution

The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and Arm does not expect this model to correspond to a realistic implementation of the architecture.

Single-copy atomicity

The form of atomicity described in Properties of single-copy atomic accesses on page B2-120.

See also Atomicity, Multi-copy atomicity.

Single-precision value

A 32-bit word that is interpreted as a basic single-precision floating-point number according to the IEEE Standard for Floating-point Arithmetic.

Spatial locality

The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

Speculative

Speculative operations are:

- Operations that are generated by instructions that appear in the Execution stream after a branch that is not architecturally resolved.

- Operations that are generated by instructions that appear in the Execution stream after an instruction where a synchronous exception condition has not been architecturally resolved.

- Operations that are generated by conditional instructions for which the conditions for the instruction have not been architecturally resolved.

- Operations that are generated by instructions that appear in the Execution stream after the point at which a precise asynchronous exception will be taken.

- Reads or writes generated by load or store instructions for which the data being written or the address being accessed comes from a register that has not been architecturally resolved.

- Operations generated by the hardware that are not directly generated by any instructions appearing in the Execution stream.

See also Execution stream.

Special-purpose register

One of a specified set of registers for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization:

- Special-purpose registers on page C5-385 specifies the AArch64 Special-purpose registers.

- AArch32 Special-purpose registers on page G1-5732 lists the AArch32 Special-purpose registers.

T32 instruction

One or two halfwords that specify an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in T32 state. T32 instructions must be halfword-aligned.

T32 instructions were previously called Thumb instructions.

See also A32 instruction, A64 instruction, T32 state.

T32 state

The AArch32 Instruction set state in which the PE executes T32 instructions.

T32 state was previously called Thumb state.

See also A32 state, T32 instruction.
**Taken locally**  
* Taken locally is a qualifier that determines which instances of an exception are counted by particular PMU events. See, in particular, *Arm recommendations for IMPLEMENTATION DEFINED event numbers on page K3-8004*. In this context, an exception that is *Taken locally* means an exception that is one of:
- Taken to the current Exception level.

  **Note**  
  This is not possible when the current Exception level is EL0.

- Taken from EL0 to EL1.
- Taken from EL0 to EL2 because the *Effective value* of HCR_EL2.{E2H, TGE} is \{1, 1\}.

  **Note**  
  An exception taken from EL0 to EL2 because the *Effective value* of HCR_EL2.{E2H, TGE} is \{0, 1\} is not *Taken locally*. This includes exceptions taken to EL2 using AArch32 when HCR.TGE is 1.

**Temporal locality**  
The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

**Thumb instruction**  
* See T32 instruction.

**TLB**  
* See Translation Lookaside Buffer (TLB).

**TLB lockdown**  
A way to prevent specific translation table walk results being accessed. This ensures that accesses to the associated memory areas never cause a translation table walk.

**Translation Lookaside Buffer (TLB)**  
A memory structure containing the results of translation table walks. They help to reduce the average cost of a memory access. Usually, there is a TLB for each memory interface of the Arm implementation.

**Translation table**  
A table held in memory that defines the properties of memory areas of various sizes from 1KB to 1MB.

**Translation table walk**  
The process of doing a full translation table lookup. It is performed automatically by hardware.

**Trap enable bits**  
In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.

**Unaligned**  
An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

**Unaligned memory accesses**  
Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

**Unallocated**  
Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or as an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

* See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE.

**UNDEFINED**  
Indicates cases where an attempt to execute a particular encoding bit pattern generates an exception, that is taken to the current Exception level, or to the default Exception level for taking exceptions if the UNDEFINED encoding was executed at EL0. This applies to:
- Any encoding that is not allocated to any instruction.
- Any encoding that is defined as never accessible at the current Exception level.
- Some cases where an enable, disable, or trap control means an encoding is not accessible at the current Exception level.
If the generated exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception.

—— Note ————

On reset, the default Exception level for taking exceptions from EL0 is EL1. However, an implementation might include controls that can change this, effectively making EL1 inactive. See the description of the Exception model for more information

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also Undefined Instruction exception on page G1-5778.

**Unified cache**

Is a cache used for both processing instruction fetches and processing data loads and stores.

**Unindexed addressing**

Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0.

In Armv7 and earlier versions of the Arm architecture, and in the M-profile, the LDC, LDC2, STC, and STC2 instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

**UNK**

An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also UNKNOWN.

**UNK/SBOP**

Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also Read-As-One (RAO), Should-Be-One-or-Preserved (SBOP), UNKNOWN.

**UNK/SBZP**

Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also Read-As-Zero (RAZ), Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

**UNKNOWN**

An UNKNOWN value does not contain valid data, and can vary from implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE, are not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value can vary from moment to moment, and instruction to instruction, unless it has previously been assigned, other than at reset, to one of the following registers:

- Any of the general-purpose registers.
- Any of the Advanced SIMD and floating-point registers.
- Any of the Scalable Vector Extension registers.
- Any of the PSTATE N, Z, C, or V flags.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.
In body text, the term UNKNOWN is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNK, UNPREDICTABLE.

**UNPREDICTABLE**

Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

Execution at Non-secure EL1 or EL0 of an instruction that is UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED.

**VA**

See Virtual address (VA).

**VFP**

In Armv7, an extension to the Arm architecture, that provides single-precision and double-precision floating-point arithmetic.

**Virtual address (VA)**

An address generated by an Arm PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address.

See also Intermediate physical address (IPA), Physical address (PA).

**Watchpoint**

A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

**Way**

See Cache way.

**WI**

Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write.

See also RAO/WI, RAZ/WI, RES0, RES1.

**Word**

A 32-bit data item. Words are normally word-aligned in Arm systems.

**Word-aligned**

Means that the address is divisible by 4.

**Write-allocate cache**

A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

**Write-back cache**

A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a copy-back cache.

**Write-through cache**

A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done via a write buffer, to avoid slowing down the PE.

**Write buffer**

A block of high-speed memory that optimizes stores to main memory.
