Debug OS Save and Restore sequences on page H6-7446 describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

If the OS Lock is unlocked, and `DoubleLockStatus()==FALSE`, debug exceptions other than Breakpoint Instruction exceptions are enabled.

If OS Lock is locked, or if `DoubleLockStatus()==TRUE`, debug exceptions other than Breakpoint Instruction exceptions are disabled.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.

D2.6 Summary of the routing and enabling of debug exceptions

Behavior is as follows:

Breakpoint Instruction exceptions

These are always enabled, regardless of the current Exception level and Security state. A Breakpoint Instruction exception taken from EL3 is always routed to EL3. A Breakpoint Instruction exception taken from EL2 is routed to EL2. A Breakpoint Instruction exception taken from EL0 or EL1 is always routed to EL_D.

All other debug exceptions

Table D2-7 on page D2-2574 shows the valid combinations of MDCR_EL3.SDD, MDCR_EL2.TDE, MDSCR_EL1.KDE, and PSTATE.D, and for each combination shows where these exceptions are enabled from and where they are taken to.

In the table:

- Lock** Means the value of (OSLSR_EL1.OSLK == '1' || DoubleLockStatus()).
- NS** Means the *Effective value* of SCR_EL3.NS.
- SDD** Means the *Effective value* of MDCR_EL3.SDD. See *Disabling debug exceptions from Secure state* on page D2-2571.
- EEL2** Means the *Effective value* of SCR_EL3.EEL2. If FEAT_SEL2 is not implemented, this is 0.
- TGE** Means the value of HCR_EL2.TGE. If EL2 is not implemented, the PE behaves as if this is 0.
- TDE** Means the value of MDCR_EL2.TDE. If EL2 is not implemented, the PE behaves as if this is 0.
- KDE** Means the value of MDSCR_EL1.KDE.
- D** Means the value of PSTATE.D.
- n/a** Means not applicable. The PE cannot be executing at this Exception level.
- Means that debug exceptions are disabled from that Exception level.

Table D2-7 Routing of Breakpoint, Watchpoint, Software Step, and Vector Catch exceptions

Debug state	Lock	NS	SDD	EEL2	TGE	TDE	KDE	D	EL _D when enabled from:			
									EL0	EL1	EL2	EL3
Yes	X	X	X	X	X	X	X	X	-	-	-	-
No	TRUE	X	X	X	X	X	X	X	-	-	-	-
									FALSE	0	1	X
	0	0	X	X	0	X	EL1	-				
							1	0	X	X	0	0
	1	0	X	X	0	X						
							1	0	0	0	0	X
	1	0	0	0	0	0						
							1	0	0	0	0	0

Table D2-7 Routing of Breakpoint, Watchpoint, Software Step, and Vector Catch exceptions

Debug state	Lock	NS	SDD	EEL2	TGE	TDE	KDE	D	EL _D when enabled from:										
									EL0	EL1	EL2	EL3							
No	FALSE	0	0	1	0	1	0	X	EL2	EL2	-	-							
								1	0	EL2	EL2	EL2	-						
								1	EL2	EL2	-	-							
							1	X	0	X	0	0	0	X	EL2	n/a	-	-	
														1	0	EL2	n/a	EL2	-
														1	EL2	n/a	-	-	
							1	X	0	0	0	0	0	X	EL1	-	-	-	
														1	0	EL1	EL1	-	-
														1	EL1	-	-	-	
							1	X	0	0	0	0	0	X	EL2	EL2	-	-	
														1	0	EL2	EL2	EL2	-
														1	EL2	EL2	-	-	
							1	X	0	0	0	0	0	X	EL2	n/a	-	-	
														1	0	EL2	n/a	EL2	-
														1	EL2	n/a	-	-	

D2.7 Pseudocode description of debug exceptions

[AArch64.DebugFault\(\)](#) returns a `FaultRecord` object that indicates that a memory access has generated a debug exception:

The [AArch64.Abort\(\)](#) function processes `FaultRecord` objects, as described in *Abort exceptions on page D4-2670*, and generates a debug exception.

Some functions called by [AArch64.Abort\(\)](#) are:

- [AArch64.BreakpointException\(\)](#).
- [AArch64.WatchpointException\(\)](#).
- [AArch64.VectorCatchException\(\)](#).
- [AArch64.InstructionAbort\(\)](#).
- [AArch64.DataAbort\(\)](#).

These functions are defined in *Chapter J1 Armv8 Pseudocode*.

D2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

For software executing in an Exception level that is using AArch64, a Breakpoint Instruction exception results from the execution of an A64 BRK instruction. However, within the AArch64 EL1&0 translation regime, executing a T32 or A32 BKPT instruction at EL0 using AArch32 generates a Breakpoint Instruction exception.

For more information about the T32 and A32 BKPT instructions, see:

- [Breakpoint instruction in the A32 and T32 instruction sets on page G2-6167.](#)
- [BKPT instructions as the first instruction in an IT block on page G2-6168.](#)

The following subsections describe Breakpoint Instruction exceptions in an AArch64 translation regime:

- [About Breakpoint Instruction exceptions on page D2-2577.](#)
- [Breakpoint instructions on page D2-2577.](#)
- [Exception syndrome information and preferred return address on page D2-2578.](#)
- [Pseudocode description of Breakpoint Instruction exceptions on page D2-2578.](#)

D2.8.1 About Breakpoint Instruction exceptions

A *breakpoint* is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint Instruction exceptions, that this section describes, are software breakpoints. [Breakpoint exceptions on page D2-2579](#) describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

- The current Exception level.
- The current Security state.
- Whether the *debug target Exception level*, EL_D , is using AArch64 or AArch32.

————— Note —————

- The debug target Exception level, EL_D , is the Exception level that debug exceptions are targeting. [Routing debug exceptions on page D2-2569](#) describes how EL_D is derived.
- Debuggers using breakpoint instructions must be aware of the Armv8 rules for concurrent modification and execution of instructions. See [Concurrent modification and execution of instructions on page B2-130](#).

D2.8.2 Breakpoint instructions

The breakpoint instruction in the A64 instruction set is BRK #<immediate>. It is unconditional.

For details of the instruction encoding, see [BRK on page C6-941](#).

The breakpoint instruction in the A32 and T32 instruction sets is BKPT #<immediate>.

For more information about the A32 and T32 breakpoint instruction, see [Breakpoint instruction in the A32 and T32 instruction sets on page G2-6167](#).

D2.8.3 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information on page D2-2578](#).
- [Preferred return address on page D2-2578](#).

Exception syndrome information

On taking a Breakpoint Instruction exception, the PE records information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- [ESR_EL1](#).
- [ESR_EL2](#).
- [ESR_EL3](#).

———— **Note** —————

Breakpoint Instruction exceptions are the only debug exception that can be taken to EL3 using AArch64.

[Table D2-8 on page D2-2578](#) shows the information that the PE records.

Table D2-8 Information recorded in the [ESR_ELx](#)

ESR_ELx field	Information recorded in ESR_EL1, ESR_EL2, or ESR_EL3.	
<i>Exception Class, EC</i>	Whether the breakpoint instruction was executed in AArch64 state or AArch32 state. The PE sets this to: <ul style="list-style-type: none"> • 0x3C for an A64 BRK instruction. • 0x38 for an A32 or T32 BKPT instruction. 	
<i>Instruction Length, IL</i>	The PE sets this to: <ul style="list-style-type: none"> • 0 for a 16-bit T32 BKPT instruction. • 1 for an A64 BRK instruction, or an A32 BKPT instruction. 	
<i>Instruction Specific Syndrome, ISS</i>	ISS[24:16]	RES0.
	ISS[15:0]	The PE copies the instruction Comment field value into here, zero extended as necessary.

———— **Note** —————

- If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Breakpoint Instruction exception is routed to EL2, [ESR_EL2.EC](#) is set to the same value as if the exception was taken to EL1.
- For information about how debug exceptions can be routed to EL2, see [Routing debug exceptions on page D2-2569](#).

Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

D2.8.4 Pseudocode description of Breakpoint Instruction exceptions

[AArch64.SoftwareBreakpoint\(\)](#) generates a Breakpoint Instruction exception that is taken to AArch64 state.

This function is defined in [Chapter J1 Armv8 Pseudocode](#).

D2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:

- [About Breakpoint exceptions on page D2-2579.](#)
- [Breakpoint types and linking of breakpoints on page D2-2580.](#)
- [Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2589.](#)
- [Breakpoint instruction address comparisons on page D2-2590.](#)
- [Breakpoint context comparisons on page D2-2592.](#)
- [Breakpoint usage constraints on page D2-2593.](#)
- [Preferred return address on page D2-2596.](#)
- [Pseudocode description of Breakpoint exceptions taken from AArch64 state on page D2-2596.](#)

D2.9.1 About Breakpoint exceptions

A *breakpoint* is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint exceptions are generated by *Breakpoint debug events*. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in [Breakpoint Instruction exceptions on page D2-2577](#).

An implementation can include between 2-16 hardware breakpoints. [ID_AA64DFR0_EL1.BRPs](#) shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The *Breakpoint Control Register*, [DBGBCR<n>_EL1](#). This contains controls for the breakpoint, for example an enable control.
- The *Breakpoint Value Register*, [DBGBVR<n>_EL1](#). This holds the value used for breakpoint matching, that is one of:
 - An instruction virtual address.
 - A Context ID.
 - A [VMID](#) value.
 - A concatenation of both a Context ID value and a [VMID](#) value.

These registers are numbered, so that:

- [DBGBCR0_EL1](#) and [DBGBVR0_EL1](#) are for breakpoint number zero.
- [DBGBCR1_EL1](#) and [DBGBVR1_EL1](#) are for breakpoint number one.
- [DBGBCR2_EL1](#) and [DBGBVR2_EL1](#) are for breakpoint number two.
- ...
- ...
- [DBGBCR<n-1>_EL1](#) and [DBGBVR<n-1>_EL1](#) are for breakpoint number (n-1).

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, `DBGBCR<n>_EL1.E`, is 1.
- The conditions specified in the `DBGBCR<n>_EL1` are met.
- The comparison with the value held in the `DBGBVR<n>_EL1` is successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its Condition code check.
- The instruction type.

If halting is allowed and `EDSCR.HDE` is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Breakpoint debug events generate Breakpoint exceptions.
- Disabled, Breakpoint debug events are ignored.

———— **Note** ————

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.

However, the behavior described also applies if breakpoints are causing entry to Debug state.

[The debug exception enable controls on page D2-2568](#) describes the enable controls for Breakpoint debug events.

D2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A *context-aware* breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
 - An instruction address match.
 - A Context ID match, with the value held in the `CONTEXTIDR_EL1`.
 - A `VMID` match, with the `VMID` value held in the `VTTBR_EL2`.
 - Both a Context ID match and a `VMID` match.
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match.

`ID_AA64DFR0_EL1.CTX_CMPs` shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an *Address breakpoint*. Breakpoints that are programmed to match on anything else are categorized as *Context breakpoints*.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an *Unlinked breakpoint*.
- Enabled for linking to another breakpoint. In this case, the breakpoint is called a *Linked breakpoint*.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match occurs. For example, a debugger might:

1. Program breakpoint number one to be a *Linked Address Match breakpoint*.
2. Program breakpoint number five to be a *Linked Context ID Match breakpoint*.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The *Breakpoint Type* field for a breakpoint, `DBGBCR<n>_EL1.BT`, controls the breakpoint type and whether the breakpoint is enabled for linking. If `BT[0]` is 1, the breakpoint is enabled for linking.

If AArch32 state is implemented, Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See [Specifying the halfword-aligned address that an Address breakpoint matches on on page D2-2591](#).

Note

Stage 1 of an AArch32 translation regimes supports two additional breakpoint types, Unlinked and Linked Address Mismatch breakpoints, `BT == 0b0100` and `BT == 0b0101`. For information about these, see [Chapter G2 AArch32 Self-hosted Debug](#). These types are reserved in stage 1 of an AArch64 translation regime. See [Reserved BT values on page D2-2594](#).

Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGBCR<n>_EL1.LBN`, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
 - `DBGBCR<n>_EL1.{SSC, HMC, PMC}` for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2589](#).
 - `DBGBCR<n>_EL1.{SSC, HMC, PMC}` for the Linked Context breakpoint are ignored.
- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is `CONSTRAINED UNPREDICTABLE`. See [Other usage constraints for Address breakpoints on page D2-2596](#).
- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.
- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

Note

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. [Watchpoint exceptions on page D2-2598](#) describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.

- Multiple Linked watchpoints.

———— **Note** ————

If `FEAT_NV2` is implemented, the hypervisor must use the `0b1101`, `Linked CONTEXTIDR_EL2 Match` breakpoint type to guarantee a linked match, see *Interaction with self-hosted and External debug* on page D5-2799.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

Figure D2-1 on page D2-2582 shows an example of permitted breakpoint and watchpoint linking.

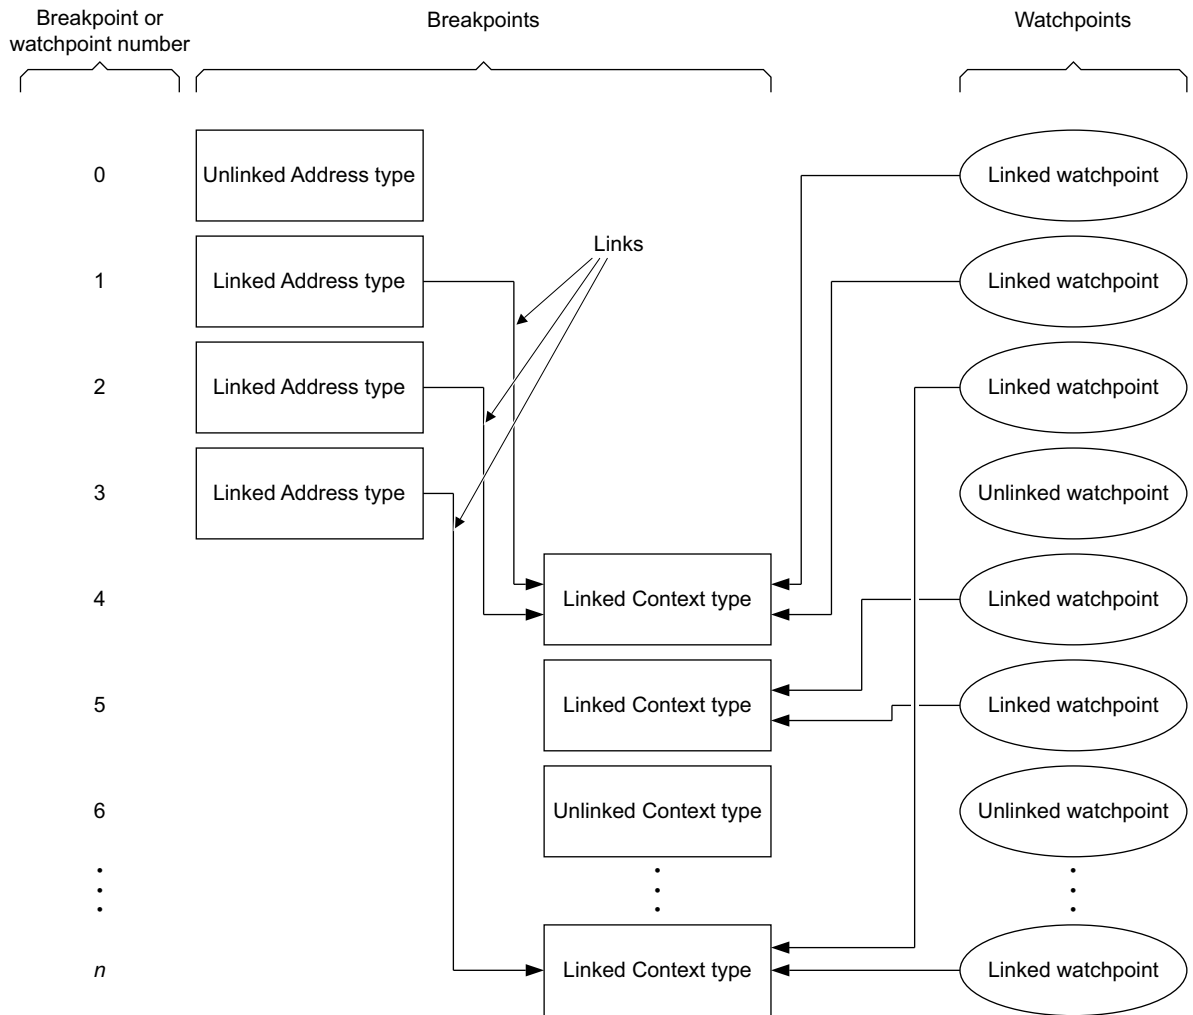

Figure D2-1 The role of linking in Breakpoint and Watchpoint exception generation

In Figure D2-1 on page D2-2582, each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links, to are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

Breakpoint types defined by DBGBCRn_EL1.BT

The following list provides more detail about each breakpoint type:

0b0000, Unlinked Address Match breakpoint

Generation of a Breakpoint exception depends on both:

- `DBGBCR<n>_EL1`. {SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2589.
- A successful address match, as described in *Breakpoint instruction address comparisons* on page D2-2590.

`DBGBCR<n>_EL1.LBN` for this breakpoint is ignored.

0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- `DBGBCR<n>_EL1`. {SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2589.
- A successful address match defined by this breakpoint, as described in *Breakpoint instruction address comparisons* on page D2-2590.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

`DBGBCR<n>_EL1.LBN` for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, Unlinked Context ID Match breakpoint

`BT == 0b0010` is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- `DBGBCR<n>_EL1`. {SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2589.
- A successful Context ID match, as described in *Breakpoint context comparisons* on page D2-2592.

The value of `DBGBCR<n>_EL1.ContextID` is compared with the current Context ID.

`CONTEXTIDR_EL2` holds the current Context ID when all of:

- The implementation includes `FEAT_VHE`.
- EL2 is implemented and enabled in the current Security state.
- EL2 using AArch64 and `HCR_EL2.E2H` is set to 1.
- The PE is executing at EL0 and `HCR_EL2.TGE` is 1, or the PE is executing at EL2.

Otherwise, `CONTEXTIDR_EL1` holds the current Context ID.

`DBGBCR<n>_EL1`. {LBN, BAS} for this breakpoint are ignored

0b0011, Linked Context ID Match breakpoint

`BT == 0b0011` is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons* on page D2-2590.

- A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-2592](#).
- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page D2-2603](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-2592](#).

The value of `DBGBVR<n>_EL1.ContextID` is compared with the current Context ID.

`CONTEXTIDR_EL2` holds the current Context ID when all of:

- The implementation includes `FEAT_VHE`.
- EL2 is implemented and enabled in the current Security state.
- EL2 using AArch64 and `HCR_EL2.E2H` is set to 1.
- The PE is executing at EL0 and `HCR_EL2.TGE` is 1, or the PE is executing at EL2.

Otherwise, `CONTEXTIDR_EL1` holds the current Context ID.

`DBGBCR<n>_EL1`.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b0100, Unlinked Address Mismatch breakpoint

BT == 0b0100 is a reserved value in stage 1 of an AArch64 translation regime. See [Reserved BT values on page D2-2594](#).

[0b0100, Unlinked Address Mismatch breakpoint on page G2-6175](#) describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

0b0101, Linked Address Mismatch breakpoint

BT == 0b0101 is a reserved value in stage 1 of an AArch64 translation regime. See [Reserved BT values on page D2-2594](#).

[0b0101, Linked Address Mismatch breakpoint on page G2-6175](#) describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

0b0110, Unlinked CONTEXTIDR_EL1 Match breakpoint

BT == 0b0110 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include `FEAT_VHE`.

In an implementation that includes `FEAT_VHE`, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- `DBGBCR<n>_EL1`.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-2592](#).

The Context ID check is made against the value in `CONTEXTIDR_EL1`. The value of `DBGBVR<n>_EL1.ContextID` is compared with the Context ID value held in `CONTEXTIDR_EL1`.

———— Note —————

The operation of this breakpoint does not depend on the value of `HCR_EL2.E2H`.

`DBGBCR<n>_EL1`.{LBN, BAS} for this breakpoint are ignored.

0b0111, Linked CONTEXTIDR_EL1 Match breakpoint

BT == 0b0111 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include `FEAT_VHE`.

In an implementation that includes [FEAT_VHE](#), for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons](#) on page D2-2590.
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons](#) on page D2-2592.
- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons](#) on page D2-2603.
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons](#) on page D2-2592.

The Context ID check is made against the value in [CONTEXTIDR_EL1](#). The value of [DBGBVR<n>_EL1.ContextID](#) is compared with the Context ID value held in [CONTEXTIDR_EL1](#).

———— **Note** —————

The operation of this breakpoint does not depend on the value of [HCR_EL2.E2H](#).

[DBGBCR<n>_EL1](#).{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- [DBGBCR<n>_EL1](#).{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See [Execution conditions for which a breakpoint generates Breakpoint exceptions](#) on page D2-2589.
- A successful VMID match, as described in [Breakpoint context comparisons](#) on page D2-2592.

[DBGBCR<n>_EL1](#).{LBN, BAS} for this breakpoint are ignored.

0b1001, Linked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See [Breakpoint instruction address comparisons](#) on page D2-2590.
 - A successful VMID match defined by this breakpoint, as described in [Breakpoint context comparisons](#) on page D2-2592.

- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page D2-2603](#).
 - A successful VMID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-2592](#).

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>_EL1**.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates a Breakpoint exception for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2589](#).
- A successful Context ID match, as described in [Breakpoint context comparisons on page D2-2592](#).
- A successful VMID match.

The value of **DBGBVR<n>_EL1**.ContextID is compared with **CONTEXTIDR_EL1**.

[Breakpoint context comparisons on page D2-2592](#) describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1011, Linked Context ID and VMID Match breakpoint

BT == 0b1011 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on all of the following:
 - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons on page D2-2590](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-2592](#).
 - A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on all of the following:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page D2-2603](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-2592](#).
 - A successful VMID match defined by this breakpoint.

The value of **DBGBVR<n>_EL1**.ContextID is compared with **CONTEXTIDR_EL1**.

[Breakpoint context comparisons on page D2-2592](#) describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1100, Unlinked CONTEXTIDR_EL2 Match breakpoint

BT == 0b1100 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful CONTEXTIDR_EL2 match, as described in *Breakpoint context comparisons* on page D2-2592.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

———— Note ————

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1101, Linked CONTEXTIDR_EL2 Match breakpoint

BT == 0b1101 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons* on page D2-2590.
 - A successful CONTEXTIDR_EL2 match, as described in *Breakpoint context comparisons* on page D2-2592.
- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons* on page D2-2603.
 - A successful CONTEXTIDR_EL2 match, as described in *Breakpoint context comparisons* on page D2-2592.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

———— Note ————

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1110, Unlinked Full Context ID Match breakpoint

BT == 0b1110 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which `FEAT_VHE` is implemented or `FEAT_Debugv8p2` is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- `DBGBCR<n>_EL1`. {SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in *Breakpoint context comparisons on page D2-2592*.

The Context ID check is made against the values in both `CONTEXTIDR_EL1` and `CONTEXTIDR_EL2`. The value of `DBGBCR<n>_EL1`[31:0] is compared with the Context ID value held in `CONTEXTIDR_EL1`, and the value of `DBGBCR<n>_EL1`[63:32] is compared with the Context ID value held in `CONTEXTIDR_EL2`. Both comparisons must match for the Context ID check.

———— **Note** —————

The operation of this breakpoint does not depend on the value of `HCR_EL2.E2H`.

`DBGBCR<n>_EL1`. {LBN, BAS} for this breakpoint are ignored.

0b1111, Linked Full Context ID Match breakpoint

`BT == 0b1111` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- `FEAT_VHE` is not implemented and `FEAT_Debugv8p2` is not implemented, which means the implementation does not include `CONTEXTIDR_EL2`.

In an implementation in which `FEAT_VHE` is implemented or `FEAT_Debugv8p2` is implemented, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons on page D2-2590*.
 - A successful Context ID match, as described in *Breakpoint context comparisons on page D2-2592*.
- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons on page D2-2603*.
 - A successful Context ID match, as described in *Breakpoint context comparisons on page D2-2592*.

The Context ID check is made against the values in both `CONTEXTIDR_EL1` and `CONTEXTIDR_EL2`. The value of `DBGBCR<n>_EL1`[31:0] is compared with the Context ID value held in `CONTEXTIDR_EL1`, and the value of `DBGBCR<n>_EL1`[63:32] is compared with the Context ID value held in `CONTEXTIDR_EL2`. Both comparisons must match for the Context ID check.

———— **Note** —————

The operation of this breakpoint does not depend on the value of `HCR_EL2.E2H`.

`DBGBCR<n>_EL1`. {LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

———— **Note** —————

See *Reserved `DBGBCR<n>_EL1.BT` values on page D2-2594* for the behavior of breakpoints programmed with reserved BT values.

D2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at EL0 in Secure state.

`DBGBCR<n>_EL1.{SSC, HMC, PMC}` defines the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

———— **Note** ————

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which Exception levels the breakpoint generates Breakpoint exceptions in.

Table D2-9 on page D2-2589 shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Exception levels breakpoints generate Breakpoint exceptions in.

In the table:

- Y** Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row can generate Breakpoint exceptions in that Exception level and Security state.
- Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row cannot generate Breakpoint exceptions in that Exception level and Security state.

For information about which combinations of HMC, SSC and PMC are reserved if an Exception level or Security state are not implemented or enabled, see [Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-2594](#).

Table D2-9 Summary of breakpoint HMC, SSC, and PMC encodings

HMC	SSC	PMC	Security state	EL3 ^a	EL2	EL1	EL0
0	00	01	Both	-	-	Y	-
0	00	10		-	-	-	Y
0	00	11		-	-	Y	Y

Table D2-9 Summary of breakpoint HMC, SSC, and PMC encodings (continued)

HMC	SSC	PMC	Security state	EL3 ^a	EL2	EL1	EL0
0	01	01	Non-secure	n/a	-	Y	-
0	01	10		n/a	-	-	Y
0	01	11		n/a	-	Y	Y
0	10	01	Secure	-	-	Y	-
0	10	10		-	-	-	Y
0	10	11		-	-	Y	Y
0	11	00	Secure	-	Y	-	-
0	11	01		-	Y	Y	-
0	11	11		-	Y	Y	Y
1	00	01	Both	Y	Y	Y	-
1	00	11		Y	Y	Y	Y
1	01	00	Non-secure	n/a	Y	-	-
1	01	01		n/a	Y	Y	-
1	01	11		n/a	Y	Y	Y
1	10	00	Secure	Y	-	-	-
1	10	01		Y	Y	Y	-
1	10	11		Y	Y	Y	Y
1	11	00	Both	-	Y	-	-
1	11	01		-	Y	Y	-
1	11	11		-	Y	Y	Y

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at EL3 using AArch64.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See *Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-2594*.

D2.9.4 Breakpoint instruction address comparisons

In this subsection, the term AddrTop represents the most significant bit of a virtual address used by breakpoint data address comparisons. AddrTop is:

- 55, if address tagging is used for the address. See *Address tagging in AArch64 state on page D5-2676*.
- 63, otherwise.

———— Note ————

When stage 1 translation is enabled, in AArch64 state, a virtual address has a maximum address width of either 48 bits or, when FEAT_LVA is implemented and the 64KB translation granule is used, 52 bits. Software can configure a smaller address width for a virtual address, see *Input address size on page D5-2691*. Attempting to translate an address that is larger than the configured input address size generates a Translation fault.

When stage 1 translation is disabled, using an address that is larger than the implemented PA size generates an Address size fault. The implemented PA size is IMPLEMENTATION DEFINED up to 52 bits, see *Physical address size* on page D5-2690.

These faults have a higher priority than breakpoints.

An address comparison is successful if bits [AddrTop:2] of the current instruction virtual address are equal to `DBGBVR<n>_EL1[AddrTop:2]`.

———— **Note** ————

`DBGBVR<n>_EL1` is a 64-bit register. The most significant bits of this register are sign-extension bits. `DBGBVR<n>_EL1[1:0]` are RES0 and are ignored.

If EL1 is using AArch64 and EL0 is using AArch32, A32 and T32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, the instruction addresses are zero-extended before comparison with the breakpoint.

Specifying the halfword-aligned address that an Address breakpoint matches on

For Address Match breakpoints, if the implementation supports AArch32 state, a debugger must program the *Byte Address Selection* field, `DBGBCR<n>_EL1.BAS`.

Table D2-10 Programmable BAS values

BAS	Match instruction at	Constraint for debuggers
0b0011	<code>DBGBCR<n>_EL1</code>	Use for T32 instructions.
0b1100	<code>DBGBCR<n>_EL1 + 2</code>	Use for T32 instructions.
0b1111	<code>DBGBCR<n>_EL1</code>	Use for A64 and A32 instructions.

If the implementation is an AArch64-only implementation, all instructions are word-aligned and `DBGBCR<n>_EL1.BAS` is RES1.

Figure D2-2 on page D2-2592 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with `DBGBCR<n>_EL1.BAS` programmed as either 0b0011 or 0b1111 generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

———— **Note** ————

To breakpoint on an A64 instruction, Arm recommends that the debugger programs `DBGBCR<n>_EL1.BAS` as 0b1111.

In the figure:

- Yes** Means that the breakpoint generates a Breakpoint exception.
- No** Means that the breakpoint does not generate a Breakpoint exception.
- UNP** Means that is it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See *Other usage constraints for Address breakpoints* on page D2-2596.

	Instruction set	Size	Location of instruction ^a								BAS[3:0]		
			-2	-1	0	+1	+2	+3	+4	+5	0b0011	0b1100	0b1111
Row 1	T32	16-bit			■						Yes	No	Yes
Row 2		16-bit					■				No	Yes	UNP
Row 3	T32	32-bit	■	■	■						UNP	No	UNP
Row 4		32-bit			■	■	■				Yes	UNP	Yes
Row 5		32-bit					■	■	■	■	No	Yes	UNP
Row 6	A32	32-bit			■	■	■				Yes	UNP	Yes
Row 7	A64	32-bit			■	■	■				Yes	UNP	Yes

a. 0 means the word-aligned address held in the `DBGBVR<n>_EL1[maxAddressSize:2]:00`.

The other locations are as follows:

- -2 means `((DBGBVR<n>_EL1[maxAddressSize:2]:00) - 2)`
- -1 means `((DBGBVR<n>_EL1[maxAddressSize:2]:00) - 1)`
- ...
- ...
- +5 means `((DBGBVR<n>_EL1[maxAddressSize:2]:00) + 5)`.

The solid areas show the location of the instruction.

Figure D2-2 Summary of BAS field meanings for Address Match breakpoints

D2.9.5 Breakpoint context comparisons

The breakpoint type defined by `DBGBCR<n>_EL1.BT` determines what context comparison is required, if any. [Table D2-11 on page D2-2592](#) shows the BT values that require a comparison, and the match required for the comparison to be successful.

Table D2-11 Breakpoint Context ID and VMID comparison tests

<code>DBGBCR<n>.BT</code>	Test required for successful context comparison
0b001x	<ul style="list-style-type: none"> • When <code>FEAT_VHE</code> is implemented, EL2 is using AArch64, the <i>Effective value</i> of <code>HCR_EL2.E2H</code> is 1, and either the PE is executing at EL0 with <code>HCR_EL2.TGE</code> set to 1, or the PE is executing at EL2, <code>CONTEXTIDR_EL2</code> must match the <code>DBGBVR<n>_EL1.ContextID</code> value. • Otherwise, <code>CONTEXTIDR_EL1</code> must match the <code>DBGBVR<n>_EL1.ContextID</code> value.
0b011x	<code>CONTEXTIDR_EL1</code> must match the <code>DBGBVR<n>_EL1.ContextID</code> value.
0b100x	<code>VTTBR_EL2.VMID</code> must match the <code>DBGBVR<n>_EL1.VMID</code> value.
0b101x	<code>CONTEXTIDR_EL1</code> must match the <code>DBGBVR<n>_EL1.ContextID</code> value and <code>VTTBR_EL2.VMID</code> must match the <code>DBGBVR<n>_EL1.VMID</code> value.
0b110x	<code>CONTEXTIDR_EL2</code> must match the <code>DBGBVR<n>_EL1.ContextID2</code> value, <code>DBGBVR<n>_EL1[63:32]</code> .
0b111x	Both: <ul style="list-style-type: none"> • <code>CONTEXTIDR_EL1</code> must match the <code>DBGBVR<n>_EL1.ContextID</code> value, <code>DBGBVR<n>_EL1[31:0]</code>. • <code>CONTEXTIDR_EL2</code> must match the <code>DBGBVR<n>_EL1.ContextID2</code> value, <code>DBGBVR<n>_EL1[63:32]</code>.

No Context ID or VMID comparison is required for other valid `DBGBCR<n>.BT` values.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of `CONTEXTIDR_EL1` and any of:
 - The PE is executing at EL3 using AArch64.
 - The PE is executing at EL2.
 - `FEAT_VHE` is implemented, EL2 is using AArch64, EL2 is enabled in the current Security state, and `HCR_EL2.{E2H, TGE} == {1, 1}`.
- The comparison uses the value of `CONTEXTIDR_EL2` and any of:
 - Neither `FEAT_VHE` is implemented, nor `FEAT_Debugv8p2` is implemented.
 - If the PE is in Secure state, and either `FEAT_SEL2` is not implemented, or Secure EL2 is disabled.
 - The PE is executing at EL3.
 - EL2 is using AArch32.
 - EL2 is not implemented.
- The comparison uses the current `VMID` value and any of:
 - EL2 is not implemented.
 - If the PE is in Secure state, and either `FEAT_SEL2` is not implemented, or Secure EL2 is disabled.
 - The PE is executing at EL2.
 - The PE is executing at EL3.
 - `FEAT_VHE` is implemented, EL2 is using AArch64, EL2 is enabled in the current Security state, and `HCR_EL2.{E2H, TGE} == {1, 1}`.

———— **Note** —————

- For all Context breakpoints, `DBGBCR<n>_EL1.BAS` is RES1 and is ignored.
- For Linked Context breakpoints, `DBGBCR<n>_EL1.{LBN, SSC, HMC, PMC}` are RES0 and are ignored.

D2.9.6 Breakpoint usage constraints

See the following sections:

- [Reserved `DBGBCR<n>_EL1.BT` values on page D2-2594.](#)
- [Reserved `DBGBCR<n>_EL1.{SSC, HMC, PMC}` values on page D2-2594.](#)
- [Reserved `DBGBCR<n>_EL1.BAS` values on page D2-2595.](#)
- [Reserved `DBGBCR<n>_EL1.LBN` values on page D2-2596.](#)
- [Other usage constraints for Address breakpoints on page D2-2596.](#)
- [Other usage constraints for Context breakpoints on page D2-2596.](#)

Reserved DBGBCR<n>_EL1.BT values

Table D2-12 on page D2-2594 shows when particular DBGBCR<n>_EL1.BT values are reserved.

Table D2-12 Reserved BT values

BT value	Breakpoint type	Reserved
0b001x	Context ID Match	If the breakpoint is not context-aware
0b010x	Address Mismatch	In stage 1 of an AArch64 translation regime, or if <code>EDSCR.HDE</code> is 1 and halting is allowed
0b011x	CONTEXTIDR_EL1 Match	If <code>FEAT_VHE</code> is not implemented, or the breakpoint is not context-aware
0b100x	VMID Match	If EL2 is not implemented, or the breakpoint is not context-aware
0b101x	Context ID and VMID Match	If EL2 is not implemented, or the breakpoint is not context-aware
0b110x	CONTEXTIDR_EL2 Match	If <code>FEAT_VHE</code> is not implemented and <code>FEAT_Debugv8p2</code> is not implemented, or if the breakpoint is not context-aware
0b111x	Full Context ID Match	

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
 - Disabled.
 - Programmed with a BT value that is not reserved, other than for a direct or external read of `DBGBCR<n>_EL1`.
- For a direct or external read of `DBGBCR<n>_EL1`, if the reserved BT value:
 - Has no function for any execution conditions, the value read back is UNKNOWN.
 - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values

Table D2-13 on page D2-2594 shows when particular combinations of `DBGBCR<n>_EL1`.{SSC, HMC, PMC} are reserved in stage 1 of an AArch64 translation regime.

Table D2-13 Reserved HMC, SSC, and PMC combinations

HMC, SSC, and PMC combination	Reserved
All combinations with SSC set to 0b01 or 0b10, except for the combination with HMC set to 1, SSC set to 0b01, and PMC set to 0b00	When EL3 is not implemented and EL2 is implemented
Any combination where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b01, and PMC set to 0b00, or combinations when SSC is set to 0b11	When both of EL2 and EL3 are not implemented
The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00	When EL2 is not implemented

Table D2-13 Reserved HMC, SSC, and PMC combinations (continued)

HMC, SSC, and PMC combination	Reserved
The combinations with SSC set to 0b11 except the combination with HMC set to 1, SSC set to 0b11 and PMC set to 0b00	When Secure EL2 is not implemented
The combination with HMC set to 1, SSC set to 0b01 and PMC set to 0b00	When Secure EL2 is not implemented
Combinations not included in Table D2-9 on page D2-2589	Always

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
 - The breakpoint must behave as if it is disabled.
 - A direct or external read of `DBGBCR<n>_EL1.{SSC, HMC, PMC}` returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.
- If the reserved combination does not have a function for other execution conditions:
 - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
 - A direct or external read of `DBGBCR<n>_EL1.{SSC, HMC, PMC}` returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:

- The values of HMC, SSC, and PMC are ignored.
- A direct or external read of `DBGBCR<n>_EL1.{SSC, HMC, PMC}` returns UNKNOWN values

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved `DBGBCR<n>_EL1.BAS` values

In an AArch64-only implementation, `DBGBCR<n>_EL1.BAS` for all breakpoints is RES1.

Otherwise:

For all Context breakpoints

`DBGBCR<n>_EL1.BAS` is RES1 and is ignored.

For all Address breakpoints

[Table D2-10 on page D2-2591](#) gives the valid values of the `DBGBCR<n>_EL1.BAS` field.

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
 - Disabled.
 - Programmed with a BAS value that is not reserved, other than for a direct or external read of `DBGBCR<n>_EL1`.
- A direct or external read of `DBGBCR<n>_EL1.BAS` returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved DBGBCR<n>_EL1.LBN values

For all Context breakpoints

DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any DBGBCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGBCR<n>_EL1.LBN return an unknown value and behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Address breakpoints

DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

Other usage constraints for Address breakpoints

For all Address breakpoints

- DBGBVR<n>_EL1[1:0] are RES0 and are ignored.
- If the implementation supports AArch32 state:
 - For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
 - If DBGBCR<n>.BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address ((DBGBVR<n>[48:2]:00) + 2). For T32 instructions, Arm recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of DBGBVR<n>_EL1 that are not used to specify Context ID or VMID are RES0 and are ignored.

For Linked Context breakpoints

If no Linked Address breakpoints or Linked watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

D2.9.7 Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.9.8 Pseudocode description of Breakpoint exceptions taken from AArch64 state

AArch64.BreakpointValueMatch() tests the value in DBGBVR<n>_EL1.

[AArch64.StateMatch\(\)](#) tests the values in [DBGBCR<n>_EL1](#). {SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

For a watchpoint, [AArch64.StateMatch\(\)](#) tests the values in [DBGWCR<n>_EL1](#). {SSC, HMC, PAC} and, if the watchpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

[AArch64.BreakpointMatch\(\)](#) tests a committed instruction against all breakpoints.

[AArch64.CheckBreakpoint\(\)](#) generates a Breakpoint exception if all of the following are true:

- [MDSR_EL1.MDE](#) is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level* on page D2-2571.
- All of the conditions required for Breakpoint exception generation are met. See *About Breakpoint exceptions* on page D2-2579.

———— **Note** —————

[AArch64.CheckBreakpoint\(\)](#) might halt the PE and cause it to enter Debug state. External debug uses Debug state.

[AArch64.BreakpointException\(\)](#) is called to generate a Breakpoint exception.

These functions are defined in [Chapter J1 Armv8 Pseudocode](#).

D2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:

- [About Watchpoint exceptions on page D2-2598.](#)
- [Watchpoint types and linking of watchpoints on page D2-2599.](#)
- [Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-2600.](#)

D2.10.1 About Watchpoint exceptions

A *watchpoint* is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as *data breakpoints*.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a *Watchpoint debug event* on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, `ID_AA64DFR0_EL1.WRPs` shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The *Watchpoint Control Register*, `DBGWCR<n>_EL1`. This contains controls for the watchpoint, for example an enable control.
- The *Watchpoint Value Register*, `DBGWVR<n>_EL1`. This holds the data virtual address used for watchpoint matching.

These registers are numbered, so that:

- `DBGWCR0_EL1` and `DBGWVR0_EL1` are for watchpoint number zero.
- `DBGWCR1_EL1` and `DBGWVR1_EL1` are for watchpoint number one.
- `DBGWCR2_EL1` and `DBGWVR2_EL1` are for watchpoint number two.
- ...
- ...
- `DBGWCR<n-1>_EL1` and `DBGWVR<n-1>_EL1` are for watchpoint number (n-1).

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a *Linked Context breakpoint*, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.

A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, `DBGWCR<n>_EL1.BAS`, to select the bytes. See [Programming a watchpoint with eight bytes or fewer on page D2-2604](#).
- Eight bytes to 2GB, provided that both of the following are true:
 - The number of bytes is a power-of-two.
 - The range starts at an address that is aligned to the range size.
 A debugger uses the *MASK* field, `DBGWCR<n>_EL1.MASK`, to program a watchpoint with eight bytes to 2GB. See [Programming a watchpoint with eight or more bytes on page D2-2605](#).

A debugger must use either the *BAS* field or the *MASK* field. If it uses both, whether the watchpoint generates Watchpoint debug events is `CONSTRAINED UNPREDICTABLE`. See [Programming dependencies of the *BAS* and *MASK* fields on page D2-2609](#).

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, `DBGWCR<n>_EL1.E`, is 1.
- The conditions specified in the `DBGWCR<n>_EL1` are met.
- The comparison with the address held in the `DBGWVR<n>_EL1` is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint also are successful. See [Figure D2-1 on page D2-2582](#). See also [Breakpoint context comparisons on page D2-2592](#).
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.
- If the access is due to a System register access instruction executed at EL1 and transformed into a memory access by the mechanism described in [Enhanced support for nested virtualization on page D5-2795](#) and one of the following is true:
 - `EDSCR.HDE` is set to 1 and halting is allowed.
 - Debug exceptions are enabled at EL2.

If halting is allowed and `EDSCR.HDE` is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

———— **Note** —————

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

[The debug exception enable controls on page D2-2568](#) describes the enable controls for Watchpoint debug events.

D2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a *Linked watchpoint*.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoint*.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the **VMID** matches.

The *Watchpoint Type* field for a watchpoint, `DBGWCR<n>_EL1.WT`, controls whether the watchpoint is enabled for linking. If `DBGWCR<n>_EL1.WT` is 1, the watchpoint is enabled for linking.

Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGWCR<n>_EL1.LBN`, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
 - `DBGWCR<n>_EL1.{SSC, HMC, PAC}` for the Linked watchpoint defines the execution conditions that the watchpoint generates Watchpoint exceptions for. See [Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-2600](#).
 - `DBGBCR<n>_EL1.{SSC, HMC, PMC}` for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is **CONSTRAINED UNPREDICTABLE**. See [Watchpoint usage constraints on page D2-2608](#).
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- If the access is due to a System register access instruction executed at EL1 and transformed into a memory access by the mechanism described in [Enhanced support for nested virtualization on page D5-2795](#), and the watchpoint is linked to a context-aware breakpoint that is programmed to match the value held in `CONTEXTIDR_EL1`, then it is **CONSTRAINED UNPREDICTABLE** whether there is a watchpoint match.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

———— **Note** —————

Multiple Address breakpoints can also link to a single Linked Context breakpoint. [Breakpoint exceptions on page D2-2579](#) describes breakpoints.

Figure D2-1 on page D2-2582 shows an example of permitted watchpoint linking.

D2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only for Non-secure EL2 accesses.

[DBGWCR<n>_EL1](#). {SSC, HMC, PAC} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

———— **Note** —————

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Exception levels the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level at which the access was made:

- Load unprivileged or Store unprivileged instructions executed at EL1, or executed at EL2 when [HCR_EL2.E2H](#) is 1, are treated as EL0 accesses.
- System register accesses executed at EL1 and transformed into a memory access by the mechanism described in [Enhanced support for nested virtualization on page D5-2795](#) are treated as EL2 accesses.

———— **Note** —————

This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at EL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on EL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A64 Load unprivileged and Store unprivileged instructions are LDTR and STTR.

[Table D2-14 on page D2-2602](#) shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Exception levels watchpoints generate Watchpoint exceptions in.

In the table:

- Y or -** Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:
- Y** Can generate Watchpoint exceptions in that Exception level and Security state.
 - Cannot generate Watchpoint exceptions in that Exception level and Security state.

For information about which combinations of HMC, SSC and PMC are reserved if an Exception level or Security state are not implemented or enabled, see [Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values on page D2-2608](#).

Table D2-14 Summary of watchpoint HMC, SSC, and PAC encodings

HMC	SSC	PAC	Security state	EL3 ^a	EL2	EL1	EL0
0	00	01	Both	-	-	Y	-
0	00	10		-	-	-	Y
0	00	11		-	-	Y	Y
0	01	01	Non-secure	n/a	-	Y	-
0	01	10		n/a	-	-	Y
0	01	11		n/a	-	Y	Y
0	10	01	Secure	-	-	Y	-
0	10	10		-	-	-	Y
0	10	11		-	-	Y	Y
0	11	00		-	Y	-	-
0	11	01		-	Y	Y	-
0	11	11		-	Y	Y	Y
1	00	01	Both	Y	Y	Y	-
1	00	11		Y	Y	Y	Y
1	01	00	Non-secure	n/a	Y	-	-
1	01	01		n/a	Y	Y	-
1	01	11		n/a	Y	Y	Y
1	10	00	Secure	Y	-	-	-
1	10	01		Y	Y	Y	-
1	10	11		Y	Y	Y	Y
1	11	00	Both	-	Y	-	-
1	11	01		-	Y	Y	-
1	11	11		-	Y	Y	Y

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Watchpoint exceptions at EL3 using AArch64.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See *Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values on page D2-2608*.

D2.10.4 Watchpoint data address comparisons

In this subsection, the term `AddrTop` represents the most significant bit of a virtual address used by watchpoint data address comparisons. `AddrTop` is:

- 55, if address tagging is used for the address. See [Address tagging in AArch64 state on page D5-2676](#).
- 63, otherwise.

Note

When stage 1 translation is enabled, in AArch64 state, a virtual address has a maximum address width of either 48 bits or, when `FEAT_LVA` is implemented and the 64KB translation granule is used, 52 bits. Software can configure a smaller address width for a virtual address. See [Input address size on page D5-2691](#). Attempting to translate an address that is larger than the configured input address size generates a Translation fault.

When stage 1 translation is disabled, using an address that is larger than the implemented PA size generates an Address size fault. The implemented PA size is IMPLEMENTATION DEFINED up to 52 bits. See [Physical address size on page D5-2690](#).

These faults have a higher priority than watchpoints.

An address comparison is successful if bits [`AddrTop:2`] of the current data address are equal to `DBGWVR<n>_EL1[AddrTop:2]`, taking into account all of the following:

- The size of the access. See [Size of the data access on page D2-2603](#).
If EL1 is using AArch64 and EL0 is using AArch32, AArch32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, data addresses are zero-extended before comparison with the watchpoint.
- The bytes selected by `DBGWVR<n>_EL1.BAS`. See [Programming a watchpoint with eight bytes or fewer on page D2-2604](#).
- Any address ranges indicated by `DBGWVR<n>_EL1.MASK`. See [Programming a watchpoint with eight or more bytes on page D2-2605](#).

Note

- `DBGWVR<n>_EL1` is a 64-bit register. The most significant bits of this register are sign-extension bits.
 - `DBGWVR<n>_EL1[1:0]` are RES0 and are ignored.
-

Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each data access must be taken into account. See [Example D2-1 on page D2-2603](#).

Example D2-1

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address `0x1009` is accessed.
2. The PE accesses the unaligned doubleword starting at address `0x1003`.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by DC ZVA instructions is the DC ZVA block size that `DCZID_EL0.BS` defines.

The size of data accesses initiated by DC IVAC instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
 - The size that `CTR_EL0.DminLine` defines.
 - 2KB.

- A power-of-two.

For both of these instructions:

- The lowest address accessed by the instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.
- The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, *Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA, DC GVA, and DC GZVA instructions* on page D2-2608.

Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, `DBGWCR<n>_EL1.BAS`, selects which bytes in the doubleword starting at the address contained in the `DBGWVR<n>_EL1` the watchpoint generates Watchpoint exceptions for.

If the address programmed into the `DBGWVR<n>_EL1` is:

- Doubleword-aligned:
 - All eight bits of `DBGWCR<n>_EL1.BAS` are used, and the descriptions given in [Table D2-15 on page D2-2604](#) apply.
- Word-aligned but not doubleword-aligned:
 - Only `DBGWCR<n>_EL1.BAS[3:0]` are used, and the descriptions given in [Table D2-16 on page D2-2604](#) apply. In this case, `DBGWCR<n>_EL1.BAS[7:4]` are RES0.

Table D2-15 Supported BAS values when the `DBGWVRn_EL1` address alignment is doubleword

BAS value	Description
0b00000000	Watchpoint never generates a Watchpoint exception.
BAS[0] == 1	Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[AddrTop:3]:000</code> is accessed.
BAS[1] == 1	Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[AddrTop:3]:001</code> is accessed.
BAS[2] == 1	Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[AddrTop:3]:010</code> is accessed.
BAS[3] == 1	Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[AddrTop:3]:011</code> is accessed.
BAS[4] == 1	Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[AddrTop:3]:100</code> is accessed.
BAS[5] == 1	Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[AddrTop:3]:101</code> is accessed.
BAS[6] == 1	Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[AddrTop:3]:110</code> is accessed.
BAS[7] == 1	Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[AddrTop:3]:111</code> is accessed.

Table D2-16 Supported BAS values when the `DBGWVRn_EL1` address alignment is word

BAS value ^a	Description
0b00000000	Watchpoint never generates a Watchpoint exception
BAS[0] == 1	Generates a Watchpoint exception if byte at address <code>DBGWVR<n>_EL1[AddrTop:2]:00</code> is accessed.
BAS[1] == 1	Generates a Watchpoint exception if byte at address <code>DBGWVR<n>_EL1[AddrTop:2]:01</code> is accessed.
BAS[2] == 1	Generates a Watchpoint exception if byte at address <code>DBGWVR<n>_EL1[AddrTop:2]:10</code> is accessed.
BAS[3] == 1	Generates a Watchpoint exception if byte at address <code>DBGWVR<n>_EL1[AddrTop:2]:11</code> is accessed.

a. `DBGWCR<n>_EL1.BAS[7:4]` are RES0.

If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see *Other usage constraints* on page D2-2610.

When programming the BAS field with anything other than 0b11111111, a debugger must program `DBGWCR<n>_EL1.MASK` to be 0b00000. See *Programming dependencies of the BAS and MASK fields* on page D2-2609.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the `DBGWVR<n>_EL1[AddrTop:3]`. See *Example D2-1* on page D2-2603.

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
 - `DBGWVR<n>_EL1` with 0x1000.
 - `DBGWCR<n>_EL1.BAS` to be 0b00001000.
- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
 - `DBGWVR<n>_EL1` with 0x2000.
 - `DBGWCR<n>_EL1.BAS` to be 0b00111000.
- If the address programmed into the `DBGWVR<n>_EL1` is doubleword-aligned:
 - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program `DBGWCR<n>_EL1.BAS` to be 0b00001111.
 - To generate a Watchpoint exception when any byte in the word starting at address `DBGWVR<n>_EL1[31:3]:100` is accessed, program `DBGWCR<n>_EL1.BAS` to be 0b11110000.

———— **Note** —————

Arm deprecates programming a `DBGWVR<n>_EL1` with an address that is not doubleword-aligned.

Programming a watchpoint with eight or more bytes

A debugger can use the `MASK` field, `DBGWCR<n>_EL1.MASK`, to program a single watchpoint with a data address range. The range must meet all of the following criteria:

- It is a size that is:
 - A power-of-two.
 - A minimum of eight bytes.
 - A maximum of 2GB.
- It starts at an address that is aligned to the size.

The `MASK` field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

MASK	0b00000	No bits are masked.
	0b00001	Reserved.
	0b00010	Reserved.
	0b00011	Three least significant bits are masked.
	0b00100	Four least significant bits are masked.
	0b00101	Five least significant bits are masked.

	0b11111	31 least significant bits are masked.

If n least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address `DBGWVR<n>_EL1[AddrTop:n]:000...`
- Address `DBGWVR<n>_EL1[AddrTop:n]:111...`
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between `DBGWVR<n>_EL1[AddrTop:4]:0000` and `DBGWVR<n>_EL1[AddrTop:4]:1111`, including these addresses.

———— **Note** ————

- The 17 most significant bits cannot be masked. This means that the full address cannot be masked.
- For watchpoint behavior when its MASK field is programmed with a reserved value, see [Reserved DBGWCR<n>_EL1.MASK values on page D2-2610](#).

When masking address bits, a debugger must both:

- Program `DBGWCR<n>_EL1.BAS` to be `0b11111111`. See [Programming dependencies of the BAS and MASK fields on page D2-2609](#).
- In the `DBGWVR<n>_EL1`, set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see [Other usage constraints on page D2-2610](#).

D2.10.5 Determining the memory location that caused a Watchpoint exception

On taking a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- `FAR_EL1`, if the exception is taken to EL1.
- `FAR_EL2`, if the exception is taken to EL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the `EDWAR`.

For more information, see the subsections that follow. These are:

- [Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions on page D2-2606](#).
- [Address recorded for Watchpoint exceptions generated by data cache maintenance instructions on page D2-2607](#)

Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions

———— **Note** ————

Despite its mnemonic, the `DC ZVA`, *Data Cache Zero by VA* instruction is not a data cache maintenance instruction.

The address recorded must be both:

- From the inclusive range between:
 - The lowest address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.
 - The highest *watchpointed address* accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint. A watchpointed address is an address that the watchpoint is watching.

- Within a naturally-aligned block of memory that is all of the following:
 - A power-of-two size.
 - No larger than the DC ZVA block size.
 - Contains a watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

Example D2-2 Address recorded for a watchpoint programmed on 0x8019

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:

- 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
- 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.

Address recorded for Watchpoint exceptions generated by data cache maintenance instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

D2.10.6 Watchpoint behavior on other instructions

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Prefetch memory instructions.
- All data cache maintenance instructions except DC IVAC.

———— Note —————

Despite its mnemonic, the DC ZVA, [Data Cache Zero by VA](#) instruction is not a data cache maintenance instruction.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an implementation defined subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are implementation defined.

The access size of the IMPLEMENTATION DEFINED instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

See also the following subsections:

- [Watchpoint behavior on accesses by Store-Exclusive instructions on page D2-2607.](#)
- [Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA, DC GVA, and DC GZVA instructions on page D2-2608.](#)

Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.

- Otherwise, the watchpoint generates a Watchpoint exception.

Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA, DC GVA, and DC GZVA instructions

DC ZVA, DC GVA and DC GZVA operations can generate Watchpoint exceptions. If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a DC IVAC instruction can generate a Watchpoint exception. Otherwise, DC IVAC operations can generate Watchpoint exceptions.

DC IVAC, DC ZVA, DC GZVA and DC GVA operations are treated as data stores by DBGWCR<n>_EL1.LSC.

———— Note —————

For the size of data accesses performed by the DC IVAC instruction and the DC ZVA instruction, see [Watchpoint data address comparisons on page D2-2603](#). The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

D2.10.7 Watchpoint usage constraints

See the following:

- [Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values on page D2-2608](#).
- [Reserved DBGWCR<n>_EL1.LBN values on page D2-2609](#).
- [Programming dependencies of the BAS and MASK fields on page D2-2609](#).
- [Reserved DBGWCR<n>_EL1.BAS values on page D2-2609](#).
- [Reserved DBGWCR<n>_EL1.MASK values on page D2-2610](#).
- [Other usage constraints on page D2-2610](#).

Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values

Table D2-17 on page D2-2608 shows when particular combinations of DBGWCR<n>_EL1.{SSC, HMC, PAC} are reserved.

Table D2-17 Reserved SSC, HMC, and PAC combinations

HMC, SSC, and PAC combination	Reserved
All combinations with SSC set to 0b01 or 0b10 except for the combination with HMC set to 1, SSC set to 0b01, and PAC set to 0b00.	When EL3 is not implemented and EL2 is implemented.
All combinations where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b01, and PAC set to 0b00 or combinations with SSC set to 0b11.	When both of EL2 and EL3 are not implemented.
The combination with HMC set to 1, SSC set to 0b11, and PAC set to 0b00.	When EL2 is not implemented.
The combinations with SSC set to 0b11 except the combination with HMC set to 1, SSC set to 0b11, and PAC set to 0b00.	When Secure EL2 is not implemented.
The combination with HMC set to 1, SSC set to 0b01, and PAC set to 0b00.	When Secure EL2 is not implemented.
Combinations not included in Table D2-14 on page D2-2602 .	Always.

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
 - Disabled.
 - Programmed with a combination that is not reserved, other than for a direct or external read of DBGWCR<n>_EL1.

- For a direct or external read of `DBGWCR<n>_EL1`, if the reserved combination:
 - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is UNKNOWN.
 - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved `DBGWCR<n>_EL1.LBN` values

For Linked Watchpoints

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any `DBGWCR<n>_EL1.LBN` value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of `DBGWCR<n>_EL1.LBN` return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Watchpoints For Unlinked watchpoints, `DBGWCR<n>_EL1.LBN` reads UNKNOWN and its value is ignored.

Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the `DBGWVR<n>_EL1` the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be `0b11111111`, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be `0b000000`, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is non-zero and a BAS field that is not set to `0b11111111`, then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

Reserved `DBGWCR<n>_EL1.BAS` values

The BAS field must be programmed with a value `Zeros(8-n-m):Ones(n):Zeros(m)`, where:

- `n` is a non-zero positive integer less-than-or-equal-to 8.
- `m` is a positive integer less-than 8.
- `n+m` is less-than-or-equal-to 8.

All other values are reserved.

————— **Note** —————

If `x` is zero, then `Zeros(x)` is an empty bitstring.

If `DBGWVR<n>_EL1[2]` is 1, `DBGWCR<n>_EL1.BAS[7:4]` are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the `DBGWVR<n>_EL1`.
- A direct or external read of `DBGWCR<n>_EL1.BAS` returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved `DBGWCR<n>_EL1.MASK` values

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
 - Disabled.
 - Programmed with an UNKNOWN value that is not reserved, that might be `0b00000`, other than for a direct or external read of `DBGWCR<n>_EL1`.
- A direct or external read of `DBGWCR<n>_EL1.MASK` returns an UNKNOWN value.

Other usage constraints

For all watchpoints:

- `DBGWVR<n>_EL1[1:0]` are RES0 and are ignored.
- If `DBGWCR<n>_EL1.MASK` is nonzero, and any masked bits of `DBGWVR<n>_EL1` are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if `DBGWCR<n>_EL1.LSC` is `0b00`.

D2.10.8 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information on page D2-2610](#).
- [Preferred return address on page D2-2611](#).

Exception syndrome information

On taking a Watchpoint exception, the PE records all of the following:

- Information about the exception in the *Exception Syndrome Register (ESR_ELx)* at the Exception level the exception is taken to.
- An address that the debugger can use to determine the memory location that caused the exception. The PE records this in a *Fault Address Register (FAR)*.

The ESR and FAR used is either:

- `ESR_EL1` and `FAR_EL1`, if the exception is taken to EL1.
- `ESR_EL2` and `FAR_EL2`, if the exception is taken to EL2.

———— **Note** —————

Watchpoint exceptions cannot be taken to EL3 using AArch64.

See [ISS encoding for an exception from a Watchpoint exception on page D13-3184](#) for more information.

Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch64 state

[AArch64.WatchpointByteMatch\(\)](#) tests an individual byte accessed by an operation.

[AArch64.StateMatch\(\)](#) tests the values in [DBGWCR<n>_EL1](#). {HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

[AArch64.WatchpointMatch\(\)](#) tests the value in [DBGWVR<n>_EL1](#).

[AArch64.CheckWatchpoint\(\)](#) generates a `FaultRecord` that [AArch64.Abort\(\)](#) raises a Watchpoint exception for if all of the following are true:

- [MDSCR_EL1.MDE](#) is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level* on page D2-2571.
- All of the conditions required for Watchpoint exception generation are met. See *About Watchpoint exceptions* on page D2-2598.

———— **Note** —————

[AArch64.CheckWatchpoint\(\)](#) might halt the PE and cause it to enter Debug state. External debug uses Debug state.

[AArch64.WatchpointException\(\)](#) is called to generate a Watchpoint exception.

These functions are defined in [Chapter J1 Armv8 Pseudocode](#).

D2.11 Vector Catch exceptions

Vector Catch exceptions are not generated in AArch64 translation regimes.

———— **Note** —————

This means that they are never taken to EL1 using AArch64 and are only supported if at least EL1 using AArch32 is supported.

A debugger that is executing in EL2 using AArch64 can route Vector Catch exceptions to EL2 using AArch64. See [Routing debug exceptions on page D2-2569](#).

`AArch64.VectorCatchException()` is called to generate a Vector Catch exception.

[Vector Catch exceptions on page G2-6209](#) describes Vector Catch exceptions.

D2.12 Software Step exceptions

The following subsections describe Software Step exceptions:

- [About Software Step exceptions](#) on page D2-2613.
- [Rules for setting MDSCR_EL1.SS to 1](#) on page D2-2613.
- [The software step state machine](#) on page D2-2613.
- [Entering the active-not-pending state](#) on page D2-2615.
- [Behavior in the active-not-pending state](#) on page D2-2618.
- [Entering the active-pending state](#) on page D2-2620.
- [Behavior in the active-pending state](#) on page D2-2621.
- [Stepping T32 IT instructions](#) on page D2-2621.
- [Exception syndrome information and preferred return address](#) on page D2-2622.
- [Additional considerations](#) on page D2-2623.
- [Pseudocode description of Software Step exceptions](#) on page D2-2625.

D2.12.1 About Software Step exceptions

Software step is an Armv8-A resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can single-step instructions at a lower Exception level.

Operation is as follows:

1. A debugger:
 - a. Enables software step by setting MDSCR_EL1.SS to 1. See [The debug exception enable controls](#) on page D2-2568.
 - b. Executes an exception return instruction, to branch to the instruction to be single-stepped in the software being debugged.
2. The PE then:
 - a. Executes the instruction to be single-stepped.
 - b. Takes a Software Step exception on the next instruction, returning control to the debugger.

However, another exception might be generated while the instruction is being stepped. This exception is either:

- A synchronous exception that is generated by the instruction being stepped.
- An asynchronous exception that is taken before or after the instruction being stepped.

The PE can only take a Software Step exception if debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Exception level](#) on page D2-2571.

A state machine describes the behavior of software step, shown in [The software step state machine](#) on page D2-2613.

Throughout this [Software Step exceptions](#) on page D2-2613 section, including in all subsections, EL_D means the Exception level that Software Step exceptions are targeting. [Routing debug exceptions](#) on page D2-2569 defines EL_D as the *debug target Exception level*.

D2.12.2 Rules for setting MDSCR_EL1.SS to 1

Debugger software must be executing in an Exception level and Security state that debug exceptions are disabled from when it sets MDSCR_EL1.SS to 1.

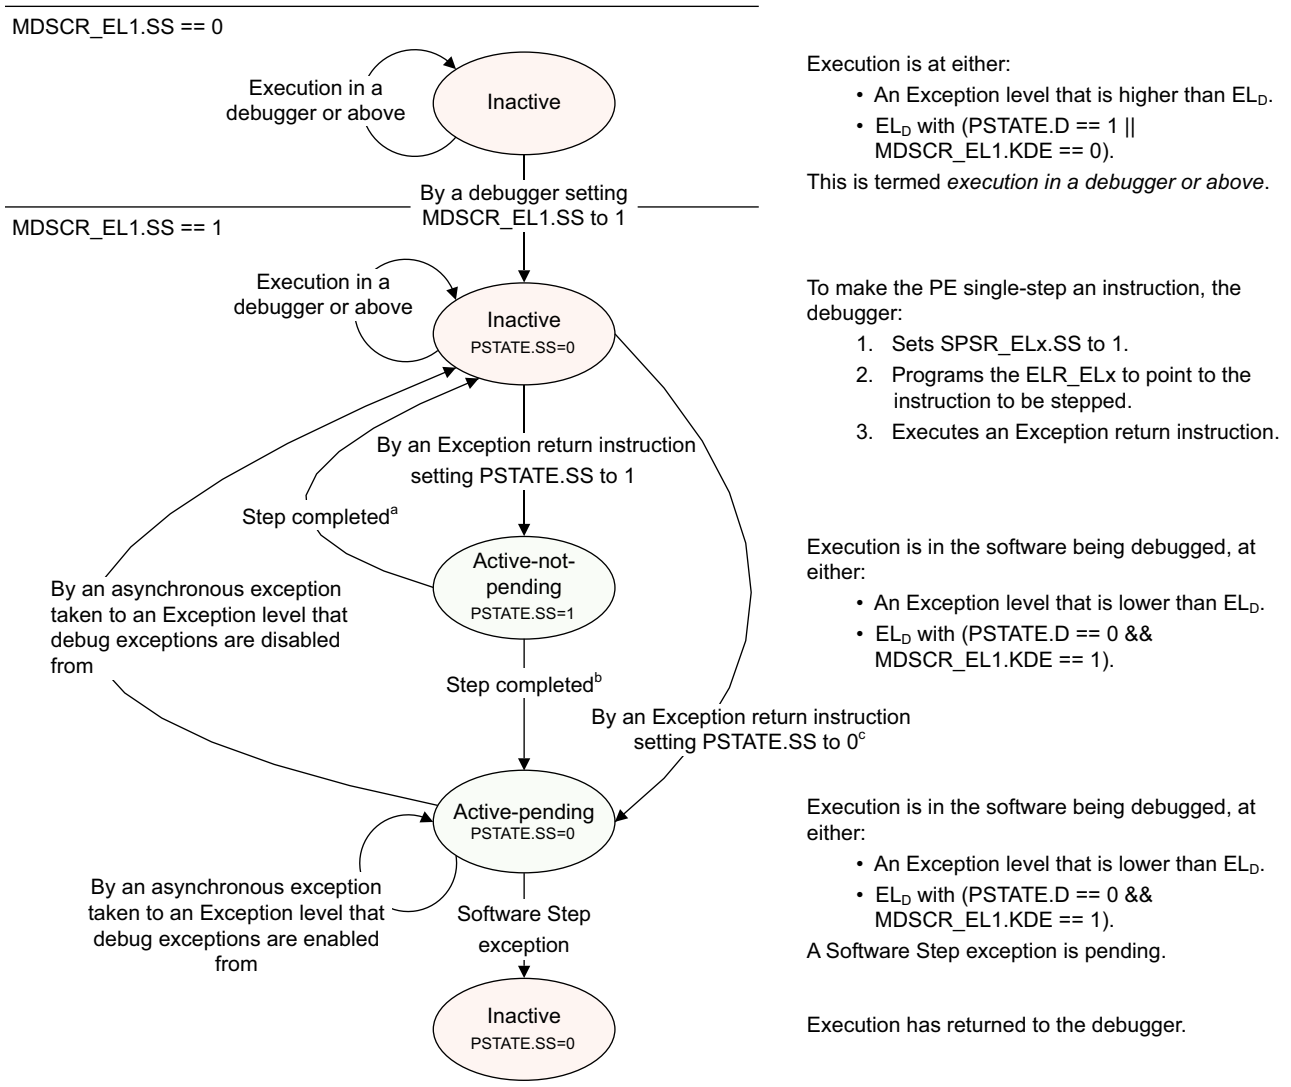

The Exception level that hosts the debugger software must be using AArch64.

D2.12.3 The software step state machine

In [Figure D2-3](#) on page D2-2614:

- The OS Lock is unlocked and DoubleLockStatus() == FALSE.

- The PE is not in Secure state with `MDCR_EL3.SDD` set to 1. That is, the PE is in Non-secure state, or is in Secure state with `MDCR_EL3.SDD` set to 0, or the implementation does not include EL3.

a. The step is the PE either:

- Taking an exception to an Exception level that debug exceptions are disabled from.
- If execution is at `ELD` with `MDCR_EL1.KDE == 1`, executing an instruction that sets `PSTATE.D` to 1.

Software step is inactive when debug exceptions are disabled from the current Exception level, and debug exceptions are disabled from `ELD` when `PSTATE.D` is 1.

b. The step is the PE either:

- Executing the instruction to be stepped without taking an exception.
- Taking an exception to an Exception level that debug exceptions are enabled from. The Exception level might be using AArch64 or AArch32.

c. Or, if execution is at `ELD` with `MDCR_EL1.KDE == 1`, by software setting `PSTATE.D` to 0.

Figure D2-3 Software step state machine

For a description of when debug exceptions are enabled or disabled from an Exception level, see [Enabling debug exceptions from the current Exception level on page D2-2571](#).

For more information about how a step is completed, see [Behavior in the active-not-pending state on page D2-2618](#).

The software step states are:

Inactive Software step is inactive. It cannot generate any Software Step exceptions or affect PE execution. Software step is inactive whenever any of the following are true:

- [MDCR_EL1.SS](#) is 0.
- EL_D is using AArch32.
- Debug exceptions are disabled from the current Exception level or Security state.

Active-not-pending

None of the conditions mentioned in [Inactive on page D2-2615](#) are true, therefore software step is active.

The current instruction is the instruction to be stepped.

Active-pending

None of the conditions mentioned in [Inactive on page D2-2615](#) are true, therefore software step is active.

A Software Step exception is pending on the current instruction.

Whenever software step is active, whether the state machine is in the active-not pending state or the active-pending state depends on [PSTATE.SS](#). [Table D2-18 on page D2-2615](#) shows this.

Table D2-18 State machine states

EL_D using:	Debug exception enable status in the current Exception level and Security state	MDCR_EL1.SS	PSTATE.SS	State machine state
AArch32	X	X	X	Inactive
AArch64	Disabled	X	X	Inactive
AArch64	Enabled	0	X	Inactive
AArch64	Enabled	1	1	Active-not-pending
AArch64	Enabled	1	0	Active-pending

D2.12.4 Entering the active-not-pending state

Software step can only enter the active-not-pending state from the inactive state.

Software step:

- Enters the active-not-pending state when an Exception return instruction writes 1 to [PSTATE.SS](#), by copying from [SPSR_ELx.SS](#) when it restores [PSTATE](#).
- Might enter the active-not-pending state on exiting Debug state when [DSPSR_EL0.SS](#) or [DSPSR.SS](#) is 1. See [Exiting Debug state on page H2-7375](#).

An Exception return instruction only copies 1 from [SPSR_ELx.SS](#) to [PSTATE.SS](#) if all of the following are true:

- [MDCR_EL1.SS](#) is 1.
- EL_D is using AArch64.
- Debug exceptions are disabled from the current Exception level.
- Debug exceptions are enabled from the Exception level that the Exception return instruction targets.

Otherwise, Exception return instructions set [PSTATE.SS](#) to 0, regardless of the value of [SPSR_ELx.SS](#).

[Table D2-19 on page D2-2616](#) shows this. In the table:

Lock Means the value of $(OSLSR_EL1.OSLK == '1' || DoubleLockStatus())$.

NS Means the *Effective value* of [SCR_EL3.NS](#).

- SDD** Means the *Effective value* of MDCR_EL3.SDD. See *Disabling debug exceptions from Secure state* on page D2-2571.
- EEL2** Means the *Effective value* of SCR_EL3.EEL2. If FEAT_SEL2 is not implemented, this is 0.
- TGE** Means the value of HCR_EL2.TGE. If EL2 is not implemented, the PE behaves as if this is 0.
- TDE** Means the *Effective value* of MDCR_EL2.TDE. See *Routing debug exceptions* on page D2-2569.
- EL1 is using** The Execution state when the EL_D is EL1.
- EL2 is using** The Execution state when the EL_D is EL2.

Table D2-19 Value an Exception return instruction writes to PSTATE.SS

MDCR_EL1.SS	Lock	NS	SDD	EEL2	TGE	TDE	EL1 is using	EL2 is using	Value an Exception return instruction writes to PSTATE.SS
0	X	X	X	X	X	X	X	X	0
1	TRUE	X	X	X	X	X	X	X	0
	FALSE	0	1	X	X	X	X	X	0
0			0	X	X	AArch32	n/a	0	
							AArch64	n/a	See Table D2-20 on page D2-2617
				1	0	0	AArch32	n/a	0
							AArch64	AArch64	See Table D2-20 on page D2-2617
						1	AArch32	AArch32	0
							X	AArch64	See Table D2-21 on page D2-2618
					1	X	n/a	AArch32	0
							n/a	AArch64	See Table D2-21 on page D2-2618
		1	X	X	0	0	AArch32	n/a	0
							AArch64	AArch64	See Table D2-20 on page D2-2617
						1	AArch32	AArch32	0
							X	AArch64	See Table D2-21 on page D2-2618
					1	X	n/a	AArch32	0
							n/a	AArch64	See Table D2-21 on page D2-2618

For:

- If EL_D is EL1 using AArch64, Table D2-20 on page D2-2617 shows the value an Exception return instruction writes to PSTATE.SS.

- If EL_D is EL2 using AArch64, [Table D2-21 on page D2-2618](#) shows the value an Exception return instruction writes to `PSTATE.SS`.

In both tables:

From EL Means the Exception level at which the PE executes the Exception return instruction.

Target EL Is the target Exception level of the Exception return instruction.

———— **Note** —————

If the Exception return instruction is an illegal exception return, the target Exception level of the Exception return instruction is the current Exception level. See *Illegal return events from AArch64 state* on page D1-2486.

KDE Is `MDSCR_EL1.KDE`. See *Enabling debug exceptions from the current Exception level* on page D2-2571.

Table D2-20 Value an Exception return instruction writes to `PSTATE.SS` if EL_D is EL1 using AArch64

From EL	Target EL	KDE	<code>PSTATE.D</code>	<code>SPSR_ELx.D</code>	Software step enable status at:		Value an Exception return instruction writes to <code>PSTATE.SS</code>
					From EL	Target EL	
EL3	EL3	X	X	X	Disabled	Disabled	0
	EL2	X	X	X	Disabled	Disabled	0
	EL1	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	<code>SPSR_EL3.SS</code>
EL0	X	X	X	Disabled	Enabled	<code>SPSR_EL3.SS</code>	
EL2	EL2	X	X	X	Disabled	Disabled	0
	EL1	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	<code>SPSR_EL2.SS</code>
EL0	X	X	X	Disabled	Enabled	<code>SPSR_EL2.SS</code>	
EL1	EL1	0	X	X	Disabled	Disabled	0
		1	0	X	Enabled ^a	- ^b	0
		1	1	1	Disabled	Disabled	0
				0	Disabled	Enabled	<code>SPSR_EL1.SS</code>
	EL0	0	X	X	Disabled	Enabled	<code>SPSR_EL1.SS</code>
	1	0	X	Enabled ^a	Enabled	0	
			1	X	Disabled	Enabled	<code>SPSR_EL1.SS</code>

a. Because `MDSCR_EL1.SS == 1`, it means that the Exception return instruction is itself being stepped.

b. Depends on `SPSR_EL1.D`.

Table D2-21 Value an Exception return instruction writes to `PSTATE.SS` if `ELD` is `EL2` using AArch64

From EL	Target EL	KDE	<code>PSTATE.D</code>	<code>SPSR_ELx.D</code>	Software step enable status at:		Value an Exception return instruction writes to <code>PSTATE.SS</code>	
					From EL	Target EL		
EL3	EL3	X	X	X	Disabled	Disabled	0	
	EL2	0	X	X	Disabled	Disabled	0	
		1	X	1	Disabled	Disabled	0	
				0	Disabled	Enabled	<code>SPSR_EL3.SS</code>	
	EL1	X	X	X	Disabled	Enabled	<code>SPSR_EL3.SS</code>	
	EL0	X	X	X	Disabled	Enabled	<code>SPSR_EL3.SS</code>	
EL2	EL2	0	X	X	Disabled	Disabled	0	
		1	0	X	Enabled ^a	- ^b	0	
			1	1	Disabled	Disabled	0	
				0	Disabled	Enabled	<code>SPSR_EL2.SS</code>	
	EL1	0	X	X	Disabled	Enabled	<code>SPSR_EL2.SS</code>	
		1	0	X	Enabled ^a	Enabled	0	
			1	X	Disabled	Enabled	<code>SPSR_EL2.SS</code>	
	EL0	0	X	X	Disabled	Enabled	<code>SPSR_EL2.SS</code>	
		1	0	X	Enabled ^a	Enabled	0	
			1	X	Disabled	Enabled	<code>SPSR_EL2.SS</code>	
	EL1	EL1	X	X	X	Enabled ^a	Enabled	0
		EL0	X	X	X	Enabled ^a	Enabled	0

a. Because `MDCR_EL1.SS == 1`, it means that the Exception return instruction is itself being stepped.

b. Depends on `SPSR_EL2.D`.

Note

No AArch32 instruction can set `PSTATE.SS` to 1.

D2.12.5 Behavior in the active-not-pending state

In this state, the PE does one of the following:

- Executes the instruction to be stepped and either:
 - Completes it without taking a synchronous exception.
 - Takes a synchronous exception if the instruction generates one.
- Takes an asynchronous exception without executing any instructions.
- Enters Debug state because of a *Halting debug event*.

If the PE executes the instruction without taking any exceptions, then the PE sets `PSTATE.SS` to 0, meaning that after the instruction has been executed:

- If the instruction has disabled debug by setting `PSTATE.D` to 1 then software step advances to the inactive state.
- If the instruction disables software step by a direct write to a System register, for example a write to `MDSCR_EL1.KDE` or `MDSCR_EL1.SS`, then software step might advance to the inactive state. These writes require explicit synchronization to guarantee their effect. See *Synchronization and the software step state machine* on page D2-2624.
- Otherwise, software step advances to the active-pending state. See *Behavior in the active-pending state* on page D2-2621.

If the PE takes either a synchronous or an asynchronous exception, behavior is as described in one of the following:

- *If the PE takes an exception to an Exception level that is using AArch64* on page D2-2619.
- *If the PE takes an exception to an Exception level that is using AArch32* on page D2-2620.

If the PE enters Debug state because of a Halting debug event, behavior is as described in *Entering Debug state and Software Step* on page H2-7347.

If the PE takes an exception to an Exception level that is using AArch64

As part of exception entry, the PE does all of the following:

- Sets `SPSR_ELx.SS` to 0 or 1, depending on the exception. See *Table D2-22* on page D2-2619.
- It is UNPREDICTABLE whether `SPSR_ELx.SS` to 0 or 1 when an SError interrupt is taken to ELx without executing the instruction.
- Sets `PSTATE.SS` to 0. This causes software step to enter either the active-pending state or the inactive state, depending on whether debug exceptions are enabled or disabled from the Exception level that the exception is taken to:
 - Enabled** Software step enters the active-pending state.
 - Disabled** Software step enters the inactive state.
 In either case, on taking the exception, a step is complete.
- Sets `PSTATE.D` to 1.

Table D2-22 Categorization of exceptions, for setting `SPSR_ELx.SS` to 0 or 1

Exception description	Exceptions	<code>SPSR_ELx.SS</code>
Exceptions whose preferred return address is for the instruction that follows the instruction to be stepped.	Supervisor Call (SVC) exceptions. Hypervisor Call (HVC) exceptions. Secure Monitor Call (SMC) exceptions.	0
Exceptions whose preferred return address is the address of the instruction to be stepped.	All other synchronous exceptions, and asynchronous exceptions that are taken before the instruction to be stepped.	1

———— **Note** ————

If an SMC instruction executed at Non-secure EL1 is trapped to EL2 because `HCR_EL2.TSC` is 1, the exception is a Trap exception, not a Secure Monitor Call exception, and so `SPSR_ELx.SS` is set to 1, not 0.

If the PE takes an exception to an Exception level that is using AArch32

This can only happen when all of the following is true:

- EL2 is implemented and is using AArch64, and the *Effective value* of MDCR_EL2.TDE is 1. Because MDCR_EL2.TDE is 1, EL_D is EL2.
- The exception is taken to EL1 using AArch32.

As part of exception entry, the PE sets PSTATE.SS to 0. This causes software step to enter the active-pending state.

———— **Note** ————

- Software step always enters the active-pending state because the exception is taken to an Exception level that debug exceptions are enabled from, EL1. Debug exceptions are enabled from EL1 because EL_D is EL2, and debug exceptions are always enabled from Exception levels that are lower than EL_D.
- AArch32 SPSRs have no SS bit.

Summary of behavior in the active-not-pending state

Table D2-23 on page D2-2620 summarizes behavior in the active-not-pending state.

Table D2-23 Summary of behavior in the active-not-pending state

Event	Value written to PSTATE.SS	Target Exception level is using:	Details ^a	Value written to SPSR_ELx.SS	Next state
No exception	0	n/a	Disables Software step	n/a	Inactive
			Otherwise	n/a	Active-pending
Exception	0	AArch64	Supervisor Call (SVC) Hypervisor Call (HVC) Secure Monitor Call (SMC)	0	Active-pending or inactive ^b
			Other	1	
		AArch32	All	0	Active-pending

a. For the *No exception* rows, this column shows the effect of the event.

For the *Exception* rows, this column shows the exception taken.

b. Which state software step enters depends on whether debug exceptions are enabled or disabled from the target Exception level. See Figure D2-3 on page D2-2614.

D2.12.6 Entering the active-pending state

Software step enters the active-pending state after any of the following operations, provided that both:

- MDCR_EL1.SS is 1.
- Debug exceptions are enabled from the Exception level and Security state that execution is in after the operation.

The operations are:

While software step is in the active-not-pending state

The PE either:

- Executing the instruction to be stepped without taking any exceptions.
- Taking an exception.

While software step is in the active-pending state

The PE takes an asynchronous exception.

While software step is in the inactive state

The PE executes either:

- An Exception return instruction when `SPSR_ELx.SS` is 0.
- An instruction that enables debug by setting `PSTATE.D` to 0.

————— **Note** —————

If entry to the active-pending state is because of the PE taking an exception, it means that the exception is one that is taken to EL1 when `MDCR_EL2.TDE` is 1 and EL2 is implemented and enabled in the current Security state. Otherwise, debug exceptions are masked by `PSTATE.D`, therefore they would be disabled from the target Exception level of the exception.

In addition, software step might enter the active-pending state either:

- After a direct write to a System register, for example a write to `MDSCR_EL1.KDE` or `MDSCR_EL1.SS`. These writes require explicit synchronization to guarantee their effect. See *Synchronization and the software step state machine* on page D2-2624.
- On exiting Debug state when `DSPSR_EL0.SS` or `DSPSR.SS` is 0. See *Exiting Debug state* on page H2-7375.

D2.12.7 Behavior in the active-pending state

When the PE is in the active-pending state, a Software Step exception is taken before the PE executes an instruction.

The Software Step exception has higher priority than all other types of synchronous exception. However, the prioritization of this exception with respect to any unmasked pending asynchronous exception is not defined by the architecture.

For more information, see the following:

- *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2490.
- *Prioritization and recognition of interrupts* on page D1-2508.
- *Architectural requirements for taking asynchronous exceptions* on page G1-6049.

D2.12.8 Stepping T32 IT instructions

The Armv8-A architecture permits a combination of an IT instruction and another 16-bit T32 instruction to comprise one 32-bit instruction.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers this combination to be one instruction.
- The PE considers this combination to be two instructions.

In an implementation that supports the ITD control, that can disable some uses of the IT instruction, it is then IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD field. For example:

- The PE might consider this combination to be one instruction, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be two instructions, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be one instruction when the applicable ITD field is 1, and two instructions when it is 0.

The applicable ITD field is one of:

- `SCTLR_EL1.ITD` if execution is at EL0 using AArch32 when EL1 is using AArch64.
- `SCTLR.ITD` if execution is at EL0 or EL1 when EL1 is using AArch32.

- [HSCTLR.ITD](#) if execution is at Non-secure EL2 using AArch32.

D2.12.9 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#) on page D2-2622.
- [Preferred return address](#) on page D2-2623.

Exception syndrome information

On taking a Software Step exception, the PE records information about the exception in the Exception Syndrome Register ([ESR_ELx](#)) at the Exception level the exception is taken to. See [ISS encoding for an exception from a Software Step exception](#) on page D13-3183 for more information.

If no instruction was stepped because software step entered the active-pending state from the inactive state without passing through the active-not-pending state, then [ESR_ELx](#).{ISV, EX} are set to 0.

When an instruction has been stepped, if the stepped instruction was a conditional Load-Exclusive instruction that failed its Condition code test, then [ESR_ELx](#).EX is set to a CONSTRAINED UNPREDICTABLE choice of 0 or 1.

When an instruction has been stepped, if the stepped instruction was an Exception return instruction or an ISB, then [ESR_ELx](#).ISV is set to a CONSTRAINED UNPREDICTABLE choice of 0 or 1, and [ESR_ELx](#).EX is set to 0.

If the *Effective value* of [MDCR_EL2](#).TDE == 1, EL2 is implemented and enabled in the current Security state, and a different exception is taken before the Software Step exception, then [ESR_ELx](#).ISV is set to a CONSTRAINED UNPREDICTABLE choice of 0 or 1. In this case:

- If [ESR_ELx](#).ISV is set to 1, then [ESR_ELx](#).EX is set to the correct value for the instruction.
- If [ESR_ELx](#).ISV is set to 0, then [ESR_ELx](#).EX is set to zero.

Other than for the cases described above, when an instruction has been stepped:

- [ESR_ELx](#).ISV is set to 1, to indicate that the EX bit is valid.
- The value of [ESR_ELx](#).EX is set according to the instruction stepped. When:
 - The instruction stepped was an instruction other than a Load-Exclusive instruction, an Exception Return instruction, or an ISB, and no other exception was taken before the Software Step exception, [ESR_ELx](#).EX is set to 0.
 - The instruction stepped was a Load-Exclusive instruction that was either not conditional or did not fail its Condition code test, [ESR_ELx](#).EX is set to 1.

———— **Note** —————

A Load-Exclusive instruction is any one of the following:

- In the A64 instruction set, any instruction that has a mnemonic starting with either LDX or LDAX.
- In the A32 and T32 instruction sets, any instruction that has a mnemonic starting with either LDREX or LDAEX.

———— **Note** —————

An implementation that always sets ISV to 0 and never sets EX is not compliant.

Table D2-24 on page D2-2623 summarizes the possible values that the PE can record in `ESR_ELx.{ISV, EX}`.

Table D2-24 Values that the PE can record in `ESR_ELx.{ISV, EX}`

Description	ESR_ELx.ISV	ESR_ELx.EX
Syndrome data is not available because no instruction was stepped.	0	0
Syndrome data is available because an instruction was stepped. The instruction stepped was a conditional Load-Exclusive instruction that failed its Condition code test.	1	0 or 1
Syndrome data is available because an instruction was stepped. The instruction stepped was an Exception Return instruction or an ISB.	0 or 1	0
A different exception is taken before the Software Step exception.	0	0
	1	Set to the correct value for the instruction.
Syndrome data is available because an instruction was stepped. The instruction stepped was an instruction other than a Load-Exclusive instruction, an Exception Return instruction, or an ISB, and no other exception was taken before the Software Step exception.	1	0
Syndrome data is available because an instruction was stepped. The instruction stepped was a Load-Exclusive instruction that was either not conditional or did not fail its Condition code test.	1	1

Preferred return address

The preferred return of a Software Step exception is the address of the instruction that was not executed because the PE took the Software Step exception instead.

D2.12.10 Additional considerations

This section contains the following:

- [Behavior when an Exception return instruction is an illegal exception return on page D2-2623.](#)
- [Behavior when the instruction stepped writes a misaligned PC value on page D2-2624.](#)
- [Stepping code that uses Exclusives monitors on page D2-2624.](#)
- [Synchronization and the software step state machine on page D2-2624.](#)

Behavior when an Exception return instruction is an illegal exception return

If the conditions for entering the active-not-pending state in [Entering the active-not-pending state on page D2-2615](#) are met, but the PE executes an Exception return instruction that is an illegal exception return, the exception return must be taken to the same Exception level that it was taken from. In this scenario, even though the Exception level remains the same before and after the Exception return instruction, software step can advance from the inactive state to one of the active states. Consider the following case:

1. `MDSCR_EL1.SS` is 1 and software step is inactive. The current Exception level is EL1 using AArch64, the OS Lock and OS Double Lock are unlocked, and `MDCR_EL2.TDE` is 0, `MDSCR_EL1.KDE` is 1, and `PSTATE.D` is 1.
`PSTATE.D == 1` is the reason why software step is inactive, because `PSTATE.D == 1` means that debug exceptions are disabled from the current Exception level.
2. The PE executes an Exception return instruction.

- The intended target of the Exception return instruction is EL2. This means that the Exception return instruction is an illegal exception return because the intended target is higher than the Exception level the Exception return instruction it is executed at. In this case, the Exception return instruction must target EL1 instead of EL2.

If `SPSR_EL1.D` is 0, then on the Exception return instruction `PSTATE.D` becomes 0 and debug exceptions become enabled from the current Exception level. Software step therefore advances from the inactive state to one of the active states.

Which active state software step advances to depends on whether `SPSR_ELx.SS` is 1 or 0:

- If `SPSR_ELx.SS` is 1, software step advances to the active-not-pending state.
In this case, an Illegal Execution state exception is pending on the instruction to be stepped, and the PE takes the Illegal Execution state exception instead of executing the instruction to be stepped.
- If `SPSR_ELx.SS` is 0, software step advances to the active-pending state.
In this case, a Software Step exception and an Illegal Execution state exception are both pending. The Software Step exception has higher priority. On taking the Software Step exception, the PE sets `SPSR_ELx.IL` to 1.

———— **Note** ————

[Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2490](#) shows the relative priorities of synchronous exceptions.

Behavior when the instruction stepped writes a misaligned PC value

An indirect branch that writes a misaligned PC value might generate a PC alignment fault exception at the target of the branch. However, if the indirect branch is stepped using software step, the PE takes a Software Step exception instead, because the Software Step exception has higher priority. Behavior on returning from the Software Step exception depends on which Execution state the Exception level being returned to is using:

AArch64 A PC alignment fault exception is generated.

AArch32 The return from the Software Step exception forces the PC to the correct alignment, and no PC alignment fault exception is generated.

Debugger software must therefore take care when using software step to single-step an indirect branch instruction executed in AArch32 state, that it does not hide a PC alignment fault exception.

Stepping code that uses Exclusives monitors

The Armv8-A architecture provides no mechanism for preserving the state of the Exclusives monitors when a Load-Exclusive or a Store-Exclusive instruction is stepped.

However, for certain progressions through the software step state machine, on taking a Software Step exception, the PE provides an indication of whether the instruction stepped was a Load-Exclusive instruction.

Debugger software can use this to detect the state of the Exclusives monitors. For example, if the PE reports that the instruction stepped was a Load-Exclusive instruction, the debugger is aware that the next Store-Exclusive operation will fail, because all Exclusives monitors are cleared on returning from the Software Step exception. The debugger must then take action to ensure that the code being stepped makes forwards progress.

For more information on how the PE reports whether the instruction stepped was a Load-Exclusive instruction, see [Exception syndrome information and preferred return address on page D2-2622](#).

Synchronization and the software step state machine

Any of the following can cause transitions between software step states:

- A direct write to a System register.
- A direct write to a Special-purpose register.

- A write to an external debug register.

The software step state machine indirectly reads some of these registers and so is not guaranteed to observe any new values until after a *Context synchronization event* has occurred.

Between a write to the register and the next *Context synchronization event*, it is CONSTRAINED UNPREDICTABLE whether software step uses the state of the PE before the write, or the state of the PE after the write.

After a *Context synchronization event*, the state machine must use the state of the PE after the write.

Example D2-3 Example of synchronization and software step state machine changing states

1. Software changes `MDSCR_EL1.SS` from 0 to 1 when debug exceptions are enabled.
2. The PE executes some instructions.
3. A *Context synchronization event* occurs.

During step 2, it is CONSTRAINED UNPREDICTABLE whether software step remains in the inactive state, as if `MDSCR_EL1.SS` is 0, or enters the active-pending state because `MDSCR_EL1.SS` is 1. If it is in the:

- Inactive state, then after the *Context synchronization event*, it must enter the active-pending state.
 - Active-pending state, the PE might take a Software Step exception before the *Context synchronization event*.
-

———— Note —————

A direct write to a Special-purpose register does not require explicit synchronization.

D2.12.11 Pseudocode description of Software Step exceptions

`SSAdvance()` advances software step from the active-not-pending state to the active-pending state, by setting `PSTATE.SS` to 0. It is called on completing execution of each instruction.

`CheckSoftwareStep()` checks whether software step is in the active-pending state, and if it is, generates a Software Step exception. It is called before each instruction executed, regardless of Execution state, before checking for any other synchronous exceptions.

`DebugExceptionReturnSS()` returns the value to write to `PSTATE.SS` on an exception return or an exit from Debug state. See *Entering the active-not-pending state on page D2-2615*.

These functions are defined in *Chapter J1 Armv8 Pseudocode*.

D2.13 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
 - External debug registers.
 - System registers, including system debug registers.
 - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a *Context synchronization event* has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a *Context synchronization event* has occurred.

For any instructions executed between the time when the change is made and the time when the next *Context synchronization event* occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

Example D2-4 Example of synchronization and Breakpoint exception generation

1. Software changes `MDSR_EL1.MDE` from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A *Context synchronization event* occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

Example D2-5 Example of synchronization and debug exceptions generation

1. Software unlocks the OS Lock.
2. The PE executes some instructions.
3. A *Context synchronization event* occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

Note

Some register updates are self-synchronizing. Others require an explicit *Context synchronization event*. For more information, see:

- [Accessing PSTATE fields on page D1-2467.](#)
 - [Synchronization requirements for AArch64 System registers on page D13-3041.](#)
 - [Synchronization of changes to the external debug registers on page H8-7462.](#)

Chapter D3

AArch64 Self-hosted Trace

This chapter describes the AArch64 self-hosted trace:

Introductory information:

- *About self-hosted trace* on page D3-2628.
- *Trace sinks* on page D3-2628.
- *Register controls to enable self-hosted trace* on page D3-2628.

Prohibited regions in trace:

- *Controls to prohibit trace at Exception levels* on page D3-2629.
- *Self-hosted trace and visibility of virtual data* on page D3-2630.

Timestamps and Synchronization:

- *Self-hosted trace timestamps* on page D3-2631.
- *Synchronization in self-hosted trace* on page D3-2632.

D3.1 About self-hosted trace

A PE Trace Unit generates trace data to describe the program flow of the PE.

The PE Trace Unit may be an implementation of a standard Arm Embedded Trace Macrocell (ETM), or another type of Arm Trace Architecture, or an IMPLEMENTATION DEFINED trace function.

If an Armv8.4-compliant PE implements an ETM Architecture PE Trace Unit that includes the ETM System register interface, `FEAT_TRF` must be implemented.

If an Armv8.4-compliant PE implements a Trace Unit that is either not an ETM Architecture PE Trace Unit or does not implement the ETM System register interface, Arm recommends that `FEAT_TRF` is implemented, but this is not mandatory.

Self-hosted trace happens when the agent controlling the trace collection is part of the same software stack as the software being traced. The agent controls prohibited regions. The information collected by the agent is sent to a trace sink.

The PE Trace Unit and the PE must have the same view of the debug authentication interface. If `FEAT_TRF` is implemented, `ExternalNoninvasiveDebugEnabled()` is always TRUE.

D3.1.1 Trace sinks

The PE Trace Unit sends the trace data to a trace sink. A system might include multiple trace sinks, and allow software to configure which trace sink or sinks are used.

An example of an internal trace sink is an Embedded Trace Router (ETR), which allows software to define a buffer in memory. Trace data is written to this buffer.

Arm recommends that a system that includes `FEAT_TRF` incorporates an ETR, and follows the system architecture described by the *CoreSight Base System Architecture (CS-BSA)*.

The self-hosted trace extensions do not describe the programmers' model trace sinks.

D3.1.2 Register controls to enable self-hosted trace

If `FEAT_TRF` is implemented, self-hosted trace is enabled if one of the following is true:

- `EDSCR.TFO == 0`.
- `EDSCR.TFO == 1`, EL3 is implemented, `MDCR_EL3.STE == 1` and `ExternalSecureNoninvasiveDebugEnabled() == FALSE`.
- `EDSCR.TFO == 1`, EL3 is not implemented, the PE executes in Secure state and `ExternalSecureNoninvasiveDebugEnabled() = FALSE`.

The pseudocode function `SelfHostedTraceEnabled()` shows these rules.

If `FEAT_TRF` is not implemented, `SelfHostedTraceEnabled()` returns FALSE.

While `SelfHostedTraceEnabled() == FALSE`, `ExternalSecureNoninvasiveDebugEnabled()` and `ExternalNoninvasiveDebugEnabled()` control whether tracing is prohibited or allowed in each Security state.

The self-hosted trace extensions do not provide any mechanism to control software access to the PE Trace Unit external debug interface.

D3.2 Prohibited regions in self-hosted trace

Trace is not generated in prohibited regions. The pseudocode function `TraceAllowed()` indicates whether tracing is allowed in the current Security state and Exception level.

The IMPLEMENTATION DEFINED debug authentication interface can allow an external agent to disable the self-hosted trace extension.

If `SelfHostedTraceEnabled() == TRUE`, tracing is prohibited in Secure state when `MDCR_EL3.STE == 0`. If `FEAT_TRF` is implemented but not enabled, tracing is prohibited in Secure state when `ExternalSecureNoninvasiveDebugEnabled() == FALSE`.

D3.2.1 Controls to prohibit trace at Exception levels

If `SelfHostedTraceEnabled() == TRUE`, `TRFCR_EL1` and `TRFCR_EL2` control whether trace is prohibited at an Exception level. While `SelfHostedTraceEnabled() == FALSE`, the registers `TRFCR_EL1` and `TRFCR_EL2` are ignored.

If `SelfHostedTraceEnabled() == TRUE`, tracing is prohibited at EL0 if one of the following is true:

- The Effective value of `HCR_EL2.TGE == 0` and `TRFCR_EL1.E0TRE == 0`.
- The Effective value of `HCR_EL2.TGE == 1` and `TRFCR_EL2.E0HTRE == 0`.

If `SelfHostedTraceEnabled() == TRUE`, tracing is prohibited at EL1 if `TRFCR_EL1.E1TRE == 0`.

If `SelfHostedTraceEnabled() == TRUE`, tracing is prohibited at EL2 if `TRFCR_EL2.E2TRE == 0`.

If `SelfHostedTraceEnabled() == TRUE`, tracing is prohibited at EL3 if one of the following is true:

- EL3 is using AArch64 state.
- EL3 is using AArch32 state and `TRFCR.E1TRE == 0`.

The pseudocode `TraceAllowed()` shows the above rules.

If `SelfHostedTraceEnabled() == TRUE`, no events are exported to the PE Trace Unit when tracing is prohibited.

If `SelfHostedTraceEnabled() == FALSE`, no events are exported to the PE Trace Unit when the PE is in Secure state and counting in Secure state is prohibited.

When `PMCR_EL0.X==0` or `PMCR.X==0`, no PMU events are exported to the PE Trace Unit.

Otherwise, PMU events are exported to the PE Trace Unit.

If `SelfHostedTraceEnabled() == TRUE`, Table D3-1 on page D3-2630 shows the prohibited regions by Exception level and state.

In the table:

STE	Means the Effective value of <code>MDCR_EL3.STE</code> or <code>SDCR.STE</code> , as applicable.
EEL2	Means the Effective value of <code>SCR_EL3.EEL2</code> .
TGE	Means the Effective value of <code>HCR_EL2.TGE</code> .
P	Means prohibited.
E2TRE	Means allowed if <code>TRFCR_EL2.E2TRE == 1</code> .
E1TRE	Means allowed if <code>TRFCR_EL1.E1TRE == 1</code> .
E0HTRE	Means allowed if <code>TRFCR_EL2.E0HTRE == 1</code> .
E0TRE	Means allowed if <code>TRFCR_EL1.E0TRE == 1</code> .

n/a Not applicable.

Table D3-1 Prohibited regions

Controls			Tracing prohibited at					
State	STE	EL3 using	EEL2	TGE	EL3	EL2	EL1	EL0
Non-secure	X	X	X	0	n/a	E2TRE	E1TRE	E0TRE
	X	X	X	1	n/a	E2TRE	n/a	E0HTRE
Secure	0	X	X	X	P	P	P	P
	1	AArch64	0	X	P	n/a	E1TRE	E0TRE
			1	0	P	E2TRE	E1TRE	E0TRE
			1	1	P	E2TRE	n/a	E0HTRE
	AArch32	X	X	E1TRE	n/a	n/a	E0TRE	

D3.2.2 Self-hosted trace and visibility of virtual data

A hypervisor can use `TRFCR_EL2.CX` to control visibility of `CONTEXTIDR_EL2` and `VTTBR_EL2.VMID`.

If `SelfHostedTraceEnabled() == TRUE` and `TRFCR_EL2.CX == 0`, or if EL2 is not implemented:

- The values of `CONTEXTIDR_EL2` and `VTTBR_EL2.VMID` are not traced.
- Comparisons between `CONTEXTIDR_EL2` and `VTTBR_EL2.VMID` do not match and results of comparison are not exposed through the comparators.

The PE Trace Unit may either prohibit trace for these values, or may record a `CONTEXTIDR_EL2` or `VTTBR_EL2.VMID` value of zero in the trace.

D3.3 Self-hosted trace timestamps

The trace timestamp is a value that represents the passage of time in real-time. It is calculated from a counter which increments all the time, when the PE is generating trace and when the PE is in a prohibited region.

While `SelfHostedTraceEnabled() == FALSE`, the external trace provides the trace timestamp. If the external trace is a standard CoreSight system, the relationship between CoreSight time and the Generic Timer counter is IMPLEMENTATION DEFINED.

When `SelfHostedTraceEnabled() == TRUE`, the trace timestamp is one of the following:

- The physical counter value `CNTPCT_EL0`.
- An offset physical counter value, which is calculated from the physical counter value `CNTPCT_EL0`, minus an offset `CNTPOFF_EL2`. When any of the following are true, the *Effective value* of `CNTPOFF_EL2` is 0 for all trace purposes:
 - EL3 is using AArch32.
 - EL2 is not implemented.
 - `FEAT_ECV` is not implemented.
 - The *Effective value* of `SCR_EL3.{NS,RW}` is {1,0}.
 - `CNTHCTL_EL2.ECV` is 0.
 - `SCR_EL3.ECVEn` is 0.
- A virtual counter value, which is calculated from the physical counter value `CNTPCT_EL0`, minus an offset `CNTVOFF_EL2`.

The fields `TRFCR_EL2.TS`, `HTRFCR.TS`, `TRFCR_EL1.TS` and `TRFCR.TS` control which counter is used for self-hosted trace.

The timestamp used for trace is shown in Table D3-2 on page D3-2631.

Table D3-2 Timestamp used for trace.

<code>SelfHostedTraceEnabled()</code>	<code>TRFCR_EL2.TS</code>	<code>TRFCR_EL1.TS</code>	Timestamp traced
FALSE	xx	xx	CoreSight time
TRUE	0b00	0b01	<code>CNTPCT_EL0 - CNTPOFF_EL2</code> ^a
	0b00	0b10	<code>CNTPCT_EL0 - CNTPOFF_EL2</code> ^a
	0b00	0b11	<code>CNTPCT_EL0</code>
	0b01	xx	<code>CNTPCT_EL0 - CNTVOFF_EL2</code>
	0b10	xx	<code>CNTPCT_EL0 - CNTPOFF_EL2</code> ^a
	0b11	xx	<code>CNTPCT_EL0</code>

a. This register is only implemented when `FEAT_ECV` is implemented.

Note

The counter value used for the trace timestamp is not affected by the value of `HCR_EL2.E2H`, or whether EL2 is enabled or disabled in the current Security state.

D3.4 Synchronization in self-hosted trace

The PE Trace Unit is an indirect observer of the System registers.

While `SelfHostedTraceEnabled() == TRUE`, indirect reads of the trace filter control fields, `TRFCR_EL1`.{E1TRE, E0TRE} and `TRFCR_EL2`.{E2TRE, E0HTRE} are treated as indirect reads made by the instruction being traced. For these register fields, in addition to the standard requirements for synchronization of System register accesses, when a trace filter control value is changed and synchronization is not explicitly specified, one of the following occurs:

- The behavior of the PE must be consistent with the control value having the old value.
- The behavior of the PE must change the control value at a point in the simple sequential execution of the program, so that before that point, the behavior of the PE is consistent with the control value having the old value, and after that point the behavior of the PE is consistent with the control value having the new value.

If there are multiple direct writes to the register without explicit synchronization, the behavior is consistent with the writes occurring in program order.

The TSB `CSYNC` operation is used to ensure that a trace operation, due to a PE Trace Unit generating trace for an instruction has completed. The TSB `CSYNC` operation may be reordered with respect to other instructions, so must be combined with at least one Context synchronization event to ensure the operations are executed in the required order. This means that a direct write to `TRFCR_EL1` or `TRFCR_EL2` is guaranteed to be observed by the PE Trace Unit only after a subsequent Context synchronization event. For more information, see *Trace Synchronization Barrier (TSB CSYNC)* on page B2-149.

While `SelfHostedTraceEnabled() == FALSE`, the PE Trace Unit might impose stronger synchronization requirements.

Chapter D4

The AArch64 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- *About the memory system architecture* on page D4-2634.
- *Address space* on page D4-2635.
- *Mixed-endian support* on page D4-2636.
- *Cache support* on page D4-2637.
- *External aborts* on page D4-2666.
- *Memory barrier instructions* on page D4-2668.
- *Pseudocode description of general memory System instructions* on page D4-2669.

D4.1 About the memory system architecture

The Arm architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see [Memory hierarchy on page B2-155](#).

If [FEAT_MTE2](#) is implemented, the definitions of the memory model which apply to data accesses and data apply to Allocation Tag accesses and Allocation tags, unless otherwise specified in [Chapter D6 Memory Tagging Extension](#).

D4.1.1 Form of the memory system architecture

The Armv8 A-profile architecture includes a *Virtual Memory System Architecture* (VMSA). [Chapter D5 The AArch64 Virtual Memory System Architecture](#) describes the AArch64 view of the VMSA.

D4.1.2 Memory attributes

[Memory types and attributes on page B2-165](#) describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

[Table D4-1 on page D4-2634](#) shows the memory attributes that are visible at the system level.

Table D4-1 Memory attribute summary

Memory type	Shareability	Cacheability
Device ^a	Outer Shareable	Non-cacheable.
Normal	One of: <ul style="list-style-type: none">Non-shareable.Inner Shareable.Outer Shareable.	One of ^b : <ul style="list-style-type: none">Non-cacheable.Write-Through Cacheable.Write-Back Cacheable.

a. Takes additional attributes, see [Device memory on page B2-169](#).

b. See also [Cacheability, cache allocation hints, and cache transient hints on page D4-2640](#).

For more information on cacheability and shareability see [Shareable Normal memory on page B2-166](#), [Non-shareable Normal memory on page B2-167](#), and [Caches and memory hierarchy on page B2-155](#).

D4.2 Address space

The Armv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of *physical address* (PA) sizes, and provides associated control and identification mechanisms. For more information, see [Address size configuration](#) on page D5-2689.

D4.2.1 Virtual address space overflow

When a PE performs a *Simple sequential execution* of instructions, it calculates:

$$(\text{address_of_current_instruction}) + (\text{size_of_executed_instruction})$$

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an instruction overflows `0xFFFF_FFFF_FFFF_FFFF`, the program counter becomes UNKNOWN.

———— **Note** —————

Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

Where an instruction accesses a sequential set of bytes that crosses the `0xFFFF_FFFF_FFFF_FFFF` boundary when tagged addresses are not used, or the `0xxxFF_FFFF_FFFF_FFFF` boundary when tagged addresses are used, then the virtual address accessed for the bytes above this boundary is UNKNOWN. When tagged addresses are used, the value of the tag associated with the address also becomes UNKNOWN.

D4.3 Mixed-endian support

A control bit, [SCTLR_EL1.E0E](#) is provided to allow the endianness of explicit data accesses made while executing at EL0 to be controlled independently of those made while executing at EL1. [Table D4-2 on page D4-2636](#) shows the endianness of explicit data accesses and translation table walks.

Table D4-2 Endianness support

Exception level	Explicit data accesses	Stage 1 translation table walks	Stage 2 translation table walks
EL0	SCTLR_EL1.E0E	SCTLR_EL1.EE	SCTLR_EL2.EE
EL1	SCTLR_EL1.EE	SCTLR_EL1.EE	SCTLR_EL2.EE
EL2	SCTLR_EL2.EE	SCTLR_EL2.EE	n/a
EL3	SCTLR_EL3.EE	SCTLR_EL3.EE	n/a

———— **Note** ————

[SCTLR_EL1.E0E](#) has no effect on the endianness of the [LDTR](#), [LDTRH](#), [LDTRSH](#), and [LDTRSW](#) instructions, or on the endianness of the [STTR](#) and [STTRH](#) instructions, when these are executed at EL1.

AArch64 state provides the following options for endianness support:

- All Exception levels support mixed-endianness:
 - [SCTLR_ELx.EE](#) is RW and [SCTLR_EL1.E0E](#) is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
 - [SCTLR_ELx.EE](#) is RES0 and [SCTLR_EL1.E0E](#) is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
 - [SCTLR_ELx.EE](#) is RES1 and [SCTLR_EL1.E0E](#) is RW.
- All Exception levels support only little-endianness:
 - [SCTLR_ELx.EE](#) is RES0 and [SCTLR_EL1.E0E](#) is RES0.
- All Exception levels support only big-endianness:
 - [SCTLR_ELx.EE](#) is RES1 and [SCTLR_EL1.E0E](#) is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by [PSTATE.E](#). For exception returns to AArch32 state, [PSTATE.E](#) is copied from [SPSR_ELx.E](#). If the target Exception level supports only little-endian accesses, [SPSR_ELx.E](#) is RES0. If the target Exception level supports only big-endian accesses, [SPSR_ELx.E](#) is RES1. [PSTATE.E](#) is ignored in AArch64 state.

The [BigEndian\(\)](#) function determines whether the current Exception level and Execution state are using big-endian data. This function is defined in [Chapter J1 Armv8 Pseudocode](#).

For more information about endianness in the Arm architecture see [Endian support on page B2-162](#).

D4.4 Cache support

This section describes the Armv8 cache identification and control mechanisms, and the A64 cache maintenance instructions, in the following sections:

- [General behavior of the caches on page D4-2637.](#)
- [Cache identification on page D4-2638.](#)
- [Cacheability, cache allocation hints, and cache transient hints on page D4-2640.](#)
- [Enabling and disabling the caching of memory accesses on page D4-2641.](#)
- [Behavior of caches at reset on page D4-2643](#)
- [Non-cacheable accesses and instruction caches on page D4-2643.](#)
- [About cache maintenance in AArch64 state on page D4-2644.](#)
- [A64 Cache maintenance instructions on page D4-2648](#)

- [Cache lockdown on page D4-2662.](#)
- [System level caches on page D4-2663.](#)
- [Branch prediction on page D4-2663.](#)
- [Execution and data prediction restriction System instructions on page D4-2663.](#)

See also [Caches in a VMSAv8-64 implementation on page D5-2835.](#)

D4.4.1 General behavior of the caches

When a memory location has a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
 - A particular implementation.
 - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

———— **Note** —————

For more information, see [The interaction of cache lockdown with cache maintenance instructions on page D4-2662.](#)

- Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.
- It is guaranteed that no memory location will be allocated into a Data or Unified cache if that location does not have a Normal Cacheable attribute in either:
 - The translation regime at the current Exception level.
 - The translation regime at any higher Exception level.
- For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all Requesters in its shareability domain.
- Any memory location is not guaranteed to remain incoherent with the rest of memory.
- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the *Cache Write-back Granule*. In some implementations the `CTR_EL0` identifies the Cache Write-back Granule.
- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer if it was previously visible to that observer.

———— **Note** —————

The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the `SCTLR_EL1`. {I, C} controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

D4.4.2 Cache identification

The Armv8 cache identification registers describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes the cache maintenance instructions that:

- Affect the entire cache, for example `IC IALLU`.
- Operate by VA, for example `IC IVAU`.
- Operate by set/way, for example `DC ISW`.

The cache identification registers are:

- The Cache Type Register, `CTR_EL0`, that defines:
 - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
 - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instruction.
 - The cache indexing and tagging policy of the Level 1 instruction cache.

———— **Note** —————

It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see [System level caches on page D4-2663](#).

- A single Cache Level ID Register, `CLIDR_EL1`, that defines:
 - The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
 - The *Level of Coherence* (LoC) for the caches. See [Terms used in describing the cache maintenance instructions on page D4-2644](#) for the definition of LoC.

- The *Level of Unification Uniprocessor* (LoUU) for the caches. See *Terms used in describing the cache maintenance instructions* on page D4-2644 for the definition of LoUU.
- An optional ICB field to indicate the boundary between the caches use for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.
- A single Cache Size Selection Register, `CSSELR_EL1`, that selects the cache level and cache type of the current Cache Size Identification Register.
- For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, `CCSIDR_EL1`, that defines:
 - Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
 - The number of sets, associativity and line length of the cache. See *Terms used in describing the cache maintenance instructions* on page D4-2644 for a definition of these terms.

———— **Note** —————

From Armv8.3, multiple formats of the Cache Size Identification Register are supported. For more information, see *Possible formats of the Cache Size Identification Register, CCSIDR_EL1* on page D4-2639.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.
2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.
3. For each cache identified at stage 2:
 - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
 - An instruction cache.
 - A data or unified cache.
 - Read the Cache Size Identification Register to find details of the cache.

Possible formats of the Cache Size Identification Register, `CCSIDR_EL1`

From Armv8.3, the Cache Size Identification Register, `CCSIDR_EL1` has two different formats available for defining the number of sets and associativity of the cache. For a definition of these terms, see *Terms used in describing the cache maintenance instructions* on page D4-2644.

When `FEAT_CCIDX` is implemented:

- `CCSIDR_EL1` is a 64-bit register.
- The length of the `CCSIDR_EL1.Assoc` field is 21 bits. This limits the associativity of the currently selected cache to 2^{21} .
- The length of the `CCSIDR_EL1.NumSets` field is 24 bits. This limits the number of sets in the currently selected cache to 2^{24} .

This is the 64-bit format of the Cache Size Identification Register.

When `FEAT_CCIDX` is not implemented:

- `CCSIDR_EL1` is a 32-bit register.
- The length of the `CCSIDR_EL1.Assoc` field is 10 bits. This limits the associativity of the currently selected cache to 2^{10} .

- The length of the `CCSIDR_EL1.NumSets` field is 15 bits. This limits the number of sets in the currently selected cache to 2^{15} .

This is the 32-bit format of the Cache Size Identification Register.

When one of these formats is implemented, it is implemented across all the levels of caching.

D4.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in *Memory types and attributes on page B2-165*, the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

In Armv8, Cacheability attributes other than Non-cacheable can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a *cache transient hint* is supported, see *Transient cacheability hint on page D4-2640*.

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hint is supported the following cache allocation hints can be assigned:

For read accesses: Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

For write accesses: Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

———— Note ————

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.
- Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.
- For VMSAv8-64 translation table walks, the `TCR_ELx.{IRGNn, ORGNn}` fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

Transient cacheability hint

In Armv8, it is IMPLEMENTATION DEFINED whether a Transient hint is supported. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

———— Note ————

The architecture does not specify what is meant by a *relatively short period*.

The description of the AArch64 `MAIR_EL1`, `MAIR_EL2`, and `MAIR_EL3` registers, and the AArch32 `MAIRO`, `MAIR1`, `HMAIRO`, and `HMAIR1` registers, includes the assignment of the Transient hint in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.

- A single Transient hint applies to both read and write accesses to a memory region.

D4.4.4 Enabling and disabling the caching of memory accesses

In Armv8, Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

Note

These Cacheability controls replace the cache enable controls provided in previous versions of the Arm architecture.

The Cacheability control fields and their effects are as follows:

For the EL1&0 translation regime

- When the value of `SCTLR_EL1.C` is 0:
 - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
 - All accesses to the EL1&0 stage 1 translation tables are Non-cacheable.
- When the value of `SCTLR_EL1.I` is 0:
 - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of `HCR_EL2.CD` is 1:
 - All stage 2 translations for data accesses to Normal memory are Non-cacheable.
 - All accesses to the EL1&0 stage 2 translation tables are Non-cacheable.
- When the value of `HCR_EL2.ID` is 1:
 - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of `HCR_EL2.DC` is 1, all stage 1 translations and all accesses to the EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of `SCTLR_EL1.{I, C}`. This applies to translations for both data and instruction accesses.

Note

- The stage 1 and stage 2 cacheability attributes are combined as described in [Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D5-2785](#).
 - The `SCTLR_EL1.{C, I}` and `HCR_EL2.DC` fields have no effect on the EL2, EL2&0, and EL3 translation regimes.
 - The `HCR_EL2.{ID, CD}` fields affect only stage 2 of the EL1&0 translation regime.
 - When EL2 is using AArch64 and EL1 is using AArch32, the `HCR_EL2.{ID, CD, DC}` controls apply as described here, but the EL1 controls are `SCTLR.{C, I}`.
 - When `FEAT_XS` is implemented, the `SCTLR_EL1.{C, I}` and `HCR_EL2.{ID, CD}` fields have no effect on the value of the XS attribute.
-

For the EL2 translation regime

- When the value of `SCTLR_EL2.C` is 0:
 - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
 - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of `SCTLR_EL2.I` is 0:
 - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

Note

- The `SCTLR_EL2`.{I, C} fields have no effect on the EL1&0 and EL3 translation regimes.
 - When `FEAT_XS` is implemented, the `SCTLR_EL2`.{I, C} fields have no effect on the value of the XS attribute.
-

For the EL2&0 translation regime

- When the value of `SCTLR_EL2.C` is 0:
 - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
 - All accesses to the EL2&0 stage 1 translation tables are Non-cacheable.
- When the value of `SCTLR_EL2.I` is 0:
 - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.

Note

When `FEAT_XS` is implemented, the `SCTLR_EL2`.{I, C} fields have no effect on the value of the XS attribute.

For the EL3 translation regime

- When the value of `SCTLR_EL3.C` is 0:
 - All data accesses to Normal memory using the EL3 translation regime are Non-cacheable.
 - All accesses to the EL3 translation tables are Non-cacheable.
- When the value of `SCTLR_EL3.I` is 0:
 - All instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

Note

- The `SCTLR_EL3`{I, C} fields have no effect on the EL1&0, EL2, and EL2&0 translation regimes.
 - When `FEAT_XS` is implemented, the `SCTLR_EL3`.{I, C} fields have no effect on the value of the XS attribute.
-

In addition:

- For translation regimes other than the EL1&0 translation regime, if the value of `SCTLR_ELx.M` is 0, indicating that stage 1 translations are disabled for that translation regime, then:
 - If the value of `SCTLR_ELx.I` is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
 - If the value of `SCTLR_ELx.I` is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.
- For the EL1&0 translation regime, if the value of `SCTLR_EL1.M` is 0, indicating that stage 1 translations are disabled for that translation regime, and the value of `HCR_EL2.DC` is 0:
 - If the value of `SCTLR_EL1.I` is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
 - If the value of `SCTLR_EL1.I` is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through Cacheable, Outer Write-Through Cacheable.

The effect of `SCTLR_ELx.C`, `HCR_EL2.DC` and `HCR_EL2.CD` is reflected in the result of the address translation instructions in the PAR when these bits have an effect on the stages of translation being reported in the PAR.

Note

- In conjunction with the requirements in *Non-cacheable accesses and instruction caches* on page D4-2643, the requirements in this section mean the architecturally required effect of SCTL_R_ELx.I is limited to its effect on caching instruction accesses in unified caches.
 - This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in *Mismatched memory attributes* on page B2-176 must be followed to manage the corresponding loss of coherency.
-

D4.4.5 Behavior of caches at reset

In Armv8:

- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.
- The Cacheability control fields described in *Enabling and disabling the caching of memory accesses* on page D4-2641 reset to values that force all memory locations to be treated as Non-cacheable.

Note

This applies only to the controls that apply to the Translation regime that is used by the Exception level and Security state entered on reset.

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
 - Provide a mechanism to ensure the correct initialization of the caches.
 - Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.
- Arm recommends that whenever an invalidation routine is required, it is based on the Armv8 cache maintenance instructions.

See also *TLB behavior at reset* on page D5-2814.

D4.4.6 Non-cacheable accesses and instruction caches

In AArch64 state, instruction accesses to Non-cacheable Normal memory can be held in instruction caches.

Correspondingly, the sequence for ensuring that modifications to instructions are available for execution must include invalidation of the modified locations from the instruction cache, even if the instructions are held in Normal Non-cacheable memory. This includes cases where System register Cacheability control fields force instruction accesses to memory to be Non-cacheable.

Therefore when using self-modified code in Non-cacheable space in a uniprocessor system, the following sequence is required:

```

; Enter this code with <Wt> containing the new 32-bit instruction
; to be held at a location pointed to by <Xn> in Normal Non-cacheable memory.
STR <Wt>, [Xn]
DSB ISH; Ensure visibility of the data stored
IC IVAU, [Xn] ; Invalidate instruction cache by VA to PoU
DSB ISH; Ensure completion of the invalidations
ISB ;

```

In a multiprocessor system, the **IC IVAU** for a non-cacheable location is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. This is despite non-cacheable normal memory locations being treated as Outer Shared in other parts of the architecture.

Additional software steps might be required to synchronize the threads with other PEs. This might be necessary so that the PEs executing the modified instructions can execute an ISB after completing the invalidation, and to avoid issues associated with concurrent modification and execution of instruction sequences. See also [Concurrent modification and execution of instructions on page B2-130](#) and [Concurrent modification and execution of instructions on page E2-4286](#).

Larger blocks of instructions can be modified using the **IC IALLU** instruction for a uniprocessor system, or a **IC IALLUIS** for a multiprocessor system.

Note

This section applies even when the Cacheability control fields force instruction accesses to memory in AArch64 state to be Non-cacheable, as described in [Enabling and disabling the caching of memory accesses on page D4-2641](#).

D4.4.7 About cache maintenance in AArch64 state

The following sections give general information about cache maintenance:

- [Terms used in describing the cache maintenance instructions on page D4-2644](#).
- [The Armv8 abstraction of the cache hierarchy on page D4-2647](#).

The following sections describe the A64 cache maintenance instructions:

- [The instruction cache maintenance instruction \(IC\) on page D4-2650](#).
- [The data cache maintenance instruction \(DC\) on page D4-2650](#).

Note

Some descriptions of the cache maintenance instructions refer to the cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the **SCTLR_EL1**.{I, C} controls.

Terms used in describing the cache maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instruction scope can be defined:

- By the virtual address of the memory location to be maintained, referred to as operating *by VA*.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating *by set/way*.

In addition, for instruction caches, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- [Terminology for cache maintenance instructions operating by set/way on page D4-2645](#).
- [Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page D4-2645](#).

Note

There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see [The effects of disabling a stage of address translation on page D5-2731](#).

Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

- Level** The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the [CLIDR_EL1](#).
- In the Arm architecture, the lower numbered cache levels are those closest to the PE. See [Memory hierarchy on page B2-155](#).
- Set** Each level of a cache is split up into a number of *sets*. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.
- In the Arm architecture, sets are numbered from 0.
- Way** The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The *way* number specifies one of these locations.
- In the Arm architecture, ways are numbered from 0.

———— **Note** —————

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, Arm expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.
2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or *stale*, copy of the memory location that has been updated.

The *Clean* and *Invalidate* instructions address these two issues. The definitions of these instructions are:

- Clean** A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.
- The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.
- Invalidate** A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.
- If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

———— **Note** —————

Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

Clean and Invalidate

A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
- For instructions operating by VA, the following conceptual points are defined:

Point of Coherency (PoC)

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location for accesses of any memory type or cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

———— **Note** ————

The presence of system caches can affect the determination of the point of coherency as described in [System level caches on page D4-2663](#).

Point of Unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

Point of Persistence (PoP)

When FEAT_DPB is implemented:

The point in a memory system, if it exists, at or beyond the Point of Coherency, where a write to memory is maintained when system power is removed, and reliably recovered when power is restored to the affected locations in memory.

When FEAT_DPB and FEAT_DPB2 are implemented:

The point in a memory system where there is a system guarantee that there is sufficient energy within the system to ensure that a write to memory will be persistent if system power is removed.

———— **Note** ————

Such memory is sometimes called non-volatile memory. For example, the Storage-class memory shown in [Figure B2-1 on page B2-156](#) could be used as target memory for this feature.

Point of Deep Persistence (PoDP)

The point in a memory system where any writes that have reached that point are persistent, even in the event of an instantaneous hardware failure of the power system.

The following fields in the [CLIDR_EL1](#) relate to the PoC and PoU:

LoC, Level of Coherence

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

LoUU, Level of Unification, uniprocessor

This field defines the last level of data cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is $0x0$, this means that no levels of data cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

LoUIS, Level of Unification, Inner Shareable

In any implementation:

- This field defines the last level of data or unified cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is $0x0$, this means that no levels of data or unified cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

The Armv8 abstraction of the cache hierarchy

The following subsections describe the Armv8 abstraction of the cache hierarchy:

- [Cache maintenance instructions that operate by VA on page D4-2647](#).
- [Cache maintenance instructions that operate by set/way on page D4-2648](#).

Cache maintenance instructions that operate by VA

The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being one of:

- Performed to the [Point of Coherency](#).
- Performed to the [Point of Unification](#).
- When [FEAT_DPB](#) is implemented, performed to the [Point of Persistence](#).

See [Terms used in describing the cache maintenance instructions on page D4-2644](#) for definitions of these terms, and for more information about possible meanings of VA.

[A64 Cache maintenance instructions on page D4-2648](#) lists the VA-based maintenance instructions.

The [CTR_EL0](#) holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of VAs, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the `CTR_EL0` defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

Cache maintenance instructions that operate by set/way

[A64 Cache maintenance instructions on page D4-2648](#) lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

D4.4.8 A64 Cache maintenance instructions

The A64 cache maintenance instructions are part of the A64 System instruction class in the register encoding space. For encoding details and other general information on these System instructions, see [System instructions on page C3-218](#), [SYS on page C6-1482](#) and [Cache maintenance instructions, and data cache zero operation on page C5-399](#).

[Table D4-3 on page D4-2648](#) shows the AArch64 System instructions that perform instruction or data cache maintenance. Instructions that take an argument include Xt in the entry in the [System instruction on page D4-2648](#) column.

———— Note ————

- In [Table D4-3 on page D4-2648](#) the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.
- In general, the AArch32 instruction and data cache maintenance instructions provide equivalent functionality to the AArch64 cache maintenance instructions, see [AArch32 cache and branch predictor maintenance instructions on page G4-6239](#). However, the Data Cache Clean to the Point of Persistence instruction, implemented when `FEAT_DPB` is implemented, is supported in AArch64 state only.

Table D4-3 System instructions for cache maintenance

System instruction	Instruction	Notes
Instruction cache maintenance instructions		
<code>IC IALLUIS</code>	Invalidate all to Point of Unification, Inner Shareable	EL1 or higher access.
<code>IC IALLU</code>	Invalidate all to Point of Unification	EL1 or higher access.
<code>IC IVAU, Xt</code>	Invalidate by virtual address to Point of Unification	When <code>SCTLR_EL1.UCI^a == 1</code> , EL0 access. Otherwise, EL1 or higher access.
Data cache maintenance instructions		
<code>DC IVAC, Xt</code>	Invalidate by virtual address to Point of Coherency	EL1 or higher access.
<code>DC IGVAC, Xt</code>	Invalidate of Allocation Tags by virtual address to Point of Coherency	EL1 or higher access.
<code>DC IGDVAC, Xt</code>	Invalidate of data and Allocation Tags by virtual address to Point of Coherency	EL1 or higher access.

Table D4-3 System instructions for cache maintenance (continued)

System instruction	Instruction	Notes
DC ISW, Xt	Invalidate by set/way	EL1 or higher access.
DC CVAC, Xt	Clean by virtual address to Point of Coherency	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CGVAC, Xt	Clean of Allocation Tags by virtual address to Point of Coherency	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CGDVAC, Xt	Clean of data and Allocation Tags by virtual address to Point of Coherency	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CVADP, Xt	Clean by virtual address to Point of Deep Persistence	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CGVADP, Xt	Clean of Allocation Tags by virtual address to Point of Deep Persistence	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CGDVADP, Xt	Clean of data and Allocation Tags by virtual address to Point of Deep Persistence	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CGDVAP, Xt	Clean of data and Allocation Tags by virtual address to Point of Persistence	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CGVAP, Xt	Clean of Allocation Tags by virtual address to Point of Persistence	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CVAP, Xt	Clean by virtual address to Point of Persistence ^b	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CSW, Xt	Clean by set/way	EL1 or higher access.
DC CVAU, Xt	Clean by virtual address to Point of Unification	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CIVAC, Xt	Clean and invalidate by virtual address to Point of Coherency	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CIGVAC, Xt	Clean and invalidate of Allocation Tags by virtual address to Point of Coherency	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CIGDVAC, Xt	Clean and invalidate of data and Allocation Tags by virtual address to Point of Coherency	When SCTLR_EL1.UCI ^a == 1, EL0 access. Otherwise EL1 or higher access.
DC CISW, Xt	Clean and invalidate by set/way	EL1 or higher access.

a. When HCR_EL2.{E2H,TGE} == {1, 1}, the control is from SCTLR_EL2.

b. Supported only when FEAT_DPB is implemented.

A DSB or DMB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.

The following subsections give more information about these instructions:

- [The instruction cache maintenance instruction \(IC\) on page D4-2650.](#)
- [The data cache maintenance instruction \(DC\) on page D4-2650.](#)
- [EL0 accessibility of cache maintenance instructions on page D4-2652.](#)
- [General requirements for the scope of maintenance instructions on page D4-2652.](#)
- [Effects of instructions that operate by VA to the PoC on page D4-2652.](#)
- [Effects of instructions that operate by VA to the PoP on page D4-2653.](#)

- [Effects of instructions that operate by VA to the PoU on page D4-2654.](#)
- [Effects of All and set/way maintenance instructions on page D4-2654.](#)
- [Effects of virtualization and Security state on the cache maintenance instructions on page D4-2654.](#)
- [Boundary conditions for cache maintenance instructions on page D4-2656.](#)
- [Ordering and completion of data and instruction cache instructions on page D4-2656.](#)
- [Performing cache maintenance instructions on page D4-2660.](#)

The instruction cache maintenance instruction (IC)

[System instructions on page C3-218](#) describes the A64 assembly syntax for this instruction.

When an IC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, or at EL2 when [HCR_EL2.E2H==1](#), the current [ASID](#).
- The current Security state.
- Whether the instruction was executed at EL1 or EL2.
- For an instruction executed at EL1, the current [VMID](#).

That VA to PA translation might fault. However, for an instruction cache maintenance instruction that operates by VA:

- It is IMPLEMENTATION DEFINED whether the instruction can generate:
 - An [Access flag fault](#).
 - A [Translation fault](#).
- The instruction cannot generate a [Permission fault](#), except for:
 - The possible generation of a [Permission fault](#) by the execution of an [IC IVAU](#) instruction at EL0 when the specified address does not have read access at EL0, as described in [EL0 accessibility of cache maintenance instructions on page D4-2652](#).
 - The possible [Permission fault](#) on a [Stage 2 fault on a stage 1 translation table walk](#).

For more information about possible faults on a cache maintenance instruction that operates by VA see [VMSAv8-64 memory aborts on page D5-2800](#).

See also [Ordering and completion of data and instruction cache instructions on page D4-2656](#).

The data cache maintenance instruction (DC)

[System instructions on page C3-218](#) describes the A64 assembly syntax for this instruction.

When a DC instruction requires a set/way/level argument this takes the form of a 64-bit register, the upper 32 bits of which are RES0.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see [Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-8423](#) or the instruction description.

When a DC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, or at EL2 when [HCR_EL2.E2H](#) is 1, the current [ASID](#).
- The current Security state.
- Whether the instruction is executed at EL1 or EL2.
- For an instruction executed at EL1, the current [VMID](#).

That VA to PA translation might fault. However, a data or unified cache maintenance instruction that operates by VA cannot generate a [Permission fault](#) except in the following cases:

- The possible generation of a [Permission fault](#) by:
 - The execution of a [DC IVAC](#) instruction when the specified address does not have write permission.
 - The execution of an enabled DC * instruction at EL0 when the specified address does not have read access at EL0, as described in [EL0 accessibility of cache maintenance instructions on page D4-2652](#).
 The description of [Permission faults](#) includes possible constraints on the generation of [Permission faults](#) on cache maintenance by VA instructions.
- The possible [Permission fault](#) on a [Stage 2 fault on a stage 1 translation table walk](#).

For more information about possible faults on a VA to PA translation see [VMSAv8-64 memory aborts on page D5-2800](#).

When executed at EL1, a [DC ISW](#) instruction performs a clean and invalidate, meaning it performs the same maintenance as a [DC CISW](#) instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- Either:
 - The value of [HCR_EL2.SWIO](#) is 1, forcing a cache clean to perform a clean and invalidate.
 - The value of [HCR_EL2.VM](#) is 1, meaning EL1&0 stage two address translation is enabled.

When executed at EL1, a [DC IVAC](#) instruction performs a clean and invalidate, meaning it performs the same maintenance as a [DC CIVAC](#) instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- The value of [HCR_EL2.VM](#) is 1, meaning EL1&0 stage two address translation is enabled.

Note

The forcing of a clean instruction to perform a clean invalidate applies to the AArch32 cache maintenance instructions [DCIMVAC](#) and [DCISW](#). See [AArch32 data cache maintenance instructions \(DC*\) on page G4-6241](#).

When [FEAT_DPB](#) is implemented, meaning the [DC CVAP](#) instruction is implemented, if the memory system does not support the Point of Persistence, a data cache clean to the [PoP](#), [DC CVAP](#), behaves as a data cache clean to the [PoC](#), [DC CVAC](#).

Note

- Support for the Point of Persistence does not change the definition or behavior of the [CLIDR_EL1](#) System register.
 - Because a [DSB SYS](#) instruction will not complete until all previous [DC CVAP](#) instructions have completed, the following sequence can be used to ensure the completion of any store to the Point of Persistence, where the store might be to Non-cacheable memory:

```

DMB           ; Note this can be any DMB that applies to both loads and stores
DC CVAP, Xt
DSB SYS
      
```
 - If caches that are invisible to the programmer exist beyond the Point of Coherency but before the Point of Persistence and hold data that is marked as Non-cacheable, the [DC CVAP](#) operation causes the Non-cacheable locations to be cleaned from those caches.
-

If a memory fault that sets the [FAR](#) for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the [FAR](#) holds the address specified in the register argument of the instruction.

Note

Despite its mnemonic, [DC ZVA](#) is not a cache maintenance instruction.

See also [EL0 accessibility of cache maintenance instructions on page D4-2652](#) and [Ordering and completion of data and instruction cache instructions on page D4-2656](#).

EL0 accessibility of cache maintenance instructions

The `SCTLR_EL1.UCI` bit enables EL0 access for the `DC CVAU`, `DC CVAC`, `DC CVAP`, `DC CIVAC`, and `IC IVAU` instructions. When EL0 use of these instructions is disabled because `SCTLR_EL1.UCI == 0`, executing one of these instructions at EL0 generates a trap to EL1, that is reported using `EC = 0x18`. When `HCR_EL2.{E2H,TGE} == 1`, the control is from `SCTLR_EL2`.

———— Note —————

`DC CVAP` is implemented only if `FEAT_DPB` is implemented.

For these instructions read access permission is required. When the value of `SCTLR_EL1.UCI` is 1:

- For the `DC CVAU`, `DC CVAC`, `DC CVAP`, and `DC CIVAC` instructions, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, a `Permission fault` might be generated.
- For the `IC IVAU` instruction, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, it is IMPLEMENTATION DEFINED whether a `Permission fault` is generated.

For more information see the description of `Permission faults`. In the case of a `DC *` instruction executed at EL0 when the address specified cannot be read at EL0 the `Permission fault` is generated unless one of the permitted constraints described in that section applies and means the fault cannot be generated.

Software can read the `CTR_EL0` to discover the stride needed for cache maintenance instructions. The `SCTLR_EL1.UCT` bit enables EL0 access to the `CTR_EL0`. When EL0 access to the Cache Type register is disabled, a register access instruction executed at EL0 is trapped to EL1 using `EC = 0x18`.

General requirements for the scope of maintenance instructions

The Armv8 specification of the cache maintenance instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in *General behavior of the caches on page D4-2637*, *Behavior of caches at reset on page D4-2643*, and *Preloading caches on page B2-159*.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

———— Note —————

Arm recommends that, for best performance, such side-effects are kept to a minimum. Arm strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

Effects of instructions that operate by VA to the PoC

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoC must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the PoC. [Table D4-4 on page D4-2653](#) shows the scope of these Data and unified cache maintenance instructions.

Table D4-4 PEs affected by cache maintenance instructions to the PoC

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The PoC of the entire system
Inner Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction	The PoC of the entire system
Outer Shareable	All PEs in the same Outer Shareable shareability domain as the PE executing the instruction	The PoC of the entire system

———— **Note** —————

It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.

Effects of instructions that operate by VA to the PoP

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoP must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the PoP. [Table D4-5 on page D4-2653](#) shows the scope of these Data and unified cache maintenance to the PoP instructions.

Table D4-5 PEs affected by cache maintenance instructions to the PoP

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The PoP of the entire system
Inner Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction	The PoP of the entire system
Outer Shareable	All PEs in the same Outer Shareable shareability domain as the PE executing the instruction	The PoP of the entire system

———— **Note** —————

It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.

Effects of instructions that operate by VA to the PoU

For cache maintenance instructions that operate by VA to the PoU, [Table D4-6 on page D4-2654](#) shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

Table D4-6 PEs affected by cache maintenance instructions to the PoU

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The PoU of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction
Inner Shareable or Outer Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction	The PoU of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction

Note

- The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.
- It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.

Effects of All and set/way maintenance instructions

The [IC IALLU](#) and [DC set/way](#) instructions apply only to the caches of the PE that performs the instruction.

The [IC IALLUIS](#) instruction can affect the caches of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. This instruction has an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

Note

- The possible presence of system caches, as described in [System level caches on page D4-2663](#), means architecture does not guarantee that all levels of the cache can be maintained using set/way instructions.
- It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.

Effects of virtualization and Security state on the cache maintenance instructions

Each Security state has its own physical address (PA) space, therefore cache entries are associated with PA space.

[Table D4-7 on page D4-2655](#) shows the effects of virtualization and security on the cache maintenance instructions. In the table, the [Specified entries on page D4-2655](#) are entries that the architecture requires the instruction to affect.

———— **Note** ————

The rules described in *General behavior of the caches* on page D4-2637 mean that an instruction might also affect other entries.

Table D4-7 Effects of virtualization and security on the maintenance instructions

Cache maintenance instructions	Security state	Specified entries
Data or unified cache maintenance instructions		
Invalidate, Clean, or Clean and Invalidate by VA: DC IVAC , DC CVAC , DC CVAP , DC CVAU , DC CIVAC , DC CVAP	Both	All lines that hold the PA that, in the current Security state, is mapped to by the combination of all of: <ul style="list-style-type: none"> The specified VA. For an instruction executed at EL1, EL0, or at EL2 when HCR_EL2.E2H is set to 1 the current ASID if the location is mapped to by a non-global page. For an instruction executed at EL1 when SCR_EL3.NS == 1 or SCR_EL3.EEL2 == 1, the current VMID.^a For an instruction executed at EL0 when (SCR_EL3.NS == 1 or SCR_EL3.EEL2 == 1) and (HCR_EL2.E2H == 0 or HCR_EL2.TGE == 0), the current VMID.^a
Invalidate, Clean, or Clean and Invalidate by set/way: DC ISW , DC CSW , DC CISW	Non-secure	Line specified by set/way provided that the entry comes from the Non-secure PA space.
	Secure	Line specified by set/way regardless of the PA space that the entry has come from.
Instruction cache maintenance instructions		
Invalidate by VA: IC IVAU	Both	All lines corresponding to the specified VA ^b in the current translation regime and: <ul style="list-style-type: none"> For an instruction executed at EL1, EL0, or at EL2 when HCR_EL2.E2H is set to 1 the current ASID. For an instruction executed at EL1 when SCR_EL3.NS == 1 or SCR_EL3.EEL2 == 1, the current VMID.^a For an instruction executed at EL0 when (SCR_EL3.NS == 1 or SCR_EL3.EEL2 == 1) and (HCR_EL2.E2H == 0 or HCR_EL2.TGE == 0), the current VMID.^a
Invalidate All: IC IALLU , IC IALLUIS	Both	For an instruction executed at: <ul style="list-style-type: none"> EL1 when SCR_EL3.NS == 0 and SCR_EL3.EEL2 == 1, all instruction cache lines containing entries associated with the current VMID. EL1 when SCR_EL3.NS == 1, all instruction cache lines containing Non-secure entries associated with the current VMID. EL2 when SCR_EL3.NS == 1, all instruction cache lines containing Non-secure entries. EL1 when the Effective value of SCR_EL3.{EEL2, NS} is {0,0}, EL2 when SCR_EL3.{EEL2,NS} is {1, 0}, or EL3, all instruction cache lines.

a. Dependencies on the VMID apply even when [HCR_EL2.VM](#) is set to 0. The architecture does not define a reset value for [VTTBR_EL2.VMID](#), and therefore, in any implementation that includes EL2, the boot software executed when reset is deasserted must initialize [VTTBR_EL2.VMID](#).

- b. The type of instruction cache used affects the interpretation of the specified entries in this table such that:
- For a PIPT instruction cache, the cache maintenance applies to all entries whose physical address corresponds to the specified address.
 - For a VIPT instruction cache, the cache maintenance applies to entries whose virtual index and physical tag corresponds to the specified address.

For information on types of instruction cache see [Instruction caches](#) on page D5-2835.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in [The interaction of cache lockdown with cache maintenance instructions](#) on page D4-2662 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, invalidate by set/way instructions can, instead, perform a clean and invalidate by set/way.
- As described in [The data cache maintenance instruction \(DC\)](#) on page D4-2650, the AArch64 Data cache invalidate instructions, [DC IVAC](#) and [DC ISW](#), when executed at EL1 and EL0, and the AArch32 Data cache invalidate instructions [DCIMVAC](#) and [DCISW](#), when executed at EL1, can be configured to perform a cache clean as well as a cache invalidation.
- TLB and instruction cache invalidate instructions executed at EL1 are broadcast across the Inner Shareable domain when all of the following is true:
 - When the value of [HCR_EL2.FB](#) is 1.
 - EL3 is not implemented, or EL3 is implemented and either [SCR_EL3.NS](#) == 1 or [SCR_EL3.EEL2](#) == 1.

When EL1 is using AArch64, this applies to the [IC IALLU](#) instruction. This means the instruction performs the invalidation that would be performed by the corresponding Inner Shareable instruction [IC IALLUIS](#).

For more information about the cache maintenance instructions, see [About cache maintenance in AArch64 state](#) on page D4-2644, [A64 Cache maintenance instructions](#) on page D4-2648, and Chapter D5 [The AArch64 Virtual Memory System Architecture](#).

Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instruction operates on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
 - Is Normal memory or Device memory.
 - Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering and completion of data and instruction cache instructions

All data cache instructions, other than [DC ZVA](#), that specify an address:

- Execute in program order relative to loads or stores that have all of the following properties:
 - Access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by [CTR_EL0.DMinLine](#).

- Use an address with the same cacheability attributes as the address passed to the data cache instruction.
- Can execute in any order relative to loads or stores that have all of the following properties:
 - Access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by `CTR_EL0.DMinLine`.
 - Use an address with different cacheability attributes as the address passed to the data cache instruction.
 - Do not have a DMB or DSB executed between the load or store instruction and the data cache instruction.
- Can execute in any order relative to loads or stores that access any address with the Device memory attribute, or with Normal memory with Inner Non-cacheable attribute unless a DMB or DSB is executed between the instructions.
- Execute in program order relative to other data cache instructions, other than DC ZVA, that specify an address within the same cache line of minimum size, as indicated by `CTR_EL0.DMinLine`.
- Can execute in any order relative to loads or stores that access an address in a different cache line of minimum size, as indicated by `CTR_EL0.DMinLine`, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to other data cache instructions, other than DC ZVA, that specify an address in a different cache line of minimum size, as indicated by `CTR_EL0.DMinLine`, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.

———— **Note** —————

Despite its mnemonic, the DC ZVA, [Data Cache Zero by VA](#) instruction is not a data cache maintenance instruction.

———— **Note** —————

- Data cache ordering rules by address are consistent with physically indexed physically tagged caches. See [Data and unified caches on page D5-2835](#).
- [Data cache zero instruction on page D4-2661](#) describes the ordering and completion rules for Data Cache Zero.

All data cache maintenance instructions that do not specify an address:

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that specify an address, other than Data Cache Zero, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to loads or stores unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache instructions, data cache instructions, loads, and stores unless a DSB is executed between the instructions.

A cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction. See also the requirements for cache maintenance instructions in [Completion and endpoint ordering on page B2-141](#).

In all cases, where the text in this section refers to a DMB or a DSB, this means a DMB or DSB whose required access type is both loads and stores.

Note

These ordering requirements are extended from the requirements in AArch32 state given in:

- [Ordering of cache and branch predictor maintenance instructions on page G4-6248.](#)
- [AArch32 instruction cache maintenance instructions \(IC*\) on page G4-6240.](#)

Ordering and completion of Data Cache Clean to Point of Persistence

The update of the persistent memory as a result of Data Cache Clean to the Point of Persistence is guaranteed to have occurred either after:

- The execution of a DSB applying to both reads and writes after the execution of the Data Cache Clean to the Point of Persistence.
- The update to persistent memory caused by a different Data Cache Clean to the Point of Persistence that is ordered after a DMB applying to both reads and writes that appears after the original Data Cache Clean to the Point of Persistence.

Note

This second point is an aspect of the fact that the Data Cache Clean to the Point of Persistence instructions are ordered by DMB, and this controls the order of arrival in persistent memory.

Note

The ordering effect for the Data Cache Clean to the Point of Persistence by DMB applying to both read and writes is not sufficient to ensure that in [Example D4-1 on page D4-2658](#), observation of the value '1' in the memory location X3 implies that the Data Cache Clean to the Point of Persistence has caused an update of persistent memory:

Example D4-1 The ordering effect for the Data Cache Clean to the Point of Persistence

```
; initial condition has [X3]=0.  
  
DC CVADP, X1  
DMB  
MOV X2, #1  
STR X2, [X3]
```

However, in [Example D4-2 on page D4-2658](#), the ordering effects of the DMB instruction will ensure that the location pointed by P0: X1 will reach the Point of Persistence before, or at the same time as, the location pointed by P1: X8.

Example D4-2 The ordering effect for the Data Cache Clean to the Point of Persistence

```
; initial conditions has P0: X3 and P1: X3 point to the same location, which is 0 at the start of this example  
  
P0  
  
    DC CVAP, X1  
    DMB  
    MOV X2, #1  
    STR X2, [X3]  
  
P1  
  
loop  
    LDR X2, [X3]  
    CBZ X2, loop
```

DMB
DC CVAP, X8

Ordering and completion of Data Cache Clean to Point of Deep Persistence

The update of the deep persistent memory as a result of Data Cache Clean to the Point of Deep Persistence is guaranteed to have occurred either after:

- The execution of a DSB applying to both reads and writes after the execution of the Data Cache Clean to the Point of Deep Persistence.
- The update to deep persistent memory caused by a different Data Cache Clean to the Point of Deep Persistence that is ordered after a DMB applying to both reads and writes that appears after the original Data Cache Clean to the Point of Deep Persistence.

Note

This second point is an aspect of the fact that the Data Cache Clean to the Point of Deep Persistence instructions are ordered by DMB, and this controls the order of arrival in deep persistent memory.

Note

The ordering effect for the Data Cache Clean to the Point of Deep Persistence by DMB applying to both read and writes is not sufficient to ensure that in [Example D4-3 on page D4-2659](#), observation of the value '1' in the memory location X3 implies that the Data Cache Clean to the Point of Deep Persistence has caused an update of deep persistent memory:

Example D4-3 The ordering effect for the Data Cache Clean to the Point of Deep Persistence

; initial conditions has [X3]=0.

```
DC CVADP, X1
DMB
MOV X2, #1
STR X2, [X3]
```

However, in [Example D4-4 on page D4-2659](#), the ordering effects of the DMB instruction will ensure that the location pointed by P0: X1 will reach the Point of Deep Persistence before, or at the same time as, the location pointed by P1: X8.

Example D4-4 The ordering effect for the Data Cache Clean to the Point of Deep Persistence

; initial conditions has P0: X3 and P1: X3 point to the same location, which is 0 at the start of this example

P0

```
DC CVADP, X1
DMB
MOV X2, #1
STR X2, [X3]
```

P1

```
loop
LDR X2, [X3]
CBZ X2, loop
DMB
```

DC CVADP, X8

Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache Arm strongly recommends that software:

- For data or unified cache maintenance, uses the [CTR_EL0.DMinLine](#) value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the [CTR_EL0.IMinLine](#) value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Note

Since the set/way instructions are performed only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Since any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the line is not affected by set/way based cache maintenance. Therefore, Arm strongly discourages the use of set/way instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and Arm advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

[System level caches on page D4-2663](#) refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency. It assumes that the current Cache Size Identification Register is in 32-bit format. For more information, see [Possible formats of the Cache Size Identification Register, CCSIDR_EL1 on page D4-2639](#).

```

MRS    X0, CLIDR_EL1
AND    W3, W0, #0x07000000    // Get 2 x Level of Coherence
LSR    W3, W3, #23
CBZ    W3, Finished
MOV    W10, #0                // W10 = 2 x cache level
MOV    W8, #1                 // W8 = constant 0b1
Loop1: ADD  W2, W10, W10, LSR #1 // Calculate 3 x cache level
LSR    W1, W0, W2             // extract 3-bit cache type for this level
AND    W1, W1, #0x7
CMP    W1, #2
B.LT  Skip                    // No data or unified cache at this level
```

```

MSR    CSSELR_EL1, X10           // Select this cache level
ISB                                         // Synchronize change of CSSELR
MRS    X1, CCSIDR_EL1             // Read CCSIDR
AND    W2, W1, #7                 // W2 = log2(lineLen)-4
ADD    W2, W2, #4                 // W2 = log2(lineLen)
UBFX   W4, W1, #3, #10            // W4 = max way number, right aligned
CLZ    W5, W4                     // W5 = 32-log2(ways), bit position of way in DC operand
LSL    W9, W4, W5                 // W9 = max way number, aligned to position in DC operand
LSL    W16, W8, W5                // W16 = amount to decrement way number per iteration
Loop2: UBFX   W7, W1, #13, #15      // W7 = max set number, right aligned
LSL    W7, W7, W2                 // W7 = max set number, aligned to position in DC operand
LSL    W17, W8, W2                // W17 = amount to decrement set number per iteration
Loop3: ORR    W11, W10, W9          // W11 = combine way number and cache number ...
ORR    W11, W11, W7               // ... and set number for DC operand
DC     CSW, X11                   // Do data cache clean by set and way
SUBS   W7, W7, W17                // Decrement set number
B.GE   Loop3
SUBS   X9, X9, X16                // Decrement way number
B.GE   Loop2
Skip:  ADD    W10, W10, #2          // Increment 2 x cache level
CMP    W3, W10
DSB                                         // Ensure completion of previous cache maintenance instruction
B.GT   Loop1
Finished:

```

Similar approaches can be used for all cache maintenance instructions.

D4.4.9 Data cache zero instruction

The Data Cache Zero by Address instruction, **DC ZVA**, writes 0x00 to each byte of a block of N bytes, aligned in memory to N bytes in size, where:

- The block in memory is identified by the address supplied as an argument to the **DC ZVA** instruction. There are no alignment restrictions on this address.

Note

This means that each byte of the block of memory that includes the supplied address is set to zero.

- The **DCZID_EL0** register indicates the block size, N bytes, that is written with byte values of zero.

Software can restrict access to this instruction. See [Configurable instruction enables and disables, and trap controls on page D1-2510](#) and the description of the **DC ZVA** instruction.

The **DC ZVA** instruction behaves as a set of stores to the location being accessed, and:

- Generates a Permission fault if the translation regime being used when the instruction is executed does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instruction.

In addition:

- When the instruction is executed, it can generate memory faults or watchpoints that are prioritized in the same way as other memory related faults or watchpoints. Where a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set to 1, which would be the case for all other cache maintenance instructions. See [ISS encoding for an exception from a Data Abort on page D13-3172](#) for more information about the encoding of the associated **ESR_ELx.ISS** field.
- If the memory region being zeroed is any type of Device memory, then **DC ZVA** generates an Alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

Note

The architecture makes no statements about whether or not a **DC ZVA** instruction causes allocation to any particular level of the cache, for addresses that have a cacheable attribute for those levels of cache.

Despite its mnemonic, the [DC ZVA](#) instruction is not a data cache maintenance instruction.

D4.4.10 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
 - Cache clean by set/way, [DC CSW](#).
 - Cache invalidate by set/way, [DC ISW](#).
 - Cache clean and invalidate by set/way, [DC CISW](#).
 - Instruction cache invalidate all, [IC IALLU](#) and [IC IALLUIS](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose, see [ISS encoding for an exception from a Data Abort on page D13-3172](#).

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, [DC CVAC](#), [DC CVAP](#), and [DC CVAU](#).
- Cache invalidate by virtual address, [DC IVAC](#).
- Cache clean and invalidate by virtual address, [DC CIVAC](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose. See [ESR_ELx on page K15-8606](#).

In an implementation that includes EL2 enabled in the current Security state, if [HCR_EL2.TIDCP](#) is set to 1, any exception relating to lockdown of an entry is routed to EL2.

———— **Note** —————

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

Arm recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED spaces reserved for Cache Lockdown, see *Reserved encodings for IMPLEMENTATION DEFINED registers* on page D12-3038.

D4.4.11 System level caches

The Arm Architecture defines a *system cache* as a cache that is not described in the PE Cache Identification registers, *CCSIDR_EL1* and *CLIDR_EL1*, and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by any cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the Arm architecture is explicitly prohibited.
2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entirety of such a cache must be performed, as in the case for power management, it must be performed using non-architectural mechanisms.
3. System caches which lie beyond the point of coherency and so are invisible to the software. The management of such caches is outside the scope of the architecture.

D4.4.12 Branch prediction

Armv8 does not define any branch predictor maintenance instructions for AArch64 state.

If branch prediction is architecturally visible, cache maintenance must also apply to branch prediction.

D4.4.13 Execution and data prediction restriction System instructions

When *FEAT_SPECRES* is implemented, the System instructions listed in *A64 System instructions for prediction restriction* on page C5-860 prevent predictions based on information gathered from earlier execution within a particular execution context (CTX), from affecting the later speculative execution within that CTX, to the extent that the speculative execution is observable through side-channels.

The prediction restriction System instructions being used by a particular CTX apply to:

- All control flow prediction resources that predict execution addresses.
- Data value prediction.

- Cache allocation prediction.

For these System instructions, the CTX is defined by:

- The Security state.
- The Exception level.
- When executing at EL1, if EL2 is implemented and enabled in the current Security state, the VMID.
- When executing at EL0, whether the EL1&0 or the EL2&0 translation regime is in use.
- When executing at EL0 when using the EL1&0 translation regime, the ASID and, if EL2 is implemented and enabled in the current Security state, the VMID.
- When executing at EL0 when using the EL2&0 translation regime, the ASID.

Note

- The data value prediction applies to all prediction resources that use some form of training to speculate data values as part of an execution.
- The cache allocation applies to all instruction and data caches, and TLB prefetching hardware used by the executing PE that applies to the supplied context.

The context information is passed as a register argument, and is restricted so that:

- Execution of the System instruction at EL0 only applies to the current hardware defined context.
- Execution of the System instruction at EL1 only applies to the current VMID and Security state, and does not apply to EL2 or EL3.
- Execution of the System instruction at EL2 can only apply to the current Security state, and does not apply to EL3.

If the System instruction is specified to apply to Exception levels that are not implemented, or which are higher than the Exception level that the System instruction is executed at, then the System instruction is treated as a NOP.

When the System instruction is complete and synchronized, no predictions of the restricted type for the affected context are influenced by the execution of the program before the System instruction in a manner that can be observed by the use of any side channels.

Note

- Prediction restriction System instructions do not require the invalidation of prediction structures so long as the behavior described for completion is met by an implementation.
- Prediction restriction System instructions are permitted to invalidate more prediction information than is defined by the supplied execution context.

These System instructions are guaranteed to be complete following a DSB that covers both read and write behavior on the same PE that executed the original instruction. A subsequent Context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

In AArch64 state, EL0 access to the System instructions is controlled by:

- When [HCR_EL2](#).{E2H, TGE} is not {1, 1}, [SCTLR_EL1](#).EnRCTX.
- When [HCR_EL2](#).{E2H, TGE} == {1, 1}, [SCTLR_EL2](#).EnRCTX.

Note

If the [SCR_EL3](#).EEL2 is changed, in order to remove all VMID tagging from Secure EL1 and Secure EL0 entries, each prediction resource should be invalidated for:

- Secure EL0 for all ASID and VMID values.

- Secure EL1 for all VMID values.
-

D4.5 External aborts

The Arm architecture defines External aborts as errors that occur in the memory system, other than those that are detected by the MMU or debug logic. An External abort might signal a data corruption to the PE. For example, a memory location might have been corrupted, and this corruption is detected by hardware using a parity or error correction code (ECC). The error might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*.

An External abort is one of the following:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see [Exception terminology on page D1-2455](#).

The RAS Extension provides a more granular taxonomy of aborts. When the RAS Extension is not implemented, the Arm architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous External aborts.

It is IMPLEMENTATION DEFINED which External aborts, if any, are supported.

External aborts on data accesses and translation table walks on data accesses can be either synchronous or asynchronous.

When [FEAT_DoubleFault](#) is not implemented, External aborts on instruction fetches and translation table walks on instruction fetches can be either synchronous or asynchronous.

When [FEAT_DoubleFault](#) is implemented, all External abort exceptions on instruction fetches and translation table walks on instruction fetches must be synchronous.

A synchronous External abort on an instruction fetch, including a translation table walk on an instruction fetch, is taken precisely using the Instruction Abort exception.

A synchronous External abort on a data read or write, including a translation table walk on a data read or write, is taken precisely using the Data Abort exception.

See [Synchronous exception types, routing and priorities on page D1-2489](#).

An asynchronous External abort is taken using the SError interrupt exception. See [Asynchronous exception types, routing, masking and priorities on page D1-2500](#).

The effect of a failed memory access is described in [Effect of Data Aborts and watchpoints on page D1-2494](#).

Normally, External aborts are rare. An imprecise asynchronous External abort is likely to be fatal to the process that is running, Arm recommends that implementations make External aborts precise wherever possible.

The following subsections give more information about possible External aborts:

- [Provision for the classification of External aborts on page D4-2666](#).
- [Parity or ECC error reporting, RAS Extension not implemented on page D4-2667](#).

D4.5.1 Provision for the classification of External aborts

In AArch64 state, an implementation can use [ESR_ELx.EA, ISS\[9\]](#), to provide more information about synchronous External aborts. For all synchronous aborts other than synchronous External aborts, [ESR_ELx.EA, ISS\[9\]](#), returns a value of 0.

If the RAS Extension is implemented:

- The [ESR_ELx.SET](#) field provides information about the state of the PE following a synchronous External abort.
- The [ESR_ELx.AET](#) field might contain more information following an asynchronous abort taken as an SError interrupt.

- The implementation might define error record registers.

For more information, see:

- [ISS encoding for an exception from an Instruction Abort](#) on page D13-3170.
- [ISS encoding for an exception from a Data Abort](#) on page D13-3172.
- [ISS encoding for an SError interrupt](#) on page D13-3181.
- *Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.*

D4.5.2 Parity or ECC error reporting, RAS Extension not implemented

The Arm architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache system. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see [Use of the ESR_EL1, ESR_EL2, and ESR_EL3](#) on page D1-2478. However, when parity or ECC error reporting is implemented, it is implementation defined whether a parity or ECC error is reported using the assigned fault code or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as External aborts.

D4.6 Memory barrier instructions

[Memory barriers on page B2-146](#) describes the memory barrier instructions. This section describes the system level controls of those instructions.

D4.6.1 EL2 control of the shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 enabled in the current Security state and supports shareability limitations on the data barrier instructions, the [HCR_EL2.BSU](#) field can modify the required shareability of an instruction that is executed at EL0 or EL1. [Table D4-8 on page D4-2668](#) shows the encoding of this field.

Table D4-8 EL2 control of shareability of barrier instructions executed at EL0 or EL1

HCR_EL2.BSU	Minimum shareability of barrier instructions
00	No effect, shareability is as specified by the instruction
01	Inner Shareable
10	Outer Shareable
11	Full system

For an instruction executed at EL0 or EL1, [Table D4-9 on page D4-2668](#) shows how the [HCR_EL2.BSU](#) is combined with the shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction.

Table D4-9 Effect of HCR_EL2.BSU on barrier instructions executed at EL1 or EL0

Shareability specified by the DMB or DSB argument	HCR_EL2.BSU	Resultant shareability
Full system	Any	Full system
Outer Shareable	00, 01, or 10	Outer Shareable
	11, Full system	Full system
Inner Shareable	00 or 01	Inner Shareable
	10, Outer Shareable	Outer Shareable
	11, Full system	Full system
Non-shareable	00, No effect	Non-shareable
	01, Inner Shareable	Inner Shareable
	10, Outer Shareable	Outer Shareable
	11, Full system	Full system

D4.7 Pseudocode description of general memory System instructions

This section lists the pseudocode describing general memory operations:

- [Memory data type definitions](#) on page D4-2669.
- [Basic memory access](#) on page D4-2669.
- [Aligned memory access](#) on page D4-2669.
- [Unaligned memory access](#) on page D4-2669.
- [Exclusives monitors operations](#) on page D4-2669.
- [Access permission checking](#) on page D4-2670.
- [Abort exceptions](#) on page D4-2670.
- [Memory barriers](#) on page D4-2671.

D4.7.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the [AddressDescriptor](#) type.
- Full address, defined by the [FullAddress](#) type.
- Memory attributes, defined by the [MemoryAttributes](#) type.
- Memory type, defined by the [MemType](#) enumeration.
- Device memory type, defined by the [DeviceType](#) enumeration.
- Normal memory attributes, defined by the [MemAttrHints](#) type.
- Cacheability attributes, defined by the [MemAttr_NC](#), [MemAttr_WT](#), and [MemAttr_WB](#) constants.
- Allocation hints, defined by the [MemHint_No](#), [MemHint_WA](#), [MemHint_RA](#), and [MemHint_RWA](#) constants.
- Access permissions, defined by the [Permissions](#) type.

These types are defined in [Chapter J1 Armv8 Pseudocode](#).

D4.7.2 Basic memory access

The [PhysMemRead\(\)](#) and [PhysMemRead\(\)](#) functions perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The attributes in `memaddrdesc.memattrs` are used by the memory system to determine caching and ordering behaviors as described in [Memory types and attributes](#) on page B2-165, [Ordering relations](#) on page B2-137, and [Atomicity in the Arm architecture](#) on page B2-128.

D4.7.3 Aligned memory access

The two `MemSingle[]` accessors, non-assignment (memory read) [AArch64.MemSingle\[\]](#) and assignment (memory write) [AArch64.MemSingle\[\]](#), make atomic, little-endian accesses of size bytes.

D4.7.4 Unaligned memory access

The two `Mem[]` accessors, Non-assignment (memory read) [Mem\[\]](#) and Assignment (memory write) [Mem\[\]](#), make accesses of the required type. If an access is not architecturally defined to be atomic, `Mem[]` synthesizes accesses from multiple calls to [AArch64.MemSingle\[\]](#). It also reverses the byte order if the access is big-endian.

The [AArch64.CheckAlignment\(\)](#) function checks the alignment of memory accesses.

D4.7.5 Exclusives monitors operations

The [AArch64.SetExclusiveMonitors\(\)](#) function sets the Exclusives monitors for a block of bytes, the size of which is determined by `size`, at the virtual address defined by `address`.

The `AArch64.ExclusiveMonitorsPass()` function checks whether the Exclusives monitors are set to include the location of a number of bytes specified by `size`, at the virtual address defined by `address`. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return `FALSE` if the virtual address is not the same as that used in the previous call to `AArch64.SetExclusiveMonitors()`.

The `ExclusiveMonitorsStatus()` function returns 0 if the previous atomic write was to the same physical memory locations selected by `AArch64.ExclusiveMonitorsPass()` and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The `MarkExclusiveGlobal()` procedure takes as arguments a `FullAddress` `address`, the PE identifier `processorid` and the size of the transfer. The procedure records that the PE `processorid` has requested exclusive access covering at least `size` bytes from `address` `address`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The `MarkExclusiveLocal()` procedure takes as arguments a `FullAddress` `address`, the PE identifier `processorid` and the size of the transfer. The procedure records in a local record that PE `processorid` has requested exclusive access to an address covering at least `size` bytes from `address` `address`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

The `IsExclusiveGlobal()` function takes as arguments a `FullAddress` `address`, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked in a global record an address range as exclusive access requested that covers at least `size` bytes from `address` `address`. It is IMPLEMENTATION DEFINED whether it returns `TRUE` or `FALSE` if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns `FALSE`.

The `IsExclusiveLocal()` function takes as arguments a `FullAddress` `address`, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked an address range as exclusive access requested that covers at least the `size` bytes from `address` `address`. It is IMPLEMENTATION DEFINED whether this function returns `TRUE` or `FALSE` if the address marked as exclusive access requested does not cover all of `size` bytes from `address` `address`. If no address is marked as exclusive access requested, then this function returns `FALSE`. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress` `address`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of `size` bytes starting from `address` `address` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of `size` bytes starting from `address` `address` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

D4.7.6 Access permission checking

The `AArch64.S1HasPermissionsFault()` and `AArch64.S2HasPermissionsFault()` functions are used by the architecture to perform access permission checking based on attributes derived from the Translation Table descriptors.

The interpretation of access permission is shown in *Memory access control* on page D5-2754.

D4.7.7 Abort exceptions

The function `AArch64.Abort()` generates either a Data Abort or an Instruction Abort exception by calling `AArch64.DataAbort()` or `AArch64.InstructionAbort()`. It also can generate a debug exception for debug related faults, see *Chapter D2 AArch64 Self-hosted Debug*.

The function `AArch64.DataAbort()` generates a Data Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, `ESR_ELx`. See *ISS encoding for an exception from a Data Abort* on page D13-3172. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, `AArch64.DataAbort()` also sets the FAR to the VA of the abort.

The function `AArch64.InstructionAbort()` generates an Instruction Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, `ESR_ELx`, see *ISS encoding for an exception from an Instruction Abort* on page D13-3170. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, `AArch64.InstructionAbort()` also sets the FAR to the VA of the abort.

The `FaultRecord` type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault.

The function `NoFault()` returns a null record that indicates no fault. The `IsFault()` function tests whether a `FaultRecord` contains a fault.

D4.7.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations `MBReqDomain` and `MBReqTypes`.

These enumerations define the required shareability domains and required access types used as arguments for DMB and DSB instructions.

The procedures `DataMemoryBarrier`, `DataSynchronizationBarrier`, and `InstructionSynchronizationBarrier` perform the memory barriers.

Chapter D5

The AArch64 Virtual Memory System Architecture

This chapter provides a system level view of the AArch64 *Virtual Memory System Architecture* (VMSAv8-64), the memory system architecture of an Armv8 implementation that is executing in AArch64 state. It contains the following sections:

- *About the Virtual Memory System Architecture (VMSA)* on page D5-2674.
- *The VMSAv8-64 address translation system* on page D5-2682.
- *VMSAv8-64 Translation Table format descriptors* on page D5-2739.
- *Memory access control* on page D5-2754.
- *Memory region attributes* on page D5-2776.
- *Virtualization Host Extensions* on page D5-2787.
- *Nested virtualization* on page D5-2793.
- *VMSAv8-64 memory aborts* on page D5-2800.
- *Translation Lookaside Buffers (TLBs)* on page D5-2810.
- *TLB maintenance requirements and the TLB maintenance instructions* on page D5-2816.
- *Caches in a VMSAv8-64 implementation* on page D5-2835.

D5.1 About the Virtual Memory System Architecture (VMSA)

This chapter describes the Armv8 *Virtual Memory System Architecture* (VMSA), and in particular how it applies to a PE that is executing in AArch64 state. In this state the PE is using VMSAv8-64, as defined in [Armv8 VMSA naming on page D5-2674](#). See [The Armv8 VMSA when some Exception levels are using AArch32 on page D5-2674](#) for information about the VMSA in other contexts.

A VMSA provides a *Memory Management Unit* (MMU) that controls address translation, access permissions, and memory attribute determination and checking, for memory accesses made by the PE. The process of address translation maps the *virtual addresses* (VAs) used by the PE onto the *physical addresses* (PAs) of the physical memory system. The mapping of a VA to a PA requires either a single stage of translation, or two sequential stages of translation.

The translations are defined independently for different Exception levels and Security states, as described in [The VMSAv8-64 address translation system on page D5-2682](#).

VMSAv8-64 supports tagging of VAs:

- Address tagging as described in [Address tagging in AArch64 state on page D5-2676](#). As that section describes, this address tagging has no effect on the address translation process.
- If FEAT_MTE2 is implemented, Memory tagging as described in [Chapter D6 Memory Tagging Extension](#).

The remainder of this chapter gives a full description of VMSAv8-64 for an implementation that includes all of the Exception levels. [The implemented Exception levels and the resulting translation stages and regimes on page D5-2687](#) describes the differences in the VMSA if some Exception levels are not implemented.

The following sections give more information about the VMSA:

- [Armv8 VMSA naming on page D5-2674](#).
- [The Armv8 VMSA when some Exception levels are using AArch32 on page D5-2674](#).
- [VMSA address types and address spaces on page D5-2675](#).
- [Address tagging in AArch64 state on page D5-2676](#).
- [Pointer authentication in AArch64 state on page D5-2678](#).

D5.1.1 Armv8 VMSA naming

The Armv8 VMSA naming model reflects the possible stages of address translation, as follows:

- VMSAv8** The overall translation scheme, within which an address translation has one or two stages.
- VMSAv8-32** The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch32.
- VMSAv8-32 is sometimes used to refer to the two stages of translation used to map a VA to a PA, where each stage is managed from an Exception level that is using AArch32.
- VMSAv8-64** The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch64.
- VMSAv8-64 is sometimes used to refer to the two stages of translation used to map a VA to a PA, where each stage is managed from an Exception level that is using AArch64.

D5.1.2 The Armv8 VMSA when some Exception levels are using AArch32

As stated at the start of the chapter, this chapter describes VMSAv8-64, the Armv8 VMSA that applies to an Exception level that is using AArch64. However, when a higher Exception level is using AArch64, and therefore using VMSAv8-64, lower Exception levels can be using AArch32. [Chapter G5 The AArch32 Virtual Memory System Architecture](#) describes VMSAv8-32, meaning it describes:

- The translation stages and translation regimes when EL3 is using AArch32.
- Any stages of address translation that are using VMSAv8-32 when EL3 is using AArch64.

However, a PE can be executing at EL0 using AArch32 when the next higher Exception level is using AArch64, for example when EL0 is using AArch32 and EL1 is using AArch64. When this is the case execution at EL0 uses a VMSAv8-64 translation regime as described in [Constraints on accesses from EL0 when EL0 is using AArch32 on page D5-2685](#).

D5.1.3 VMSA address types and address spaces

A description of the VMSA refers to the following address types.

———— **Note** ————

These descriptions relate to the VMSAv8 description and therefore give more detail than the generic definitions given in the glossary.

———— **Virtual address (VA)** ————

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

———— **Note** ————

This means that an address held in the PC, LR, SP, or an ELR, is a VA.

In AArch64 state, the VA has a maximum address width of one of the following:

- 48 bits.
- 52 bits when [FEAT_LVA](#) is implemented and the 64KB translation granule is used.
- 52 bits when all of the following are true:
 - [FEAT_LPA2](#) is implemented.
 - [TCR_ELx.DS](#)==1 for the translation regime controlled by that register.
 - The 4KB or 16KB translation granule is used.

As [About address translation and supported input address ranges on page D5-2686](#) describes, a stage of address translation can support one or two VA ranges:

Translation stage can support only a single VA range

For a translation stage that supports a single VA range, a 48-bit VA width gives a VA range of 0x0000000000000000 to 0x0000FFFFFFFFFFFF.

For a translation stage that supports a single VA range, the 52-bit VA width gives a VA range of 0x0000000000000000 to 0x000FFFFFFFFFFFFFFF.

Translation stage can support two VA ranges

For a translation stage that supports two VA subranges, one at the bottom of the full 64-bit address range, and one at the top, as follows:

- The bottom VA range runs up from address 0x0000000000000000.
 - With a maximum VA width of 48 bits this gives a VA range of 0x0000000000000000 to 0x0000FFFFFFFFFFFF.
 - With a maximum VA width of 52 bits this gives a VA range of 0x0000000000000000 to 0x000FFFFFFFFFFFFFFF.
 - The top VA subrange runs up to address 0xFFFFFFFFFFFFFFFF.
 - With a maximum VA width of 48 bits this gives a VA range of 0xFFFF000000000000 to 0xFFFFFFFFFFFFFFFF.
 - With a maximum VA width of 52 bits this gives a VA range of 0xFFFF000000000000 to 0xFFFFFFFFFFFFFFFF.
- Reducing the VA width for this subrange increases the bottom address of the range.

———— **Note** ————

- When [FEAT_VHE](#) is not implemented, the only translation stage that can support two VA ranges is stage 1 of the EL1&0 translation regime.

- When **FEAT_VHE** is implemented and the value of **HCR_EL2.E2H** is 1, stage 1 of the EL2, or EL2&0, translation regime also can support two VA ranges.

A 48-bit VA range corresponds to an address space of 256TB. A 52-bit VA range corresponds to an address space of 4PB.

Each translation regime that takes a VA as an input address can be configured to support fewer than the maximum number of bits of VA space, see [Address size configuration on page D5-2689](#).

Intermediate physical address (IPA)

In a translation regime that provides two stages of address translation, the IPA is:

- The OA from the stage 1 translation.
- The IA for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA. Alternatively, the translation regime can be considered as having no concept of IPAs.

The EL3, Secure EL1, and if **FEAT_SEL2** is implemented, Secure EL2 Exception levels provide independent definitions of the PA spaces for Secure and Non-secure operation. This means they provide two independent address spaces, where:

- A VA accessed in Secure state can be translated to either the Secure or the Non-secure PA space.
- When in Non-secure state, a VA is always mapped to the Non-secure PA space.

For more information about maximum address widths, see [Address size configuration on page D5-2689](#).

Physical address (PA)

The address of a location in a physical memory map. That is, an output address from the PE to the memory system.

The EL3, Secure EL1, and if **FEAT_SEL2** is implemented, Secure EL2 Exception levels provide independent definitions of the PA spaces for Secure and Non-secure operation. This means they provide two independent address spaces, where:

- A VA accessed in Secure state can be translated to either the Secure or the Non-secure PA space.
- When in Non-secure state, a VA is always mapped to the Non-secure PA space.

For more information about maximum address widths, see [Address size configuration on page D5-2689](#).

D5.1.4 Address tagging in AArch64 state

In AArch64 state, the Armv8 architecture supports the tagging of addresses.

Note

Address tagging in this section is not to be confused with memory tagging that is described in [Chapter D6 Memory Tagging Extension](#).

In the case of Address tagging the top eight bits of the VA are ignored when determining:

- If the translation system is enabled, whether the address is out of range and therefore causes a Translation fault.
- If the translation system is not enabled, whether the address is out of range and therefore causes an Address size fault.
- Whether the address requires invalidation when performing a TLB invalidation instruction by address.

The use of address tags is controlled as follows:

For addresses when stage 1 translation can support two VA ranges

The value of bit[55] of the VA determines the register bit that controls the use of address tags, as follows:

- | | |
|-----------|---|
| VA[55]==0 | TCR_ELx.TBI0 determines whether address tags are used. If stage 1 translation is enabled, TTBR0_ELx holds the base address of the translation tables used to translate the address. |
| VA[55]==1 | TCR_ELx.TBI1 determines whether address tags are used. If stage 1 translation is enabled, TTBR1_ELx holds the base address of the translation tables used to translate the address. |

For addresses when stage 1 translation supports only a single VA range

TCR_ELx.TBI determines whether address tags are used. If stage 1 translation is enabled, TTBR0_ELx holds the base address of the translation tables used to translate the address.

———— **Note** —————

The TCR_ELx.TBI{n} bit determines whether address tags are used regardless of whether the corresponding translation regime is enabled.

When FEAT_PAuth is implemented, TBID{n} bits are added to TCR_ELx registers.

When a TCR_ELx.TBI{n} bit enables the use of address tagging, the corresponding TBID{n} bit determines whether address tagging is used for both instruction and data addresses, or only for data addresses.

———— **Note** —————

Restricting address tagging to data addresses means instruction addresses can use larger Pointer authentication code fields. See *Pointer authentication in AArch64 state on page D5-2678*.

An address tag enable bit also has an effect on the PC value in the following cases:

- On taking an exception to the controlled Exception level, regardless of whether this is also the Exception level from which the exception was taken.
- Any branch within the controlled Exception level, unless that branch generates an Illegal exception return.
- On performing an exception return that is not an Illegal exception return to the controlled Exception level, regardless of whether this is also the Exception level from which the exception return was performed.

———— **Note** —————

On an Illegal exception return, bits[63:32] of the PC become UNKNOWN.

- Exiting from debug state to the controlled Exception level.

———— **Note** —————

As an example of what is meant by the *controlled Exception level*, TCR_EL3.TBI controls this effect for:

- A branch or procedure return within EL3.
- Taking an exception to EL3.
- Performing an exception return or a debug state exit to EL3.

The effect of the controlling TBI{n} bit is:

For a translation regime where stage 1 translation can support two VA ranges

If the controlling TBI{n} bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be a sign-extension of bit[55] of that address.

For a translation regime where stage 1 translation supports only a single VA range

If the controlling TBI bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be 0x00.

However, when FEAT_PAAuth is implemented and the value of a TCR_ELx.TBID{n} field is 1, the *Effective value* of the corresponding TCR_ELx.TBI{n} field is 0 for any of:

- A branch or procedure return within an Exception level.
- Taking an exception to an Exception level.
- Exception return to an Exception level.
- Exit from Debug state to an Exception level.

The AddrTop() pseudocode function shows the algorithm determining the most significant bit of the VA, and therefore whether the VA is using tagging. For a translation regime where the stage 1 translation supports two VA ranges, this pseudocode includes the selection between TTBR0_ELx and TTBR1_ELx described in *Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D5-2723*.

———— Note —————

The required behavior prevents a tagged address being propagated to the program counter.

When address tagging is enabled for an address that causes a Data Abort or a Watchpoint, the address tag is included in the VA returned in the FAR.

D5.1.5 Pointer authentication in AArch64 state

FEAT_PAAuth adds functionality that supports the authentication of the contents of a register before that register is used as the target of an indirect branch, or as a load. This functionality is supported only in AArch64 state.

For pointer authentication, this functionality provides:

- An instruction that inserts a *Pointer Authentication Code* (PAC) into the upper bits of a register. The bits used are the extension bits that do not hold valid address bits. The inserted PAC value is calculated from the value of the register and one other 64-bit value.
- An instruction that extracts the PAC from the upper bits of a register, and checks that the value is correct, based on the value of the register and one other 64-bit value, and:
 - If the value is correct, replaces the PAC with the extension bits.
 - Otherwise, replaces the PAC with the extension bits, except that two bits of the extension are set to a fixed unique number. This means that, if the register is used as the target of an indirect branch, execution branches to an address that generates a Translation fault because the VA is not mapped.
- An instruction that removes the PAC, replacing it with the extension bits, without any verification.

Multiple versions of these instructions are provided to support different use cases. These include instructions that combine a pointer authentication operation with another operation. *Pointer authentication instructions on page C3-220* summarizes these instructions.

FEAT_PAAuth2 adds enhanced functionality that changes the mechanism by which a PAC is added to the pointer. The mechanism exclusive-ORs the upper bits of the pointer with the PAC instead of replacing the upper bits of the pointer with the PAC.

———— Note —————

If FEAT_PAAuth2 is implemented but FEAT_FPAC is not implemented, when stage 1 translation is disabled, and TCR_ELx.T0SZ or TCR_ELx.T1SZ is set to indicate an address range that is smaller than the PA size, for some PAC values, the address generated by a failed PAC authentication can still be an address within the PA size. This means that using such an address that has failed PAC authentication for a memory access will not generate an Address size fault. Instead, the memory access will be performed that has its upper bits, those between the PA size and the size indicated by the TCR_ELx.T0SZ or TCR_ELx.T1SZ field, taken from the result of the authentication

process. As a result, if `FEAT_PAuth2` is implemented but `FEAT_FPAC` is not implemented, when stage 1 translation is disabled, Arm recommends not setting the `TCR_ELx.T0SZ` or `TCR_ELx.T1SZ` values to indicate an address range that is smaller than the PA size.

For the Pointer authentication instructions, it is IMPLEMENTATION DEFINED whether PACs are generated using:

- The QARMA algorithm, see *The QARMA Block Cipher Family*. When this is the case, the value of `ID_AA64ISAR1_EL1.APA` is non-zero.
- An IMPLEMENTATION DEFINED algorithm. When this is the case, the value of `ID_AA64ISAR1_EL1.API` is non-zero.

`FEAT_PAuth` provides a generic authentication instruction, PACGA, that generates a 32-bit PAC from two 64-bit values.

Note

The PACGA instruction can be used to provide protection for small blocks of memory. Instructions can be chained to allow protection of an arbitrary-sized block.

For the PACGA instruction, it is IMPLEMENTATION DEFINED whether PACs are generated using:

- The QARMA algorithm, see *The QARMA Block Cipher Family*. When this is the case, the value of `ID_AA64ISAR1_EL1.GPA` is non-zero.
- An IMPLEMENTATION DEFINED algorithm. When this is the case, the value of `ID_AA64ISAR1_EL1.GPI` is non-zero.

The pseudocode descriptions of the operation of these instructions describe the use of the QARMA algorithm. When an IMPLEMENTATION DEFINED algorithm is used the `ComputePAC()` function:

- Must have the same arguments as the function defined in this Manual.
- For a set of arguments passed to the function, must give the same result for all PEs that a thread of execution could migrate between.

Pointer authentication is implemented if the value of at least one of `ID_AA64ISAR1_EL1`.{APA, API, GPA, GPI} are not `0b0000`.

Note

Pointer authentication functionality is useful only when address translation is enabled. However, this functionality is the same whether address translation is enabled or disabled.

The following sections give more information about the `FEAT_PAuth`, `FEAT_PAuth2`, and `FEAT_FPAC` functionality:

- *Supported PAC field and relation to the use of address tagging on page D5-2679.*
- *Keys for PAC generation and verification on page D5-2680.*
- *System register control of pointer authentication on page D5-2681.*
- *Faulting on pointer authentication on page D5-2681.*

Supported PAC field and relation to the use of address tagging

As stated earlier in this section, the PAC is held in the extension bits of a register, that do not hold valid address bits. However, as described in *Address tagging in AArch64 state on page D5-2676*, when address tagging is used, the tag is held in `Xn[63:56]`. Therefore, when `Xn` is a 64-bit register holding an address:

When address tagging is used

The PAC field is `Xn[54:bottom_PAC_bit]`.

When address tagging is not used

The PAC field is $Xn[63:56, 54:\text{bottom_PAC_bit}]$.

In the PAC field definitions, $\text{bottom_PAC_bit} == 64 - \text{TCR_ELx.TnSZ}$,

Note

$Xn[55]$ determines whether the address lies in the upper or lower address range for the purpose of determining whether address tagging is used, see [Address tagging in AArch64 state on page D5-2676](#). The value of $Xn[55]$ is the value of n in $TnSZ$. Therefore, it also determines whether $Xn[63:56]$ are part of the PAC field, and which of $\text{TCR_ELx}\{T0SZ, T1SZ\}$ determines the value of bottom_PAC_bit .

If the value of TCR_ELx.TnSZ is outside its permitted range then it is CONSTRAINED UNPREDICTABLE whether the value used to determine bottom_PAC_bit is the programmed value of the field, or is forced to the maximum or minimum permitted value of the field. However, if the PE treats an out of range $TnSZ$ value as the maximum or minimum permitted value of the field for all purposes except reading the value of the field then that behavior also applies to determining bottom_PAC_bit .

[FEAT_PAuth](#) adds a new control to TCR_ELx , that disables the use of address tagging for instruction addresses, see [Address tagging in AArch64 state on page D5-2676](#).

Note

This control means software can use larger PAC field for instruction addresses, while using tagging and the smaller PAC field for data addresses.

Keys for PAC generation and verification

For pointer authentication, two 128-bit keys are provided for each of instruction addresses and data addresses, and a fifth 128-bit key is provided for the generic authentication instruction, as follows:

Keys for instruction address PACs

APIAKey_EL1

The concatenation of the register values $\text{APIAKeyHi_EL1}:\text{APIAKeyLo_EL1}$.

APIBKey_EL1

The concatenation of the register values $\text{APIBKeyHi_EL1}:\text{APIBKeyLo_EL1}$.

Keys for data address PACs

APDAKey_EL1

The concatenation of the register values $\text{APDAKeyHi_EL1}:\text{APDAKeyLo_EL1}$.

APDBKey_EL1

The concatenation of the register values $\text{APDBKeyHi_EL1}:\text{APDBKeyLo_EL1}$.

Key for generic authentication

APGAKey_EL1

The concatenation of the register values $\text{APGAKeyHi_EL1}:\text{APGAKeyLo_EL1}$.

Note

Keys are not banked by Exception level. Arm expects software to switch the keys between Exception levels, typically by swapping the values with zero so that the current key values are not present in memory.

System register control of pointer authentication

[FEAT_PAAuth](#) adds controls to the [SCTLR_ELx](#) registers that enable generation and validation of PACs for data and instruction addresses. Formally, the definition of these fields is that when the functionality is disabled the `AddPAC<I|D><A|B>()` and `Auth<I|D><A|B>()` pseudocode functions return the value of the first parameter passed to them. This means:

- Except for PACGA, the instructions listed in [Table C3-13 on page C3-220](#), that add a PAC to an address in a register, execute as NOPs.
- The instructions listed in [Table C3-14 on page C3-221](#), that authenticate a pointer, execute as NOPs.
- For the Combined instructions listed in [Table C3-16 on page C3-222](#), the `Auth<I|D><A|B>()` function has no effect on the operation of the instruction, which operates as the equivalent non-Authenticate pointer instruction. This means that, for example:
 - A RETAA instruction operates as a RET instruction.
 - A LDRAA Xt, [Xn, #<sim10>! instruction operates as a LDR Xt, [Xn, #<sim10>:000]! instruction.

These controls do not affect the PACGA and XPAC* instructions, that are always enabled.

The controls added to the [SCTLR_ELx](#) registers are:

EnIA	Controls instructions that apply to PACs for instruction addresses that are generated using the APIAKey_EL1 key.
EnIB	Controls instructions that apply to PACs for instruction addresses that are generated using the APIBKey_EL1 key.
EnDA	Controls instructions that apply to PACs for data addresses that are generated using the APDAKey_EL1 key.
EnDB	Controls instructions that apply to PACs for data addresses that are generated using the APDBKey_EL1 key.

See the [SCTLR_ELx](#).{EnIA, EnIB, EnDA, EnDB} field descriptions for more information.

———— Note —————

These fields are RES0 in versions of the architecture before Armv8.3, and therefore should be written as 0 by legacy software.

Faulting on pointer authentication

In addition to [FEAT_PAAuth2](#), [FEAT_FPAC](#) introduces faulting on instructions that authenticate a PAC and, optionally, on the combined instructions that include pointer authentication. If the PAC supplied is incorrect on any instructions listed in [Table C3-14 on page C3-221](#), that authenticate a PAC, the instruction generates a synchronous exception.

It is IMPLEMENTATION DEFINED whether the combined instructions listed in [Table C3-16 on page C3-222](#) generate an exception directly from an authorization failure, rather than changing the address in a way that will generate a Translation fault when the address is accessed.

If an exception from an authorization failure is generated at EL0 and [HCR_EL2.TGE](#)==1, the exception is taken at EL2. Otherwise, the exception is taken at EL1.

An exception from the authorization failure generated at any other Exception level is taken at the same Exception level. The [ESR_ELx.EC](#) code used for such an exception is 0x1C.

[Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2490](#) describes the prioritization of exceptions taken from an authorization failure.

D5.2 The VMSAv8-64 address translation system

The following subsections describe the VMSAv8-64 address translation system, which maps VAs to PAs:

- [About the VMSAv8-64 address translation system on page D5-2682.](#)
- [The implemented Exception levels and the resulting translation stages and regimes on page D5-2687.](#)
- [Controlling address translation stages on page D5-2688.](#)
- [Memory translation granule size on page D5-2698.](#)
- [Translation tables and the translation process on page D5-2704.](#)
- [Overview of the VMSAv8-64 address translation stages on page D5-2708.](#)

D5.2.1 About the VMSAv8-64 address translation system

The *Memory Management Unit* (MMU) controls address translation, memory access permissions, and memory attribute determination and checking, for memory accesses made by the PE.

The general model of MMU operation is that the MMU takes information about a required memory access, including an *input address* (IA), and either:

- Returns an associated *output address* (OA), and the *memory attributes* for that address.
- Is unable to perform the translation for one of a number of reasons, and therefore causes an exception to be generated. This exception is called an MMU fault. System registers are used to report any MMU faults that occur.

The process of mapping an IA to an OA is an *address translation*, or more precisely a single stage of address translation.

When using a VMSA, a *translation regime* maps a VA to a PA using one or two stages of translation, and:

- [The AArch64 translation regimes on page D5-2683](#) defines the translation regimes.
- [VMSA address types and address spaces on page D5-2675](#) give more information about VAs and PAs.

The *translation granule* specifies the granularity of the mapping from IA to OA. That is, it defines both:

- The *page size* for a stage of address translation, where a page is the smallest block of memory for which an IA to OA mapping can be specified.
- The size of a complete translation table for that stage of address translation.

The MMU is controlled by System registers that provide independent control of each address translation stage, including a control to disable the stage of address translation. [The effects of disabling a stage of address translation on page D5-2731](#) defines how the MMU handles an access for which a required address translation stage is disabled.

This section describes the address translation system for an implementation that includes all of the Exception levels, and gives a complete description of translations that are controlled by an Exception level that is using AArch64. In addition:

- [The Armv8 VMSA when some Exception levels are using AArch32 on page D5-2674](#) gives information about the VMSA when some Exception levels are using AArch32.
- [The implemented Exception levels and the resulting translation stages and regimes on page D5-2687](#) describes the effect on the address translation model when some Exception levels are not implemented.

Each enabled stage of address translation uses a set of address translations and associated memory properties held in memory mapped tables called *translation tables*. A single translation table lookup can resolve only a limited number of bits of the IA, and therefore a single address translation can require multiple lookups. These are described as different levels of lookup.

Translation table entries can be cached in a *Translation Lookaside Buffer* (TLB).

As well as defining the OA that corresponds to the IA, the translation table entries define the following properties:

- For accesses made from Secure state, whether the access is to the Secure or Non-secure address map.
- Memory access permissions.
- Memory region attributes.

For more information, see [Memory attribute fields in the VMSAv8-64 Translation Table format descriptors on page D5-2746](#).

The following subsections give more information:

- [The AArch64 translation regimes on page D5-2683](#).
- [About address translation and supported input address ranges on page D5-2686](#).
- [The VMSAv8-64 translation table format on page D5-2686](#).

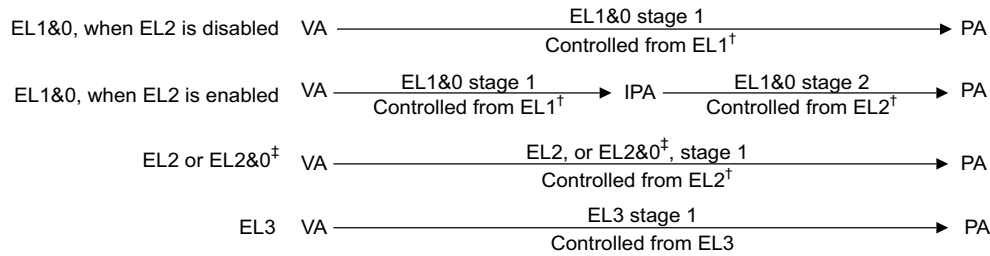

The AArch64 translation regimes

The architecture defines a number of *translation regimes*, where a translation regime comprises either:

- A single stage of address translation.
This maps an input VA to an output PA.
- Two, sequential, stages of address translation, where:
 - Stage 1 maps an input VA to an output IPA.
 - Stage 2 maps an input IPA to an output PA.

[Figure D5-1 on page D5-2684](#) shows these translation stages and translation regimes when EL3 is using AArch64.

Translation regimes, when EL3 is using AArch64

† Typically controlled from this Exception level, but also accessible from higher Exception levels

‡ Only when the implementation includes FEAT_VHE and the value of HCR_EL2.E2H is 1

Figure D5-1 VMSAv8 AArch64 translation regimes, translation stages, and associated controls

This means that in VMSAv8-64 the set of translation regimes is:

The Secure EL1&0 translation regime, when EL2 is disabled

This has a single stage of translation, stage 1, that maps VAs to PAs and can support two VA ranges and the use of ASIDs.

This translation regime is used:

- For memory accesses from EL1 or EL0 when the value of HCR_EL2.{E2H, TGE} is {0,0}.

The Non-secure EL1&0 translation regime, when EL2 is disabled

This has a single stage of translation, stage 1, that maps VAs to PAs and can support two VA ranges and the use of ASIDs.

This translation regime is used:

- For memory accesses from EL1 or EL0 when the value of HCR_EL2.{E2H, TGE} is {0,0}.

The memory access will be Non-secure when SCR_EL3.NS is 1.

The Secure EL1&0 translation regime, when EL2 is enabled

If cached in a TLB, a translation table lookup for this regime is associated with the VMID that identifies the current virtual machine. This regime has two stages of lookup:

Stage 1 Maps VAs to IPAs. This stage can support two VA ranges and the use of ASIDs.

Stage 2 Maps IPAs to PAs. This stage supports a single IPA range.

This translation regime is used:

- For memory access from EL1 or EL0 when the value of HCR_EL2.{E2H, TGE} is {0, 0}.

The Non-secure EL1&0 translation regime, when EL2 is enabled

If cached in a TLB, a translation table lookup for this regime is associated with the VMID that identifies the current virtual machine. This regime has two stages of lookup:

Stage 1 Maps VAs to IPAs. This stage can support two VA ranges and the use of ASIDs.

Stage 2 Maps IPAs to PAs. This stage supports a single IPA range.

This translation regime is used:

- For memory access from EL1 or EL0 when the value of HCR_EL2.{E2H, TGE} is {0,0}.

The Secure EL2&0 translation regime

When FEAT_VHE is implemented, this regime has a single stage of translation, stage 1, that maps VAs to PAs and can support two VA ranges and the use of ASIDs.

This translation regime is used:

- For memory accesses from EL0 when the value of HCR_EL2.{E2H, TGE} is {1,1}.

- For memory accesses from EL2 when the value of `HCR_EL2.E2H` is 1.

This translation regime is present when `FEAT_SEL2` is implemented and enabled.

The Non-secure EL2&0 translation regime

When `FEAT_VHE` is implemented, this regime has a single stage of translation, stage 1, that maps VAs to PAs and can support two VA ranges and the use of `ASIDs`.

This translation regime is used:

- For memory accesses from EL0 when the value of `HCR_EL2.{E2H, TGE}` is {1, 1}.
- For memory accesses from EL2 when the value of `HCR_EL2.E2H` is 1.

The Secure EL2 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

This translation regime is used:

- For all memory accesses from EL2 in implementations that do not include `FEAT_VHE`.
- For all memory access from EL2, when `FEAT_VHE` is implemented and `HCR_EL2.E2H` is 0.

This translation regime is present when `FEAT_SEL2` is implemented and enabled.

The Non-secure EL2 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

This translation regime is used:

- For all memory accesses from EL2 in implementations that do not include `FEAT_VHE`.
- For all memory access from EL2, when `FEAT_VHE` is implemented and `HCR_EL2.E2H` is 0.

The Secure EL3 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

An MMU fault might be generated by a particular stage of translation. An MMU fault is described as either a stage 1 MMU fault or a stage 2 MMU fault.

————— Note —————

- In the Arm architecture, a software agent, such as an operating system, that uses or defines stage 1 memory translations, might be unaware of the second stage of translation, and of the distinction between `IPA` and `PA`.
- A more generalized description of the translation regimes is that a regime always comprises two sequential stages of translation, but in some regimes the stage 2 translation both:
 - Returns an OA that equals the IA. This is called a *flat mapping* of the IA to the OA.
 - Does not change the memory attributes returned by the stage 1 address translation.

Constraints on accesses from EL0 when EL0 is using AArch32

Armv8 permits execution with EL0 using AArch32 when the next higher Exception level is using AArch64. This happens in the following situations:

- EL1 is using AArch64. Execution at EL0 using AArch32 uses the VMSAv8-64 EL1&0 translation regime.
- EL2 is using AArch64 and the *Effective value* of `HCR_EL2.{E2H, TGE}` is {0, 1} or {1, 0}. Execution at EL0 using AArch32 uses the VMSAv8-64 EL1&0 translation regime.
- In an implementation that includes `FEAT_VHE`, EL2 is using AArch64 and the value of `HCR_EL2.{E2H, TGE}` is {1, 1}. Execution at EL0 using AArch32 uses the VMSAv8-64 EL2&0 translation regime.

In this case, accesses from EL0 using AArch32 are using:

- The stated VMSAv8-64 translation regime, EL1&0 or EL2&0.
- The AArch32 memory model.

In particular, this means the accesses from EL0 are limited to a 32-bit VA range.

About address translation and supported input address ranges

For a single stage of address translation, a *Translation table base register (TTBR_ELx)* indicates the start of the first translation table required for a mapping from input address (IA) to output address (OA). For a stage of address translation that supports two VA ranges each VA range is an independent mapping from IA to OA. This means that each implemented translation stage shown in *VMSAv8 AArch64 translation regimes, translation stages, and associated controls on page D5-2684* requires:

- Two associated sets of translation tables if it supports two IA ranges.
- One associated set of translation tables if it supports a single IA range.

Note

- Stage 2 translations never support two IA ranges. This means that, for the translation stages that support two IA ranges the IA is always a VA.
- *Example use of the split VA range, and the TTBR0_ELx and TTBR1_ELx controls on page D5-2724* shows how two supported VA ranges might be used.

Controlling address translation stages on page D5-2688 summarizes the System registers that control address translation by the MMU, and *Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D5-2723* gives more information about the address translation stages that support two VA ranges.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single IA to OA translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:

- The high bits of the required output address.
- The *attributes* and *access permissions* of the addressed memory.

Translation table entries can be cached in a *Translation Lookaside Buffer*, see *Translation Lookaside Buffers (TLBs) on page D5-2810*.

The VMSAv8-64 translation table format

Stages of address translation that are controlled by an Exception level that is using AArch64 use the VMSAv8-64 translation table format. This format uses 64-bit descriptor entries in the translation tables.

Note

This format is an extension of the VMSAv8-32 Long-descriptor translation table format originally defined by the Armv7 Large Physical Address Extension, and extended slightly by Armv8. VMSAv8-32 also supports a Short-descriptor translation table format. *Chapter G5 The AArch32 Virtual Memory System Architecture* describes both of these formats.

The VMSAv8-64 translation table format provides:

- Up to four levels of address lookup.
- A translation granule size of 4KB, 16KB, or 64KB.
- Input addresses of:
 - Up to 52 bits when all of the following are true:
 - FEAT_LPA2 is implemented.
 - TCR_ELx.DS=1 for the translation regime controlled by that register.
 - The 4KB or 16KB translation granule is used.
 - Up to 52 bits if FEAT_LVA is implemented and the 64KB translation granule is used.
 - Otherwise, up to 48 bits.

- Output addresses of:
 - Up to 52 bits when all of the following are true:
 - FEAT_LPA2 is implemented.
 - TCR_ELx.DS=1 for the translation regime controlled by that register.
 - The 4KB or 16KB translation granule is used.
 - Up to 52 bits if FEAT_LPA is implemented and the 64KB translation granule is used.
 - Otherwise, up to 48 bits.

For more information about input address and output address sizes, see [Address size configuration on page D5-2689](#).

D5.2.2 The implemented Exception levels and the resulting translation stages and regimes

[About the VMSAv8-64 address translation system on page D5-2682](#) describes an implementation that includes all Exception levels. [Controlling address translation stages on page D5-2688](#) describes the control of address translation by Exception levels that are using AArch64. This subsection describes how the address translation scheme changes if an implementation does not include all of the Exception levels.

If an implementation does not include EL3, it has only a single Security state, with MMU controls equivalent to the Secure state MMU controls.

If an implementation does not include EL2 then:

- If it also does not include EL3, the MMU provides only a single EL1&0 stage 1 translation regime.
- If it includes EL3, the MMU provides an EL1&0 stage 1 translation regime in each Security state.

[Figure D5-1 on page D5-2684](#) shows the set of translation regimes for an implementation that implements all of the Exception levels. [Table D5-1 on page D5-2687](#) shows how the supported translation stages depend on the implemented Exception levels, and in some cases on the Execution state being used by the highest implemented Exception level.

Table D5-1 The relation between the implemented translation stages and Exception levels for AArch64

Translation stage	Requires
Secure EL3 stage 1	EL3 implemented and using AArch64.
Secure EL2 ^a stage 1	EL2 implemented and using AArch64.
Secure EL2&0 ^{ab} stage 1	EL2 implemented and using AArch64.
Secure EL1&0 ^a stage 2	EL2 implemented and using AArch64.
Secure EL1&0 stage 1	Either: <ul style="list-style-type: none"> • EL3 implemented and using AArch64. • Only EL1 and EL0 implemented, all operation is in Secure state, and EL1 is using AArch64.
Non-secure EL2 stage 1	EL2 implemented.
Non-secure EL2&0 ^b stage 1	EL2 implemented.
Non-secure EL1&0 stage 2	EL2 implemented.
Non-secure EL1&0 stage 1	Any implementation except: <ul style="list-style-type: none"> • Only EL1 and EL0 implemented, with all operation in the Secure state.

a. This translation regime is supported only if an implementation includes FEAT_SEL2. When supported, it is used when the value of SCR_EL3.EEL2 is 1.

b. The EL2&0 translation regime is supported only if an implementation includes FEAT_VHE. When supported, it is used when the value of HCR_EL2.E2H is 1.

D5.2.3 Controlling address translation stages

The implemented *Exception levels and the resulting translation stages and regimes* on page D5-2687 defines the translation regimes and stages. For each supported address translation stages controlled from AArch64, Table D5-2 on page D5-2688 shows:

- A System register bit enables the stage of address translation, `SCTLR_ELx.M` or `HCR_EL2.VM`.
- A System register bit determines the endianness of the translation table lookups, `SCTLR_ELx.EE`.
- A *Translation Control Register* (`TCR_ELx`) controls the stage of address translation.
- If a stage of address translation supports two *VA* ranges then that stage of translation provides:
 - A single `TCR_ELx`.
 - A `TTBR_ELx` for each *VA* range. `TTBR0_ELx` points to the translation tables for the address range that starts at `0x0000000000000000`, and `TTBR1_ELx` points to the translation tables for the address range that ends at `0xFFFFFFFFFFFFFFF`.

Otherwise, a stage of translation provides a single `TCR_ELx` and a single `TTBR_ELx` that holds the address of the translation table that must be used for the first lookup for the stage of address translation.

Table D5-2 Enable and endianness bits for the AArch64 translation stages

Translation stage	Controlled from	Controlling registers
Secure EL3 stage 1	EL3	<code>SCTLR_EL3</code> .{EE, M} <code>TCR_EL3</code> <code>TTBR0_EL3</code>
Secure EL2 ^a stage 1	Secure EL2	<code>SCTLR_EL2</code> .{EE, M} <code>TCR_EL2</code> <code>TTBR0_EL2</code>
Secure EL2&0 ^b stage 1	Secure EL2	<code>SCTLR_EL2</code> .{EE, M} <code>TCR_EL2</code> <code>TTBR0_EL2</code> <code>TTBR1_EL2</code>
Secure EL1&0 ^a stage 2	Secure EL2	<code>SCTLR_EL2.EE</code> <code>HCR_EL2.VM</code> <code>VSTCR_EL2</code> <code>VSTTBR_EL2</code> <code>VTCR_EL2</code> <code>VTTBR_EL2</code>
Secure EL1&0 stage 1	Secure EL1	<code>SCTLR_EL1</code> .{EE, M} <code>TCR_EL1</code> <code>TTBR0_EL1</code> <code>TTBR1_EL1</code>
Non-secure EL2 stage 1	Non-secure EL2	<code>SCTLR_EL2</code> .{EE, M} <code>TCR_EL2</code> <code>TTBR0_EL2</code>
Non-secure EL2&0 ^b stage 1	Non-secure EL2	<code>SCTLR_EL2</code> .{EE, M} <code>TCR_EL2</code> <code>TTBR0_EL2</code> <code>TTBR1_EL2</code>
Non-secure EL1&0 stage 2	Non-secure EL2	<code>SCTLR_EL2.EE</code> <code>HCR_EL2.VM</code> <code>VTCR_EL2</code> <code>VTTBR_EL2</code>
Non-secure EL1&0 stage 1	Non-secure EL1	<code>SCTLR_EL1</code> .{EE, M} <code>TCR_EL1</code> <code>TTBR0_EL1</code> <code>TTBR1_EL1</code>

- a. This translation regime is supported only if an implementation includes `FEAT_SEL2`. When supported, it is used when the value of `SCR_EL3.EEL2` is 1.
- b. The EL2&0 translation regime is supported only if an implementation includes `FEAT_VHE`. When supported, it is used when the value of `HCR_EL2.E2H` is 1.

———— **Note** ————

If the **PA** of the software that enables or disables a particular stage of address translation differs from its **VA**, speculative instruction fetching can cause complications. Arm strongly recommends that the **PA** and **VA** of any software that enables or disables a stage of address translation are identical if that stage of translation controls translations that apply to the software currently being executed.

The following subsections give more information about controlling address translation:

- [System registers relevant to MMU operation on page D5-2689](#).
- [Address size configuration on page D5-2689](#).
- [Atomicity of register changes on changing virtual machine on page D5-2697](#).
- [Use of out-of-context translation regimes on page D5-2697](#).
- If **FEAT_MTE2** is implemented, [Chapter D6 Memory Tagging Extension](#) provides further controls for the checking of Tagged and Untagged addresses.

System registers relevant to MMU operation

In AArch64 state, System registers have a suffix that indicates the lowest Exception level from which they can be accessed. In some general descriptions of MMU control and address translation, this chapter uses a [Common abbreviation on page D5-2689](#) for each of the System registers that affects MMU operation, as [Table D5-3 on page D5-2689](#) shows. The common abbreviation is used when describing features that apply to multiple translation regimes or stages.

———— **Note** ————

The only translation regime that supports a stage 2 translation is the EL1&0 translation regime, when EL2 is enabled.

Table D5-3 Abbreviations for System registers used in this chapter

Common abbreviation	Translation stage	Exception level		
		EL1	EL2	EL3
SCTLR_ELx	-	SCTLR_EL1	SCTLR_EL2	SCTLR_EL3
TCR_ELx	Stage 1	TCR_EL1	TCR_EL2	TCR_EL3
	Stage 2	-	VTCR_EL2 VSTCR_EL2 ^a	-
TTBR_ELx	Stage 1	TTBR0_EL1, TTBR1_EL1	TTBR0_EL2	TTBR0_EL3
	Stage 2	-	VTTBR_EL2, VSTTBR_EL2 ^a	-
TTBR0_ELx	Stage 1	TTBR0_EL1	TTBR0_EL2	TTBR0_EL3
TTBR1_ELx	Stage 1	TTBR1_EL1	TTBR1_EL2 ^b	-

a. Only when both the implementation includes [FEAT_SEL2](#) and the value of [SCR_EL3.EEL2](#) is 1.

b. Only when both the implementation includes [FEAT_VHE](#) and the value of [HCR_EL2.E2H](#) is 1.

Address size configuration

The following subsections specify the configuration of the **PA** size and of the input and output address sizes for each of the stages of address translation:

- [Physical address size on page D5-2690](#).
- [Output address size on page D5-2690](#).

- [Input address size on page D5-2691.](#)
- [Supported IPA size on page D5-2693.](#)

Physical address size

The `ID_AA64MMFR0_EL1.PARange` field indicates the implemented PA size, as [Table D5-4 on page D5-2690](#) shows.

Table D5-4 Physical address size implementation options

<code>ID_AA64MMFR0_EL1.PARange</code>	Total PA size	PA address size
0000	4 GB	32 bits, PA[31:0]
0001	64 GB	36 bits, PA[35:0]
0010	1 TB	40 bits, PA[39:0]
0011	4 TB	42 bits, PA[41:0]
0100	16 TB	44 bits, PA[43:0]
0101	256 TB	48 bits, PA[47:0]
0110	4PB	52 bits, PA[51:0] ^a

- a. Only when `FEAT_LPA` is implemented and the 64KB translation granule is used, see [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695](#), or when `FEAT_LPA2` is implemented and the value of `TCR_ELx.DS` is 1, see [Extending addressing above 48 bits when using the 4KB or 16KB translation granule on page D5-2696](#).

All other `PARange` values are reserved.

Output address size

For each enabled stage of address translation, `TCR_ELx.{I}PS` must be programmed to maximum output address size for that stage of translation, using the encodings as shown in [Table D5-5 on page D5-2690](#).

Table D5-5 Output address size implementation options

<code>TCR_ELx.{I}PS</code>	Total output size	Output address size
000	4 GB	32 bits, PA[31:0]
001	64 GB	36 bits, PA[35:0]
010	1 TB	40 bits, PA[39:0]
011	4 TB	42 bits, PA[41:0]
100	16 TB	44 bits, PA[43:0]
101	256 TB	48 bits, PA[47:0]
110	4PB	52 bits, PA[51:0] ^a

- a. Only when `FEAT_LPA` is implemented and the 64KB translation granule is used, see [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695](#) or when `FEAT_LPA2` is implemented and the value of `TCR_ELx.DS` is 1, see [Extending addressing above 48 bits when using the 4KB or 16KB translation granule on page D5-2696](#).

Note

- The naming of this field is as follows:
 - IPS**
 - In `TCR_EL1`.
 - In an implementation that includes `FEAT_VHE`, in `TCR_EL2` when the value of `HCR_EL2.E2H` is 1.
 - PS** Otherwise.
- The `{I}PS` fields are 3-bit fields, corresponding to the least-significant `PARange` bits shown in [Table D5-4 on page D5-2690](#).

If `{I}PS` is programmed to a value larger than the implemented `PA` size, then the PE behaves as if programmed with the implemented `PA` size, but software must not rely on this behavior. That is, the output address size is never larger than the implemented `PA` size. [Table D5-4 on page D5-2690](#) shows the implemented `PA` size.

The PE checks that the `TTBR_ELx`, translation table entries, and the output address for the stage of address translation have the address bits above the output address size set to zero. If this is not the case, an Address size fault is generated for the level and stage of translation that caused the fault. An Address size fault from the `TTBR_ELx` is always reported as a level 0 fault. When a translation granule of 4KB or 16KB is in use and the *Effective value* of `TCR_ELx.DS` is 0, all output addresses are treated as having bits[51:48] set to `0b0000`. For a description of the *Effective value* of `TCR_ELx.DS`, see [Extending addressing above 48 bits when using the 4KB or 16KB translation granule on page D5-2696](#).

If stage 1 translation is disabled and the input address is larger than the implemented `PA` size, then a stage 1 level 0 Address size fault is generated.

Note

These faults are reported as level 0 faults even if they occur in a translation stage that does not perform level 0 lookups.

When using two stages of translation:

- If stage 2 translation is disabled and the output address from the stage 1 translation is larger than the implemented `PA` size, then a stage 1 Address size fault is generated for the level of the stage 1 translation that generated the output address.
- If stage 2 translation is enabled and the output address from the stage 1 translation does not generate a stage 1 Address size fault, but is larger than the input address size specified for the stage 2 translation, then a stage 2 Translation fault is generated.

Input address size

For each enabled stage of address translation, the `TCR_ELx.TxSZ` fields specify the input address size:

For a stage of translation that can support two VA ranges

The `TCR_ELx` has two `TxSZ` fields, corresponding to the two `VA` ranges:

- `TCR_ELx.T0SZ` specifies the size for the lower `VA` range, translated using `TTBR0_ELx`.
- `TCR_ELx.T1SZ` specifies the size for the upper `VA` range, translated using `TTBR1_ELx`.

For a stage of translation that supports only a single input address (IA) range

The `TCR_ELx` has a single `T0SZ` field, and IAs are translated using `TTBR0_ELx`.

Attempting to translate an address that is larger than the configured input address size generates a Translation fault. This means:

- For a `TCR_ELx` with a single `T0SZ` field and a 48-bit address size, [Figure D5-2 on page D5-2692](#) shows the input address map:

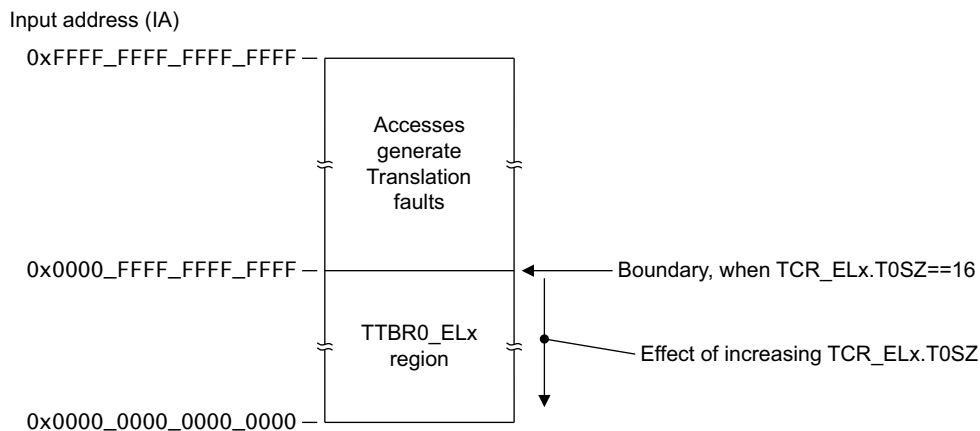

Figure D5-2 AArch64 input address map when using a single TTBR and 48-bit input address size

- For a `TCR_ELx` with two `TxSZ` fields, the input address is always a `VA`, and [Selection between `TTBR0_ELx` and `TTBRI_ELx` when two `VA` ranges are supported on page D5-2723](#) describes the `VA` address map.

For the EL1&0 translation regime when EL2 is enabled, when both stages of translation are enabled, if the output address from the stage 1 translation does not generate a stage 1 address size fault, and is larger than the input address specified by `VTCR_EL2.T0SZ` or `VSTCR_EL2.T0SZ`, then the input address size check for the stage 2 translation generates a Translation fault.

Although software can configure the input address size to be smaller than 48 bits, all implemented AArch64 `TTBR_ELx`s must support input address sizes of up to 48 bits, and in an implementation that includes `FEAT_LVA`, all `TTBR_ELx`s must support input address sizes of up to 52 bits.

[Overview of the VMSAv8-64 address translation stages on page D5-2708](#) gives more information about the relationship between the required input address size, the value of `TxSZ`, and the required initial lookup level, and how these are affected by the translation granule size. However:

For all translation stages

If `FEAT_TTST` is implemented, while the PE is executing in AArch64 state and is using 4KB or 16KB translation granules, the maximum `TxSZ` value is 48.

If `FEAT_TTST` is implemented, while the PE is executing in AArch64 state and is using 64KB translation granules, the maximum `TxSZ` value is 47.

If `FEAT_TTST` is not implemented or while the PE is executing in AArch32 state, the maximum `TxSZ` value is 39.

If `TxSZ` is programmed to a value larger than the defined maximum then it is IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field is programmed to the maximum for all purposes other than reading back the value of the field.
- Any use of the `TxSZ` value generates a Level 0 Translation fault for the stage of translation at which `TxSZ` is used.

For a stage 1 translation

The effective minimum value of `TxSZ` is determined as follows:

- If `FEAT_LVA` is not implemented, the effective minimum value of `TxSZ` is 16.
- If `FEAT_LVA` is implemented, the *Effective value* of `TCR_ELx.DS` is 0, and the 4KB or 16KB translation granule size is used, the effective minimum value of `TxSZ` is 16.
- If `FEAT_LVA` is implemented, and the 64KB translation granule size is used, the effective minimum value of `TxSZ` is 12.
- If `FEAT_LPA2` is implemented and the value of `TCR_ELx.DS` is 1, the effective minimum value of `TxSZ` is 12.

If TxSZ is programmed to a value smaller than the effective minimum value, and if FEAT_LVA is not supported, then it is IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field were programmed to 16 for all purposes other than reading back the value of the field.
- Any use of the TxSZ value generates a stage 1 level 0 Translation fault.

If TxSZ is programmed to a value smaller than the effective minimum value when FEAT_LVA is supported, then any use of the TxSZ value generates a stage 1 level 0 Translation fault.

For more information, see [Extending addressing above 48 bits when using the 64KB translation granule](#) on page D5-2695.

For a stage 2 translation

[Supported IPA size](#) on page D5-2693 defines the effective minimum value of T0SZ, that depends on the supported PA size, and also describes the possible effects of programming T0SZ to a value that is smaller than this effective minimum value.

Supported IPA size

When EL2 is enabled in the current Security state, for the EL1&0 translation regime, the maximum IPA size is the maximum input address size for the second stage of translation is specified by VTCR_EL2.T0SZ or VSTCR_EL2.T0SZ. For more information, see [Input address size](#) on page D5-2691 and [Output address size](#) on page D5-2690.

The maximum IPA size is constrained by the implemented PA size that is specified by ID_AA64MMFR0_EL1.PARange, see [Physical address size](#) on page D5-2690.

The implemented PA size also constrains the following values that specify the initial lookup level:

- VTCR_EL2.SL0 and VSTCR_EL2.SL0.
- When the *Effective value* of VTCR_EL2.DS is 1, VTCR_EL2.SL2 and VSTCR_EL2.SL2.

SL0 and SL2 also depend on the translation granule, as described in [Overview of the VMSAv8-64 address translation stages](#) on page D5-2580.

Table D5-6 PA size implications for the VTCR_EL2.T0SZ and VSTCR_EL2.T0SZ fields

Supported PA size	Effective minimum T0SZ value	Valid initial lookup levels		
		4KB granule	16KB granule	64KB granule
32 bits	32 if EL1 is using AArch64 24 if EL1 is using AArch32	3 ^a , 2, 1	3, 2	3, 2
36 bits	28 if EL1 is using AArch64 24 if EL1 is using AArch32	3 ^a , 2, 1	3, 2	3, 2
40 bits	24	3 ^a , 2, 1	3, 2	3, 2
42 bits	22	3 ^a , 2, 1	3, 2, 1	3, 2
44 bits	20	3 ^a , 2, 1, 0	3, 2, 1	3, 2, 1
48 bits	16	3 ^a , 2, 1, 0	3, 2, 1	3, 2, 1
52 bits	12 ^b	3 ^a , 2, 1, 0, -1	3, 2, 1, 0	3, 2, 1

a. Only supported if FEAT_TTST is implemented, while the PE is executing in AArch64 state.

b. For the 64KB granule, only supported if FEAT_LPA is implemented. For the 4KB and 16KB granules, only supported if the *Effective value* of VTCR_EL2.DS is 1.

If `VTCCR_EL2.TOSZ` is programmed to a value smaller than the effective minimum value shown in [Table D5-6 on page D5-2693](#), and if `FEAT_LPA` is not implemented, then the implementation consistently does one of the following:

- Treats the `VTCCR_EL2.TOSZ` field as being programmed to the effective minimum value for all purposes other than reading back the value of the field.
- Treats the `VTCCR_EL2.TOSZ` field as being programmed to the effective minimum value for all purposes other than:
 - Reading back the value of the field.
 - Checking whether the value of `VTCCR_EL2.TOSZ` is consistent with the value of `VTCCR_EL2.SL0`.
- Generates a stage 2 level 0 Translation fault on any memory access that uses the second stage of translation.

If `TOSZ` is programmed to a value smaller than the effective minimum value when `FEAT_LPA` is supported, then any use of the `TOSZ` value generates a stage 2 level 0 Translation fault.

For more information, see [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695](#).

———— **Note** —————

Programming `VTCCR_EL2.TOSZ` to a value smaller than the effective minimum value shown in [Table D5-6 on page D5-2693](#) can never provide support for a larger address range than the range given by the effective minimum value, because the stage 1 output address will give an Address size fault if it is larger than either:

- The `PA` size, for a VMsAv8-64 stage 1 translation.
- 40 bits, for a VMsAv8-32 stage 1 translation.

If `FEAT_LPA2` is implemented, then `VTCCR_EL2.SL2` and `VSTCR_EL2.SL2` have the following properties:

- If `VTCCR_EL2.DS==0`, then `SL2` is `RES0`.
- If the translation granule is not 4KB, then `SL2` is `RES0`.
- If `VTCCR_EL2.DS==1` and the translation granule is 4KB, then `SL2` is combined with `SL0` to determine the initial lookup level for a stage 2 translation table walk, as shown in [Table D5-7 on page D5-2694](#).

Table D5-7 SL2^a and SL0 encoding for initial lookup level in a 4KB translation granule

SL2 ^a	SL0	Initial lookup level
0	00	Level 2
0	01	Level 1
0	10	Level 0
0	11	Level 3
1	00	Level -1
1	01	Reserved
1	10	Reserved
1	11	Reserved

a. Requires implementation of `FEAT_LPA2`.

If any of `VTCCR_EL2.SL0`, `VTCCR_EL2.SL2`, `VSTCR_EL2.SL0`, or `VSTCR_EL2.SL2` are programmed to represent an initial lookup level not shown in [Table D5-7 on page D5-2694](#), or are programmed to a reserved value, then any memory access that uses the second stage of translation generates a stage 2 level 0 Translation fault.

Extending addressing above 48 bits

The following features provide support for 52-bit addressing:

FEAT_LVA When using the 64KB translation granule, supports 52-bit VAs. The maximum IPA and PA sizes remain 48-bit unless **FEAT_LPA** is implemented.

FEAT_LPA When using the 64KB translation granule, supports 52-bit IPAs and PAs. The maximum VA size remains 48-bit unless **FEAT_LVA** is implemented.

FEAT_LPA2 When using the 4KB or 16KB translation granule, supports 52-bit VAs, IPAs, and PAs.

FEAT_LPA and **FEAT_LVA** can be implemented independently of each other. **FEAT_LPA2** requires the implementation of both **FEAT_LVA** and **FEAT_LPA**.

For more information on using addresses larger than 48 bits with the 64KB granule, see [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695](#).

For more information on using addresses larger than 48 bits with the 4KB and 16 KB granules, see [Extending addressing above 48 bits when using the 4KB or 16KB translation granule on page D5-2696](#).

———— Note ————

The **ID_AA64MMFR2_EL1.VA** field indicates the supported VA size.

The **ID_AA64MMFR0_EL1.PA**range field indicates the supported PA and IPA size.

Extending addressing above 48 bits when using the 64KB translation granule

When using the 64KB translation granule, **FEAT_LPA** supports Block descriptors in level 1 translation tables. In this case, a block covers a 4TB address range.

When the 64KB translation granule is used and **FEAT_LVA** is implemented, the 52-bit VA size is supported as follows:

- For stage 1 translations, the minimum value of the **TCR_ELx.TnSZ** field is 12. If **TCR_ELx.TnSZ** is programmed to a value less than 12, any use of the **TCR_ELx.TnSZ** bit generates a stage 1 level 0 Translation fault.
- For stage 2 translations, the minimum value of **VTCR_EL2.T0SZ** and **VSTCR_EL2.T0SZ** is 12. If **VTCR_EL2.T0SZ** or **VSTCR_EL2.T0SZ** is programmed to a value less than 12, then any use of a stage 2 translation generates a stage 2 level 0 Translation fault.

[Table D5-26 on page D5-2730](#) shows the Translation Table descriptor addressing for each level of lookup when using the 64KB translation granule.

When the 64KB translation granule is used and **FEAT_LPA** is implemented, the 52-bit IPA and PA sizes are supported as follows:

- Bits[15:12] of each valid Translation Table descriptor hold bits[51:48] of the output address, or of the address of the translation table to be used for the initial lookup at the next level of translation. If the implementation does not support 52-bit physical addresses, then it is IMPLEMENTATION DEFINED whether non-zero values for these bits generate an Address size fault. In this case, not generating an Address Size Fault is deprecated.
- For a stage 1 translation, bits[5:2] of **TTBR0_ELx** or **TTBR1_ELx** holds bits[51:48] of the address of the translation table to be used for the initial lookup of that translation regime. If the implementation does not support 52-bit physical addresses, then non-zero values for these bits generate an Address size fault.
- For a stage 2 translation, bits[5:2] of **VTTBR_EL2** or **VSTTBR_EL2** holds bits[51:48] of the address of the translation table to be used for the initial lookup of the stage 2 translation. If the implementation does not support 52-bit physical addresses, then non-zero values for these bits generate an Address size fault.
- The minimum alignment of a translation table containing fewer than eight entries is 64 bytes.

———— **Note** ————

This is because, when the OA space is more than 48 bits, `TTBR_ELx[5:2]` specifies bits[51:48] of the translation table base address, and a translation table of fewer than eight entries would require one or more bits of `TTBR_ELx[5:2]` to be RES0 if the table was aligned to its size.

For more information, see *VMSAv8-64 translation table level -1, level 0, level 1, and level 2 descriptor formats on page D5-2739* and *Armv8 translation table level 3 descriptor formats on page D5-2744*.

Extending addressing above 48 bits when using the 4KB or 16KB translation granule

When using the 4KB translation granule, `FEAT_LPA2` supports Block descriptors in level 0 translation tables. In this case, a block covers a 512GB address range.

When using the 16KB translation granule, `FEAT_LPA2` supports Block descriptors in level 1 translation tables. In this case, a block covers a 64GB address range.

If `FEAT_LPA2` is implemented, `TCR_ELx.DS` and `VTCCR_EL2.DS` control when the 4KB and 16KB translation granules can use an address size greater than 48 bits:

- When `DS=0`, the maximum address size for the translation regime is 48 bits.
- When `DS=1`, the maximum address size for the translation regime is 52 bits.

———— **Note** ————

`TCR_ELx.DS` and `VTCCR_EL2.DS` are RES0 when using the 64KB translation granule.

If `FEAT_LPA2` is not implemented, the *Effective value* of the `TCR_ELx.DS` and `VTCCR_EL2.DS` bit is 0.

To support the larger address size when the translation regime's `TCR_ELx.DS` or `VTCCR_EL2.DS` bit is 1, the shareability field in the Block and Page descriptors is used for addressing, see *VMSAv8-64 Translation Table format descriptors on page D5-2739*. For a stage 1 translation, the shareability of a cacheable block or page is taken from the shareability attribute field in the translation regime's `TCR_ELx` register, see *Stage 1 Shareability when FEAT_LPA2 is implemented on page D5-2778*. For a stage 2 translation, the shareability of a cacheable block or page is taken from the shareability attribute field in the translation regime's `VTCCR_EL2` register, see *Stage 2 Shareability attribute, for Normal memory on page D5-2780*.

For a translation regime, when the `TCR_ELx.DS` or `VTCCR_EL2.DS` bit is 1, the 52-bit VA size is supported in the 4KB and 16KB translation granules as follows:

- For stage 1 translations, the minimum value of the `TCR_ELx.TnSZ` field is 12.
If `TCR_ELx.TnSZ` is programmed to a value less than 12, any use of the `TCR_ELx.TnSZ` bit generates a stage 1 level 0 Translation fault.
- For stage 2 translations, the minimum value of `VTCCR_EL2.T0SZ` and `VSTCCR_EL2.T0SZ` is 12.
If `VTCCR_EL2.T0SZ` or `VSTCCR_EL2.T0SZ` is programmed to a value less than 12, any use of a stage 2 translation generates a stage 2 level 0 Translation fault.

[Table D5-24 on page D5-2728](#) shows the Translation Table descriptor addressing for each level of lookup when using the 4KB translation granule. [Table D5-25 on page D5-2729](#) shows the Translation Table descriptor addressing for each level of lookup when using the 16KB translation granule.

For a translation regime, when the `TCR_ELx.DS` or `VTCCR_EL2.DS` bit is 1, the 52-bit IPA and PA size is supported in the 4KB and 16KB translation granules as follows:

- Bits[49:48] of each valid Translation Table descriptor hold bits[49:48] of the output address, or of the address of the translation table to be used for the initial lookup at the next level of translation.
- Bits[9:8] of each valid Translation Table descriptor hold bits[51:50] of the output address, or of the address of the translation table to be used for the initial lookup at the next level of translation.
- For a stage 1 translation, bits[5:2] of `TTBR0_ELx` or `TTBR1_ELx` holds bits[51:48] of the address of the translation table to be used for the initial lookup of that translation regime.
- For a stage 2 translation, bits[5:2] of `VTTBR_EL2` or `VSTTBR_EL2` holds bits[51:48] of the address of the translation table to be used for the initial lookup of the stage 2 translation.
- The minimum alignment of a translation table containing fewer than eight entries is 64 bytes.

———— **Note** —————

This is because, when the OA space is more than 48 bits, [TTBR_ELx\[5:2\]](#) specifies bits[51:48] of the translation table base address, and a translation table of fewer than eight entries would require one or more bits of [TTBR_ELx\[5:2\]](#) to be RES0 if the table was aligned to its size.

For more information, see [VMSAv8-64 translation table level -1, level 0, level 1, and level 2 descriptor formats on page D5-2739](#) and [Armv8 translation table level 3 descriptor formats on page D5-2744](#).

The following register fields determine support for 52-bit input and output addresses using [FEAT_LPA2](#):

- [ID_AA64MMFR0_EL1.TGran4](#) determines 52-bit address support for the 4KB translation granule at stage 1.
- [ID_AA64MMFR0_EL1.TGran4_2](#) determines 52-bit address support for the 4KB translation granule at stage 2.
- [ID_AA64MMFR0_EL1.TGran16](#) determines 52-bit address support for the 16KB translation granule at stage 1.
- [ID_AA64MMFR0_EL1.TGran16_2](#) determines 52-bit address support for the 16KB translation granule at stage 2.

Atomicity of register changes on changing virtual machine

From the viewpoint of software executing at EL1 or EL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for the EL1&0, when EL2 is enabled, translation regime. This means that all of the following registers must change atomically:

- The registers associated with the stage 1 translations:
 - [MAIR_EL1](#) and [AMAIR_EL1](#).
 - [TTBR0_EL1](#), [TTBR1_EL1](#), [TCR_EL1](#), and [CONTEXTIDR_EL1](#).
 - [SCTLR_EL1](#).
- The registers associated with the stage 2 translations:
 - [VTBR_EL2](#) and [VTCR_EL2](#).
 - [SCTLR_EL2](#).

———— **Note** —————

Only some bits of [SCTLR_EL1](#) affect the stage 1 translation, and only some bits of [SCTLR_EL2](#) affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution using the EL1&0, when EL2 is enabled, translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are *out of context* when they are updated, and no synchronization precautions are required.

Similar considerations apply when [FEAT_VHE](#) is implemented.

Use of out-of-context translation regimes

The architecture requires that:

- When executing at EL3 or EL2, the PE must not use the registers associated with the EL1&0 translation regime for speculative memory accesses.
- When executing at EL3 the PE must not use the registers associated with the EL2 or EL2&0 translation regime for speculative memory accesses.

If the Statistical Profiling Unit (SPU) is not in use for a lower Exception level when entering an Exception level, on completion of a DSB instruction, then no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered will be observed by any observers, to the extent that those accesses are required to be observed as determined by the shareability and cacheability of those translation table entries.

If the SPU is in use for a lower Exception level when entering an Exception level, on completion of a PSB CSYNC and a subsequent DSB instruction, then no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered will be observed by any observers, to the extent that those accesses are required to be observed as determined by the shareability and cacheability of those translation table entries.

———— **Note** —————

- This does not require that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.
- This requirement does not imply that, on taking an exception to a higher Exception level, any translation table walks started before the exception was taken will be completed by the time the higher Exception level is entered, and therefore memory accesses required for such a translation table walk might, in effect, be performed speculatively. However, the execution of a DSB on entry to the higher Exception level ensures that these accesses are complete.

D5.2.4 Memory translation granule size

The memory translation granule size defines both:

- The maximum size of a single translation table.
- The memory *page* size. That is, the granularity of a translation table lookup.

VMsAv8-64 supports translation granule sizes of 4KB, 16KB, and 64KB. Support for each granule size is optional. If *FEAT_GTG* is implemented, support for granule size in Stage 1 is indicated as shown in [Table D5-8 on page D5-2698](#), and support for granule size in Stage 2 is indicated as shown in [Table D5-9 on page D5-2699](#). Otherwise, support for granule size in both Stages 1 and 2 is indicated as shown in [Table D5-8 on page D5-2698](#):

Table D5-8 Identifying supported granule sizes for stage 1 translation

Granule size	Support indicated by:		Values	Description
	Field	Values		
4KB	ID_AA64MMFR0_EL1.TGran4	0b0000	4KB granule size with 48-bit addresses supported.	
		0b0001	4KB granule size with 52-bit addresses supported.	
		0b1111	4KB granule size not supported.	
16KB	ID_AA64MMFR0_EL1.TGran16	0b0000	16KB granule size not supported.	
		0b0001	16KB granule size with 48-bit addresses supported.	
		0b0010	16KB granule size with 52-bit addresses supported.	
64KB	ID_AA64MMFR0_EL1.TGran64	0b0000	64KB granule size supported.	
		0b1111	64KB granule size not supported.	

Table D5-9 Identifying supported granule sizes for stage 2 translation

Granule size	Support indicated by:		Values
	Field		
4KB	ID_AA64MMFR0_EL1.TGran4_2	0b0010	4KB granule size with 48-bit addresses supported at stage 2.
		0b0001	4KB granule size not supported at stage 2.
		0b0011	4KB granule size with 52-bit addresses supported at stage 2.
16KB	ID_AA64MMFR0_EL1.TGran16_2	0b0010	16KB granule size with 48-bit addresses supported at stage 2.
		0b0001	16KB granule size not supported at stage 2.
		0b0011	16KB granule size with 52-bit addresses supported at stage 2.
64KB	ID_AA64MMFR0_EL1.TGran64_2	0b0010	64KB granule size supported at stage 2.
		0b0001	64KB granule size not supported at stage 2.

———— **Note** ————

From a hardware viewpoint, the TGran*_2 fields hold the same information as the corresponding TGran* fields.

In VMSAv8-64, each address translation stage is configured, independently, to use one of the supported granule sizes.

———— **Note** ————

- Using a larger granule size can reduce the maximum required number of levels of address lookup because:
 - The increased translation table size means the translation table holds more entries. This means a single lookup can resolve more bits of the input address.
 - The increased page size means more of the least-significant address bits are required to address a page. These address bits are flat mapped from the input address to the output address, and therefore do not require translation.
- Arm recommends that memory-mapped peripherals are separated by an integer multiple of the largest granule size supported by the operating system or hypervisor, to allow each peripheral to be managed independently.

[Table D5-10 on page D5-2699](#) summarizes the effects of the different granule sizes.

Table D5-10 Effect of granule size on a stage of address translation

Property	4KB granule	16KB granule	64KB granule	Notes
Maximum number of entries in a translation table	512	2048 (2K)	8192 (8K)	-
Address bits resolved in one level of lookup	9	11	13	$2^9=512$, $2^{11}=2K$, $2^{13}=8K$
Page size	4KB	16KB	64KB	-
Page address range	VA[11:0] = PA[11:0]	VA[13:0] = PA[13:0]	VA[15:0] = PA[15:0]	$2^{12}=4K$, $2^{14}=16K$, $2^{16}=64K$

How the granule size affects the address translation process

As [Table D5-10 on page D5-2699](#) shows, the translation granule determines the number of address bits:

- Required to address a memory page.

- That can be resolved in a single translation table lookup.

This means the translation granule determines how the *input address* (IA) is resolved to an *output address* (OA) by the translation process.

Because a single translation table lookup can resolve only a limited number of address bits, the IA to OA resolution requires multiple *levels* of lookup.

Considering the resolution of an IA range of 48 bits, with a translation granule size of 2^n bytes:

- The least-significant n bits of the IA address the memory page. This means $OA[(n-1):0]=IA[(n-1):0]$.
- The remaining $(48-n)$ bits of the IA, $IA[47:n]$, must be resolved by the address translation.
- A Translation Table descriptor is 8 bytes. Therefore:
 - A complete translation table holds $2^{(n-3)}$ descriptors.
 - A single level of translation can resolve a maximum of $(n-3)$ bits of address.

Consider the translation process, working back from the final level of lookup, that resolves the least significant of the address bits that require translation. Because the translation needs to resolve $IA[47:n]$ and a level of lookup can resolve $(n-3)$ bits of address:

- The final level of lookup resolves $IA[(2n-4):n]$.
- The previous level of lookup resolves $IA[(3n-7):(2n-3)]$.

However, the level of lookup that resolves the most significant bits of the IA might not require a full-sized translation table. Therefore, in general, for a 48-bit IA the address bits resolved in a level of lookup are:

$$IA[\text{Min}(47, ((3-m)(n-3)+2n-4)):(n+(3-m)(n-3))], \text{ where:}$$

Min(a, b) Is a function that returns the minimum of a and b .

m Indicates the level of lookup. This is defined so that the level that resolves the least significant bit of the translated IA bits is level 3.

Figure D5-3 on page D5-2700 shows how a 52-bit IA is resolved when using the 4KB translation granule. An input address size greater than 48 bits requires implementation of [FEAT_LPA2](#).

Using the 4KB translation granule

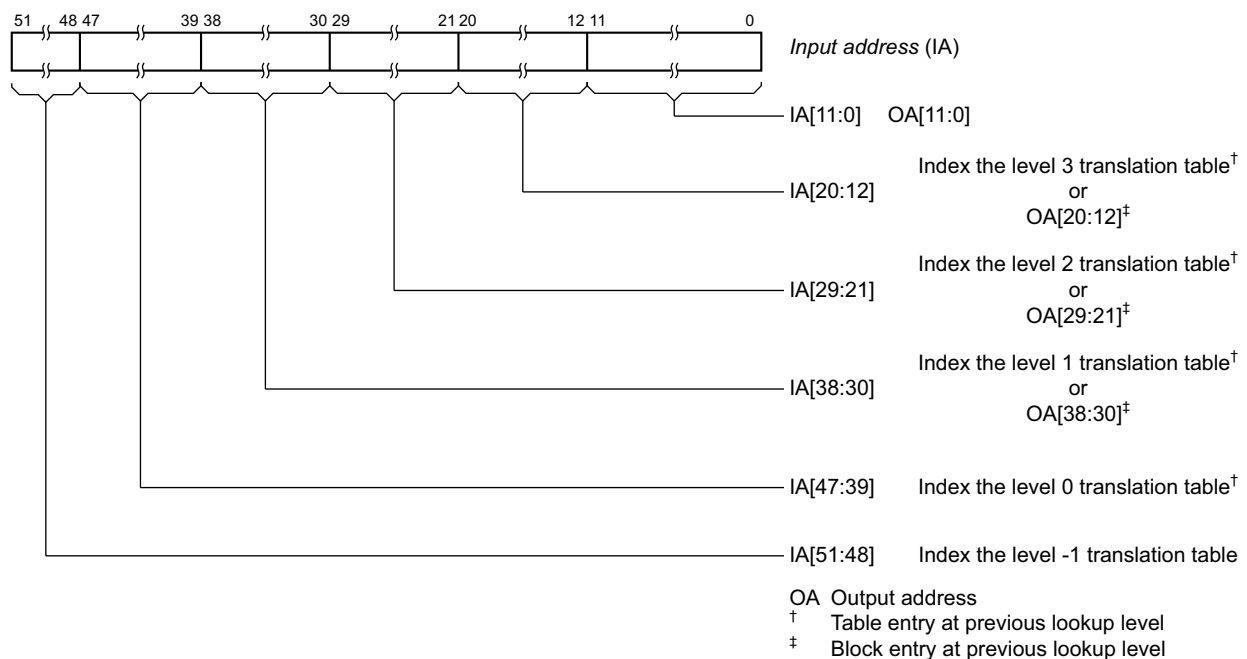

Figure D5-3 How a 52-bit IA is resolved when using the 4KB translation granule

Figure D5-4 on page D5-2701 shows how a 52-bit IA is resolved when using the 16KB translation granule. An input address size greater than 48 bits requires implementation of FEAT_LPA2.

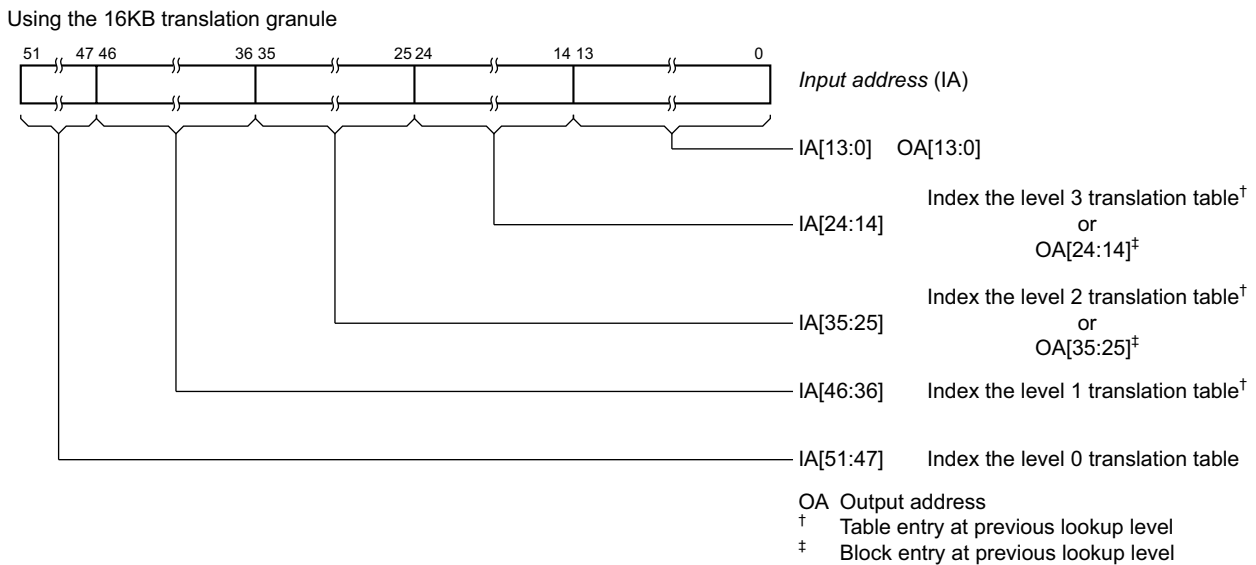

Figure D5-4 How a 52-bit IA is resolved when using the 16KB translation granule

Figure D5-5 on page D5-2701 shows how a 52-bit IA is resolved when using the 64KB translation granule. An input address size greater than 48 bits requires implementation of FEAT_LVA for stage 1 translations, and FEAT_LPA for stage 2 translations.

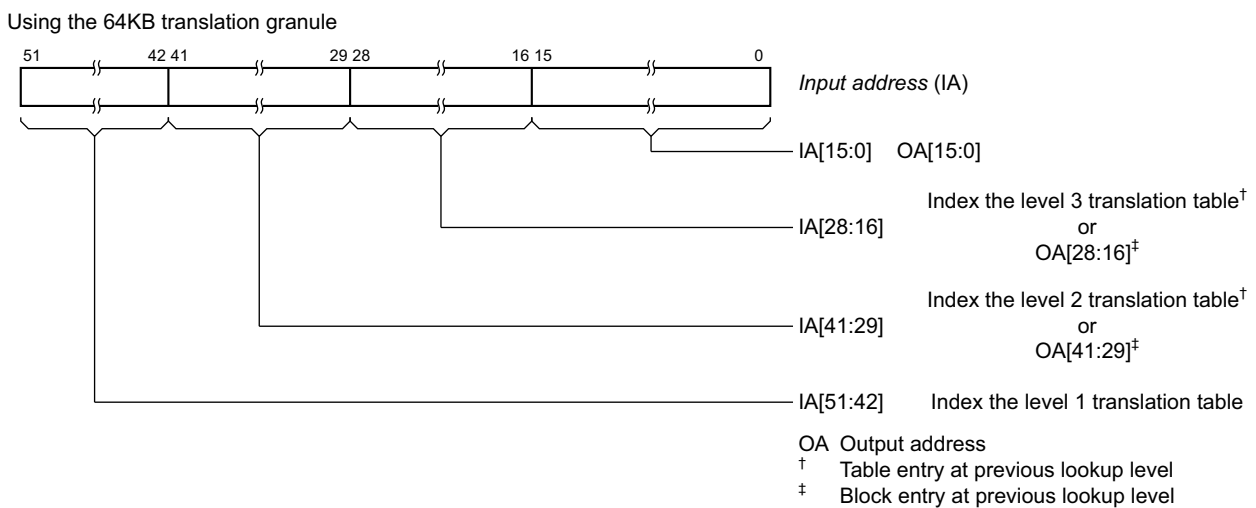

Figure D5-5 How a 52-bit IA is resolved when using the 64KB translation granule

Later sections of this chapter give more information about the translation process, and explain the terminology used in these figures.

Effect of granule size on translation table addressing and indexing

Table D5-11 on page D5-2702 shows the effect of the translation granule size on the addressing and indexing of the TTBR_ELx, and on the input address range that must be resolved.

In [Table D5-11 on page D5-2702](#), the entries in the *Addressed by* and *Translation resolves* columns apply as follows:

- For the 4KB and 16KB granules, the second entry is for an implementation that includes [FEAT_LPA2](#) and has selected an IA space larger than 48 bits, see [Extending addressing above 48 bits when using the 4KB or 16KB translation granule on page D5-2696](#). The first entry applies otherwise.
- For the 64KB granule, the second entry is for an implementation that includes [FEAT_LVA](#) and has selected an IA space larger than 48 bits, see [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695](#). The first entry applies otherwise.

Table D5-11 The effect of translation granule size on the translation tables

Granule size	Translation table		Translation resolves ^a	Notes
	Addressed by	Indexed by ^b		
4KB	TTBR_ELx [47:12] TTBR_ELx [5:2, 47:12]	IA[(x + 8):x]	IA[47:12] ^c IA[51:12]	One lookup level resolves up to ^c 9 IA bits
16KB	TTBR_ELx [47:14] ^c TTBR_ELx [5:2, 47:14]	IA[(x + 10):x]	IA[47:14] ^c IA[51:14]	One lookup level resolves up to 11 IA bits
64KB	TTBR_ELx [47:16] TTBR_ELx [5:2, 47:16]	IA[(x + 12):x]	IA[47:16] IA[51:16]	One lookup level resolves up to 13 IA bits

- When translating a maximum-sized input address, and accessing a page of memory.
- Where the value of *x* depends on the lookup level, see [Table D5-12 on page D5-2702](#).
- Depending on the IA size, the initial lookup might resolve fewer bits of the IA.

[Table D5-12 on page D5-2702](#) shows the IA bits resolved at each level of lookup, and how these correspond to the possible values of *x* in [Table D5-11 on page D5-2702](#).

Table D5-12 IA bits resolved at different levels of lookup

Lookup level	4KB granule size	16KB granule size	64KB granule size
Minus one	IA[51 ^b :48], <i>x</i> = 48	- ^a	- ^a
Zero	IA[47:39], <i>x</i> = 39	IA[47 ^b], <i>x</i> = 47 ^c IA[51 ^b :47], <i>x</i> = 47	- ^d
First	IA[38:30], <i>x</i> = 30	IA[46:36], <i>x</i> = 36	IA[47 ^b :42], <i>x</i> = 42 ^e IA[51 ^b :42], <i>x</i> = 42
Second	IA[29:21], <i>x</i> = 21	IA[35:25], <i>x</i> = 25	IA[41:29], <i>x</i> = 29
Third	IA[20:12], <i>x</i> = 12	IA[24:14], <i>x</i> = 14	IA[28:16], <i>x</i> = 16

- Level -1 lookup only possible with the 4KB granule size in an implementation that includes [FEAT_LPA2](#).
- Smaller value than indicated in [Table D5-11 on page D5-2702](#), as explained in this section.
- The second entry applies to an implementation that includes [FEAT_LPA2](#) and has selected an IA space larger than 48 bits, see [Extending addressing above 48 bits when using the 4KB or 16KB translation granule on page D5-2696](#). The first entry applies otherwise.
- Level 0 lookup not possible with 64KB granule size
- The second entry applies to an implementation that includes [FEAT_LVA](#) and has selected an IA space larger than 48 bits, see [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695](#). The first entry applies otherwise.

Table D5-11 on page D5-2702 refers to accessing a complete translation table, of 4KB, 16KB, or 64KB. However, the Armv8 translation system supports the following possible variations from the information in Table D5-11 on page D5-2702:

Reduced IA width

Depending on the configuration and implementation choices, the required input address width for the initial level of lookup might be smaller than the number of address bits that can be resolved at that level. This means that, for this initial level of lookup:

- The translation table size is reduced. The size of the translation table is halved for each 1-bit reduction in the input address size.

Note

- This has no effect on the translation table size for subsequent levels of lookup, for which the lookups always use full-sized translation tables.
 - For a stage 2 translation, it might be possible to start the translation at a lower level, see [Concatenated translation tables on page D5-2703](#).
-

- More low-order `TTBR_ELx` bits are needed to hold the translation table base address. [Example D5-1 on page D5-2703](#) shows how this applies to translating a 35-bit input address range using the 4KB granule.

Example D5-1 Effect of an IA width of 35 bits when using the 4KB granule size

With a 4KB granule size, a single level of lookup can resolve up to 9 bits of IA. If an implementation has a 35-bit input address range, `IA[34:0]`, [Table D5-12 on page D5-2702](#) shows that lookup must start at level 1, and that the initial lookup must resolve `IA[34:30]`, meaning it resolves 5 bits of address. This 4-bit reduction in the required resolution means:

- The translation table size is divided by 2^4 , giving a size of 256B.
 - The `TTBR_ELx` requires 4 more bits for the translation table base address, which becomes `TTBR_ELx[47:8]`.
-

When using the 64KB translation granule to translate the maximum IA size of 48 bits, [Table D5-12 on page D5-2702](#) shows that a level 1 lookup must resolve only `IA[47:42]`. This is 6 bits of address, compared to the 13 bits that can be resolved at a single level of lookup. This 7-bit reduction in the required resolution means:

- The translation table size is divided by 2^7 , giving a size of 512B.
- The `TTBR_ELx` requires 7 more bits for the translation table base address, which becomes `TTBR_ELx[47:9]`.

Concatenated translation tables

For stage 2 address translations, for the initial lookup, up to 16 translation tables can be concatenated. This means additional IA bits can be resolved at that lookup level. The block of concatenated translation tables must be aligned to the size of the block of translation tables.

This means that each additional IA bit resolved:

- Doubles the number of translation tables required. Resolving an additional n bits requires 2^n concatenated translation tables at the initial lookup level.
- Reduces by 1 bit the width of the translation table base address held in the `TTBR_ELx`.

This means that, for the initial lookup of a stage 2 translation table, the IA ranges shown in [Table D5-12 on page D5-2702](#) can be extended by up to 4 bits. [Example D5-2 on page D5-2704](#) shows how concatenation can be used to resolve a 40-bit IA when using the 4KB translation granule.

Example D5-2 Concatenating translation tables to resolve a 40-bit IA range, with the 4K granule

Table D5-12 on page D5-2702 shows that, when using the 4KB translation granule, a level 1 lookup can resolve a 39-bit IA, with the first lookup resolving IA[38:30]. For a stage 2 translation, to extend the IA width to 40 bits and resolve IA[39:30] with the first lookup:

- Two translation tables are concatenated, giving a total size of 8KB.
- The `TTBR_ELx` requires 1 fewer bit for the translation table base address, which becomes `TTBR_ELx[47:13]`.

For more information, see *Use of concatenated translation tables for the initial stage 2 lookup* on page D5-2724.

In all cases, the translation table, or block of concatenated translation tables, must be aligned to the actual size of the table or block of concatenated tables.

The translation table base address held in the `TTBR_ELx` is defined in the OA map for that stage of address translation. The information given in this section assumes this stage of translation has the maximum OA size, meaning the translation table base address is:

- `TTBR_ELx[47:12]` if using the 4KB translation granule with an OA of 48 bits.
- In an implementation that includes `FEAT_LPA2` and is using the 4KB translation granule, OA[51:12], where:
 - `TTBR_ELx[5:2]` holds OA[51:48].
 - `TTBR_ELx[47:12]` holds OA[47:12].
- `TTBR_ELx[47:14]` if using the 16KB translation granule with an OA of 48 bits.
- In an implementation that includes `FEAT_LPA2` and is using the 16KB translation granule, OA[51:12], where:
 - `TTBR_ELx[5:2]` holds OA[51:48].
 - `TTBR_ELx[47:12]` holds OA[47:12].
- `TTBR_ELx[47:16]` if using the 64KB translation granule with an OA of 48 bits.
- In an implementation that includes `FEAT_LPA` and is using the 64KB translation granule, OA[51:16], where:
 - `TTBR_ELx[5:2]` holds OA[51:48].
 - `TTBR_ELx[47:16]` holds OA[47:16].

If the OA address is smaller than 48 bits then the upper bits of this field must be written as zero. For example, for a 40-bit OA range:

- If using the 4KB translation granule:
 - `TTBR_ELx[47:40]` must be set to zero.
 - `TTBR_ELx[39:12]` holds the translation table base address.
- If using the 16KB translation granule:
 - `TTBR_ELx[47:40]` must be set to zero.
 - `TTBR_ELx[39:14]` holds the translation table base address.
- If using the 64KB translation granule:
 - `TTBR_ELx[47:40]` must be set to zero.
 - `TTBR_ELx[39:16]` holds the translation table base address.

In all cases, if `TTBR_ELx[47:40]` is not zero, any attempt to access the translation table generates an Address size fault.

D5.2.5 Translation tables and the translation process

The following subsections describe general properties of the translation tables and translation table walks, that are largely independent of the translation table format:

- *Translation table walks* on page D5-2705.
- *Ordering of memory accesses from translation table walks* on page D5-2707.
- *Security state of translation table lookups* on page D5-2707.
- *Control of translation table walks* on page D5-2707.

See also [Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D5-2723](#).

Translation table walks

A *translation table walk* comprises one or more *translation table lookups*. The translation table walk is the set of lookups that are required to translate the VA to the PA. For the EL1&0, when EL2 is enabled, translation regime, this set includes lookups for both the stage 1 translation and the stage 2 translation, but *translation table walk* can also be used to refer to either:

- The set of lookups required for the stage 1 translation, that translates the VA to the IPA. This is the *stage 1 translation table walk*.
- The set of lookups required for the stage 2 translation, that translates the IPA to the PA. This is the *stage 2 translation table walk*.

The information returned by a successful translation table walk is:

- The required PA. If the access is from Secure state this includes identifying whether the access is to the Secure PA space or the Non-secure PA space, see [Security state of translation table lookups on page D5-2707](#).
- The memory attributes for the target memory region, as described in [Memory types and attributes on page B2-165](#). For more information about how the Translation Table descriptors specify these attributes, see [Memory region attributes on page D5-2776](#).
- The access permissions for the target memory regions. For more information about how the Translation Table descriptors specify these permissions, see [Memory access control on page D5-2754](#).

The translation table walk starts with a read of the translation table for the initial lookup. The TTBR_ELx for the stage of translation holds the base address of this table. Each translation table lookup returns a descriptor that indicates one of the following:

- The entry is the final entry of the walk. In this case, the entry contains the OA, and the permissions and attributes for the access.
- An additional level of lookup is required. In this case, the entry contains the translation table base address for that lookup. In addition:
 - The descriptor provides hierarchical attributes that are applied to the final translation, see [Hierarchical control of Secure or Non-secure memory accesses on page D5-2753](#) and [Hierarchical control of data access permissions on page D5-2759](#).
 - If the translation is in a Secure translation regime, the descriptor indicates whether that base address is in the Secure or Non-secure address space, unless a hierarchical control at a previous level of lookup has indicated that it must be in the Non-secure address space.
- The descriptor is invalid. In this case, the memory access generates a Translation fault.

[Figure D5-6 on page D5-2705](#) gives a generalized view of a single stage of address translation where three levels of lookup are required.

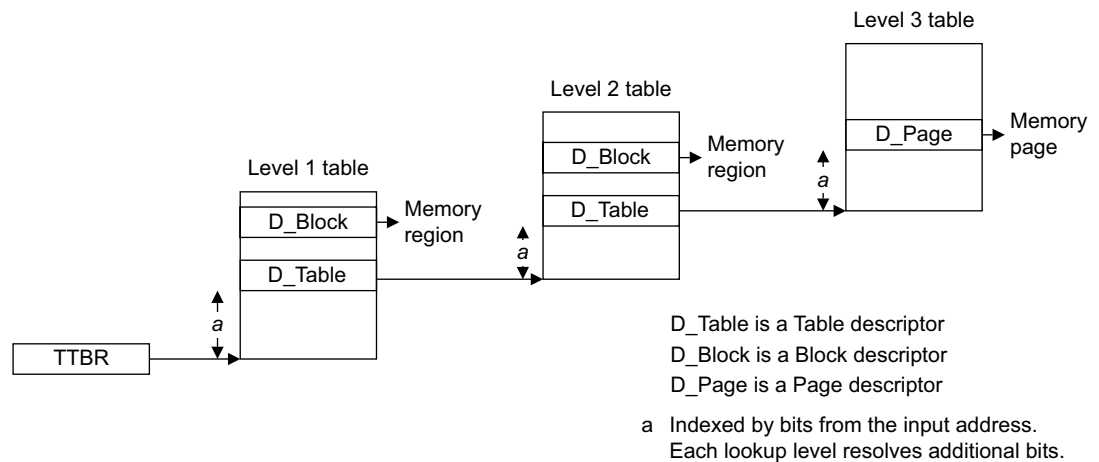

Figure D5-6 Generalized view of a stage of address translation

A translation table lookup from VMsAv8-64 performs a single-copy atomic 64-bit access to the translation table entry. This means the translation table entry is treated as a 64-bit object for the purpose of endianness. [SCTLR_ELx.EE](#) determines the endianness of the translation table lookups.

Note

Dynamically changing translation table endianness

Because any change to an [SCTLR_ELx.EE](#) bit requires synchronization before it is visible to subsequent operations, Arm strongly recommends that any EE bit is changed only when either:

- Executing at an Exception level that does not use the translation tables affected by the EE bit being changed.
- Executing with address translation disabled for any stage of translation affected by the EE bit being changed.

Address translation stages are disabled by setting an [SCTLR_ELx.M](#) bit or the [HCR_EL2.VM](#) bit to 0. See the appropriate register description for more information.

The appropriate [TTBR_ELx](#) holds the output address of the base of the translation table used for the initial lookup, and:

- For all address translation stages other than EL1&0, when EL2 is enabled, stage 1 translations, the output address held in the [TTBR_ELx](#), and any translation table base address returned by a Translation Table descriptor, is the [PA](#) of the base of the translation table.
- For EL1&0, when EL2 is enabled, stage 1 translations, the output address held in the [TTBR_ELx](#), and any translation table base address returned by a Translation Table descriptor, is the [IPA](#) of the base of the translation table. This means that if stage 2 address translation is enabled, each of these OAs is subject to second stage translation.

Note

TLB caching can be used to minimize the number of translation table lookups that must be performed. For the EL1&0, when EL2 is enabled, translation regime, because each stage 1 OA generated during a translation table walk is subject to a stage 2 translation, if the caching of translation table entries is ineffective, a [VA](#) to [PA](#) address translation with two stages of translation can give rise to multiple translation table lookups. The number of lookups required is given by the following equation:

$$(S1+1)*(S2+1) - 1$$

Where, for this translation regime, S1 is the number of levels of lookup required for a stage 1 translation, and S2 is the number of levels of lookup required for a stage 2 translation.

The [TCR_ELx](#) determines the memory cacheability and shareability attributes that apply, for the corresponding stage of translation, to all translation table lookups generated by that stage of translation.

The Normal memory type is the memory type defined for a translation table lookup for a stage of translation.

Note

- In a two-stage translation regime, a translation table lookup from stage 1, that has the Normal memory type defined at stage 1 by this rule, can still be given the Device memory type as part of the stage 2 translation of that address. Arm strongly recommends against such a remapping of the memory type, and the architecture includes a trap of this behavior to EL2. For more information, see [Stage 2 fault on a stage 1 translation table walk on page D5-2806](#).
- The rules about mismatched attributes given in [Mismatched memory attributes on page B2-176](#) apply to the relationship between translation table walks and explicit memory effects to the translation tables in the same way that they apply to the relationship between different explicit memory effects to the same location. For this reason, Arm strongly recommends that the attributes that the [TCR_ELx](#) applies to the translation tables are the same as the attributes that are applied for explicit memory effects to the memory that holds the translation tables.

For more information, see [Overview of the VMsAv8-64 address translation stages on page D5-2708](#).

See also [Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D5-2723](#).

Ordering of memory accesses from translation table walks

A translation table walk is considered to be a separate observer. An explicit memory write effect to the translation tables might be observed by that separate observer for either of the following:

- A translation table walk caused by a different explicit memory write effect generated by the same instruction.
- A translation table walk caused by an explicit memory effect generated by any instruction appearing in program order after the instruction doing the explicit memory write effect to the translation table.

The explicit memory write effect to the translation tables is guaranteed to be observable, to the extent required by the shareability attributes, only after the execution of a DSB instruction. This DSB instruction and the instruction that performed the explicit memory write effect to the translation tables must have been executed by the same PE.

Any writes to the translation tables are not seen by any translation table accesses associated with an explicit memory effect generated by a load or store that occurs in program order before the instruction that performs the write to the translation tables.

If `FEAT_ETS` is implemented, and a memory access RW_1 is **Ordered-before** a second memory access RW_2 , then RW_1 is also **Ordered-before** any translation table walk generated by RW_2 that generates any of the following:

- A Translation fault.
- An Address size fault.
- An Access flag fault.

Security state of translation table lookups

For a Non-secure translation regime, all translation table lookups are performed to Non-secure output addresses.

For a Secure translation regime, for the first stage of translation, the initial translation table lookup is performed to a Secure IPA.

If the Translation Table descriptor returned as a result of that initial lookup points to a second translation table, then the NSTable bit in that descriptor determines whether that translation table lookup is made to a Secure or to a Non-secure IPA.

This applies for all subsequent translation table lookups as part of that translation table walk, with the additional rule that any Translation Table descriptor that is returned from Non-secure memory is treated as if the NSTable bit in that descriptor indicates that the subsequent translation table lookup is to Non-secure memory.

Where the Secure IPA from a first stage translation table is translated by the second stage translation, the security of the output address of that memory access is determined by:

- For accesses made to Secure IPA space, the `VSTCR_EL2.SA` bit.
- For accesses made to Non-secure IPA space, the `VTCR_EL2.NSA` bit.

For a Secure translation regime, for the second stage of translation, the security of the output address of the translation table walk is determined by:

- For translation table walks for the Secure IPA space, the `VSTCR_EL2.SW` bit.
- For translation table walks for the Non-secure IPA space, the `VTCR_EL2.NSW` bit.

Control of translation table walks

When stage 1 translations of a translation can support two VA ranges the `TCR_ELx`.{EPD0, EPD1} bits determine whether, for that regime, the two sets of translation tables for stage 1 are valid. EPD0 indicates whether the tables that `TTBR0_ELx` points to is valid, and EPD1 indicates whether the tables that `TTBR1_ELx` points to is valid. The effect of these bits is:

EPD n == 0 The translation tables are valid, and can be used for a translation table lookup.

EPD n == 1 If a TLB miss occurs based on `TTBR_ELx`, a Translation fault is returned, and no translation table walk is performed. The fault is reported as a level 0 fault.

D5.2.6 Overview of the VMSAv8-64 address translation stages

As shown in *Memory translation granule size* on page D5-2698, the granule size determines significant aspects of the address translation process. *Effect of granule size on translation table addressing and indexing* on page D5-2701 shows, for each granule size:

- How the required input address range determines the required initial lookup levels.
- For stage 2 translations, the possible effect described in *Concatenated translation tables* on page D5-2703.
- The `TTBR_ELx` addressing and indexing for the initial lookup.

The following subsections summarize the multiple levels of lookup that can be required for a single stage of address translation that might require the maximum number of lookups:

- *Overview of VMSAv8-64 address translation using the 4KB translation granule* on page D5-2708.
- *Overview of VMSAv8-64 address translation using the 16KB translation granule* on page D5-2712.
- *Overview of VMSAv8-64 address translation using the 64KB translation granule* on page D5-2716.

Overview of VMSAv8-64 address translation using the 4KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 4KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding `TCR_ELx.TnSZ` field. When using the 4KB translation granule, [Table D5-13](#) on page D5-2708 shows this requirement.

Table D5-13 `TCR_ELx.TnSZ` values and IA ranges, 4KB granule with no concatenation of tables

Initial lookup level	TnSZ values for and input address ranges ^a for starting at this level			
	TnSZ _{min}	IA _{max}	TnSZ _{max}	IA _{min}
-1 ^b	12	IA[51:12]	15	IA[48:12]
0	16	IA[47:12]	24	IA[39:12]
1	25	IA[38:12]	33	IA[30:12]
2	34	IA[29:12]	42 ^c	IA[21:12]
3 ^d	43	IA[20:12]	48 ^d	IA[15:12]

- The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.
- Lookup level -1 is only supported when `FEAT_LPA2` is implemented and `TCR_ELx.DS` is 1.
- If `FEAT_TTST` is not implemented, or while the PE is executing in AArch32 state, TnSZ_{max} is 39.
- Only available if `FEAT_TTST` is implemented, while the PE is executing in AArch64 state.

These configuration options are also permitted for stage 2 translations.

Note

Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA, When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

Figure D5-7 on page D5-2709 shows the stage 1 address translation using the 4KB granule and an input address size up to 52 bits. An input address size greater than 48 bits requires implementation of FEAT_LPA2.

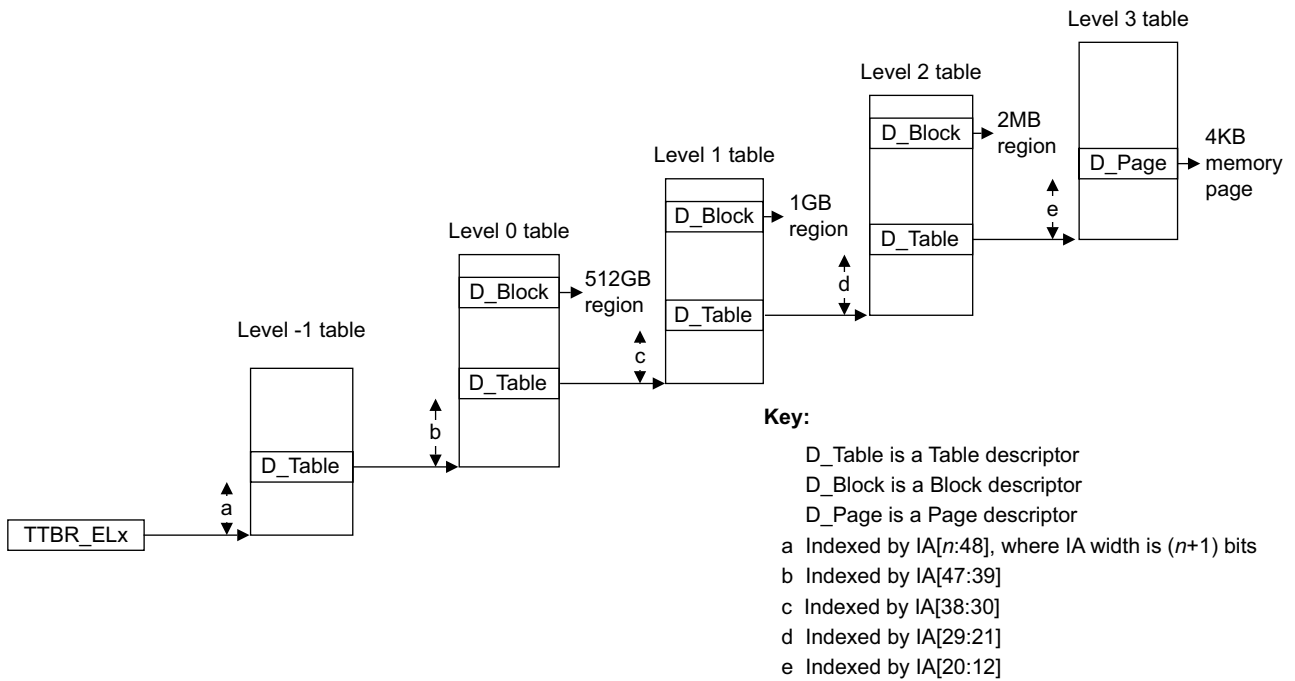

Figure D5-7 General view of VMSAv8-64 stage 1 address translation, 4KB granule, up to 52 bit IA

Overview of stage 2 translations, 4KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information, see *Use of concatenated translation tables for the initial stage 2 lookup* on page D5-2724.

When using the 4KB translation granule, Table D5-14 on page D5-2709 shows all possibilities for the initial lookup for a stage 2 translation.

Table D5-14 VTCR_EL2.T0SZ values and IA ranges, 4KB granule with possible concatenation of translation tables

Tables ^a	1	2	4	8	16					
	T0SZ values and input address ranges^b for starting at this level									
Initial lookup level	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA
-1 ^c	12-15	IA[51:12]- IA[48:12]								
0	16-24	IA[47:12]- IA[39:12]	15 ^c	IA[48:1 2]	14 ^c	IA[49:1 2]	13 ^c	IA[50:1 2]	12 ^c	IA[51:1 2]

Table D5-14 VTCR_EL2.T0SZ values and IA ranges, 4KB granule with possible concatenation of translation tables

Tables ^a	1		2		4		8		16	
Initial lookup level	T0SZ values and input address ranges ^b for starting at this level									
	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA
1	25-33	IA[38:12]- IA[30:12]	24	IA[39:1 2]	23	IA[40:1 2]	22	IA[41:1 2]	21	IA[42:1 2]
2	34-42 ^d	IA[29:12]- IA[21:12]	33	IA[30:1 2]	32	IA[31:1 2]	31	IA[32:1 2]	30	IA[33:1 2]
3 ^c	43-48	IA[20:12]- IA[15:12]	42	IA[21:1 2]	41	IA[22:1 2]	40	IA[23:1 2]	39	IA[24:1 2]

- Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, also shown in [Table D5-13 on page D5-2708](#).
- The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the Note that follows.
- Only supported when the *Effective value* of VTCR_EL2.DS is 1.
- If FEAT_TTST is not implemented or while the PE is executing in AArch32 state, the maximum value of T0SZ is 39 with corresponding IA[29:12]-IA[24:12].
- If FEAT_TTST is implemented, while the PE is executing in AArch64 state, and is using 4KB granules, an initial lookup level 3, (VTCR_EL2.SL0 == 3) is possible.

Note

- Because concatenating translation tables reduces the number of levels of lookup required, when using the 4KB translation granule:
 - When the input address is 48 bits or less, tables cannot be concatenated at level -1.
 - When the input address is more than 48 bits, tables cannot be concatenated at level -1.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

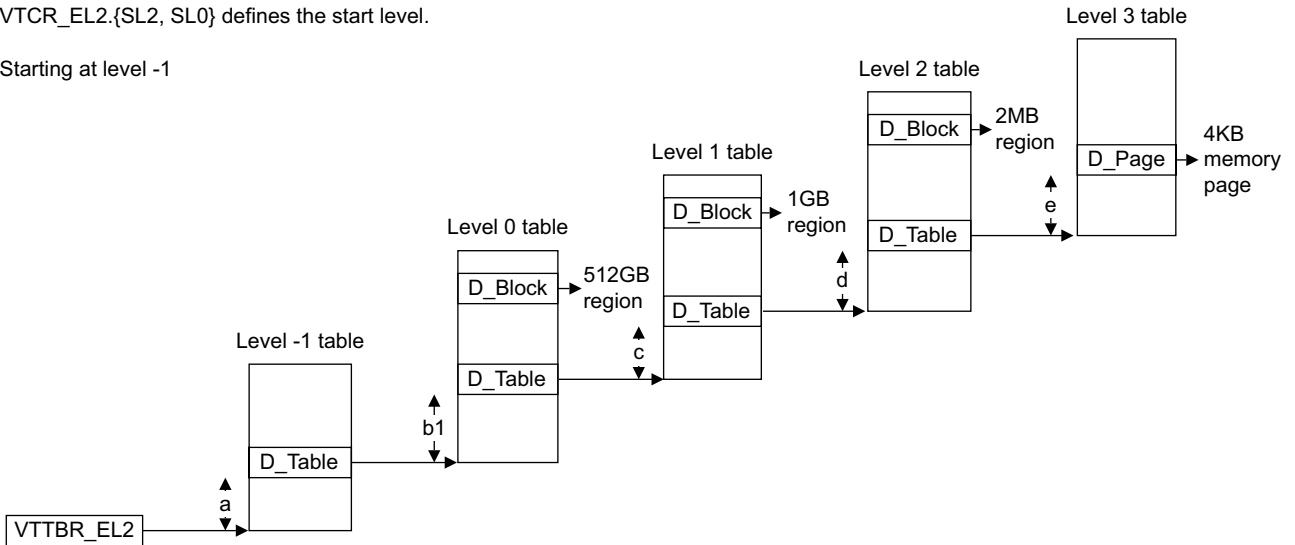

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0, SL2} values. [Table D5-14 on page D5-2709](#) shows the permitted T0SZ values for each initial lookup level. [Table D5-7 on page D5-2694](#) shows the relationship between the permitted VTCR_EL2.{T0SZ, SL0, SL2} values.

If FEAT_LPA2 is implemented, lookup level -1 is the initial lookup level when VTCR_EL2.{SL0, SL2} is {0,1}. For all other lookup levels, the *Effective value* of VTCR_EL2.SL2 is 0. When a translation table walk is started, if the T0SZ value is not consistent with the combined SL0 and SL2 value, or VTCR_EL2.{SL0, SL2} is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

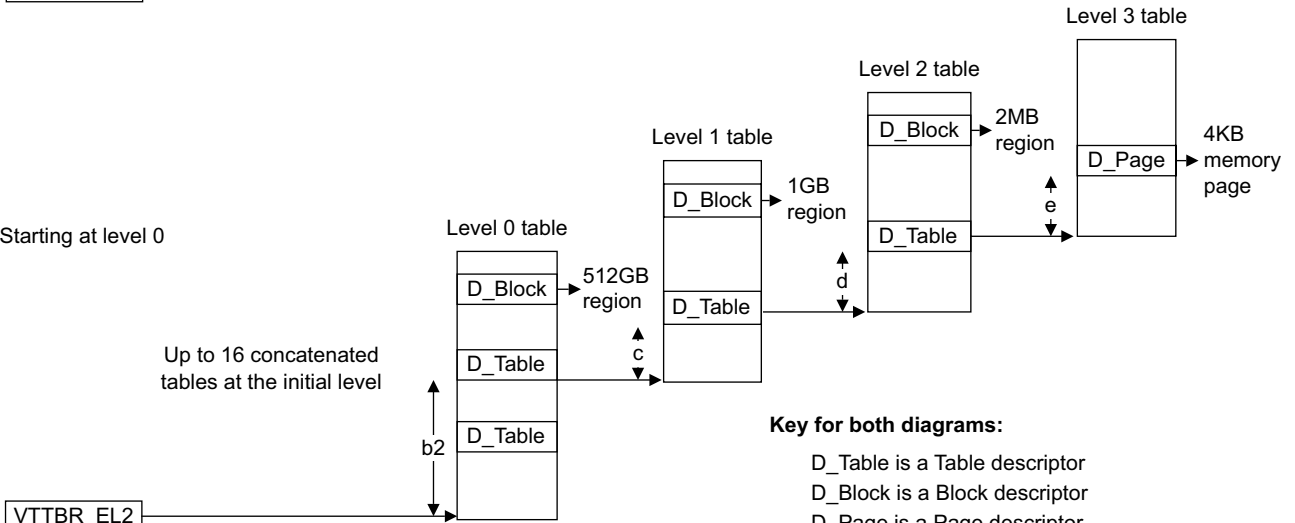

[Figure D5-8 on page D5-2711](#) shows the stage 2 address translation using the 4KB granule and an input address size up to 52 bits. For an input address size greater than 48 bits, the lookup can start at either level -1 or level 0. An input address size greater than 48 bits requires implementation of FEAT_LPA2.

VTCR_EL2.{SL2, SL0} defines the start level.

Starting at level -1

Starting at level 0

Key for both diagrams:

- D_Table is a Table descriptor
- D_Block is a Block descriptor
- D_Page is a Page descriptor
- a Indexed by IA[n:48], where IA width is (n+1) bits
- b1 Indexed by IA[47:39]
- b2 Indexed by IA[n:39], where IA width is (n+1) bits
- c Indexed by IA[38:30]
- d Indexed by IA[29:21]
- e Indexed by IA[20:12]

Figure D5-8 General view of VMSAv8-64 stage 2 address translation, 4KB granule, up to 52 bit IA

Overview of VMSAv8-64 address translation using the 16KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 16KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding `TCR_ELx.TnSZ` field. When using the 16KB translation granule, [Table D5-15 on page D5-2712](#) shows this requirement.

Table D5-15 `TCR_ELx.TnSZ` values and IA ranges, 16KB granule with no concatenation of tables

Initial lookup level	TnSZ values for and input address ranges ^a for starting at this level			
	TnSZ _{min}	IA _{max}	TnSZ _{max}	IA _{min}
0	12 ^b	IA[51:14] ^b	16	IA[47:14]
1	17	IA[46:14]	27	IA[36:14]
2	28	IA[35:14]	38	IA[25:14]
3	39	IA[24:14]	48 ^c	IA[15:14]

- The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.
- If the *Effective value* of `TCR_ELx.DS` is 0, TnSZ_{min} is 16, and IA_{max} is IA[47:14].
- If `FEAT_TTST` is not implemented, the maximum is 39.

The configuration options for an initial lookup at level 1, level 2, or level 3 are also permitted for stage 2 translations. If the *Effective value* of `TCR_ELx.DS` is 1, an initial lookup at level 0 is permitted for stage 2 translations. Otherwise, an initial lookup at level 0 is not permitted.

Note

- When using the 16KB translation granule, if `FEAT_LPA2` is not implemented, a maximum of 1 bit of IA is resolved by a level 0 lookup.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

[Figure D5-9 on page D5-2713](#) shows the stage 1 address translation using the 16KB granule and an input address size up to 52 bits. An input address size greater than 48 bits requires implementation of `FEAT_LPA2`.

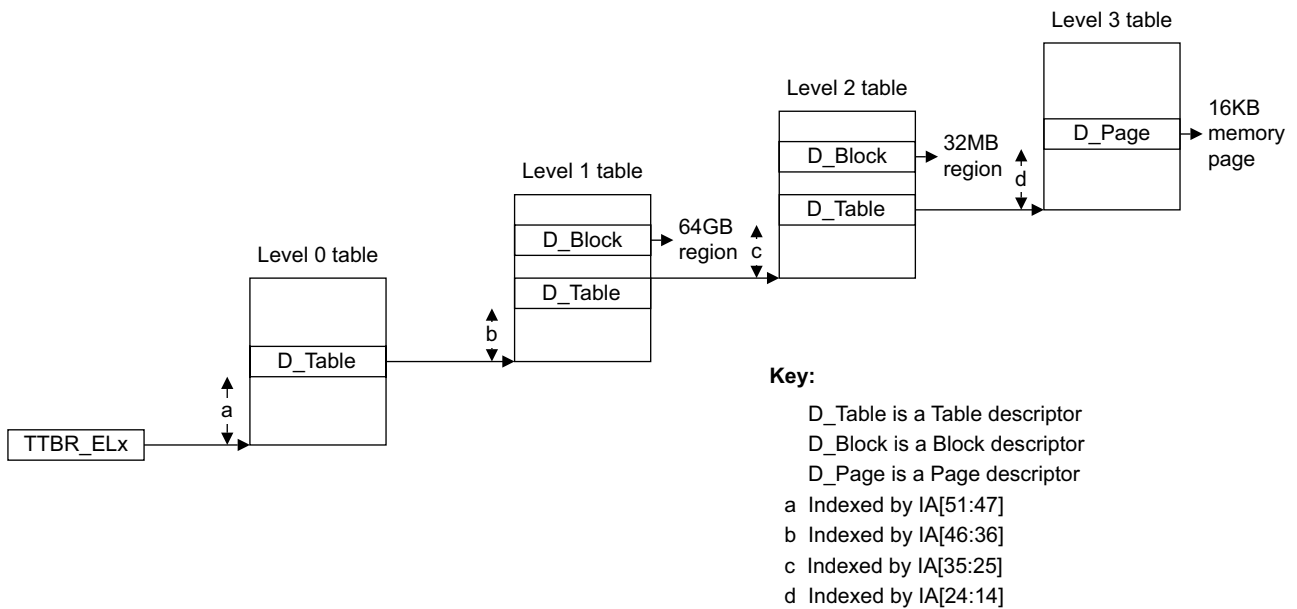

Figure D5-9 General view of VMSAv8-64 stage 1 address translation, 16KB granule, up to 52 bit IA

Overview of stage 2 translations, 16KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information, see [Use of concatenated translation tables for the initial stage 2 lookup on page D5-2724](#).

When using the 16KB granule, for a stage 2 translation with an input address size of 48 bits, the initial lookup is determined as follows:

- If the *Effective value* of VTCR_EL2.DS is 0, the initial lookup must be at level 1, with two concatenated translation tables at this level.
- If the *Effective value* of VTCR_EL2.DS is 1, the initial lookup can be at level 0, with up to 16 concatenated translation tables at this level.

When using the 16KB translation granule, [Table D5-16 on page D5-2714](#) shows all possibilities for the initial lookup for a stage 2 translation.

Table D5-16 VTCR_EL2.T0SZ values and IA ranges, 16KB granule with possible concatenation of translation tables

Tables ^a	T0SZ values and input address ranges ^b for starting at this level									
Initial lookup level (SL0 value)	1		2		4		8		16	
	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA
0 ^c (3)	16-26	IA[47:14] - IA[37:14]	15	IA[48:14]	14	IA[49:14]	13	IA[50:14]	12	IA[51:14]
1 (2)	17-27	IA[46:14] - IA[36:14]	16	IA[47:14]	15 ^c	IA[48:14]	14 ^c	IA[49:14]	13 ^c	IA[50:14]
2 (1)	28-38	IA[35:14] - IA[25:14]	27	IA[36:14]	26	IA[37:14]	25	IA[38:14]	24	IA[39:14]
3 (0)	39-48 ^d	IA[24:14] - IA[15:14]	38	IA[25:14]	37	IA[26:14]	36	IA[27:14]	35	IA[28:14]

- a. Number of concatenated translation tables at the initial lookup level. *1 table* corresponds to no concatenation, also shown in [Table D5-15 on page D5-2712](#).
- b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the Note that follows.
- c. Only supported when the *Effective value* of VTCR_EL2.DS is 1.
- d. If FEAT_TTST is not implemented or while the PE is executing in AArch32 state, the maximum value of T0SZ is 39 with corresponding IA[24:14].

———— **Note** —————

Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

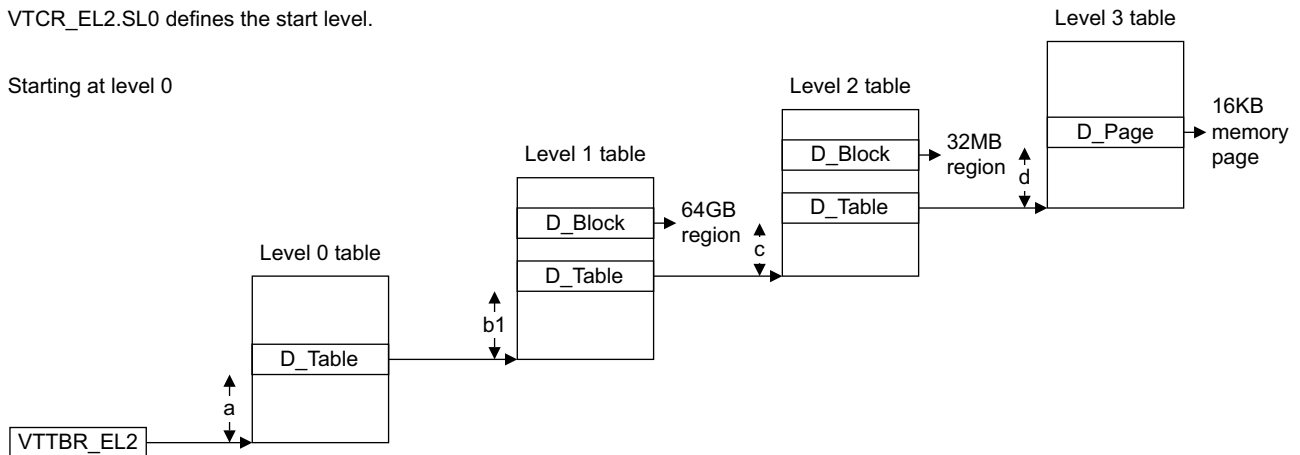

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. [Table D5-16 on page D5-2714](#) shows the permitted values of T0SZ for each initial lookup level.

When a translation table walk is started, if the T0SZ value is not consistent with the SL0 value, or VTCR_EL2.SL0 is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

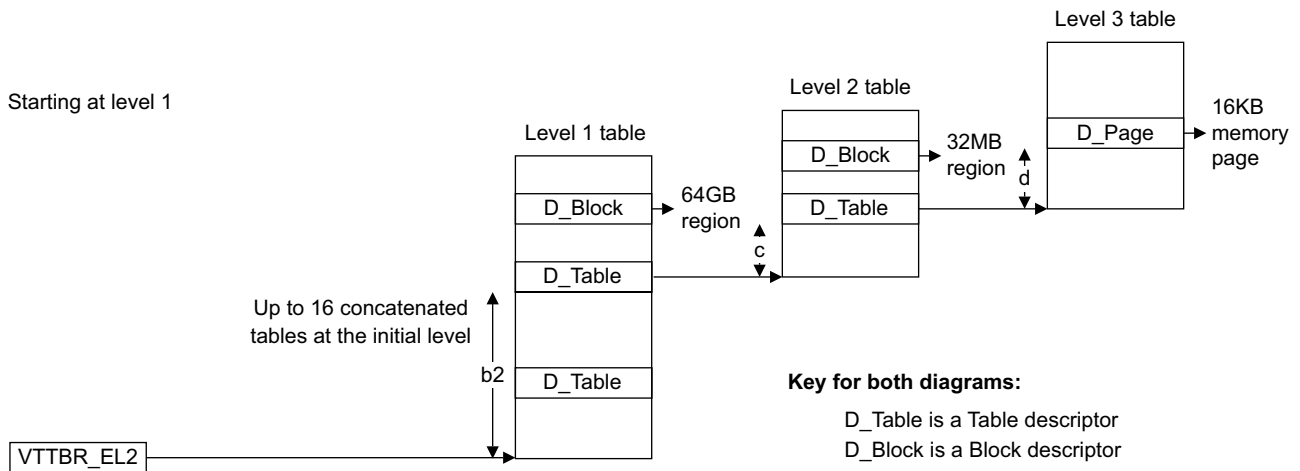

[Figure D5-10 on page D5-2715](#) shows the stage 2 address translation using the 16KB granule with an input address size up to 52 bits. An input address size greater than 48 bits requires implementation of FEAT_LPA2. When stage 2 translation supports a 48-bit input address range and FEAT_LPA2 is not implemented, translation must start with a level 1 lookup using two concatenated translation tables.

VTCR_EL2.SL0 defines the start level.

Figure D5-10 General view of VMSAv8-64 stage 2 address translation, 16KB granule, up to 52 bit IA

Overview of VMSAv8-64 address translation using the 64KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 64KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding `TCR_ELx.TnSZ` field. When using the 64KB translation granule, [Table D5-17 on page D5-2716](#) shows this requirement.

Table D5-17 `TCR_ELx.TnSZ` values and IA ranges, 64KB granule with no concatenation of tables

Lookup level	TnSZ values for and input address ranges ^a for starting at this level			
	TnSZ _{min}	IA _{max}	TnSZ _{max}	IA _{min}
1 ^b	12	IA[51:16]	21	IA[42:16]
1	16	IA[47:16]	21	IA[42:16]
2	22	IA[41:16]	34	IA[29:16]
3	35	IA[28:16]	47 ^c	IA[16:16]

- a. The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.
- b. Supported only if `FEAT_LVA` is implemented and the 64KB translation granule is used, see [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695](#).
- c. If `FEAT_TTST` is not implemented or while the PE is executing in AArch32 state, the maximum value of `TnSZ` is 39 with IA[24:16].

These configuration options are also permitted for stage 2 translations.

Note

- When using the 64KB translation granule, there are no level 0 lookups.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, IA[15:0] = OA[15:0] for all translations.
- When `FEAT_LPA` is implemented, a level 1 block attribute is supported when using the 64KB granule.

Figure D5-11 on page D5-2717 shows the stage 1 address translation using the 64KB granule with an input address size up to 52 bits. An input address size greater than 48 bits requires implementation of FEAT_LVA.

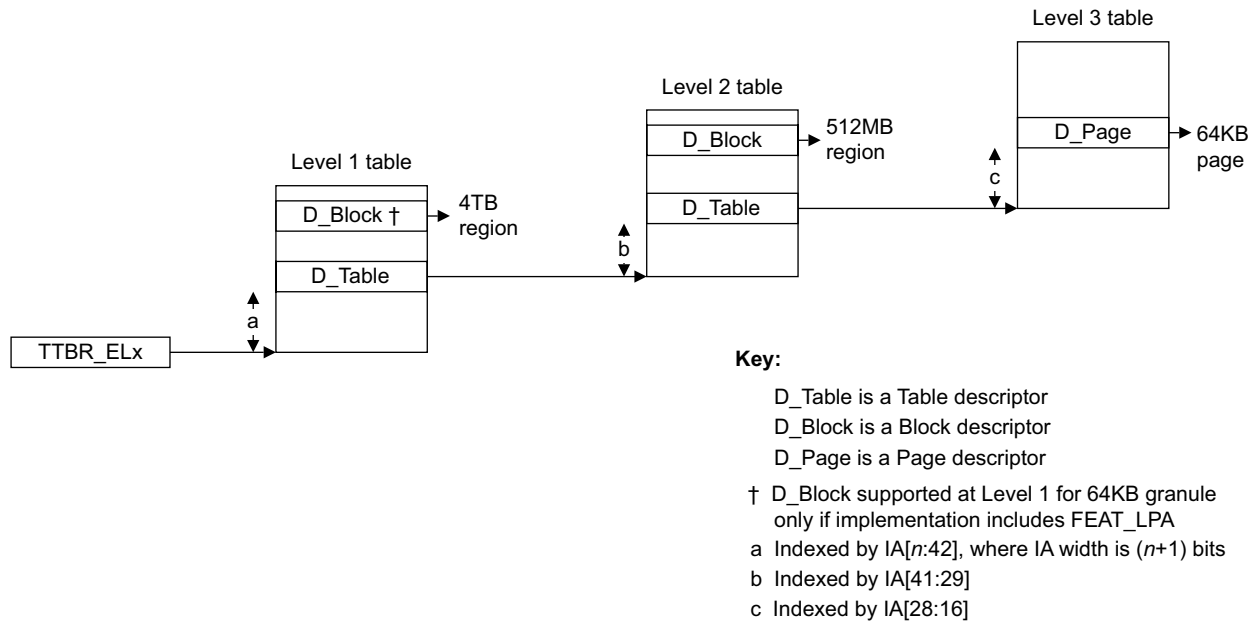

Figure D5-11 General view of VMSAv8-64 stage 1 address translation, 64KB granule with 52-bit VA support

Overview of stage 2 translations, 64KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information, see [Use of concatenated translation tables for the initial stage 2 lookup on page D5-2724](#).

When using the 64KB translation granule, [Table D5-18 on page D5-2717](#) shows all possibilities for the initial lookup for a stage 2 translation.

Table D5-18 VTCR_EL2.T0SZ values and IA ranges, 64KB granule with possible concatenation of translation tables

Tables ^a	1		2		4		8		16	
Initial lookup level (SL0 value)	T0SZ values and input address ranges ^b for starting at this level									
	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA
1 ^c (2)	12-21	IA[51:16]- IA[48:16]	-	-	-	-	-	-	-	-
1 (2)	16-21	IA[47:16]- IA[42:16]	-	-	-	-	-	-	-	-
2 (1)	22-34	IA[41:16]- IA[29:16]	21	IA[42:16]	20	IA[43:16]	19	IA[44:16]	18	IA[45:16]
3 (0)	35-47 ^d	IA[28:16]- IA[16:16]	34	IA[29:16]	33	IA[30:16]	32	IA[31:16]	31	IA[32:16]

a. Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, also shown in [Table D5-17 on page D5-2716](#).

- b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the *Note* that follows.
- c. Only supported if the PA size is 52 bits, see [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695](#).
- d. If `FEAT_TTST` is not implemented or while the PE is executing in AArch32 state, the maximum T0SZ value is 39, with IA[24:16].

Note

- When using the 64KB translation granule, there are no level 0 lookups.
- Because concatenating translation tables reduces the number of levels of lookup required, when using the 64KB translation granule, tables cannot be concatenated at level 1.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, $IA[15:0] = OA[15:0]$ for all translations.

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted `VTCR_EL2.{T0SZ, SL0}` values. [Table D5-18 on page D5-2717](#) shows the permitted values of T0SZ for each initial lookup level.

When a translation table walk is started, if the T0SZ value is not consistent with the SL0 value, or `VTCR_EL2.SL0` is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

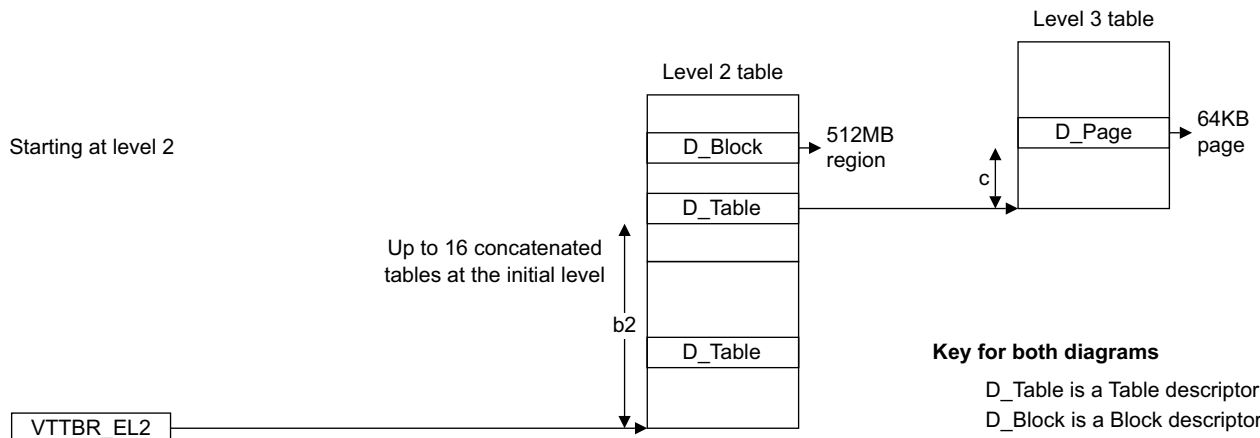

[Figure D5-12 on page D5-2718](#) shows the stage 2 address translation, for an input address size of between 43 and 46 bits. This means the lookup can start at either level 1 or level 2.

`VTCR_EL2.SL0` defines the start level.

Starting at level 1

Starting at level 2

Figure D5-12 General view of VMSAv8-64 stage 2 address translation, 64KB granule

D5.2.7 The VMSAv8-64 translation table format

This section provides the full description of the VMSAv8-64 translation table format, its use for address translations that are controlled by an Exception level using AArch64. For these translation regimes:

For a stage 1 translation that can support two VA ranges

- For the lower VA range, that uses [TTBR0_ELx](#):
 - The [TCR_ELx](#).{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
 - The [TCR_ELx](#).TG0 field defines the Translation granule size.
 - If [FEAT_LPA2](#) is implemented, when using the 4KB and 16KB translation granules, the [TCR_ELx](#).DS field determines whether addresses greater than 48 bits are supported.
- For the upper VA range, that uses [TTBR1_ELx](#):
 - The [TCR_ELx](#).{SH1, ORGN1, IRGN1} fields define memory region attributes for the translation table walks.
 - The [TCR_ELx](#).TG1 field defines the Translation granule size.
 - If [FEAT_LPA2](#) is implemented, when using the 4KB and 16KB translation granules, the [TCR_ELx](#).DS field determines whether addresses greater than 48 bits are supported.
- Each of [TTBR0_ELx](#) and [TTBR1_ELx](#) contains an ASID field, and the [TCR_ELx](#).A1 field selects which of these specifies the [ASID](#) to use.

For a stage 1 translation that supports only one VA range

The translation table walks use [TTBR0_ELx](#), and:

- The [TCR_ELx](#).{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The [TCR_ELx](#).TG0 field defines the Translation granule size.
- If [FEAT_LPA2](#) is implemented, when using the 4KB and 16KB translation granules, the [TCR_ELx](#).DS field determines whether addresses greater than 48 bits are supported.

For a stage 2 translation

The Non-secure translation table walks use [VTTBR_EL2](#), and:

- The [VTCR_EL2](#).{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The [VTCR_EL2](#).TG0 field defines the Translation granule size.
- If [FEAT_LPA2](#) is implemented:
 - When using the 4KB and 16KB translation granules, the [VTCR_EL2](#).DS field determines whether addresses greater than 48 bits are supported.
 - When using the 4KB translation granule and [VTCR_EL2](#).DS is 1, the [VTCR_EL2](#).SL2 field is combined with the [VTCR_EL2](#).SL0 field to determine the initial lookup level.

The Secure translation table walks use [VSTTBR_EL2](#), and:

- The [VTCR_EL2](#).{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The [VSTCR_EL2](#).TG0 field defines the Translation granule size.
- If [FEAT_LPA2](#) is implemented:
 - When using the 4KB and 16KB translation granules, the [VTCR_EL2](#).DS field determines whether addresses greater than 48 bits are supported.
 - When using the 4KB translation granule and [VSTCR_EL2](#).DS is 1, the [VSTCR_EL2](#).SL2 field is combined with the [VSTCR_EL2](#).SL0 field to determine the initial lookup level.

For the VMSAv8-64 translation table format, [Overview of the VMSAv8-64 address translation stages on page D5-2708](#) summarizes the lookup levels, and [Descriptor encodings, Armv8 level 0, level 1, and level 2 formats on page D5-2742](#) describes the translation table entries.

The following subsections describe the use of this translation table format:

- [Translation granule size and associated block and page sizes on page D5-2720.](#)
- [Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D5-2723.](#)
- [Use of concatenated translation tables for the initial stage 2 lookup on page D5-2724.](#)
- [Possible errors in programming the translation table registers on page D5-2726.](#)

Translation granule size and associated block and page sizes

Table D5-19 on page D5-2720 shows the supported granule sizes, block sizes and page sizes, for the different granule sizes. In the table, the OA bit ranges are the OA bits that the Translation Table descriptor specifies to address the block or page of memory, in an implementation that supports a 52-bit OA range.

Table D5-19 Translation granule sizes, with block and page sizes, and output address ranges

Granule size	Table level	Block size and OA bit range	Page size and OA bit range
4KB	Minus one ^a	-	-
	Zero	512GB, OA[51:39] ^a	-
	One	1GB, OA[47:30]	-
	Two	2MB, OA[47:21]	-
	Three	-	4KB, OA[47:12]
16KB	Zero	-	-
	One	64GB, OA[51:36] ^a	-
	Two	32MB, OA[47:25]	-
	Three	-	16KB, OA[47:14]
64KB	One	4TB, OA[51:42] ^b	-
	Two	512MB, OA[47:29]	-
	Three	-	64KB, OA[47:16]

a. Only available when FEAT_LPA2 is implemented, see [Extending addressing above 48 bits when using the 4KB or 16KB translation granule on page D5-2696.](#)

b. Only available when FEAT_LPA is implemented, see [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695.](#)

Bit[1] of a Translation Table descriptor identifies whether the descriptor is a Block descriptor, and:

- The 4KB granule size supports Block descriptors in level 1 and level 2 translation tables. If FEAT_LPA2 is implemented and the implementation supports 52 bits of physical address, Block descriptors in level 0 translation tables are also supported
- The 16KB granule size supports Block descriptors in level 2 translation tables. If FEAT_LPA2 is implemented and the implementation supports 52 bits of physical address, Block descriptors in level 1 translation tables are also supported.
- The 64KB granule size supports Block descriptors in level 2 translation tables. If FEAT_LPA is implemented and the implementation supports 52 bits of physical address, Block descriptors in level 1 translation tables are also supported.

If descriptor bit[1] is 0 in a translation table that does not support Block descriptors then a translation table walk that accesses that descriptor generates a level 1 Translation fault.

For translations managed from AArch64 state, the following tables expand the information for each granule size, showing for an access to a single translation table at each lookup level:

- The maximum IA size, and the address bits that are resolved for that maximum size.
- The maximum OA range resolved by the Translation Table descriptors at this level, and the corresponding memory region size.
- The maximum size of the translation table. This is the size required for the maximum IA size.

Table D5-20 on page D5-2721 shows this information for the 4KB translation granule size, Table D5-21 on page D5-2721 shows this information for the 16KB translation granule size, and Table D5-22 on page D5-2722 shows this information for the 64KB translation granule size.

Table D5-20 Properties of the address lookup levels, 4KB granule size

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region ^a		
Minus one ^b	4PB	Address[51:48]	Address[51:48]	256TB	Up to 16 ^c	No
Zero	256TB	Address[47:39]	Address[47:39]	512GB	Up to 512	No
			Address[51:39] ^b	512GB	Up to 512	Yes ^b
One	512GB	Address[38:30]	Address[47:30]	1GB	Up to 512	Yes
			Address[51:30] ^b	1GB	Up to 512	Yes
Two	1GB	Address[29:21]	Address[47:21]	2MB	Up to 512	Yes
			Address[51:21] ^b	2MB	Up to 512	Yes
Three	2MB	Address[20:12]	Address[47:12]	4KB	512	Page only
			Address[51:21] ^b	4KB	512	Page only

- a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.
b. Only when FEAT_LPA2 is supported.
c. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.

Table D5-21 Properties of the address lookup levels, 16KB granule size

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region ^a		
Zero	256TB	Address[47]	Address[47]	128TB	2 ^b	No
	4PB ^c	Address[51:47] ^c	Address[51:47] ^c	128TB	Up to 32 ^{bc}	No
One	128TB	Address[46:36]	Address[47:36]	64GB	Up to 2048	No
			Address[51:36] ^c	64GB	Up to 2048	Yes ^c

Table D5-21 Properties of the address lookup levels, 16KB granule size (continued)

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region ^a		
Two	64GB	Address[35:25]	Address[47:25]	32MB	Up to 2048	Yes
			Address[51:25] ^c	32MB		
Three	32MB	Address[24:14]	Address[47:14]	16KB	2048	Page only
			Address[51:14] ^c	16KB		

- a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.
b. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.
c. Only when [FEAT_LPA2](#) is supported.

Table D5-22 Properties of the address lookup levels, 64KB granule size

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region ^a		
One	256TB	Address[47:42]	Address[47:42]	4TB	Up to 64 ^b	No
			Address[51:42] ^c	Address[51:42] ^d		
Two	4TB	Address[41:29]	Address[47:29]	512MB	Up to 8192	Yes
			Address[51:29] ^d	512MB		
Three	512MB	Address[28:16]	Address[47:16]	64KB	8192	Page only
			Address[51:16] ^d	64KB		

- a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.
b. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.
c. For stage 1 translations, only when [FEAT_LVA](#) is supported. For stage 2 translations, only when [FEAT_LPA](#) is supported.
d. Only when [FEAT_LPA](#) is supported.

For the initial lookup level:

- If the IA range specified by the [TCR_ELx.TxSZ](#) field is smaller than the maximum size shown in these table then this reduces the number of addresses in the table and therefore reduces the table size. The smaller translation table is aligned to its table size.
- For stage 2 translations, multiple translation tables can be concatenated to extend the maximum IA size beyond that shown in these tables. For more information, see the stage 2 translation overviews in [Overview of the VMSAv8-64 address translation stages on page D5-2708](#) and [Use of concatenated translation tables for the initial stage 2 lookup on page D5-2724](#).

If a supplied input address is larger than the configured input address size, a Translation fault is generated.

———— **Note** ————

Larger translation granule sizes typically requires fewer levels of translation tables to translate a particular size of VA.

For the `TCR_ELx` programming requirements for the initial lookup, see *Overview of the VMSAv8-64 address translation stages* on page D5-2708.

Selection between `TTBR0_ELx` and `TTBR1_ELx` when two VA ranges are supported

Every translation table walk starts by accessing the translation table addressed by the `TTBR_ELx` for the stage 1 translation for the required translation regime.

For a stage 1 translation that can support two VA ranges, [Figure D5-13 on page D5-2723](#) shows this VA range split when using 48-bit VAs, and:

- `TTBR0_ELx` points to the initial translation table for the lower VA range, that starts at address `0x0000000000000000`.
- `TTBR1_ELx` points to the initial translation table for the upper VA range, that runs up to address `0xFFFFFFFFFFFFFFFF`.

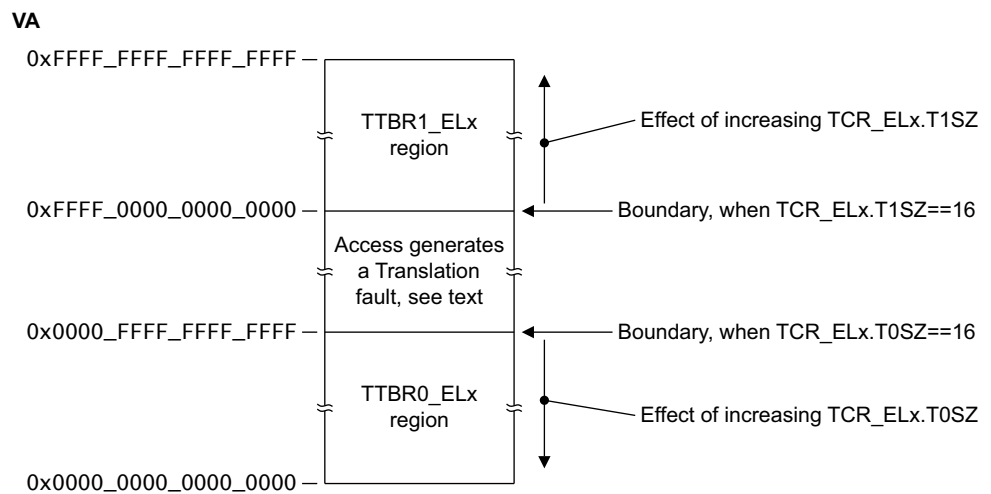

Figure D5-13 AArch64 `TTBRn` boundaries and VA ranges for 48-bit VAs

As [Figure D5-13 on page D5-2723](#) shows, for 48-bit VAs:

- The address range translated using `TTBR0_ELx` is `0x0000000000000000` to `0x0000FFFFFFFFFFFFFF`.
- The address range translated using `TTBR1_ELx` is `0xFFFF000000000000` to `0xFFFFFFFFFFFFFFFF`.

For 52-bit VAs, if `FEAT_LVA` is implemented and the 64KB translation granule is used, or the *Effective value* of `TCR_ELx.DS` is 1 and the 4KB or 16KB translation granule is used:

- The address range translated using `TTBR0_ELx` is `0x0000000000000000` to `0x000FFFFFFFFFFFFFFF`.
- The address range translated using `TTBR1_ELx` is `0xFFFF000000000000` to `0xFFFFFFFFFFFFFFFF`.

Which `TTBR_ELx` is used depends only on the VA presented for translation. The most significant bits of the VA must all be the same value and:

- If the most significant bits of the VA are zero, then `TTBR0_ELx` is used.
- If the most significant bits of the VA are one, then `TTBR1_ELx` is used.

However, it is configurable whether `VA[63:56]` are considered when determining which `TTBR_ELx` is used, as described in *Address tagging in AArch64 state* on page D5-2676.

Note

The handling of the Contiguous bit can mean that the boundary between the translation regions defined by the `TCR_ELx.TnSZ` values and the region for which an access generates a Translation fault is wider than shown in [Figure D5-13 on page D5-2723](#). That is, if the descriptor for an access to the region shown as generating a fault has the Contiguous bit set to 1, the access might not generate a fault. [Possible errors in programming the translation table registers on page D5-2726](#) describes this possibility.

[Example D5-3 on page D5-2724](#) shows a typical application of this VA split.

Example D5-3 Example use of the split VA range, and the TTBR0_ELx and TTBR1_ELx controls

An example of using the split VA range is:

TTBR0_ELx Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- `TTBR0_ELx` is updated to point to the level 1 translation table for the new context
- `TCR_ELx` is updated if this change changes the size of the translation table
- `CONTEXTIDR_ELx` is updated.

TTBR1_ELx Used for operating system and I/O addresses, that do not change on a context switch.

For each VA subrange, the input address size is $2^{(64-TnSZ)}$, where `TnSZ` is one of `TCR_ELx.{T0SZ, T1SZ}`,

This means the two VA subranges are:

Lower VA subrange `0x0000_0000_0000_0000` to $(2^{(64-T0SZ)} - 1)$.

Upper VA subrange $(2^{64} - 2^{(64-T1SZ)})$ to `0xFFFF_FFFF_FFFF_FFFF`.

If `FEAT_E0PD` is implemented, the `TCR_ELx.E0PD1` field can prevent unprivileged access to the addresses translated by `TTBR1_ELx`.

For the situation where the minimum `TnSZ` value is 16, corresponding to a maximum input address range of 48 bits, [Example D5-4 on page D5-2724](#) shows the two VA subranges when `T0SZ` and `T1SZ` are both set to this minimum value.

Example D5-4 Maximum VA ranges when a stage of translation supports two ranges

The maximum VA subranges correspond to `T0SZ` and `T1SZ` each having a minimum value of 16. In this case the subranges are:

Lower VA subrange `0x0000_0000_0000_0000` to `0x0000_FFFF_FFFF_FFFF`.

Upper VA subrange `0xFFFF_0000_0000_0000` to `0xFFFF_FFFF_FFFF_FFFF`.

[Figure D5-13 on page D5-2723](#) indicates the effect of varying the `TnSZ` values.

As described in [Overview of the VMSAv8-64 address translation stages on page D5-2708](#), the `TnSZ` values also determine the initial lookup level for the translation.

Use of concatenated translation tables for the initial stage 2 lookup

[Overview of the VMSAv8-64 address translation stages on page D5-2708](#) introduced the ability to concatenate translation tables for the initial stage 2 translation lookup. This section gives more information about that concatenation.

If a stage 2 translation would require 16 entries or fewer in its top-level translation table, that stage of translation can, instead, be configured so that:

- It requires the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- The stage 2 translation starts at that next translation level.

When using the 16KB translation granule, if a 48-bit input address size is required for the stage 2 translations, lookup must start with two concatenated translation tables at level 1.

The use of concatenated translation tables requires the software that is defining the translation to:

- Define the concatenated translation tables with the required overall alignment.
- Program `VTTBR_EL2` or `VSTTBR_EL2` to hold the address of the first of the concatenated translation tables.
- Program `VTCR_EL2` or `VSTCR_EL2` to indicate the required input address range and initial lookup level.

———— **Note** ————

The use of concatenated translation tables avoids the overhead of an additional level of translation.

Concatenating additional translation tables at the initial level of look up resolves additional address bits at that level. To resolve n additional address bits requires 2^n concatenated translation tables. [Example D5-5 on page D5-2725](#) shows how, for level 1 lookups using the 4KB translation granule, translation tables can be concatenated to resolve three additional address bits.

Example D5-5 Adding three bits of address resolution at level 1 lookup, using the 4KB granule

When using the 4KB translation granule, a level 1 lookup with a single translation table resolves address bits[38:30]. To add three more address bits requires 2^3 translation tables, that is, eight translation tables. This means:

- The total size of the concatenated translation tables is $8 \times 4\text{KB} = 32\text{KB}$.
- This block of concatenated translation tables must be aligned to 32KB.
- The address range resolved at this lookup level is $A[41:30]$, of which:
 - Bits $A[41:39]$ select the 4KB translation table.
 - Bits $A[38:30]$ index a descriptor within that translation table.

As an example of the concatenation of translation tables at the initial lookup level, when using the 4KB translation granule, [Table D5-23 on page D5-2725](#) shows the possible uses of concatenated translation tables to permit lookup to start at level 1 rather than at level 0. For completeness, the table starts with the case where the required `IPA` range means lookup starts at level 1 with a single translation table at that level.

Table D5-23 Possible uses of concatenated translation tables for level 1 lookup, 4KB granule

Configured stage 2 IA size		Lookup starts at level 0	Lookup starts at level 1	
<code>IPA</code> range	Size	Required level 0 entries	Number of concatenated tables	Required alignment ^a
<code>IPA[38:0]</code>	2^{36} bytes	-	1	4KB
<code>IPA[39:0]</code>	2^{37} bytes	2	2	8KB
<code>IPA[40:0]</code>	2^{38} bytes	4	4	16KB
<code>IPA[41:0]</code>	2^{39} bytes	8	8	32KB
<code>IPA[42:0]</code>	2^{40} bytes	16	16	64KB

a. Required alignment of the set of concatenated level 2 tables.

Note

Because concatenation is permitted only for a stage 2 translation, the input addresses in the table are [IPAs](#).

[Overview of the VMSAv8-64 address translation stages on page D5-2708](#) identifies all of the possible uses of concatenation. In all cases, the block of concatenated translation tables must be aligned to the block size.

Possible errors in programming the translation table registers

This subsection describes possible errors in programming the translation table registers.

Misprogramming the `VTCR_EL2.{T0SZ, SL0, SL2}` and `VSTCR_EL2.{T0SZ, SL0, SL2}` fields

The following programming errors can cause a stage 2 level 0 Translation fault to occur during a stage 2 translation table walk:

- Programming the `VTCR_EL2`{T0SZ, SL0} or `VSTCR_EL2`{T0SZ, SL0} fields to inconsistent values.
- Programming the `VTCR_EL2.SL0` or `VSTCR_EL2.SL0` to a reserved value.
- If the *Effective value* of `VTCR_EL2.DS` is 1 and the 4KB translation granule is used, programming the `VTCR_EL2`{T0SZ, SL0, SL2} or `VSTCR_EL2`{T0SZ, SL0, SL2} fields to inconsistent values.

For more information, see [Overview of the VMSAv8-64 address translation stages on page D5-2708](#).

Misprogramming of the Contiguous bit

For more information about the Contiguous bit, and the range of translation table entries that must have the bit set to 1 to mark the entries as contiguous, see [The Contiguous bit on page D5-2782](#).

If one or more of the following errors is made in programming the translation tables, the TLB might contain overlapping entries:

- One or more of the contiguous translation table entries does not have the Contiguous bit set to 1.
- One or more of the contiguous translation table entries holds an output address that is not consistent with all of the entries pointing to the same aligned contiguous address range.
- The attributes and permissions of the contiguous entries are not all the same.

Such misprogramming of the translation tables means the output address, memory permissions, or attributes for a lookup might be corrupted, and might be equal to values that are not consistent with any of the programmed translation table values.

In some implementations, such misprogramming might also give rise to a TLB Conflict abort.

The architecture guarantees that misprogramming of the Contiguous bit cannot provide a mechanism for any of the following to occur:

- Software executing at EL1 or EL0 accessing regions of physical memory that are not accessible by programming the translation tables, from EL1, with arbitrary chosen values that do not misprogram the Contiguous bit.
- Software executing at EL1 or EL0 accessing regions of physical memory with attributes or permissions that are not possible by programming the translation tables, from EL1, with arbitrary chosen values that do not misprogram the Contiguous bit.
- Software executing in Non-secure state accessing Secure physical memory.

Note

Hardware implementations must ensure that use of the Contiguous bit cannot provide a mechanism for avoiding output address range checking. This might occur if a Contiguous bit block size of 0.5GB or 1GB is used in a system with the output address size configured to 4GB. The architecture permits the implemented mechanism for preventing any avoidance of output address range checking to suppress the use of the Contiguous bit for such entries in such a system.

Where the Contiguous bit is used to mark a set of blocks as contiguous, if the address range translated by a set of blocks marked as contiguous is larger than the size of the input address supported at a stage of translation used to translate that address at that stage of translation, as defined by the `TCR_ELx.TxSZ` field, then this is a programming error. An implementation is permitted, but not required, to:

- Treat such a block within a contiguous set of blocks as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation, as defined by the `TCR_ELx.TxSZ` field.
- Treat such a block within a contiguous set of blocks as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, as defined by the `TCR_ELx.TxSZ` field, provided that both of the following apply:
 - The block is valid.
 - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

When `FEAT_LVA` is implemented, level 1 Block descriptors for the 64KB granule do not support the Contiguous bit, and that field is `RES0`. When the *Effective value* of `VTCR_EL2.DS` is 1, level 0 Block descriptors for the 4KB granule and level 1 Block descriptors for the 16KB granule do not support the Contiguous bit, and that field is `RES0`.

D5.2.8 The algorithm for finding the Translation Table descriptors

This subsection gives the algorithms for finding the Translation Table descriptor that corresponds to a given IA, for each required level of lookup. The algorithms encode the descriptions of address translation given earlier in this section. The algorithm details depend on the translation granule size for the stage of address translation, see:

- [Finding the Translation Table descriptor when using the 4KB translation granule on page D5-2728.](#)
- [Finding the Translation Table descriptor when using the 16KB translation granule on page D5-2729.](#)
- [Finding the Translation Table descriptor when using the 64KB translation granule on page D5-2730.](#)

Each subsection uses the following terms:

BaseAddr	The base address for the level of lookup, as defined by: <ul style="list-style-type: none"> • For the initial lookup level, the value of the appropriate <code>TTBR_ELx.BADDR</code> field. • Otherwise, the translation table address returned by the previous level of lookup.
PAMax	The supported <code>PA</code> width, in bits.
IA	The supplied IA for this stage of translation.
TnSZ	The translation table size for this stage of translation: <ul style="list-style-type: none"> For EL1&0 stage 1 <code>TCR_EL1.T0SZ</code> or <code>TCR_EL1.T1SZ</code>, as appropriate. For Non-secure EL1&0 stage 2 <code>VTCR_EL2.T0SZ</code>. For Secure EL1&0 stage 2 <code>VSTCR_EL2.T0SZ</code>. For EL2 stage 1 <code>TCR_EL2.T0SZ</code>. For EL2&0 stage 1 <code>TCR_EL2.T0SZ</code> or <code>TCR_EL2.T1SZ</code>, as appropriate. For EL3 stage 1 <code>TCR_EL3.T0SZ</code>.
SL0	The initial lookup level for this stage of translation: <ul style="list-style-type: none"> For Non-secure EL1&0 stage 2 translation <code>VTCR_EL2.SL0</code> For Secure EL1&0 stage 2 translation <code>VSTCR_EL2.SL0</code>

SL2 Combined with SL0, the initial lookup level for this stage of translation when the *Effective value* of `VTCR_EL2.DS` is 1 and using the 4KB translation granule:

For Non-secure EL1&0 stage 2 translation

`VTCR_EL2.SL2`

For Secure EL1&0 stage 2 translation

`VSTCR_EL2.SL2`

These subsections show only architecturally-valid programming of the `TCR_ELx`. See also *Possible errors in programming the translation table registers* on page D5-2726.

Finding the Translation Table descriptor when using the 4KB translation granule

Table D5-24 on page D5-2728 shows the Translation Table descriptor address, for each level of lookup, when using the 4KB translation granule. See the start of *The algorithm for finding the Translation Table descriptors* on page D5-2727 for more information about terms used in the table.

Table D5-24 Translation table entry addresses when using the 4KB translation granule

Lookup level	Entry address and conditions		General conditions
	Stage 1 translation	Stage 2 translation	
Minus one ^a	BaseAddr[PAMax-1:x]:IA[y:48]:0b000 if ^b $12 \leq TnSZ \leq 15$ then $x = (19 - TnSZ)$	BaseAddr[PAMax-1:x]:IA[y:48]:0b000 if $SL0 == 0$ and $SL2 == 1$ then if ^b $12 \leq T0SZ \leq 15$ then $x = (19 - T0SZ)$	$y = (x + 44)$
Zero	BaseAddr[PAMax-1:x]:IA[y:39]:0b000 if ^b $16 \leq TnSZ \leq 24$ then $x = (28 - TnSZ)$ else ^{a,c} $x = 12$	BaseAddr[PAMax-1:x]:IA[y:39]:0b000 if $SL0 == 2$ then if ^b $16 \leq T0SZ \leq 24$ then $x = (28 - T0SZ)$ elseif ^{a,c} $SL0 == 0$ and $SL2 == 1$ then $x = 12$	$y = (x + 35)$
One	BaseAddr[PAMax-1:x]:IA[y:30]:0b000 if ^b $25 \leq TnSZ \leq 33$ then $x = (37 - TnSZ)$ else ^c $x = 12$	BaseAddr[PAMax-1:x]:IA[y:30]:0b000 if $SL0 == 1$ then if ^b $21 \leq T0SZ \leq 33$ then $x = (37 - T0SZ)$ elseif ^c $SL0 == 2$ or $(SL0 == 0$ and $SL2 == 1)$ ^a then $x = 12$	$y = (x + 26)$
Two	BaseAddr[PAMax-1:x]:IA[y:21]:0b000 if ^b $34 \leq TnSZ \leq 42$ then $x = (46 - TnSZ)$ else ^c $x = 12$	BaseAddr[PAMax-1:x]:IA[y:21]:0b000 if $SL0 == 0$ then if ^b $30 \leq T0SZ \leq 42$ then $x = (46 - T0SZ)$ elseif ^c $SL0 == 1$ or 2 or $(SL0 == 0$ and $SL2 == 1)$ ^a then $x = 12$	$y = (x + 17)$
Three	BaseAddr[PAMax-1:x]:IA[y:12]:0b000 if ^b $43 \leq TnSZ \leq 48$ then $x = (55 - TnSZ)$ else ^c $x = 12$	BaseAddr[PAMax-1:x]:IA[y:12]:0b000 if $SL0 == 3$ then if ^b $39 \leq T0SZ \leq 48$ then $x = (55 - T0SZ)$ elseif ^c $SL0 = 0, 1, \text{ or } 2$ then $x = 12$	$y = (x + 8)$

a. Only when the *Effective value* of `VTCR_EL2.DS` is 1.

b. This line indicates the range of permitted values for `TnSZ`, for a lookup that starts at this level, see *Overview of VMSAv8-64 address translation using the 4KB translation granule* on page D5-2708.

c. This is the case where this level of lookup is not the initial level of lookup.

Table D5-8 on page D5-2698 shows how software can determine whether an implementation supports the 4KB granule size.

Finding the Translation Table descriptor when using the 16KB translation granule

Table D5-25 on page D5-2729 shows the Translation Table descriptor address, for each level of lookup, when using the 16KB translation granule. See the start of *The algorithm for finding the Translation Table descriptors* on page D5-2727 for more information about terms used in the table.

Table D5-25 Translation table entry addresses when using the 16KB translation granule

Lookup level	Entry address and conditions		General conditions
	Stage 1 translation	Stage 2 translation	
Zero ^a	BaseAddr[PAMax-1:x]:IA[y:47]:0b000 if ^b $12 \leq TnSZ \leq 16$ then $x = (20 - TnSZ)$	BaseAddr[PAMax-1:x]:IA[y:47]:0b000 if $SL0 == 3$ then if ^b $12 \leq T0SZ \leq 16$ then $x = (20 - T0SZ)$	$y = (x + 43)$
Zero	BaseAddr[PAMax-1:4]:IA[47]:0b000 if ^b $16 == TnSZ$	-	Only applies to stage 1
One	BaseAddr[PAMax-1:x]:IA[y:36]:0b000 if ^b $17 \leq TnSZ \leq 27$ then $x = (31 - TnSZ)$ else ^c $x = 14$	BaseAddr[PAMax-1:x]:IA[y:36]:0b000 if $SL0 == 2$ then if ^b $z \leq T0SZ \leq 27$ then $x = (31 - T0SZ)$ elseif ^{a,c} $SL0 == 3$ then $x = 14$	$y = (x + 32)$ $z = 16$ or 13^a
Two	BaseAddr[PAMax-1:x]:IA[y:25]:0b000 if ^b $28 \leq TnSZ \leq 38$ then $x = (42 - TnSZ)$ else ^c $x = 14$	BaseAddr[PAMax-1:x]:IA[y:25]:0b000 if $SL0 == 1$ then if ^b $24 \leq T0SZ \leq 38$ then $x = (42 - T0SZ)$ elseif ^c $SL0 == 2$ or 3^a then $x = 14$	$y = (x + 21)$
Three	BaseAddr[PAMax-1:x]:IA[y:14]:0b000 if ^b $39 \leq TnSZ \leq 48$ then $x = (53 - TnSZ)$ else ^c $x = 14$	BaseAddr[PAMax-1:x]:IA[y:14]:0b000 if $SL0 == 0$ then if ^b $35 \leq T0SZ \leq 48$ then $x = (53 - T0SZ)$ elseif ^c $SL0 == 1, 2,$ or 3^a then $x = 14$	$y = (x + 10)$

- a. Only when the *Effective value* of `VTCR_EL2.DS` is 1.
- b. This line indicates the range of permitted values for `TnSZ`, for a lookup that starts at this level, see *Overview of VMSAv8-64 address translation using the 16KB translation granule* on page D5-2712.
- c. This is the case where this level of lookup is not the initial level of lookup.

Table D5-8 on page D5-2698 shows how software can determine whether an implementation supports the 16KB granule size.

Finding the Translation Table descriptor when using the 64KB translation granule

Table D5-26 on page D5-2730 shows the Translation Table descriptor address, for each level of lookup, when using the 64KB translation granule. See the start of *The algorithm for finding the Translation Table descriptors* on page D5-2727 for more information about terms used in the table.

Table D5-26 Translation table entry addresses when using the 64KB translation granule

Lookup level	Entry address and conditions		General conditions
	Stage 1 translation	Stage 2 translation	
One	BaseAddr[PAMax-1:x]:IA[y:42]:0b000 if ^a $z^b \leq TnSZ \leq 21$ then $x = (25 - TnSZ)$	BaseAddr[PAMax-1:x]:IA[y:42]:0b000 if $SL0 == 2$ then if ^a $z^b \leq T0SZ \leq 21$ then $x = (25 - T0SZ)$	$y = (x + 38)$ $z = 16$ or 12^b
Two	BaseAddr[PAMax-1:x]:IA[y:29]:0b000 if ^a $22 \leq TnSZ \leq 34$ then $x = (38 - TnSZ)$ else ^c $x = 16$	BaseAddr[PAMax-1:x]:IA[y:29]:0b000 if $SL0 == 1$ then if ^a $18 \leq T0SZ \leq 34$ then $x = (38 - T0SZ)$ elseif $SL0^c == 2$ then $x = 16$	$y = (x + 25)$
Three	BaseAddr[PAMax-1:x]:IA[y:16]:0b000 if ^a $35 \leq TnSZ \leq 47$ then $x = (51 - TnSZ)$ else ^c $x = 16$	BaseAddr[PAMax-1:x]:IA[y:16]:0b000 if $SL0 == 0$ then if ^a $31 \leq T0SZ \leq 47$ then $x = (51 - T0SZ)$ elseif $SL0^c == 1$ or 2 then $x = 16$	$y = (x + 12)$

- This line indicates the range of permitted values for $TnSZ$, for a lookup that starts at this level, see *Overview of VMSAv8-64 address translation using the 64KB translation granule* on page D5-2716.
- If `FEAT_LVA` is implemented, the value of z is 12, see *Extending addressing above 48 bits when using the 64KB translation granule* on page D5-2695. Otherwise, the value of z is 16.
- This is the case where this level of lookup is not the initial level of lookup.

Table D5-8 on page D5-2698 shows how software can determine whether an implementation supports the 64KB granule size.

D5.2.9 The effects of disabling a stage of address translation

The following sections describe the effect on MMU behavior of disabling each stage of translation:

- [Behavior when stage 1 address translation is disabled on page D5-2731.](#)
- [Behavior when stage 2 address translation is disabled on page D5-2732.](#)
- [Behavior of instruction fetches when all associated stages of translation are disabled on page D5-2732.](#)

Behavior when stage 1 address translation is disabled

When a stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of translation are treated as follows:

EL1 and EL0 accesses if the `HCR_EL2.DC` bit is set to 1

For the EL1&0, when EL2 is enabled, translation regime, when the value of `HCR_EL2.DC` is 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate memory attributes.

———— **Note** —————

This applies for both instruction and data accesses.

When `FEAT_XS` is implemented, if `HCR_EL2.DC` is 1, the `XS` attribute is set to 0 at stage 1 of the translation. Otherwise, the `XS` attribute is set to 1 at stage 1 of the translation.

All other accesses

For all other accesses, when stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

Instruction access

The stage 1 translation assigns the Normal memory attribute, with the cacheability and shareability attributes determined by the value of the `SCTLR_ELx.I` bit for the translation regime, as follows:

When the value of `I` is 0

The stage 1 translation assigns the Non-cacheable and Outer Shareable attributes.

When the value of `I` is 1

The stage 1 translation assigns the Cacheable, Inner Write-Through Read-Allocate No Write-Allocate, Outer Write-Through Read-Allocate No Write-Allocate Outer Shareable attribute.

Secure accesses and Non-secure accesses

For accesses from the Non-secure state, the output address is to the Non-secure output address space.

For accesses from the Secure state, the output address is to the Secure output address space.

For this stage of translation:

- No memory access permission checks are performed, and therefore no MMU Permission faults can be generated for this stage of address translation.
- No memory is guarded.

———— **Note** —————

Alignment checking is performed, and therefore Alignment faults can occur.

For every access, the input address of the stage 1 translation is flat-mapped to the output address.

For a EL1 or EL0 access, if EL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

When the value of `HCR_EL2.DC` is 1:

- The `SCTLR_EL1.M` bit behaves as if it is 0, for all purposes other than reading the value of the bit. This means EL1&0 stage 1 address translation is disabled.
- The `HCR_EL2.VM` bit behaves as if it is 1, for all purposes other than reading the value of the bit. This means that EL1&0 stage 2 address translation is enabled.

See also [Behavior of instruction fetches when all associated stages of translation are disabled on page D5-2732](#).

Effect of disabling address translation on maintenance and address translation instruction instructions

Cache maintenance instructions act on the target cache regardless of whether any stages of address translation are disabled, and regardless of the values of the memory attributes. However, if a stage of address translation is disabled, they use the flat address mapping for that translation stage.

TLB invalidate operations act on the target TLB regardless of whether any stage of address translation is disabled.

The value of `HCR_EL2.DC` affect some address translation instructions, see [Address translation instructions, AT*](#) on page D5-2735.

Behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:

- The `IPA` output from the stage 1 translation maps flat to the `PA`.
- The memory attributes and permissions from the stage 1 translation apply to the `PA`.

When both stages of address translation are disabled, see also [Behavior of instruction fetches when all associated stages of translation are disabled on page D5-2732](#).

Secure accesses and Non-secure accesses

For accesses from the Non-secure IPA address space, the output address is to the Non-secure physical address space.

For accesses from the Secure IPA address space, the output address is to the Secure physical address space.

Behavior of instruction fetches when all associated stages of translation are disabled

When EL3 is using AArch64, this section applies to:

- The Secure EL1&0, when EL2 is disabled, translation regime when stage 1 address translation is disabled in that regime.
- The EL3 translation regime when stage 1 address translation is disabled in that regime.
- The Secure EL2, or Secure EL2&0, translation regime when stage 1 address translation is disabled in that regime
- The Non-secure EL1&0, when EL2 is enabled, translation regime, when both stages of address translation are disabled.

Note

- The behaviors in Non-secure state apply regardless of the Execution state that EL3 is using.
- When the value of `HCR_EL2.DC` is 1, then the behavior of the EL1&0 translation regime is as if stage 1 translation is disabled and stage 2 translation is enabled, as described in [Behavior when stage 1 address translation is disabled on page D5-2731](#).

In these cases, when execution is in AArch64 state, a memory location might be accessed as a result of an instruction fetch if either:

- The memory location is in the same block of memory as, or in the next contiguous block of memory to, an instruction that a simple sequential execution of the program either requires to be fetched now or has required to be fetched since the last reset.
- The memory location is the target of a direct branch that a simple sequential execution of the program would have taken since the most recent of:
 - The last reset.
 - The last synchronization of instruction cache maintenance targeting the address of the branch instruction.

In this description, the blocks of memory referred to are of the size of the minimum implemented translation granule and are aligned to that size.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

———— **Note** —————

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when all associated stages of address translation are disabled are located in blocks of the address space, of the translation granule size, that contain only memory that is tolerant to speculative accesses.
- Each block of the address space, of the translation granule size, that immediately follows a similar block that holds instructions that will be executed when all associated stages address translation are disabled, contains only memory that is tolerant to speculative accesses.

D5.2.10 Pseudocode description of VMSAv8-64 address translation

The following subsections outline a pseudocode description of the translation table walk:

- [Full Physical Address on page D5-2733](#).
- [Address translation on page D5-2733](#).
- [Translation table walk on page D5-2734](#).
- [Hardware update of Translation Table descriptors on page D5-2734](#).
- [Address decoding and calculation on page D5-2734](#).
- [Memory attribute decoding on page D5-2734](#).
- [Fault detection on page D5-2735](#).

Full Physical Address

A complete physical address necessary to identify a location in physical memory is captured by the type `FullAddress`. This is composed of:

- A bitstring address, which identifies the physical address.
- An enumeration paspace which identifies the physical address space.

Address translation

`AArch64.TranslateAddress()` acts as the entry point to VMSAv8-64 and performs the required address translation based on the provided parameters and system register configurations. The function returns an `AddressDescriptor()` structure holding valid data for either of the following:

- Target memory address and attributes for a non-faulting translation.
- Fault details holding data to be populated in syndrome registers.

`AArch64.FullTranslate()` selects the translation regime and performs first and potentially second stage of translation returning the physical address (PA) and attributes of target memory. `AArch64.S1Translate()` carries out the first stage of translation when stage 1 is not disabled, mapping the virtual address (VA) to the intermediate physical address

(IPA) and carrying out permission checks. Otherwise, `AArch64.S1DisabledOutput()` assigns the appropriate memory attributes and flat maps the input address to the output address. `AArch64.S2Translate()` carries out stage 2 translation for the EL1&0 translation regime when enabled mapping the IPA to the PA. Otherwise, the IPA is the PA.

Translation table walk

Each stage of translation has a separate walk function, `AArch64.S1Walk()` and `AArch64.S2Walk()`, corresponding to the first and second stage of translation respectively. Each use walk parameters extracted from related system registers. Parameters are collected based on the active translation regime. For instance, stage 1 EL2 translation regime parameters are obtained and returned by the function `AArch64.S1TTWParamsEL2()`. Given these parameters, a walk initializes a walk state of the type `TTWState`, holding the base address of the first translation table.

The walk progressively fetches and decodes Translation Table descriptors, updating the walk state to the next base address as it descends through the levels of tables until a Block or Page descriptor is discovered or an invalid descriptor is fetched. Decoding the descriptor for both stage 1 and stage 2 walks is carried out by the function `AArch64.DecodeDescriptorType()`.

For a non-faulting walk, three items are returned by a translation table walk:

- The final walk state.
- The final descriptor fetched.
- The address of the final descriptor.

The final descriptor and its address are used to update the descriptor as specified by *Hardware management of the Access flag and dirty state on page D5-2767*.

A faulting walk could report one of the following at a specified level:

- Translation Fault.
- Address Size Fault.
- Access Flag Fault.

Hardware update of Translation Table descriptors

The walk parameters collected from system registers indicate the ability to update the Access flag or set write permissions within descriptors. This is controlled by the Dirty Bit Modifier, and the conditions specified in *Hardware management of the Access flag and dirty state on page D5-2767*. The translation functions `AArch64.S1Translate()` or `AArch64.S2Translate()` set the appropriate descriptor bits returned by the walk functions and call `AArch64.MemSwapTableDesc()` to swap the old descriptor for the updated one in an atomic fashion.

Address decoding and calculation

The walk state is initialized to hold the base address of the first translation table, using `AArch64.TTBaseAddress()` to decode `TTBR0_ELx` and `TTBR1_ELx` registers. The walk progressively fetches and decodes Translation Table descriptors, updating the walk state to the next base address utilizing `AArch64.NextTableBase()` as it descends through the levels of tables. Prior to every descriptor fetch the base address is indexed by the function `AArch64.TTEntryAddress()` to point to the specific table entry. Indexing at the start level of stage 2 tables is shown in `AArch64.S2SLTEntryAddress()` which caters for concatenated tables. The final walk state would hold the base address for the output block or page; this is extracted from the Leaf descriptor in `AArch64.BlockBase()` or `AArch64.PageBase()` respectively.

Memory attribute decoding

If a stage of translation is enabled, fetched descriptors that are blocks or pages encode memory attributes assigned to the output of translation. Stage 1 memory attributes are decoded by the function `S1DecodeMemAttrs()`. Likewise, the stage 2 memory attributes are decoded by the function `S2DecodeMemAttrs()` followed by combining stage 1 and stage 2 attributes by the function `S2CombineS1MemAttrs()`. However, if `FEAT_S2FWB` is enabled, this behavior is overridden and memory attributes are decoded as specified in *Stage 2 memory region type and Cacheability attributes when FEAT_S2FWB is implemented on page D5-2780*. This is captured by the function `AArch64.S2ApplyFWBMemAttrs()`.

Fault detection

As soon as translation is invoked a reserve `FaultRecord` accompanies the process capturing the stage and level of translation as it proceeds. When a fault is detected, it is reflected in the `FaultRecord` and reported back as the result of translation with the most recent state to be reported already captured within. The following functions detect a certain type of fault, their outputs are all boolean with a TRUE value on detection:

- The `AArch64.S1HasPermissionsFault()` and `AArch64.S2HasPermissionsFault()` function detect a permissions fault for stage 1 and stage 2 respectively.

———— **Note** —————

For atomic instructions introduced by `FEAT_LSE`, these functions are called twice, once to check for read permissions and another for write allowing the correct failure to be reported.

- The `AArch64.S1HasAlignmentFault()` and `AArch64.S2HasAlignmentFault()` functions detect an alignment fault for stage 1 and stage 2 respectively.
- The `AArch64.S1InvalidTxSZ()` and `AArch64.S2InvalidTxSZ()` functions detect a translation fault caused by erroneous configuration of `TCR_ELx.TxSZ` field. Additionally, the `AArch64.S2InconsistentSL()` and `AArch64.S2InvalidSL()` functions detect a stage 2 translation faults caused by erroneous configuration of the `VSTCR_EL2.{SL2, SLO}` and `VTCR_EL2.{SL2, SLO}` fields.
- `AArch64.VAIsOutOfRange()` detects a stage 1 translation fault caused by virtual addresses larger than the address input size configured. Similarly, `AArch64.IPAIsOutOfRange()` detects a stage 2 translation fault caused by the output of stage 1 being larger than the configured input size for stage 2.
- `AArch64.ContiguousBitFaults()` detects a stage 1 or 2 translation fault caused by a mis-programmed contiguous bit within a fetched descriptor.

D5.2.11 Address translation instructions

Each of the Armv8 instruction sets provides instructions that return the result of translating an input address, supplied as an argument to the instruction, using a specified translation stage or regime.

The available instructions only perform translations that are accessible from the Security state and Exception level at which the instruction is executed. That is:

- No instruction executed in Non-secure state can return the result of a Secure address translation stage.
- No instruction can return the result of an address translation stage that is controlled by an Exception level that is higher than the Exception level at which the instruction is executed.

*Address translation instructions, AT** on page D5-2735 summarizes the A64 address translation instructions.

See also *A64 System instructions for address translation* on page C5-567.

If `FEAT_MTE2` is implemented, the behavior of `AT*` instructions in AArch64 state are modified. For more information, see *Virtual address translation* on page D6-2843.

Address translation instructions, AT*

The A64 assembly language syntax for address translation instructions is:

```
AT <operation>, <Xt>
```

Where:

<operation> Is one of S1E1R, S1E1RP, S1E1W, S1E1WP, S1E0R, S1E0W, S1E1R, S1E1W, S1E0R, S1E0W, S1E2R, S1E2W, S1E3R, or S1E3W.

<operation> has a structure of <stages><level><read|write><pan>, where:

<stages> Is one of:

S1 Stage 1 translation.

S12 Stage 1 translation followed by stage 2 translation.

<level> Describes the Exception level that the translation applies to. Is one of:
E0 EL0.
E1 EL1.
E2 EL2.
E3 EL3.
If <level> is higher than the current Exception level, the instruction is UNDEFINED.

<read|write>
Is one of:
R Read.
W Write.

<pan>
Only available when FEAT_PAN2 is implemented. Optional, but if present:
P Determines action based on value of PSTATE.PAN.
Only permitted for <stages>=S1 and <level>=E1.

<Xt> The address to be translated. No alignment restrictions apply for the address.

If EL2 is not implemented, the AT S1E2R and AT S1E2W instructions are UNDEFINED.

———— **Note** ————

If EL2 is not implemented but EL3 is implemented, the AT S1E** instructions are not UNDEFINED, but behave the same way as the equivalent AT S1E** instructions. This is consistent with the behavior if EL2 is implemented but stage 2 translation is disabled.

In each case, the address being translated is held in the 64-bit address argument register, Xt. If the address translation instruction uses a translation regime that is using AArch32, meaning it requires a VA of only 32 bits, then VA[63:32] is RES0.

If the address translation is successful, the resulting output address is returned in PAR_EL1.PA, and PAR_EL1.F is set to 0 to indicate that the translation was successful. Otherwise, see *Synchronous faults generated by address translation instructions on page D5-2737*.

———— **Note** ————

The architecture provides a single PAR, PAR_EL1, that is used regardless of:

- The Exception level at which the instruction was executed.
- The Exception level that controls the stage or stages of translation used by the instruction.

For all of these instructions, the current context information determines which entries in TLB caching structures are used, and how the translation table walk is performed. However, it is IMPLEMENTATION DEFINED whether the Address translation instructions return the values held in a TLB or the result of a translation table walk. Therefore, Arm recommends that these instructions are not used at a time when the TLB entries might be different from the underlying translation tables held in memory.

If EL3 is implemented, then for instructions that apply to the EL1 or EL0 Exception level, SCR_EL3.NS determines the translation regime to which the instruction applies, as follows:

SCR_EL3.NS == 0 Secure EL1&0 translation regime.

SCR_EL3.NS == 1 Non-secure EL1&0 translation regime.

All relevant context information used for the translation depends on this determination.

When EL1&0 stage 1 address translation is disabled, any AT S1E0*, AT S1E1*, AT S1E0*, or AT S1E1* address translation instruction that accesses the Non-secure state translation reflects the effect of the HCR_EL2.DC bit as described in *Behavior when stage 1 address translation is disabled on page D5-2731*.

If Secure EL2 translation regime is disabled, executing AT S1E2R or AT S1E2W at EL3 with SCR_EL3.NS == 0 is UNDEFINED.

———— **Note** ————

AT S12E** instructions at EL3 with `SCR_EL3.NS == 0` are not UNDEFINED but behave the same way as the equivalent AT S1E** instructions.

Synchronous faults generated by address translation instructions

The address translation instructions use the translation mechanism, and that mechanism can generate the following synchronous faults:

- Translation fault.
- Access flag fault.
- Permission fault.
- Domain fault, when translating using the AArch32 translation systems.
- Address size fault.
- TLB conflict fault.
- Synchronous External aborts during a translation table walk.

In addition:

- If the address translation instruction requires two stages of translation then these faults could arise from either stage 1 or stage 2.
- For a stage 1 translation for the EL1&0 translation regime, the fault might be generated on the stage 2 translation of an address accessed as part of the stage 1 translation table walk, see [Stage 2 fault on a stage 1 translation table walk on page D5-2806](#).

Except as described in this section, these faults are not taken as an exception for the address translation instructions, but instead the `PAR_EL1.FST` field holds the Fault status information. In these cases the `PAR_EL1.PA` field does not hold the output address of the translation.

The exceptions to this reporting the fault in `PAR_EL1` are:

- Synchronous External aborts during a translation table walk are taken as a Data Abort exception. For an address translation instruction executed at a particular Exception level, if the synchronous External abort is generated on a stage 1 translation table walk, the Data Abort exception is taken to the Exception level to which a synchronous External abort on a stage 1 translation table walk for a memory access from that Exception level would be taken.

If the synchronous External abort is generated on a stage 2 translation table walk then:

- If the address translation instruction was executed at EL3, the synchronous Data Abort exception is taken to EL3.
- If the address translation instruction was executed at EL2 or EL1, the Data Abort exception is taken to the Exception level to which a synchronous External abort on a stage 2 translation table walk for a memory access from that Exception level would be taken.

In any case where the address translation instruction causes a synchronous Data Abort exception to be taken:

- The `PAR_EL1` is UNKNOWN.
- The `ESR_ELx` of the target Exception level of the exception indicates that the fault was due to a translation table walk for a cache maintenance instruction.
- The `FAR_ELx` of the target Exception level holds the `VA` for the translation request.

- For the AT S1E0* and AT S1E1* instructions executed from EL1, if there is a synchronous stage 2 fault on a memory access made as part of the translation table walk then:
 - If the fault is a synchronous External abort on a stage 2 translation table and `SCR_EL3.EA` is 1, then a synchronous External abort on a stage 2 translation table walk is taken to EL3.
 - Otherwise the fault is taken as an exception to EL2.

If the exception is taken to EL2 the following apply:

- `PAR_EL1` is UNKNOWN.
- `ESR_EL2` indicates that the fault occurred on a translation table walk, and that the operation that faulted was a cache maintenance instruction.
- `HPFAR_EL2` holds the `IPA` that faulted.
- `FAR_EL2` holds the `VA` that the executing software supplied to the address translation instruction.

This fault can occur for any of the following reasons:

- Stage 2 Translation fault.
- Stage 2 Access fault.
- Stage 2 Permission fault.
- Stage 2 Address size fault.
- Synchronous External abort on a stage 2 translation table walk.

Synchronization requirements of the address translation instructions

Where an instruction results in an update to a System register, as is the case with the AT * address translation instructions, explicit synchronization must be performed before the result is guaranteed to be visible to subsequent direct reads of the [PAR_EL1](#).

———— **Note** —————

This is consistent with the AArch32 requirement, where the VA to PA translation instructions are executed as writes to the (coproc==0b1111) System register encoding space, and the effect of those writes to other registers require explicit synchronization before the result is guaranteed to be visible to subsequent instructions.

D5.3 VMSAv8-64 Translation Table format descriptors

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry that points to the next-level translation table.
- A block entry that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the Armv8 Translation Table descriptor formats:

- [VMSAv8-64 translation table level -1, level 0, level 1, and level 2 descriptor formats on page D5-2739.](#)
- [Armv8 translation table level 3 descriptor formats on page D5-2744.](#)

[Memory attribute fields in the VMSAv8-64 Translation Table format descriptors on page D5-2746](#) then gives more information about the descriptor attribute fields, and [Control of Secure or Non-secure memory access on page D5-2753](#) describe how the NS and NSTable together control whether a memory access from Secure state accesses the Secure memory map or the Non-secure memory map.

D5.3.1 VMSAv8-64 translation table level -1, level 0, level 1, and level 2 descriptor formats

The difference in the level -1, level 0, level 1 and level 2 VMSAv8-64 Translation Table descriptor formats depends on the following:

- The translation granule size.
- Whether a Block descriptor is permitted.
- If a Block descriptor is permitted, the size of the memory region described by that entry.
- The maximum supported OA size.

4KB granule If the *Effective value* of TCR_ELx.DS is 1

Level -1 translation tables do not support Block descriptors.

A Block descriptor:

- In a level 0 table describes the mapping of the associated 512GB input address range.
- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

The maximum OA size of a lookup is 52 bits.

If the *Effective value* of TCR_ELx.DS is 0

Level -1 lookup is not supported.

Level 0 translation tables do not support Block descriptors.

A Block descriptor:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

The maximum OA size of a lookup is 48 bits.

16KB granule Level -1 lookup is not supported.

If the *Effective value* of TCR_ELx.DS is 1

Level 0 translation tables do not support Block descriptors.

A Block descriptor:

- In a level 1 table describes the mapping of the associated 64GB input address range.
- In a level 2 table describes the mapping of the associated 32MB input address range.

The maximum OA size of a lookup is 52 bits.

If the *Effective value* of TCR_ELx.DS is 0

Level 0 and level 1 translation tables do not support Block descriptors.

A Block descriptor in a level 2 table describes the mapping of the associated 32MB input address range.

The maximum OA size of a lookup is 48 bits.

64KB granule Level -1 and level 0 lookups are not supported.

If FEAT_LPA is implemented

A Block descriptor:

- In a level 1 table describes the mapping of the associated 4TB input address range.
- In a level 2 table describes the mapping of the associated 512MB input address range.

The maximum OA size of a lookup is 52 bits.

If FEAT_LPA is not implemented

Level 1 translation tables do not support Block descriptors.

A Block descriptor in a level 2 table describes the mapping of the associated 512MB input address range.

The maximum OA size of a lookup is 48 bits.

When a lookup returns a Table descriptor, the OA is the next-level table address.

Figure D5-14 on page D5-2740 shows the Armv8 level 0, level 1, and level 2 descriptor formats that provide 48-bit OAs:

With the 4KB granule size, for the level 1 descriptor n is 30, and for the level 2 descriptor, n is 21.

With the 16KB granule size, for the level 2 descriptor, n is 25.

With the 64KB granule size, for the level 2 descriptor, n is 29.

With the 4KB granule size m is 12^\ddagger , with the 16KB granule size m is 14, and with the 64KB granule size, m is 16.

A level 0 Table descriptor returns the address of the level 1 table.

A level 1 Table descriptor returns the address of the level 2 table.

A level 2 Table descriptor returns the address of the level 3 table.

[‡] When m is 12, the RES0 field shown for bits[($m-1$):12] is absent.

Figure D5-14 VMSAv8-64 level 0, level 1 and level 2 descriptor formats with 48-bit OAs

If the *Effective value* of TCR_ELx.DS or VTCR_EL2.DS is 1, when a 4KB or 16KB granule is used, the Block and Table descriptors are redefined as Figure D5-15 on page D5-2741 shows:

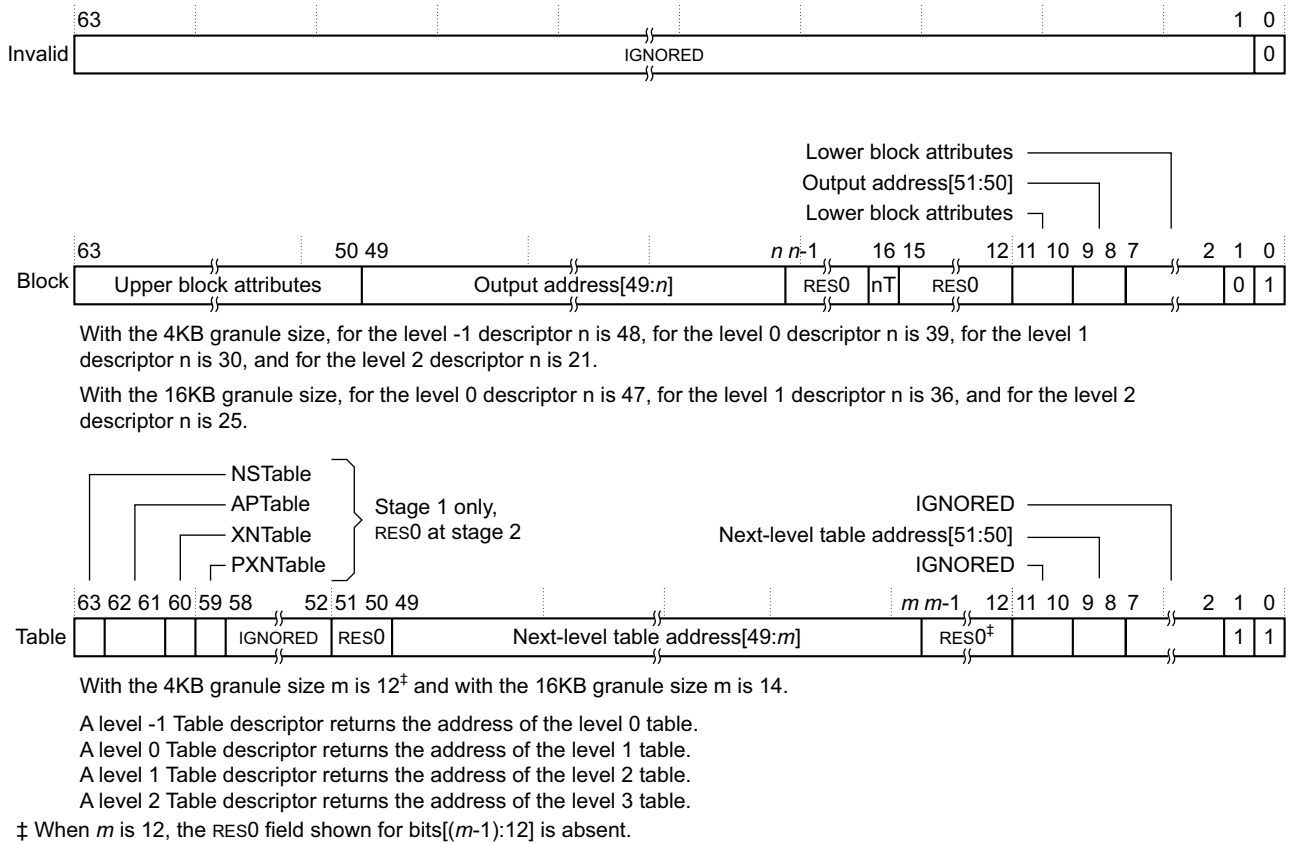

Figure D5-15 VMSAv8-64 level -1, level 0, level 1 and level 2 descriptor formats, 4KB or 16KB granule with 52-bit OAs

In an implementation that includes `FEAT_LPA`, when the 64KB granule is used, the Block and Table descriptors are redefined as [Figure D5-16 on page D5-2741](#) shows:

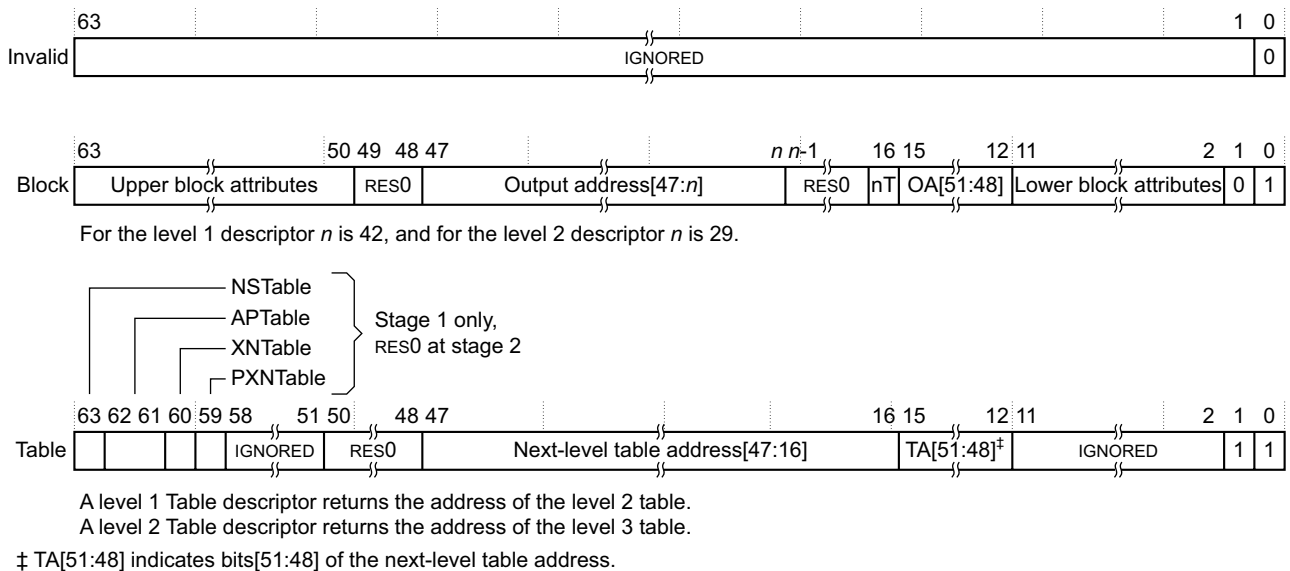

Figure D5-16 VMSAv8-64 level 1 and level 2 descriptor formats, 64KB granule with 52-bit OAs

———— **Note** ————

The effects on the Non-secure EL1 descriptors when `FEAT_HPDS` is enabled and `HCR_EL2.{NV, NV1} == {1,1}` are detailed in *Effect of HCR_EL2.{NV, NV1}* on page D5-2793.

Descriptor encodings, Armv8 level 0, level 1, and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- 0, Block** The descriptor gives the base address of a block of memory, and the attributes for that memory region.
- 1, Table** The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

Block descriptor

Gives the base address and attributes of a block of memory, as follows:

4KB translation granule

If the *Effective value* of `TCR_ELx.DS` or `VTCR_EL2.DS` is 1:

- For a level 0 Block descriptor, bits[9:8] are bits[51:50] of the output address and bits[49:39] are bits[49:39] of the output address. This output address specifies a 512GB block of memory.
- For a level 1 Block descriptor, bits[9:8] are bits[51:50] of the output address and bits[49:30] are bits[49:30] of the output address. This output address specifies a 1GB block of memory.
- For a level 2 Block descriptor, bits[9:8] are bits[51:50] of the output address and bits[49:21] are bits[49:21] of the output address. This output address specifies a 2MB block of memory.

If the *Effective value* of `TCR_ELx.DS` or `VTCR_EL2.DS` is 0:

- For a level 1 Block descriptor, bits[47:30] are bits[47:30] of the output address. This output address specifies a 1GB block of memory.
- For a level 2 Block descriptor, bits[47:21] are bits[47:21] of the output address. This output address specifies a 2MB block of memory.

16KB translation granule

If the *Effective value* of `TCR_ELx.DS` or `VTCR_EL2.DS` is 1:

- For a level 1 Block descriptor, bits[9:8] are bits[51:50] of the output address and bits[49:36] are bits[49:36] of the output address. This output address specifies a 64GB block of memory.
- For a level 2 Block descriptor, bits[9:8] are bits[51:50] of the output address and bits[49:25] are bits[49:25] of the output address. This output address specifies a 32MB block of memory.

If the *Effective value* of `TCR_ELx.DS` or `VTCR_EL2.DS` is 0:

- A level 1 Block descriptor is not supported.
- For a level 2 Block descriptor, bits[47:25] are bits[47:25] of the output address. This output address specifies a 32MB block of memory.

64KB translation granule

If **FEAT_LPA** is implemented:

- For a level 1 Block descriptor, bits[15:12] are bits[51:48] of the output address and bits[47:42] are bits [47:42] of the output address. This output address specifies a 4TB block of memory.
- For a level 2 Block descriptor, bits[15:12] are bits[51:48] of the output address, and bits[47:29] are bits [47:29] of the output address. This output address specifies a 512MB block of memory.

If **FEAT_LPA** is not implemented:

- A level 1 Block descriptor is not supported.
- For a level 2 Block descriptor, bits[47:29] are bits[47:29] of the output address. This output address specifies a 512MB block of memory.

The following bits provide attributes for the target memory block:

- If the *Effective value* of **TCR_ELx.DS** or **VTCCR_EL2.DS** is 0, bits[63:52, 11:2].
- If the *Effective value* of **TCR_ELx.DS** or **VTCCR_EL2.DS** is 1, bits[63:52, 11:10, 7:2].
- If **FEAT_HAFDBS** is implemented, bit 51 is also used as an attribute.

For more information, see *Memory attribute fields in the VMSAv8-64 Translation Table format descriptors on page D5-2746*.

Note

- In Armv8.0, the position and contents of bits[63:52, 11:2] are identical to bits[63:52, 11:2] in the Page descriptors.
- When **FEAT_HAFDBS** is implemented, the position and contents of bits[63:51, 11:2] are identical to bits[63:51, 11:2] in the Page descriptors.
- When **FEAT_HPDS2** is implemented, hardware can use bits[62:59] of the Block descriptors for IMPLEMENTATION DEFINED purposes, see *Memory attribute fields in the VMSAv8-64 Translation Table format descriptors on page D5-2746*.
- When the *Effective value* of **TCR_ELx.DS** or **VTCCR_EL2.DS** is 1, the position and contents of bits[63:51, 11:10, 7:2] are identical to bits[63:51, 11:10, 7:2] in the Page descriptors.

Table descriptor

Gives the translation table address for the next-level lookup, as follows:

4KB translation granule

- Bits[47:12] are bits[47:12] of the address of the required next-level table, which is:
 - When the *Effective value* of **TCR_ELx.DS** or **VTCCR_EL2.DS** is 1, for a level -1 Table descriptor, the address of a level 0 table.
 - For a level 0 Table descriptor, the address of a level 1 table.
 - For a level 1 Table descriptor, the address of a level 2 table.
 - For a level 2 Table descriptor, the address of a level 3 table.
- When the *Effective value* of **TCR_ELx.DS** or **VTCCR_EL2.DS** is 1, bits[49:48] are bits[49:48] of the required next-level table, and bits[9:8] are bits[51:50] of the required next-level table.
- Bits[11:0] of the table address are zero.

16KB translation granule

- Bits[47:14] are bits[47:14] of the address of the required next-level table, which is:
 - For a level 0 Table descriptor, the address of a level 1 table.
 - For a level 1 Table descriptor, the address of a level 2 table.
 - For a level 2 Table descriptor, the address of a level 3 table.
- When the *Effective value* of **TCR_ELx.DS** or **VTCCR_EL2.DS** is 1, bits[49:48] are bits[49:48] of the required next-level table, and bits[9:8] are bits[51:50] of the required next-level table.

- Bits[13:0] of the table address are zero.

64KB translation granule

- Bits[47:16] are bits[47:16] of the address of the required next-level table, which is:
 - For a level 1 Table descriptor, the address of a level 2 table.
 - For a level 2 Table descriptor, the address of a level 3 table.
- When [FEAT_LPA](#) is implemented, bits[15:12] are bits[51:48] of the required next-level table.
- Bits[15:0] of the table address are zero.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see [Memory attribute fields in the VMSAv8-64 Translation Table format descriptors on page D5-2746](#).

If the translation table defines either the Secure or Non-secure EL1&0, when EL2 is enabled, stage 1 translations, then the output address in the descriptor is the [IPA](#) of the target block or table. Otherwise, it is the [PA](#) of the target block or table.

D5.3.2 Armv8 translation table level 3 descriptor formats

For the 4KB granule size, each entry in a level 3 table describes the mapping of the associated 4KB input address range.

For the 16KB granule size, each entry in a level 3 table describes the mapping of the associated 16KB input address range.

For the 64KB granule size, each entry in a level 3 table describes the mapping of the associated 64KB input address range.

[Figure D5-17 on page D5-2745](#) shows the Armv8 level 3 descriptor formats for both 52-bit and 48-bit output addresses.

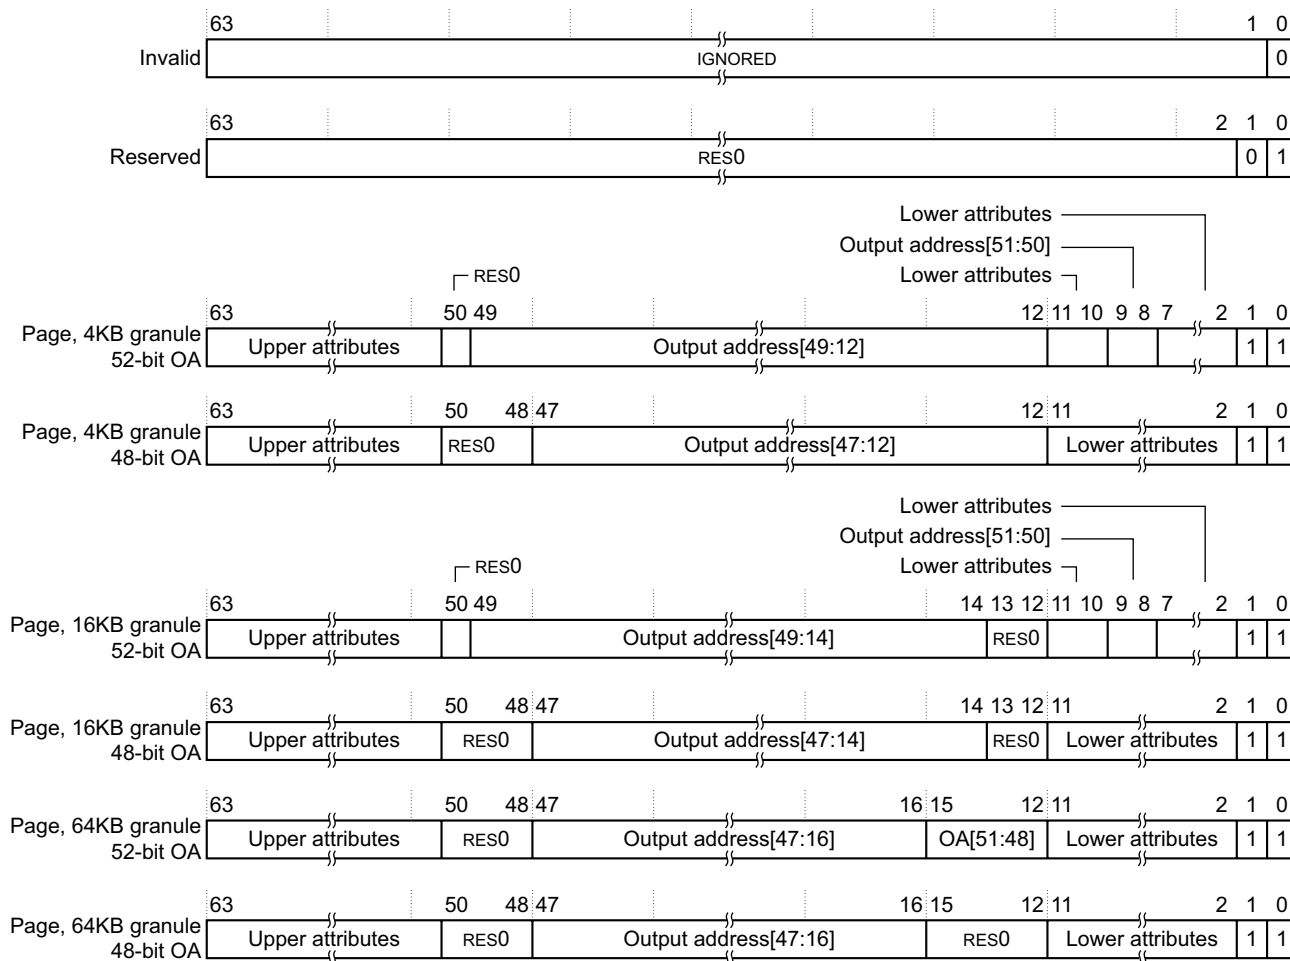

Figure D5-17 VMSAv8-64 level 3 descriptor format

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Reserved, invalid

Behaves identically to encodings with bit[0] set to 0.

This encoding must not be used in level 3 translation tables.

1, Page Gives the address and attributes of a 4KB, 16KB, or 64KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

Page descriptor

Gives the output address of a page of memory, as follows:

4KB translation granule

If the *Effective value* of *TCR_ELx.DS* or *VTCCR_EL2.DS* is 1, bits[9:8] are bits[51:50] of the output address and bits[49:12] are bits[49:12] of the output address for a page of memory.

If the *Effective value* of TCR_ELx.DS or VTCR_EL2.DS is 0, bits[47:12] are bits[47:12] of the output address for a page of memory.

16KB translation granule

If the *Effective value* of TCR_ELx.DS or VTCR_EL2.DS is 1, bits[9:8] are bits[51:50] of the output address and bits[49:14] are bits[49:14] of the output address for a page of memory.

If the *Effective value* of TCR_ELx.DS or VTCR_EL2.DS is 0, bits[47:14] are bits[47:14] of the output address for a page of memory.

64KB translation granule

If FEAT_LPA is implemented, bits[15:12] are bits[51:48] and bits[47:16] are bits[47:16] of the output address for a page of memory.

If FEAT_LPA is not implemented, bits[47:16] are bits[47:16] of the output address for a page of memory.

The following bits provide attributes for the target memory page:

- If the *Effective value* of TCR_ELx.DS or VTCR_EL2.DS is 0, bits[63:52, 11:2].
- If the *Effective value* of TCR_ELx.DS or VTCR_EL2.DS is 1, bits[63:52, 11:10, 7:2].

For more information, see *Memory attribute fields in the VMSAv8-64 Translation Table format descriptors* on page D5-2746.

Note

- In Armv8.0, the position and contents of bits[63:52, 11:2] are identical to bits[63:52, 11:2] in the level 0, level 1, and level 2 Block descriptors.
- When FEAT_HAFDBS is implemented, the position and contents of bits[63:51, 11:2] are identical to bits[63:51, 11:2] in the level 0, level 1, and level 2 Block descriptors.
- When FEAT_HPDS2 is implemented, hardware can use bits[62:59] of the Page descriptors for IMPLEMENTATION DEFINED purposes, see *Memory attribute fields in the VMSAv8-64 Translation Table format descriptors* on page D5-2746.

For either the Secure or Non-secure EL1&0, when EL2 is enabled, stage 1 translations, the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

D5.3.3 Memory attribute fields in the VMSAv8-64 Translation Table format descriptors

Memory region attributes on page D5-2776 describes the region attribute fields. The following subsections summarize the descriptor attributes as follows:

Table descriptor

Table descriptors for stage 2 translations do not include any attribute field. For a summary of the attribute fields in a stage 1 Table descriptor, that define the attributes for the next lookup level, see *Next-level attributes in stage 1 VMSAv8-64 Table descriptors* on page D5-2747.

Block and Page descriptors

These descriptors define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:

- *Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors* on page D5-2749
- *Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors* on page D5-2751.

Next-level attributes in stage 1 VMSAv8-64 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the attributes for the next-level translation table access, and bits[58:51] are IGNORED:

Next-level descriptor attributes, stage 1 only

† UXNTable for a translation regime that can apply to execution at EL0, otherwise XNTable.
‡ RES0 for a translation regime that cannot apply to execution at EL0.

These attributes are:

NSTable, bit[63]

For memory accesses from Secure state, specifies the Security state for subsequent levels of lookup, see [Hierarchical control of Secure or Non-secure memory accesses on page D5-2753](#).

For memory accesses from Non-secure state, including all accesses in the EL2 or EL2&0 translation regime, this bit is RES0 and is ignored by the PE.

APTable, bits[62:61]

Access permissions limit for subsequent levels of lookup, see [Hierarchical control of data access permissions on page D5-2759](#).

APTable[0] is RES0:

- In the EL2 translation regime.

———— Note ————

In an implementation that includes [FEAT_VHE](#), when the value of [HCR_EL2.E2H](#) is 1 the translation regime for memory accesses from EL2 is the EL2&0 translation regime. APTable[0] can be valid (not RES0) in the EL2&0 translation regime.

- In the EL3 translation regime.

From Armv8.1, when [FEAT_HPDS](#) is implemented, this field can be disabled. When the value of [TCR_ELx.HPD{0}](#) or [TCR_ELx.HPD1](#) is 1:

- The value of the corresponding APTable field is IGNORED by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding APTable field is 0.

———— Note ————

From Armv8.3, if EL2 is enabled in the current Security state, in the EL1 translation regime, when the value of [HCR_EL2.{NV, NV1}](#) == {1, 1}, bit[61] is treated as 0 regardless of the actual value, see [Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2794](#).

UXNTable or XNTable, bit[60]

XN limit for subsequent levels of lookup, see [Hierarchical control of instruction fetching on page D5-2764](#).

The naming of this field depends on whether stage 1 of the translation regime can support two VA ranges:

Stage 1 can support two VA ranges

This field is UXNTable, and determines whether execution at EL0 of instructions fetched from the region identified at a lower level of lookup permitted.

Note

PXNTable is the equivalent control of execution at a higher Exception level.

Stage 1 supports only one VA range

This field is XNTable.

From Armv8.1, when [FEAT_HPDS](#) is implemented, this field can be disabled. When the value of [TCR_ELx.HPD{0}](#) or [TCR_ELx.HPD1](#) is 1:

- The value of the corresponding UXNTable field is IGNORED by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding UXNTable field is 0.

Note

From Armv8.3, if EL2 is enabled in the current Security state, in the EL1 translation regime, when the value of [HCR_EL2.{NV, NV1}](#) == {1, 1}, bit[60] holds PXNTable, see [Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2794](#).

PXNTable, bit[59]

PXN limit for subsequent levels of lookup, see [Hierarchical control of instruction fetching on page D5-2764](#).

This field is valid only for a stage 1 translation that can support two VA ranges. It is RES0 for stage 1 translations that can support only one VA range.

From Armv8.1, when [FEAT_HPDS](#) is implemented, this field can be disabled. When the value of [TCR_ELx.HPD{0}](#) or [TCR_EL1.HPD1](#) is 1:

- The value of the corresponding PXNTable field is IGNORED by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding PXNTable field is 0.

Note

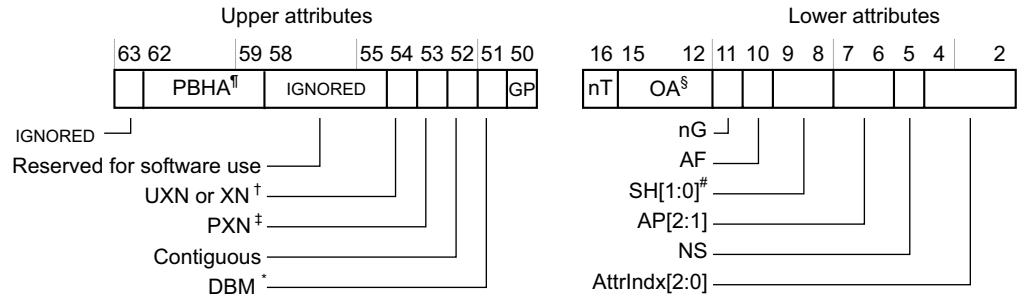

From Armv8.3, if EL2 is enabled in the current Security state, in the EL1&0 translation regime, when the value of [HCR_EL2.{NV, NV1}](#) == {1, 1}, bit[59] is RES0, see [Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2794](#).

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-8682](#). For more information about these fields, see [Other fields in the VMSAv8-64 Translation Table format descriptors on page D5-2781](#).

Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 1 translation:

Attribute fields for VMSAv8-64 stage 1 Block and Page descriptors

¶ IGNORED if FEAT_HPDS2 is not implemented.

† UXN for a translation regime that can apply to execution at EL0, otherwise XN.

‡ RES0 for a translation regime that cannot apply to execution at EL0.

* RES0 if FEAT_HAFDBS is not implemented.

§ RES0 if FEAT_LPA is not implemented.

OA[51:50] if the Effective value of TCR_Elx.DS or VTCR_EL2.DS is 1.

For a stage 1 descriptor, the attributes are:

PBHA, bits[62:59]

Page-based Hardware Attributes bits.

These bits are IGNORED when FEAT_HPDS2 is not implemented.

When FEAT_HPDS2 is implemented, each TCR_ELx has a control bit for each PBHA bit in the translation tables that it controls. When the value of that control bit is 1, and the value of the corresponding Hierarchical permission disables bit, TCR_ELx.HPD{n} is 1, hardware can use that PBHA bit for IMPLEMENTATION DEFINED purposes. When the PBHA bit is used for IMPLEMENTATION DEFINED purposes, the value of 0 in the PBHA bit is a safe default setting that gives the same behavior as when the PBHA bit is not used for IMPLEMENTATION DEFINED purposes.

The TCR_ELx control bits for this feature are:

For a translation regime that supports only a single VA range

HWU0nn Controls whether Block or Page descriptor bit[nn] can be used by hardware. These controls apply only when the value of TCR_ELx.HPD0 is 1.

For a translation regime that can support two VA ranges

HWU0nn For the translation tables indicated by TTBR0_ELx, controls whether Block or Page descriptor bit[nn] can be used by hardware. These controls apply only when the value of TCR_ELx.HPD0 is 1.

HWU1nn For the translation tables indicated by TTBR1_ELx, controls whether Block or Page descriptor bit[nn] can be used by hardware. These controls apply only when the value of TCR_ELx.HPD1 is 1.

If FEAT_HPDS2 is not implemented, then the TCR_ELx control bits are RAZ/WI.

XN or UXN, bit[54]

The Execute-never or Unprivileged execute-never field, see [Access permissions for instruction execution on page D5-2760](#).

————— Note —————

From Armv8.3, in the Non-secure EL1 translation regime, when the value of HCR_EL2.{NV,NV1} == {1,1}, bit[54] holds PXN, see [Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2794](#).

- PXN, bit[53]** The Privileged execute-never field, see [Access permissions for instruction execution on page D5-2760](#).
This field is valid only when stage 1 of the translation regime can support two VA ranges. It is RES0 when stage 1 can support only one VA range.
-
- Note**
- From Armv8.3, in the Non-secure EL1 translation regime, when the value of `HCR_EL2.{NV,NV1}` == {1, 1}, bit[53] is RES0, see [Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2794](#).
-
- Contiguous, bit[52]**
A hint bit indicating that the translation table entry is one of a contiguous set of entries, that might be cached in a single TLB entry, see [The Contiguous bit on page D5-2782](#).
- DBM, bit[51]** Dirty Bit Modifier, see [The dirty state on page D5-2766](#).
- GP, bit[50]** Guarded Page.
If `FEAT_BTI` is implemented, this field is present in stage 1 block and page translation table entries. Otherwise, this field is RES0.
This field is RES0 in stage 2 block and page translation table entries.
- nT, bit[16]** Block translation entry, see [Block translation entry on page D5-2766](#).
If `FEAT_BBM` is implemented, this field is present in stage 1 block translation table entries. Otherwise, this field is RES0.
- nG, bit[11]** The not global bit. If a lookup using this descriptor is cached in a TLB, determines whether the TLB entry applies to all ASID values, or only to the current ASID value. See [Global and process-specific translation table entries on page D5-2813](#).
This field is valid only when stage 1 of the translation regime can support two VA ranges. It is RES0 when stage 1 can support only one VA range.
- AF, bit[10]** The Access flag, see [The Access flag on page D5-2765](#).
- SH, bits[9:8]** If the *Effective value* of `TCR_ELx.DS` or `VTCCR_EL2.DS` is 0, descriptor bits[9:8] are the Shareability field, see [Memory region attributes on page D5-2776](#). If the *Effective value* of `TCR_ELx.DS` or `VTCCR_EL2.DS` is 1, descriptor bits[9:8] are OA[51:50] and Shareability is determined by `TCR_ELx.SHn`, see [Stage 1 Shareability when FEAT_LPA2 is implemented on page D5-2778](#).
- AP[2:1], bits[7:6]**
Data Access Permissions bits, see [Memory access control on page D5-2754](#).
-
- Note**
- The Armv8 Translation Table descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.
-
- AP[1] is valid only for stage 1 of a translation regime that can support two VA ranges. It is RES1 when stage 1 translations can support only one VA range.
-
- Note**
- From Armv8.3, in the Non-secure EL1 translation regime, when the value of `HCR_EL2.{NV,NV1}` == {1, 1}, bit[6] is treated as 0 regardless of its actual value, see [Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2794](#).
-
- NS, bit[5]** Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in the Secure or Non-secure address map, see [Control of Secure or Non-secure memory access on page D5-2753](#).

For memory accesses from Non-secure state this bit is RES0 and is ignored by the PE.

AttrIndx[2:0], bits[4:2]

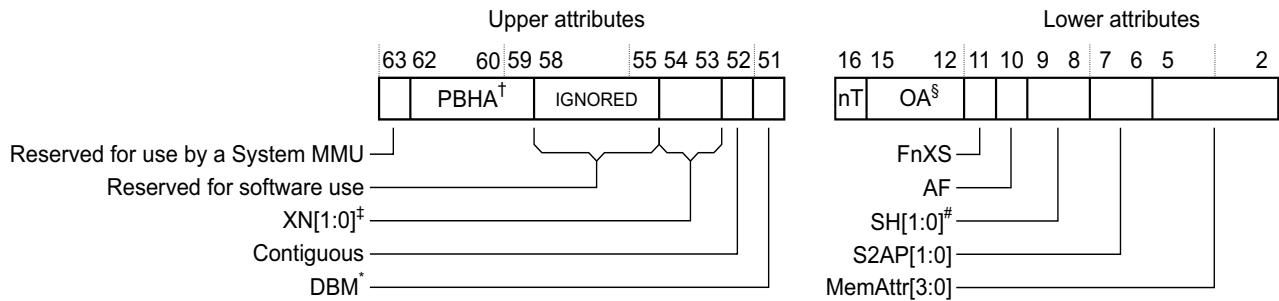

Stage 1 memory attributes index field, for the MAIR_ELx, see [Stage 1 memory region type and Cacheability attributes on page D5-2776](#).

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-8682](#). For more information about these fields, see [Other fields in the VMSAv8-64 Translation Table format descriptors on page D5-2781](#).

Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 2 translation:

Attribute fields for VMSAv8-64 stage 2 Block and Page descriptors

[‡] Bit[53] is RES0 if FEAT_XNX is not implemented.

[†] Bits [62:60] are IGNORED and reserved for use by System MMU if FEAT_HPDS2 is not implemented.

Bits [59] is IGNORED if FEAT_HPDS2 is not implemented.

* RES0 if FEAT_HAFDBS is not implemented.

§ RES0 if FEAT_LPA is not implemented.

OA[51:50] if the Effective value of TCR_ELx.DS or VTCR_EL2.DS is 1.

For a stage 2 descriptor, the attributes are:

PBHA[3:1], bits[62:60]

Page-based hardware attributes bits.

These bits are IGNORED and reserved for System MMU use when [FEAT_HPDS2](#) is not implemented.

When [FEAT_HPDS2](#) is implemented, [VTCR_EL2](#) has a control bit for each PBHA bit in the EL1&0 stage 2 translation tables:

- When the value of that control bit is 1, hardware can use the corresponding PBHA bit for IMPLEMENTATION DEFINED purposes. When the PBHA bit is used for IMPLEMENTATION DEFINED purposes, the value of 0 in the PBHA bit is a safe default setting that gives the same behavior as when the PBHA bit is not used for IMPLEMENTATION DEFINED purposes.
- When the value of that control bit is 0, the corresponding PBHA bit is IGNORED and reserved for System MMU use.

PBHA[0], bit[59]

Page-based hardware attributes bit.

This bit is IGNORED when [FEAT_HPDS2](#) is not implemented.

When **FEAT_HPDS2** is implemented, **VTCCR_EL2** has a control bit for this bit in the EL1&0 stage 2 translation tables:

- When the value of that control bit is 1, hardware can use this bit for IMPLEMENTATION DEFINED purposes. When the PBHA bit is used for IMPLEMENTATION DEFINED purposes, the value of 0 in the PBHA bit is a safe default setting that gives the same behavior as when the PBHA bit is not used for IMPLEMENTATION DEFINED purposes.
- When the value of that control bit is 0, this bit is IGNORED.

XN[1:0], bits[54:53]

The Execute-never field, see [Access permissions for instruction execution on page D5-2760](#).

If **FEAT_XNX** is not implemented, bit[53] is RES0.

Contiguous, bit[52]

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see [The Contiguous bit on page D5-2782](#).

DBM, bit[51] Dirty Bit Modifier, see [The dirty state on page D5-2766](#).

nT, bit[16] Block translation entry, see [Block translation entry on page D5-2766](#).

If **FEAT_BBM** is implemented, this field is present in stage 2 block translation table entries. Otherwise, this field is RES0.

FnXS, bit[11] XS attribute modifier, see [XS attribute modifier on page D5-2766](#).

When **FEAT_XS** is implemented, this field is present in stage 2 block and page translation table entries. Otherwise, this field is RES0.

AF, bit[10] The Access flag, see [The Access flag on page D5-2765](#).

SH, bits[9:8] If the *Effective value* of **TCR_ELx.DS** or **VTCCR_EL2.DS** is 0, descriptor bits[9:8] are the Shareability field, see [The stage 2 memory region attributes, EL1&0 translation regime on page D5-2778](#). If the *Effective value* of **TCR_ELx.DS** or **VTCCR_EL2.DS** is 1, descriptor bits[9:8] are **OA[51:50]** and Shareability is determined by **VTCCR_EL2.SH0**, see [Stage 2 Shareability attribute, for Normal memory on page D5-2780](#).

S2AP, bits[7:6]

Stage 2 data Access Permissions bits, see [The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime on page D5-2759](#).

———— **Note** —————

In the original VMSAv7-32 Long-descriptor attribute definition, this field was called **HAP[2:1]**, for consistency with the **AP[2:1]** field in the stage 1 descriptors and despite there being no **HAP[0]** bit. Armv8 renames the field for greater clarity.

MemAttr, bits[5:2]

Stage 2 memory attributes, see [The stage 2 memory region attributes, EL1&0 translation regime on page D5-2778](#).

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-8682](#). For more information about these fields, see [Other fields in the VMSAv8-64 Translation Table format descriptors on page D5-2781](#).

D5.3.4 Control of Secure or Non-secure memory access

As this section describes, the NS bit in the translation table entries:

- For accesses from Secure state, if the translation table entry was held in secure memory, determines whether the access is to Secure or Non-secure memory.
- Is ignored by:
 - Accesses from Non-secure state.
 - Accesses from Secure state if the translation table entry was held in Non-secure memory.

In the VMSAv8-64 translation table format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, that affects accesses at lower levels of lookup, see *Hierarchical control of Secure or Non-secure memory accesses* on page D5-2753.

The NS and NSTable bits are valid only for memory accesses from Secure state described by Translation Table descriptors that are fetched from Secure memory, and:

- In the Translation Table descriptors in a Non-secure translation table, the NS and NSTable bits are SBZ.
- Memory accesses from Non-secure state, including all accesses from EL2, ignore the values of these bits.

In the Secure translation regimes, for Translation Table descriptors that are fetched from Secure memory, the NS bit in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map, as follows:

NS == 0 Access the Secure PA space.
NS == 1 Access the Non-secure PA space.

For Non-secure translation regimes, and for Translation Table descriptors fetched from Non-secure memory, the corresponding bit is RES0 and is ignored by the PE. The access is made to Non-secure memory, regardless of the value of the bit.

Hierarchical control of Secure or Non-secure memory accesses

For VMSAv8-64 Table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

NSTable == 0 The defined table address is in the Secure PA space. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.

NSTable == 1 The defined table address is in the Non-secure PA space. Because this table is fetched from the Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:

- The value of the NS bit in any Block or Page descriptor is ignored. The block or page address refers to Non-secure memory.
- The value of the NSTable bit in any Table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any Block or Page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if it is part of a stage 1 translation which supports both global and non-global entries, and the stage 1 translation was read from a Non-secure stage 1 output address. These entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see *Global and process-specific translation table entries* on page D5-2813.

The effect of NSTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore a change to NSTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

D5.4 Memory access control

The access control fields in the Translation Table descriptors determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the Translation Table descriptor. If a translation stage does not permit the access then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- [About access permissions on page D5-2754.](#)
- [About PSTATE.PAN on page D5-2755.](#)
- [About PSTATE.UAO on page D5-2756.](#)
- [About PSTATE.BTYPE on page D5-2756.](#)
- [Data access permission controls on page D5-2758.](#)
- [Access permissions for instruction execution on page D5-2760.](#)
- [The Access flag on page D5-2765.](#)
- [The dirty state on page D5-2766.](#)
- [Software management of the Access flag on page D5-2766.](#)
- [Hardware management of the Access flag and dirty state on page D5-2767.](#)
- [Ordering of hardware updates to the translation tables on page D5-2773.](#)
- [Restriction on memory types for hardware updates on translation tables on page D5-2773.](#)
- [Use of the Contiguous bit with hardware updates of the translation table entries on page D5-2774.](#)

Note

This section describes the access controls for each of the translation regimes, and for each stage of translation in the EL1&0, when EL2 is enabled, translation regime.

A translation applies to memory accesses from either:

- Only a single Exception level, for example the EL3 translation regime.
- EL0 and one higher Exception level, for example the EL1&0 translation regime.

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of the target memory region. These fields can be classified as address map control, access control, and region attribute fields. [Control of Secure or Non-secure memory access on page D5-2753](#) describes the address map control, and [Memory region attributes on page D5-2776](#) describes the other fields.

D5.4.1 About access permissions

The Translation Table descriptors include fields that define access permissions for data accesses and for instruction fetches. This section introduces those fields. In addition:

- System register controls can prevent execution from writable locations, see [Preventing execution from writable locations on page D5-2765.](#)
- For the effect of disabling a stage of address translation on the access permissions, see [The effects of disabling a stage of address translation on page D5-2731.](#)
- From Armv8.1, the PSTATE.PAN bit can affect the access permissions for privileged data accesses, see [About PSTATE.PAN on page D5-2755.](#)
- From Armv8.2, the PSTATE.UAO bit can affect the access permissions for unprivileged instructions, see [About PSTATE.UAO on page D5-2756.](#)

Note

This section gives a general description of memory access permissions. In an implementation that includes EL2, software executing at EL1 can see only the access permissions defined by the EL1&0, when EL2 is enabled, stage 1 translations. However, software executing at EL2 can modify these permissions. This modification is invisible to the software executing at EL1 or EL0.

The access permission bits control access to the corresponding memory region. The VMSAv8-64 translation table format:

- In stage 1 translations, uses AP[2:1] to define the data access permissions, see *The AP[2:1] data access permissions, for stage 1 translations on page D5-2758*.

———— **Note** —————

The description of the access permission field as AP[2:1] is for consistency with the VMSAv8-32 Short-descriptor translation table format, see *The VMSAv8-32 Short-descriptor translation table format on page G5-6279*. The VMSAv8-64 translation table format does not define an AP[0] bit.

- In stage 2 translations, uses S2AP[1:0] to define the data access permissions, see *The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime on page D5-2759*.
- Uses the UXN, XN and PXN fields to define access controls for instruction fetches, see *Access permissions for instruction execution on page D5-2760*.

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation.

———— **Note** —————

In an implementation that includes EL2, each stage of the translation of a memory access made using the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime has its own, independent, permission check.

D5.4.2 About PSTATE.PAN

When the value of PSTATE.PAN is 1, any privileged data access from EL1, or EL2 when HCR_EL2.E2H is 1, to a virtual memory address that is accessible to data accesses at EL0, generates a Permission fault.

When the value of PSTATE.PAN is 0, the translation system is the same as in Armv8.0.

When FEAT_PAN is implemented, the SPSR_EL1.PAN, SPSR_EL2.PAN, and SPSR_EL3.PAN bits are used for exception returns, and the DSPSR_EL0 register is used for entry to or exit from Debug state.

When FEAT_PAN is implemented, the SCTLR_EL1.SPAN and SCTLR_EL2.SPAN bits are used to control whether the PAN bit is set on an exception to EL1 or EL2.

When HCR_EL2.{E2H, TGE} == {1, 1} SCTLR_EL1.SPAN and SCTLR_EL2.SPAN are ignored.

When FEAT_PAN3 is implemented, the SCTLR_EL1.EPAN and SCTLR_EL2.EPAN bits are used to control whether the PAN bit affects instruction accesses from EL1 or EL2. SCTLR_EL2.EPAN is available when HCR_EL2.E2H is 1.

When FEAT_PAN3 is implemented, it is IMPLEMENTATION DEFINED whether SCR_EL3.SIF is also used to determine instruction access permission for the purpose of PAN.

———— **Note** —————

The SCTLR_EL1.EPAN and SCTLR_EL2.EPAN bits affect the AT S1E1RP and AT S1E1WP instructions, consistent with those instructions using PSTATE.PAN to determine whether the memory access causes a Permission fault.

The PAN bit has no effect on:

- Data Cache instructions other than DC ZVA.
- Address translation instructions, other than ATS1E1RP and ATS1E1WP when FEAT_PAN2 is implemented.
- Unprivileged instructions, LDTR, LDTRB, LDTRH, LDTRSB, LDTRSH, LDTRSW, STTR, STTRB, and STTRH, unless HCR_EL2.{E2H, TGE} == {1, 0}.

The PAN bit has no effect when the first stage of translation is disabled for the current translation regime or when the first stage of translation for the current translation regime does not describe the permissions for access at EL0.

If access is disabled, then the access will cause a stage 1 Permission fault.

On an exception that is taken from AArch64 state to AArch64 state, PSTATE.PAN is copied to SPSR_ELx.PAN.

On an exception return from AArch64 state:

- [SPSR_ELx.PAN](#) is copied to [PSTATE.PAN](#), when the target Exception level is in AArch64 state.
- [SPSR_ELx.PAN](#) is copied to [CPSR.PAN](#), when the target Exception level is in AArch32 state.

———— **Note** —————

- In Non-debug state, in AArch64 state:
 - Software can use an MSR PAN, #Imm4 or MSR PAN, Xt instruction to modify [PSTATE.PAN](#), or an MRS Xt, PAN instruction to read [PSTATE.PAN](#).
 - In EL1, when [HCR_EL2](#).{NV, NV1} == {1, 1}, [PSTATE.PAN](#) is treated as 0 for all purposes except reading the value of the bit.
- In Debug state, in AArch64 state, a debugger can use the DRPS instruction to modify [PSTATE.PAN](#).

D5.4.3 About PSTATE.UAO

When the value of [PSTATE.UAO](#) is 1, a load/store unprivileged instruction executed at EL1, or executed at EL2 when the *Effective value* of [HCR_EL2](#).{E2H, TGE} is {1, 1} is subject to the memory access permissions that apply to the Exception level at which it is executed, rather than being subject to the EL0 access permissions. This means the load/store unprivileged instruction is subject to the same access permissions as the corresponding load/store register instruction. See [Load/store unprivileged on page C3-228](#) and [Load/store register on page C3-224](#).

When [FEAT_UAO](#) is implemented and [PSTATE.UAO](#) is 0, it has no effect on the described behavior of any load/store unprivileged instruction.

A corresponding UAO bit is added to [SPSR_EL1](#), [SPSR_EL2](#), and [SPSR_EL3](#) for exception returns, and [DSPSR_EL0](#) for entry to or exit from Debug state.

On an exception that is taken from AArch64 state to AArch64 state, [PSTATE.UAO](#) is copied to [SPSR_ELx.UAO](#) and then set to 0.

On an exception that is taken from AArch32 state to AArch64 state:

- [PSTATE.UAO](#) is set to 0.
- [SPSR_ELx.UAO](#) is set to 0.

On an exception return from AArch64 state to AArch64 state, [SPSR_ELx.UAO](#) is copied to [PSTATE.UAO](#).

———— **Note** —————

- In Non-debug state, in AArch64 state, software can use an MSR UAO, #Imm4 or MSR UAO, Xt instruction to modify [PSTATE.UAO](#), or an MRS Xt, UAO instruction to read [PSTATE.UAO](#).
- In Debug state, in AArch64 state, a debugger can use the DRPS instruction to modify [PSTATE.UAO](#).

D5.4.4 About PSTATE.BTYPE

When [FEAT_BTI](#) is implemented, on execution of an instruction, the guarded status of the memory region and the register that is accessed by the instruction determines the value that the [PSTATE.BTYPE](#) field is set at the end of the execution of the instruction as shown in [Table D5-27 on page D5-2756](#):

Table D5-27 Values taken by PSTATE.BTYPE on execution of an instruction

Instruction executed	Memory region	Register accessed	PSTATE.BTYPE
BR , BRAA , BRAAZ , BRAB , BRABZ	Guarded	Any register other than X16 or X17	0b11
BLR , BLRAA , BLRAAZ , BLRAB , BLRABZ	Any	Any register	0b10

Table D5-27 Values taken by PSTATE.BTYPE on execution of an instruction (continued)

Instruction executed	Memory region	Register accessed	PSTATE.BTYPE
BR, BRAA, BRAAZ, BRAB, BRABZ	Guarded	X16 or X17	0b01
BR, BRAA, BRAAZ, BRAB, BRABZ	Non-guarded	Any register	0b01
Any instruction other than BR, BRAA, BRAAZ, BRAB, BRABZ, BLR, BLRAA, BLRAAZ, BLRAB, BLRABZ, RET, RETAA, RETAB	Any	Any register	0b00

The BTI instructions <targets> operand identifies the compatibility of the BTI instruction to different PSTATE.BTYPE values, as seen in [Table D5-28 on page D5-2757](#).

Table D5-28 Compatibility of BTI instruction to different PSTATE.BTYPE values

<targets>	PSTATE.BTYPE value			
	0b00	0b01	0b10	0b11
(omitted)	n/a	Not compatible	Not compatible	Not compatible
c	n/a	Compatible	Compatible	Not compatible
j	n/a	Compatible	Not compatible	Compatible
jc	n/a	Compatible	Compatible	Compatible

When accessing a guarded memory region and if PSTATE.BTYPE has a value of 0b01, 0b10, or 0b11, then a BTI instruction that is compatible with the current value of PSTATE.BTYPE will not generate a Branch Target exception and will allow execution of subsequent instructions within the memory region.

A Branch Target exception is generated for an instruction that lies within a guarded page if PSTATE.BTYPE field is not 0b00 and if the instruction is not any of:

- A BTI instruction that is compatible with the PSTATE.BTYPE field.
- A PACIASP or PACIBSP instruction, and the PSTATE.BTYPE is consistent with implicit BTI behavior of these instructions.
- A Breakpoint Instruction exception.
- A Halt Instruction debug event.

A Branch Target exception is taken to:

- EL1 when executing at EL0 and HCR_EL2.TGE == 0.
- EL2 when executing at EL0 and HCR_EL2.TGE == 1.
- ELx when executing at ELx, where x is 1, 2, or 3.

The ESR_ELx.EC code for a Branch Target exception is 0x0D, see [ISS encoding for an exception from Branch Target Identification instruction on page D13-3186](#).

When accessing a guarded memory region, PACIASP and PACIBSP instructions have an implicit branch target identification instruction. This means that they are a target that is compatible with:

- A PSTATE.BTYPE value of 0b10 or 0b01.
- When the associated SCTLR_ELx.{BT0, BT1, BT} bits are 0, a PSTATE.BTYPE value of 0b11.

Note

- The implicit branch target identification property of PACIASP and PACIBSP is independent of the setting of the SCTLR_ELx.{EnIA, EnIB} bits.
- The Branch Target Identification instructions are NOPs in a non-guarded page.
- There is no direct way of reading or writing to the PSTATE.BTYPE field.

D5.4.5 Data access permission controls

The following subsections describe the data access permission controls:

- [Preventing EL0 access to halves of the address map on page D5-2758](#)
- [The AP\[2:1\] data access permissions, for stage 1 translations on page D5-2758.](#)
- [The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime on page D5-2759.](#)
- [Hierarchical control of data access permissions on page D5-2759.](#)

Preventing EL0 access to halves of the address map

If [FEAT_E0PD](#) is implemented, the [TCR_ELx](#).{E0PD0, E0PD1} fields can prevent unprivileged access to the addresses translated by [TTBR0_ELx](#) or [TTBR1_ELx](#). If access is prevented, the fault is reported as a level 0 Translation fault. The fault should take the same time to generate, whether the address is present in the TLB or not, to mitigate attacks that use fault timing. This type of fault is not counted as a TLB miss for performance monitoring features.

The AP[2:1] data access permissions, for stage 1 translations

In VMSAv8-64, for a translation regime that applies to both EL0 and a higher Exception level, the AP[2:1] bits control the stage 1 data access permissions, and:

- AP[2]** Selects between read-only and read/write access.
AP[1] Selects between Application level (EL0) control and the higher Exception level control.

This provides four permission settings for data accesses:

- Read-only at all levels.
- Read/write at all levels.
- Read-only at the higher Exception level, no access by software executing at EL0.
- Read/write at the higher Exception level, no access by software executing at EL0.

———— **Note** —————

In an implementation that does not include [FEAT_VHE](#), the only translation regime that applies to EL0 and a higher Exception level is the EL1&0 translation regime. In an implementation that includes [FEAT_VHE](#), the EL2&0 translation regime applies to both Non-secure EL0 and EL2 when the value of [HCR_EL2](#).{E2H, TGE} is {1, 1}.

For translation regimes that apply only to accesses from a single Exception level, AP[2] determines the stage 1 data access permissions, and AP[1] is RES1, meaning it is ignored by hardware and is treated as if it is 1.

[Table D5-29 on page D5-2758](#) shows the meaning of the AP[2:1] field for stage 1 of a translation regime that applies to both EL0 and a higher Exception level. In this table, an entry of None indicates that any access from that Exception level faults.

Table D5-29 Data access permissions for stage 1 translations that applies to EL0 and a higher Exception level

AP[2:1]	Access from higher Exception level	Access from EL0
00	Read/write	None
01	Read/write	Read/write
10	Read-only	None
11	Read-only	Read-only

For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime:

- The stage 2 translation also defines data access permissions, see [The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime on page D5-2759.](#)

- When both stages of translation are enabled, [Combining the stage 1 and stage 2 data access permissions on page D5-2784](#) describes how these permissions are combined.

[Table D5-30 on page D5-2759](#) shows the effect of the AP[2] field for stage 1 of a translation regime that applies to only a single Exception level.

Table D5-30 Data access permissions for stage 1 translations that apply to only a single Exception level

AP[2]	Access permission
0	Read/write
1	Read-only

The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime

In the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, when stage 2 address translation is enabled, the S2AP field in the stage 2 Translation Table descriptors define the data access permissions as [Table D5-31 on page D5-2759](#) shows. In this table, an entry of None indicates that any access generates a Permission fault.

Table D5-31 Data access permissions for stage 2 of the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime

S2AP	Access from Non-secure EL1 or Non-secure EL0
00	None
01	Read-only
10	Write-only
11	Read/write

The S2AP access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined by AP[2:1], see [Combining the stage 1 and stage 2 data access permissions on page D5-2784](#).

[Combining the stage 1 and stage 2 attributes, EL1&0 translation regime on page D5-2783](#) gives more information about the use of the stage 1 and stage 2 access permissions in an implementation of virtualization.

Hierarchical control of data access permissions

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the data access permissions.

———— **Note** —————

Similar hierarchical controls apply to instruction fetching, see [Hierarchical control of instruction fetching on page D5-2764](#).

However, in an implementation that includes FEAT_HPDS, when the value of a TCR_ELx.HPD{0} field is 1, or the value of the TCR_ELx.HPD1 field is 1, the hierarchical control of data access permissions is disabled for the translation stage controlled by that TCR_ELx, and the information in this subsection does not apply.

The restrictions apply only to subsequent levels of lookup for the same stage of translation. The APTable[1:0] field restricts the access permissions, as [Table D5-32 on page D5-2760](#) shows. As stated in the table footnote, for a translation regime that applies to only a single Exception level, APTable[0] is RES0, meaning it is ignored by the hardware.

Table D5-32 Effect of APTable[1:0] on subsequent levels of lookup

APTable[1:0]	Effect
00	No effect on permissions in subsequent levels of lookup.
01 ^a	Access at EL0 not permitted, regardless of permissions in subsequent levels of lookup.
10	Write access not permitted, at any Exception level, regardless of permissions in subsequent levels of lookup.
11 ^a	Regardless of permissions in subsequent levels of lookup: <ul style="list-style-type: none"> • Write access not permitted, at any Exception level. • Read access not permitted at EL0.

a. Not valid for any translation regime that applies to only a single Exception level. In the translation tables for such a regime, APTable[0] is RES0.

———— **Note** ————

The APTable[1:0] settings are combined with the translation table access permissions in the Translation Tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The VMSAv8-64 provides APTable[1:0] control only for stage 1 translations. The corresponding bits are RES0 in the stage 2 Translation Table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

D5.4.6 Access permissions for instruction execution

Execute-never controls determine whether instructions can be executed from a memory region. These controls are:

UXN, Unprivileged execute-never, stage 1 only

Descriptor bit[54], defined as UXN only for stage 1 of any translation regime for which stage 1 translation can support two VA ranges.

This field applies only to execution at EL0. A value of 0 indicates that this control permits execution.

XN, Execute-never

Descriptor bit[54], defined as XN for:

- Stage 1 of any translation regime for which the stage 1 translation can support only a single VA range.
- Stage 2 translations when [FEAT_XNX](#) is not implemented.

———— **Note** ————

[XN\[1:0\], Execute-never, stage 2 only](#) describes the stage 2 control when [FEAT_XNX](#) is implemented.

This field applies to execution at any Exception level to which the stage of translation applies. A value of 0 indicates that this control permits execution.

PXN, Privileged execute-never, stage 1 only

Descriptor bit[53], used only for stage 1 of any translation regime for which stage 1 translation can support two VA ranges.

- For stage 1 of a translation regime for which the stage 1 translation supports only a single VA range the stage 1 descriptors define a PXN field that is RES0, meaning it is ignored by hardware.

This field applies only to execution at an Exception level higher than EL0. A value of 0 indicates that this control permits execution.

XN[1:0], Execute-never, stage 2 only

Descriptor bits[54:53], defined as XN[1:0] for:

- Stage 2 translations when [FEAT_XNX](#) is implemented.

[Table D5-33 on page D5-2761](#) shows the operation of this control.

Table D5-33 XN[1:0] stage 2 access permissions model

XN[1]	XN[0]	Access
0	0	The stage 2 control permits execution at EL1 and EL0
0	1	The stage 2 control does not permit execution at EL1, but permits execution at EL0
1	0	The stage 2 control does not permit execution at EL1 or EL0
1	1	The stage 2 control permits execution at EL1, but does not permit execution at EL0

Note

For stage 2 translations when [FEAT_XNX](#) is not implemented, descriptor bit[53] is RES0, meaning it is ignored by hardware.

Note

In an implementation that does not include [FEAT_VHE](#), the only translation regime for which stage 1 translation can support two VA ranges is the EL1&0 translation regime. In an implementation that includes [FEAT_VHE](#):

- When the value of [HCR_EL2.E2H](#) is 1, [TCR_EL2](#) controls the EL2&0 translation regime, and this regime:
 - Supports two VA ranges, corresponding to [TTBR0_EL2](#) and [TTBR1_EL2](#).
 - Always supports both UXN and PXN fields.
- Memory accesses from EL0 are translated using the EL2&0 translation regime only when the value of [HCR_EL2.{E2H, TGE}](#) is {1, 1}.

[Table D5-33 on page D5-2761](#) shows the operation of the stage 2 XN[1:0] control, and for each single-bit execute-never field a value of 1 indicates that, at an Exception level to which the control applies, instructions cannot be executed from the target memory region. In addition:

- For a translation regime that applies to EL0 and a higher Exception level, if the value of the AP[2:1] bits is 0b01, permitting write access from EL0, then the PXN field is treated as if it has the value 1, regardless of its actual value.
- In a translation regime with two stages of translation, a region is execute-never if execution is not permitted by the value of the applicable execute-never field in one or both of:
 - The stage 1 Translation Table descriptor.
 - The stage 2 Translation Table descriptor.
- For each translation regime, if the value of the corresponding [SCTLR_ELx.WXN](#) field is 1 then any memory region that is writable is treated as XN, regardless of the value of the corresponding UXN, XN, or PXN field. For more information, see [Preventing execution from writable locations on page D5-2765](#).
- The [SCR_EL3.SIF](#) bit prevents execution in Secure state of any instruction fetched from Non-secure memory, see [Restriction on Secure instruction fetch on page D5-2765](#).

The execute-never controls apply to speculative instruction fetching, meaning speculative instruction fetch from a memory region that is execute-never at the current Exception level is prohibited.

Note

- Although the execute-never controls apply to speculative fetching, on a speculative instruction fetch from an execute-never location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an execute-never location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.
- The software that defines a translation table must mark any region of memory that is read-sensitive as execute-never, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as execute-never. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.
- When no stage of address translation for the translation regime is enabled, memory regions cannot have UXN, XN, or PXN attributes assigned. *Behavior of instruction fetches when all associated stages of translation are disabled on page D5-2732* describes how disabling all stages of address translation affects instruction fetching.

The following subsections give more information about the instruction fetch and execution permission controls:

- *Stage 1 instruction access and execution permissions on page D5-2762.*
- *Stage 2 instruction execution permissions on page D5-2764.*
- *Hierarchical control of instruction fetching on page D5-2764.*
- *Preventing execution from writable locations on page D5-2765.*
- *Restriction on Secure instruction fetch on page D5-2765.*

Stage 1 instruction access and execution permissions

Table D5-34 on page D5-2762 and Table D5-35 on page D5-2763 include the AP[2:1] read and write permissions shown in Table D5-29 on page D5-2758 and Table D5-30 on page D5-2759. These permissions are shown as:

- R** Indicates Read permission granted.
- W** Indicates Write permission granted.

Table D5-34 on page D5-2762 shows the stage 1 access permissions for instruction execution when using a translation regime that applies to EL0 and a higher Exception level.

Table D5-34 Stage 1 access permissions for instruction execution for a translation regime that applies to EL0 and a higher Exception level

UXN	PXN	AP[2:1]	SCTLR_ELx.WXN ^a	Access from higher Exception level	Access from EL0
0	0	00	0	R, W, Executable	Executable
			1	R, W, Not executable ^b	Executable
		01	0	R, W, Not executable ^c	R, W, Executable
			1	R, W, Not executable	R, W, Not executable ^d
		10	x	R, Executable	Executable
		11	x	R, Executable	R, Executable

Table D5-34 Stage 1 access permissions for instruction execution for a translation regime that applies to EL0 and a higher Exception level (continued)

UXN	PXN	AP[2:1]	SCTLR_ELx.WXN ^a	Access from higher Exception level	Access from EL0	
0	1	00	x	R, W, Not executable	Executable	
		01	0	R, W, Not executable	R, W, Executable	
			1	R, W, Not executable	R, W, Not executable ^d	
		10	x	R, Not executable	Executable	
		11	x	R, Not executable	R, Executable	
1	0	00	0	R, W, Executable	Not executable	
			1	R, W, Not executable ^b	Not executable	
		01	x	R, W, Not executable ^c	R, W, Not executable	
		10	x	R, Executable	Not executable	
		11	x	R, Executable	R, Not executable	
	1	1	00	x	R, W, Not executable	Not executable
			01	x	R, W, Not executable	R, W, Not executable
			10	x	R, Not executable	Not executable
			11	x	R, Not executable	R, Not executable

- a. Where ELx is the higher Exception level to which the translation regime applies.
- b. Not executable because of SCTLR_ELx.WXN control, because region is writable at ELx.
- c. Not executable, because AArch64 execution treats all regions writable at EL0 as being PXN.
- d. Not executable because of SCTLR_ELx.WXN control, because region is writable at EL0.

Table D5-35 on page D5-2763 shows the stage 1 access permissions for instruction execution when using a translation regime that applies to only a single Exception level.

Table D5-35 Access permissions for instruction execution for a translation regime that applies to only a single Exception level

XN	AP[2]	SCTLR_ELx.WXN ^a	Access permission
0	0	0	R, W, Executable
		1	R, W, Not executable ^b
		1	x
1	0	x	R, W, Not executable
		1	x

- a. Where ELx is the higher Exception level to which the translation regime applies.
- b. Not executable because of the SCTLR_ELx.WXN control, because region is writable at ELx.

Note

The Access permissions for an AArch64 translation regime that applies to only a single Exception level are consistent with the following fields in the translation table entries being treated as shown:

- [AP](#) treated as RES1.
 - [APTable\[0\]](#) treated as RES0.
 - [PXN](#) treated as RES0.
 - [PXNTable](#) treated as RES0.
-

Stage 2 instruction execution permissions

For the Secure or Non-secure EL1&0, when EL2 is enabled, stage 2 translation, the XN fields in the stage 2 Translation Table descriptors control the execution permission, and this control is completely independent of the S2AP access permissions:

- When [FEAT_XNX](#) is not implemented the stage 2 XN field is a 1-bit field that applies to execution at both EL0 and EL1, see [XN, Execute-never on page D5-2760](#).
- When [FEAT_XNX](#) is implemented the stage 2 XN field is a 2-bit field that provides independent control of execution from EL0 and execution from EL1, see [XN\[1:0\], Execute-never, stage 2 only on page D5-2761](#).

See also [Combining the stage 1 and stage 2 instruction execution permissions on page D5-2784](#).

Hierarchical control of instruction fetching

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the instruction fetching controls.

Note

Similar hierarchical controls apply to data accesses, see [Hierarchical control of data access permissions on page D5-2759](#).

However, in an implementation that includes [FEAT_HPDS](#), when the value of a [TCR_ELx.HPD{0}](#) field is 1, or the value of the [TCR_ELx.HPD1](#) field is 1, the hierarchical control of instruction fetching is disabled for the translation stage controlled by that [TCR_ELx](#), and the information in this subsection does not apply.

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- [UXNTable](#) or [XNTable](#) restricts the execute-never control:
 - When the value of the [XNTable](#) bit is 1, the [XN](#) bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
 - When the value of the [UXNTable](#) bit is 1, the [UXN](#) bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
 - When the value of a [UXNTable](#) or [XNTable](#) bit is 0 the bit has no effect.
- For a translation regime that applies to EL0 and a higher Exception level, [PXNTable](#) restricts the [PXN](#) control:
 - When the value of [PXNTable](#) is 1, the [PXN](#) bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
 - When the value of [PXNTable](#) is 0 it has no effect.

Note

The [UXNTable](#), [XNTable](#), and [PXNTable](#) settings are combined with the [XN](#), [UXN](#), and [PXN](#) bits in the Translation Table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The [UXNTable](#), [XNTable](#), and [PXNTable](#) controls are provided only for stage 1 translations. The corresponding bits are RES0 in the stage 2 Translation Table descriptors.

The effect of [UXNTable](#), [XNTable](#), or [PXNTable](#) applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to [UXNTable](#), [XNTable](#), or [PXNTable](#) requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

Preventing execution from writable locations

Armv8 provides control bits that, when corresponding stage 1 address translation is enabled, force writable memory to be treated as execute-never:

- For a translation regime that applies to EL0 and a higher Exception level, ELx, when the value of the applicable [SCTLR_ELx.WXN](#) field is 1:
 - All regions that are writable from EL0 at stage 1 of the address translation are treated as stage 1 execute-never at EL0.
 - All regions that are writable from ELx at stage 1 of the address translation are treated as stage 1 execute-never at ELx.
- For a translation regime that applies to only a single Exception level, ELx, when the value of the applicable [SCTLR_ELx.WXN](#) field is 1, all regions that are writable at stage 1 of the address translation are treated as stage 1 execute-never at ELx.

Note

- The [SCTLR_ELx.WXN](#) controls are intended to be used in systems with very high security requirements.
 - Setting a WXN field to 1 changes the interpretation of the translation table entry, overriding a zero value of a [XN](#), [UXN](#), or [PXN](#) field. It does not cause any change to the translation table entry.
-

For any given virtual machine, Arm expects WXN to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular [VMID](#) reflect the effect of the values of these fields. This means that any change of these fields without a corresponding change of [VMID](#) might require synchronization and TLB invalidation, as described in [TLB maintenance requirements and the TLB maintenance instructions](#) on page D5-2816.

Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, [SCR_EL3.SIF](#). When the value of this bit is 1, and execution is using the EL3 translation regime, the Secure EL2 translation regime, or the Secure EL1&0 translation regime, any attempt to execute an instruction fetched from memory marked in the first stage of translation as Non-secure memory causes a Permission fault. TLB entries might reflect the value of this bit, and therefore any change to the value of this bit requires synchronization and TLB invalidation, as described in [TLB maintenance requirements and the TLB maintenance instructions](#) on page D5-2816.

In an implementation that does not implement EL3, the *Effective value* of this bit is 0.

D5.4.7 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding Translation Table descriptor was set to 0.

The AF bit in the Translation Table descriptors is the Access flag.

In Armv8.0, the Access flag is managed by software as described in [Software management of the Access flag](#) on page D5-2766.

From Armv8.1, the Access flag can be managed by hardware as described in [Hardware management of the Access flag](#) on page D5-2767.

Note

The support for hardware management of the Access flag applies only to the VMSAv8-64 translation regimes.

D5.4.8 The dirty state

The dirty state indicates whether a page or section of memory is modified.

The dirty state can be managed by hardware as described in [Hardware management of dirty state on page D5-2768](#).

Where the dirty state is managed in hardware, the dirty state information is encoded using the access permission bits AP[2] and S2AP[1] in conjunction with the DBM bit.

D5.4.9 Block translation entry

While the nT bit is set, if the implementation meets either level 1 or level 2 support, the PE either:

- Generates a Translation fault when using a translation table entry that has the nT bit set. Such an entry is not permitted to be cached within the TLB.
- Guarantees that using a translation table entry that has the nT bit set does not break coherency, ordering guarantees or uniprocessor semantics, or fail to clear the Exclusives monitors when an entry that does not have the nT bit set is translating the same address cached within the TLB.

———— **Note** —————

Using a translation table entry that has the nT bit set might significantly impact the performance of the translation.

For more information, see [Support levels for changing block size on page D5-2818](#).

D5.4.10 XS attribute modifier

The FnXS bit indicates whether the XS attribute is modified by the stage 2 translation regime:

- When the FnXS bit is 0, the XS attribute of the resultant memory translation is not modified by this mechanism.
- When the FnXS bit is 1, the XS attribute of the resultant memory translation is set to 0 for this translation.

When [HCR_EL2.FWB](#) is 1 and forces the memory type to be Normal Inner Write-Back, Outer Write-Back Cacheable, the XS attribute is set to 0 on the resultant memory translation. This is not dependent on value of the FnXS bit in the stage 2 translation regime.

This stage 2 impact applies for stage 1 translations in the EL1&0 translation regime from AArch32 or AArch64.

See also:

- [Enabling and disabling the caching of memory accesses on page D4-2641](#).
- [The stage 1 memory region attributes on page D5-2776](#).

D5.4.11 Software management of the Access flag

Armv8.0 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a Translation Table descriptor entry for which the value of Access flag is 0.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

———— **Note** —————

If a system incorporates components that can autonomously update translation table entries that are shared with the Arm PE, then the software must be aware of the possibility that such components can update the access flag autonomously.

In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.

D5.4.12 Hardware management of the Access flag and dirty state

Armv8.1 introduces the following OPTIONAL features that perform hardware updates to the translation tables:

- [Hardware management of the Access flag on page D5-2767.](#)
- [Hardware management of dirty state on page D5-2768.](#)

The support for hardware management of the Access flag and dirty state is identified by the feature [FEAT_HAFDBS](#).

When the hardware management of the Access flag is enabled, in situations where, without this feature, an Access flag fault would be generated, the hardware instead performs an atomic read-modify-write of the appropriate Translation Table descriptor to update the Access flag from 0 to 1.

When the hardware management of dirty state is enabled, if the Block or Page descriptor in a translation table indicates that a data access does not have write permission, then in situations where, without this feature, a data access would generate a Permission fault only because of this lack of write permission, the hardware checks the value of the DBM field in the Block or Page descriptor. If this field is 1, then instead of generating a Permission fault, the hardware performs an atomic read-modify-write of the Translation Table descriptor, to change the value of the bit that prohibits the write access.

It is permissible, but not required, that a stage 2 permission failure on the stage 1 translation table walk is generated (and has priority over the stage 1 abort generated by the stage 1 translation table entry) if all of the following are true:

- Stage 1 hardware updating of either access or dirty information is enabled.
- A stage 1 translation table entry would result in the stage 1 translation table entry having the access or dirty bit updated.
- The stage 1 translation table entry has stage 2 read permission but not stage 2 write permission.
- The stage 1 translation entry generates an abort (which might be one of an address size fault, an alignment fault caused by memory type or a Permission fault).

Hardware management of the Access flag

Hardware management of the Access flag is enabled, for the corresponding stage of address translation, by the following configuration fields:

For stage 1 translations

- [TCR_EL1.HA](#).
- [TCR_EL2.HA](#).
- [TCR_EL3.HA](#).

For stage 2 translations

- [VTCR_EL2.HA](#).

Implementations are not required to support the hardware management of the Access flag. If [FEAT_HAFDBS](#) is not supported, then the HA bit in [TCR_EL1](#), [TCR_EL2](#), [TCR_EL3](#), and [VTCR_EL2](#) is RES0.

When the value of a configuration bit, HA, is 1, then when a memory access is made using a translation table Block or Page descriptor from the corresponding stage of address translation:

- The PE sets the value of the Access flag to 1 in the translation table descriptor in memory, in a coherent manner, by an atomic read-modify-write of the Translation Table descriptor, if both of the following conditions are true:
 - The descriptor does not generate a Permission fault or an Alignment fault based on the memory type.
 - If the hardware update mechanism was disabled or not implemented, the access would have generated an Access flag fault.
- When the PE updates the Access flag in this way no Access flag fault is generated.
- It is CONSTRAINED UNPREDICTABLE whether the PE sets the value of the Access flag in the translation table entry in memory to 1, in a coherent manner, by an atomic read-modify-write of the Translation Table descriptor, if both of the following conditions are true:
 - The descriptor generates a Permission fault or an Alignment fault based on the memory type.
 - If the hardware update mechanism was disabled or not implemented, the access would have generated an Access flag fault.

This means that the value of the Access flag becomes UNKNOWN if the above conditions are all true.

The Access flag might be set to 1 as a result of speculative accesses by the PE.

Note

A consequence of the architectural rules for translation table accesses is that the architecture requires that for any translation to which an architecturally executed memory access occurs, the Access flag is set to 1, except as indicated in [Using break-before-make when updating translation table entries on page D5-2818](#). However, because the architecture permits speculative accesses, the Access flag is permitted to be set to 1, even if there is no architecturally executed memory accesses by the processor.

When hardware updating of the Access flag is enabled, each stage of translation is treated independently. This means that a single memory access can cause a hardware update to either or both:

- The stage 1 Access flag.
- The stage 2 Access flag.

Note

Since speculative accesses are permitted to update the Access flags, it is permissible for:

- The stage 1 Access flag for a translation of a virtual address to be updated in situations where the stage 2 translation of the associated intermediate physical address that is returned by the stage 1 of the virtual address does not permit access.
- The stage 2 Access flag for a translation of an intermediate physical address to be updated in situations where the stage 1 translation of the associated virtual address which returned that intermediate physical address does not permit access.

An address translation instruction for an address is permitted, but not required, to set the Access flag in the translation table entries for that address. Correspondingly, it is IMPLEMENTATION DEFINED whether such an instruction can generate a Data Abort if the Access flag for a stage of translation is updated to be set.

When hardware updates of the Access flag are enabled for a stage of translation an address translation instruction that uses that stage of translation will not report that the address will give rise to an Access flag fault in the PAR, and the result in PAR will be as if the value of the Access flag in the translation table entries for that address was 1.

Hardware management of dirty state

The hardware management of dirty state mechanism can only be enabled if hardware management of the Access flag is enabled. For information on the hardware management of the Access flag, see [Hardware management of the Access flag on page D5-2767](#).

Note

The hardware management of dirty state mechanism uses:

- In a stage 1 translation table access, the AP[2] bit in conjunction with the DBM bit in the Translation Table descriptors.
- In a stage 2 translation table access, the S2AP[1] bit in conjunction with the DBM bit in the Translation Table descriptors.

Hardware management of dirty state is enabled, for the corresponding stage of address translation, by the following configuration fields:

For stage 1 translations

- [TCR_EL1.HD](#).
- [TCR_EL2.HD](#).
- [TCR_EL3.HD](#).

For stage 2 translations

- [VTCCR_EL2.HD](#).

Implementations are not required to support the dirty state mechanism. If this mechanism is not supported, then the HD bit in [TCR_EL1](#), [TCR_EL2](#), [TCR_EL3](#), and [VTCR_EL2](#) is RES0.

When hardware management of dirty state is enabled, and a memory access is made using a translation table Block or Page descriptor:

- For a stage 1 address translation, if the value of the [TCR_ELx.HD](#) field corresponding to the address translation is 1, then the PE sets AP[2] to 0 in the Translation descriptor in memory, in a coherent manner by an atomic read-modify-write of the Translation Table descriptor, if both of the following conditions are true:
 - The value of the DBM field in the descriptor is 1.
 - If the hardware update mechanism was disabled or not implemented, the access using this descriptor would have generated a Permission fault only because the value of the AP[2] field is 1, indicating that the access does not have write permission.

When the PE updates AP[2] in this way no Permission fault is generated because of the value of the AP[2] field.

- For a stage 2 address translation, if the value of the [VTCR_EL2.HD](#) field is 1, then the PE sets S2AP[1] to 1 in the Translation descriptor in memory, in a coherent manner by an atomic read-modify-write of the Translation Table descriptor, if both of the following conditions are true:
 - The value of the DBM field in the descriptor is 1.
 - If the hardware update mechanism was disabled or not implemented, the access using this descriptor would have generated a Permission fault only because the value of the S2AP[1] field is 0, indicating that the access does not have write permission.

When the PE updates S2AP[1] in this way no Permission fault is generated because of the value of the S2AP[1] field.

Note

The PE that does the atomic update of the Translation Table descriptor is expected to ensure that any cached copy of that Translation Table descriptor for that PE is similarly updated, or removed from the TLB, so that multiple writes from the same thread on the same PE do not lead to multiple updates to the table. This is only a performance expectation.

If, for a write access, the PE finds that a cached copy of the descriptor in a TLB had the DBM bit set to 1 and the AP[2] or S2AP[1] bit set to the value that forbids writes, then the PE must check that the cached copy is not stale with regard to the descriptor entry in memory, and if necessary perform an atomic read-modify-write update of the descriptor in memory. This applies if the cached copy of the descriptor in a TLB is either:

- A stage 1 descriptor in which DBM has the value 1 and AP[2] has the value 1.
- A stage 2 descriptor in which DBM has the value 1 and S2AP[1] has the value 0.

Note

Arm expects that, in many implementations, any atomic update of a translation table entry required by the dirty state management mechanism will cause a translation table walk.

For the hardware updating of the AP[2] and S2AP[1] bits, each translation stage is treated independently. This means a single memory access can update either or both of:

- The stage 1 AP[2] bit.
- The stage 2 S2AP[1] bit.

The architecture does not permit updates to AP[2] and S2AP[1] by the hardware management of the dirty state mechanism to occur as a result of speculative accesses by the PE that are not performed architecturally, except that for translation table entries for which the value of DBM is 1:

- A non-speculative access that passes stage 1 permissions check can update AP[2] if writes to that stage translation table are permitted and subsequently encounter a stage 2 fault. A non-speculative access that passes its stage 1 permission check but subsequently encounters a stage 2 fault is also permitted (but not required) to generate a stage 2 Permission fault on the stage 1 translation table walk if all of the following are true:
 - The stage 1 hardware updating of the access flag or dirty state is enabled.

- The stage 2 translation table entry translating the last level stage 1 translation entry has S2AP[1] == 0 and either DBM == 0 or hardware updating of the dirty state information is not enabled.

———— **Note** —————

These are cases where there is no stage 2 write permission for the hardware updating of the last level stage 1 translation table entry.

- A non-speculative access that generates an Alignment fault only because the memory type accessed is Device memory by a stage of translation can update AP[2] or S2AP[1] of that stage of translation if the memory access would have updated that translation table bit had the memory access not generated the Alignment fault.
- If the stage 2 hardware management of dirty state mechanism is enabled, the S2AP[1] field of a stage 2 translation table entry that is translating a stage 1 translation table without generating a stage 2 MMU fault:
 - Is updated from 0 to 1 as a result of a speculative update of the Access flag in an entry of that stage 1 translation table.
 - Is permitted to be updated speculatively from 0 to 1 as a result of performing a translation table walk using that stage 1 translation table, even if the entry in the stage 1 translation table is not updated. The speculative update is permitted to generate a synchronous External abort or an IMPLEMENTATION DEFINED abort caused by the memory type not supporting an atomic read-modify-write.

———— **Note** —————

This applies even if the stage 1 translation table contains entries that are not the final level entries and therefore would not be updated. This relaxation avoids the hardware complexity of having to detect whether the stage 1 entry is a final level entry before deciding to set the stage 2 dirty state information.

- If an instruction that generates more than one single-copy atomic memory access has a fault on some, but not all, of those memory accesses, then AP[2] and S2AP[1] bits associated with accesses from that instruction, which do not fault are permitted to be updated if the associated hardware update of dirty state mechanism is enabled.
- If the hardware update of dirty state mechanism is enabled and a write to memory is prevented by a Synchronous Tag Check Fault, the AP[2] and S2AP[1] bits associated with that write are permitted to be updated. For more information, see [Chapter D6 Memory Tagging Extension](#).
- When enabled, the Statistical Profiling Unit can update the AP[2] or S2AP[1] for any Page or Block translation table entry in the Profiling Buffer. See [Hardware management of dirty state and the Access flag by the Statistical Profiling Extension on page D9-2975](#).
- The dirty state information for a stage of translation can be updated to indicate dirty even if the store performing the access has an exception which has a lower priority than a Permission fault from that stage of translation, as determined by [Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2490](#) and [AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D5-2807](#).

For a Block or Page Translation Table descriptor for which the AF bit is 0, the DBM bit is 1, and either the value of the stage 1 AP[2] bit is 1 or the value of the stage 2 S2AP[1] bit is 0, both AF can be set to 1, and either AP[2] set to 0 or S2AP[1] set to 1, in a single atomic read-modify-write operation, as a result of an attempted write to a memory location that uses the translation table entry.

Implications of enabling the dirty state management mechanism

This subsection describes behaviors that result from having the dirty state management mechanism enabled for a particular stage of address translation.

For the final level of lookup in a stage 1 translation:

In the EL3 translation regime

The OA of the lookup is treated as writable if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2] is 1.
- In the descriptor for every higher level of lookup, the value of APTable[1] is 0.

In this case, if the value of `SCTLR_EL3.WXN` is 1 then the OA is treated as Execute-never.

In the EL2 or EL2&0 translation regime, when the value of `HCR_EL2.{E2H, TGE}` is not {1, 1}

Note

When the value of `HCR_EL2.E2H` is 1, `TCR_EL2` controls the EL2&0 translation regime, and otherwise it controls the EL2 translation regime.

The OA of the lookup is treated as writable if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of `DBM` is 1 and the value of `AP[2]` is 1.
- In the descriptor for every higher level of lookup, the value of `APTable[1]` is 0.

In this the value of `SCTLR_EL2.WXN` is 1 then the OA is treated as Execute-never.

In addition, if the value of `HCR_EL2.E2H` is 1, the OA is treated as Privileged execute-never if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of `DBM` is 1 and the value of `AP[2:1]` is `0b11`.
- In the descriptor for every higher level of lookup, the value of `APTable[1:0]` is `0b00`.

Note

When the value of `HCR_EL2.{E2H, TGE}` is not {1, 1}, memory accesses from EL0 do not use the EL2, or EL2&0, translation regime.

In the EL2&0 translation regime, when the value of `HCR_EL2.{E2H, TGE}` is {1, 1}

The OA of the lookup is treated as writable at EL2 and EL0, Privileged execute-never, if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of `DBM` is 1 and the value of `AP[2:1]` is `0b11`.
- In the descriptor for every higher level of lookup, the value of `APTable[1:0]` is `0b00`.

In this case, if the value of `SCTLR_EL2.WXN` is 1 then the OA is also treated as Unprivileged execute-never.

The OA of the lookup is treated as writable at EL2 but not writable at EL0 if either:

- Both:
 - In the descriptor for the final level of lookup, the value of `DBM` is 1 and the value of `AP[2:1]` is `0b10`.
 - In the descriptor for every higher level of lookup the value of `APTable[1:0]` is `0b0x`.

In this case, if the value of `SCTLR_EL2.WXN` is 1 then the OA is treated as Privileged execute-never.

- Both:
 - In the descriptor for the final level of lookup, the value of `DBM` is 1 and the value of `AP[2:1]` is `0b11`.
 - In at least one of the descriptors for higher levels of lookup the value of `APTable[1:0]` is `0b01`.

In this case, if the value of `SCTLR_EL2.WXN` is 1 then the OA is treated as Privileged execute-never.

In the EL1&0 translation regime

The OA of the lookup is treated as writable at EL1 and EL0, Privileged execute-never, if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of `DBM` is 1 and the value of `AP[2:1]` is `0b11`.
- In the descriptor for every higher level of lookup, the value of `APTable[1:0]` is `0b00`.

In this case, if the value of `SCTLR_EL1.WXN` is 1 then the OA is treated as Unprivileged execute-never.

The OA of the lookup is treated as writable at EL1 but not writable at EL0 if either:

- Both:
 - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of `AP[2:1]` is `0b11`.
 - In at least one of the descriptors for higher levels of lookup the value of `APTable[1:0]` is `0b01`.

In this case, if the value of `SCTLR_EL1.WXN` is 1 then the OA is treated as Privileged execute-never.

- Both:
 - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of `AP[2:1]` is `0b10`.
 - In the descriptor for every higher level of lookup the value of `APTable[1:0]` is `0b0x`.

In this case, if the value of `SCTLR_EL1.WXN` is 1 then the OA is treated as Privileged execute-never.

The OA of a translation table entry where the DBM bit is 1, and the stage 1 `AP[2]` bit is 1 or the stage 2 `S2AP[1]` bit is 0, is treated as writable:

- For data cache invalidation instructions that require write permission, that is for the DC IVAC instruction.
- For address translation instructions that require write permission, that is for the AT S1E0W, AT S1E1W, AT S1E0W, AT S1E1W, AT S1E2W, and AT S1E3W instructions.

Cache invalidation and address translation instructions never cause the stage 1 `AP[2]` bit or the stage 2 `S2AP[1]` bit in the translation table entry to be updated.

For a Store-Exclusive instruction to a memory location for which the DBM bit is 1 and the stage 1 `AP[2]` bit is 1, if the Store-Exclusive fails because the Exclusives monitor is not in the exclusive state, it is IMPLEMENTATION DEFINED whether the `AP[2]` bit in the translation table is updated.

For a Store-Exclusive instruction to a memory location for which the DBM bit is 1, and the stage 2 `S2AP[1]` bit is 0, if the Store-Exclusive fails because the Exclusives monitor is not in the Exclusive access state, it is IMPLEMENTATION DEFINED whether the `S2AP[1]` bit in the translation table is updated.

For a store to a memory location for which the DBM bit is 1, and the stage 1 `AP[2]` bit is 1, it is IMPLEMENTATION DEFINED whether the `AP[2]` bit in the translation table is updated:

- If the memory location generates a synchronous External abort on a write for a store to a memory location.
- If the memory location generates a watchpoint on a write.

For a store to a memory location for which the DBM bit is 1, and the stage 2 `S2AP[1]` bit is 0, it is IMPLEMENTATION DEFINED whether the `S2AP[1]` bit in the translation table is updated:

- If the memory location generates a synchronous External abort on a write for a store to a memory location.
- If the memory location generates a watchpoint on a write.

In the event of a PE setting the stage 1 `AP[2]` bit to 0, it is not required that all associated entries are removed from the TLBs of other PEs in the system.

In the event of a PE setting the stage 2 `S2AP[1]` bit to 1, it is not required that all associated entries are removed from the TLBs of other PEs in the system.

For the stage 2 translation tables, it is CONSTRAINED UNPREDICTABLE whether the stage 2 `S2AP[1]` entry is updated in response to a stage 1 translation table walk where the stage 1 translation system is configured to perform hardware updates to the Access flag or stage 1 `AP[2]` bit, but the values of the Access flag and `AP[2]` bit are such that a hardware update to the stage 1 translation table entry being accessed is not required.

In the event of a PE encountering a situation for a data write for which the DBM bit is 1 and the stage 1 `AP[2]` bit is 1 in a TLB, it is required that the hardware checks that the cached copy is not stale with regards to the translation table entry in memory and performs the atomic read-modify-write update with respect to table entry in memory.

In the event of a PE encountering a situation for a data write for which the DBM bit is 1 and stage 2 S2AP[1] bit is 0 in a TLB, it is required that the hardware checks that the cached copy is not stale with regards to the translation table entry in memory and performs the atomic read-modify-write update with respect to table entry in memory.

For a CAS or CASP instruction to a memory location for which the DBM bit is 1, and the stage 1 AP[2] bit is 1, if the compare fails, and the location is not updated, it is CONstrained UNPREDICTABLE whether the AP[2] bit in the translation table is updated.

For a CAS or CASP instruction to a memory location for which the DBM bit is 1, and the stage 2 S2AP[1] bit is 0, if the compare fails, and the location is not updated, it is CONstrained UNPREDICTABLE whether the S2AP[1] bit in the translation table is updated.

For an atomic instruction to a memory location for which the DBM bit is 1, and the stage 2 S2AP[0:1] is 0b00, if the instruction generates a stage 2 Permission fault as a result of not having read permission, it is CONstrained UNPREDICTABLE whether the S2AP[1] bit in the translation table is updated.

D5.4.13 Ordering of hardware updates to the translation tables

A hardware update to the translation table that is caused by a load or a store, including an atomic instruction, is guaranteed to be observed, to the extent required by the shareability attributes:

- Before a load or store, including an atomic instruction, to an arbitrary address, other than the address of the translation table entry, that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load or store.
- Before a load to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load.
- Before a store or atomic access to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry.
- Before a cache maintenance instruction to an arbitrary address appearing in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction that caused the update to the translation table entry and the subsequent cache maintenance instruction.

An update to the translation table that is caused by a load is not ordered with respect to the load itself.

An update to the translation table that is caused by a store or an atomic access is observed by all observers, to the extent required by the shareability attributes, before the store itself in the case that the store is to the same location as the translation table update.

An update to the translation table that is caused by a store or an atomic access is not ordered with respect to the store itself in the case that the store is not the same location as the translation table update.

D5.4.14 Restriction on memory types for hardware updates on translation tables

Translation tables can be placed in Normal memory with any cacheability, but the hardware updates to the translation tables require an atomic update of memory. The properties of the atomicity can be met only by functionality outside the PE. Some system implementations might not implement this functionality for all regions of memory. This can apply to:

- Any type of memory in the system that does not support hardware cache coherency.
- Non-cacheable memory, or memory that is treated as Non-cacheable, in an implementation that does not support hardware cache coherency.

An implementation can choose which memory type is treated as Non-cacheable.

The memory types for which it is architecturally guaranteed that the hardware updates of the translation tables will be atomic are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

The architecture only requires that *Conventional memory* that is mapped in this way supports this functionality.

If the hardware updates of the translation tables are not atomic in regard to other agents that access memory, then performing a hardware update to such a location can have one or more of the following effects:

- The hardware update generates a synchronous External abort, which is presented as an External abort on a translation table walk.
- The instruction generates a SError interrupt.
- The hardware update generates an Unsupported atomic hardware update MMU fault reported using the Fault status code of:
 - `ESR_ELx.DFSC = 110001` for Data Abort exceptions.
 - `ESR_ELx.IFSC = 110001` for Instruction Abort exceptions.
 - `PMSR_EL1.FSC = 110001` for an abort on a write to the Statistical Profiling buffer.

For the Secure or Non-secure EL1&0 translation regime, when EL2 is implemented and enabled in the current Security state, if atomic hardware update is not supported because of the memory type that is defined in the first stage of translation, or the second stage of translation is not enabled, then this exception is a first stage abort and is taken to EL1. Otherwise, the exception is a second stage abort and is taken to EL2.

The priority of this MMU fault for a stage of the translation lies at an IMPLEMENTATION DEFINED point between:

- Immediately before the priority of an Access Flag fault generated by the same stage of translation as the stage of this MMU fault.
 - Immediately after the priority of a Permission fault generated by the same stage of translation as the stage of this MMU fault.
- The hardware updates are performed, but there is no guarantee that the memory accesses were performed atomically in regard to other agents that access memory. In this case, the instruction might also generate a SError interrupt.

The execution of an address translation instruction can report an Unsupported atomic hardware update fault, in `PAR_EL1`, using the Fault status code of `0b110001`, as follows:

- On an address translation instruction executed at EL1, if hardware updates to the translation tables are enabled for stage 1, and the stage 1 translation tables are held in memory with a memory type that means that hardware updates of the translation tables are not atomic as observed by other agents that can access memory, then the architecture permits, but does not require, that `PAR_EL1` reports a Translation table hardware update fault.
- On an address translation instruction executed at EL2 or EL3, if hardware updates to the translation tables used by the instruction are enabled, and those translation tables are held in memory with a memory type that means that hardware updates of the translation tables are not atomic as observed by other agents that can access memory, then the architecture permits, but does not require, that `PAR_EL1` reports a Translation table hardware fault.

D5.4.15 Use of the Contiguous bit with hardware updates of the translation table entries

Hardware updates of the Access flag, and the AP[2] or S2AP[1] bit, only apply to a single translation table entry. An update to one of these bits in a translation table entry that also has the Contiguous bit set to 1 can give rise to translation table entries that have different Access flag, or different AP[2] or S2AP[1] bits, within the members of a group of contiguous translation table entries.

This is acceptable under the architecture when using hardware updates of the translation table entries. In addition, an access or a write to a location translated by an entry that has the Contiguous bit set might not result in a hardware update of the Access flag or the AP[2] or S2AP[1] bit, if at least one entry in the set of contiguous translation table entries has the Access flag set to 1, or the AP[2] or S2AP[1] bit indicating that the entry is dirty.

Note

- The provision of the Contiguous bit permits, but does not require, the hardware to hold a single entry in a TLB for the set of translation table entries in the group, and to have updated only one or more of the Access flags and the AP[2] bit or S2AP[1] bit for the single translation table entry that gave rise to the TLB entry.
- A consequence of this is that software must combine the Access flag values, and AP[2] or S2AP[1] values, across all translation table entries in a contiguous group to determine whether any of the entries have been accessed or written to.

For more information on the Contiguous bit, see [The Contiguous bit on page D5-2782](#).

D5.5 Memory region attributes

The memory region attribute fields control the memory type, accesses to the caches, and whether the memory region is Shareable and therefore is coherent. This section also describes some additional translation table fields that this manual groups with the memory region attributes.

In the EL1&0 translation regime, each enabled stage of address translation assigns memory region attributes, as described in this section. When both stages of translation are enabled, [Combining the stage 1 and stage 2 attributes, EL1&0 translation regime on page D5-2783](#) describes how the assignments from the two stages are combined.

———— Note ————

In a virtualization implementation, a hypervisor, executing at EL2, might usefully:

- Reduce the permitted cacheability of a region.
- Increase the required shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

The following sections describe these attributes:

- [The stage 1 memory region attributes on page D5-2776](#).
- [The stage 2 memory region attributes, EL1&0 translation regime on page D5-2778](#).
- [Other fields in the VMSEA8-64 Translation Table format descriptors on page D5-2781](#).
- [Combining the stage 1 and stage 2 attributes, EL1&0 translation regime on page D5-2783](#).

———— Note ————

- This section describes the memory region attributes for each of the translation regimes, and for each stage of translation in the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime.
- A translation applies to memory accesses from either:
 - Only a single Exception level, for example the EL3 translation regime.
 - EL0 and one higher Exception level, for example the EL1&0 translation regime.
- In general, attribute assignment is simpler in a regime that applies to only a single Exception level, and in these regimes behavior is consistent with fields in the translation tables being treated as follows:
 - `AP[1]` is RES1, meaning the PE ignores the value of the bit and behaves as if it is 1.
 - `APTable[0]` is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.
 - The `PXN` field is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.
 - The `PXNTable` bit is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.

D5.5.1 The stage 1 memory region attributes

The description of the memory region attributes in a Translation descriptor divides into:

Memory type and Cacheability

These are described indirectly, by registers referenced by bits in the Table descriptor. This is described as *remapping* the memory type and attribute description. [Stage 1 memory region type and Cacheability attributes on page D5-2776](#) describes this encoding.

Shareability The SH[1:0] field in the Translation Table descriptor encodes shareability information. [Stage 1 Shareability attribute, for Normal memory on page D5-2777](#) describes this encoding.

Stage 1 memory region type and Cacheability attributes

In the VMSEA8-64 translation table format, the AttrIdx[2:0] field in a Block or Page Translation Table descriptor for a stage 1 translation indicates the 8-bit field in the MAIR_ELx that specifies the attributes for the corresponding memory region. The required field is Attr_n, where $n = \text{AttrIdx}[2:0]$. For more information about AttrIdx[2:0], see [Attribute fields in stage 1 VMSEA8-64 Block and Page descriptors on page D5-2749](#).

Note

Each `MAIR_ELx` is a 64-bit register that is architecturally mapped to a pair of AArch32 registers. See the `MAIR_ELx` register descriptions for more information.

Each `MAIR_ELx.Attrn` field defines, for the corresponding memory region:

- The memory type: Device or Normal.
- For Device memory:
 - The Device memory type, one of: Device-nGnRnE, Device-nGnRE, Device-nGRE, Device-GRE.
 - The XS attribute, used when `FEAT_XS` is implemented. See *Stage 1 definition of the XS attribute on page D5-2777*.
- For Normal memory:
 - The inner and outer cacheability: Non-cacheable, Write-Through, or Write-Back.
 - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is *Allocate* or *No Allocate*, and the Transient allocation hints, if supported.
 - If `FEAT_MTE2` is implemented, the Tagged attribute.
 - The XS attribute, used when `FEAT_XS` is implemented. See *Stage 1 definition of the XS attribute on page D5-2777*.

For more information about the memory type and attributes, see *Memory types and attributes on page B2-165*, *Cacheability, cache allocation hints, and cache transient hints on page D4-2640*, and *Tagged and Untagged Addresses on page D6-2843*.

Stage 1 definition of the XS attribute

When `FEAT_XS` is implemented, all stage 1 memory types defined in the `MAIR_ELx` or `TCR_ELx` registers have the XS attribute set to 1, unless they are any of the following, which have the XS attribute set to 0:

- For Device memory:
 - Device memory types that use the `MAIR_ELx.Attrn` encoding `0b0000dd01`.
- For Normal memory:
 - Inner Write-Back Cacheable, Outer Write-back Cacheable memory types defined in the `MAIR_ELx` or `TCR_ELx` registers, including any memory types that are treated as Write-Back Cacheable as a result of IMPLEMENTATION DEFINED choices in the architecture.
 - Inner Write-through Cacheable and Outer Write-through Cacheable memory types that use the `MAIR_ELx.Attrn` encoding `0b1010000`.
 - Inner Non-cacheable, Outer Non-cacheable memory types that use the `MAIR_ELx.Attrn` encoding `0b01000000`.

Stage 1 Shareability attribute, for Normal memory

If the *Effective value* of `TCR_ELx.DS` is 0, when using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page Translation Table descriptor specifies the Shareability attributes of the corresponding memory region. *Table D5-36 on page D5-2777* shows the encoding of this field.

Table D5-36 SH[1:0] field encoding for Normal memory, VMSAv8-64 translation table format

SH[1:0]	Normal memory
00	Non-shareable
01	Reserved, CONSTRAINED UNPREDICTABLE ^a
10	Outer Shareable
11	Inner Shareable

- a. See *Reserved values in System and memory-mapped registers and translation table entries* on page K1-8423 for the permitted CONSTRAINED UNPREDICTABLE behavior.

———— Note ————

The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes.

If the *Effective value* of `TCR_ELx.DS` is 1, descriptor bits[9:8] are OA[51:50] and Shareability is determined by `TCR_ELx.SHn`, see *Stage 1 Shareability when FEAT_LPA2 is implemented* on page D5-2778.

See *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D5-2786 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

Stage 1 Shareability when FEAT_LPA2 is implemented

If `FEAT_LPA2` is implemented, when `TCR_ELx.DS==1`, OA[51:50] replaces the SH[1:0] field in the Block or Page descriptor for the stage 1 translation regime controlled by that register. In that case, the Shareability of normal cacheable locations determined by a Block or Page descriptor is taken from the following:

- For the EL3 translation regime, `TCR_EL3.SH0`.
- For the EL2 translation regime if `HCR_EL2.E2H==0`, `TCR_EL2.SH0`.
- For the EL2 and EL2&0 translation regimes, if `HCR_EL2.E2H==1` and the VA is an address that is translated using tables pointed to by `TTBR0_EL2`, `TCR_EL2.SH0`.
- For the EL2 and EL2&0 translation regimes, if `HCR_EL2.E2H==1` and the VA is an address that is translated using tables pointed to by `TTBR1_EL2`, `TCR_EL2.SH1`.
- For the EL1&0 translation regime, if the VA is an address that is translated using tables pointed to by `TTBR0_EL1`, `TCR_EL1.SH0`.
- For the EL1&0 translation regime, if the VA is an address that is translated using tables pointed to by `TTBR1_EL1`, `TCR_EL1.SH1`.

See *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D5-2786 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

D5.5.2 The stage 2 memory region attributes, EL1&0 translation regime

In the stage 2 Translation Table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- *Stage 2 memory region type and Cacheability attributes* on page D5-2779 describes how the MemAttr[3:0] field defines these attributes.
- If the *Effective value* of `VTCR_EL2.DS` is 0, the SH[1:0] field in the Translation Table descriptor encodes shareability information. *Stage 2 Shareability attribute, for Normal memory* on page D5-2780 describes this encoding.

If the *Effective value* of `VTCR_EL2.DS` is 1, descriptor bits[9:8] are OA[51:50] and Shareability is determined by `VTCR_EL2.SH0`, see *Stage 2 Shareability attribute, for Normal memory* on page D5-2780.

The following sections describe how, when both stages of address translation are enabled, the memory region attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- *Combining the stage 1 and stage 2 memory type attributes* on page D5-2784.
- *Combining the stage 1 and stage 2 cacheability attributes for Normal memory* on page D5-2785.
- *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D5-2786.

D5.5.3 Stage 2 memory region type and Cacheability attributes

Table D5-37 on page D5-2779 shows how MemAttr[3:2] gives a top-level definition of the memory type, and of the Outer cacheability of a Normal memory region.

Table D5-37 VMSAv8-64 MemAttr[3:2] encoding, stage 2 translation

MemAttr[3:2]	Memory type	Outer cacheability
00	Device. MemAttr[1:0] encodes the Device memory type.	Not applicable
01	Normal. MemAttr[1:0] encodes the Inner Cacheability.	Outer Non-cacheable
10		Outer Write-Through Cacheable
11		Outer Write-Back Cacheable

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

- When MemAttr[3:2] == 0b00, indicating Device memory, Table D5-38 on page D5-2779 shows the encoding of MemAttr[1:0].

Table D5-38 MemAttr[1:0] encoding for Device memory

MemAttr[1:0]	Meaning when MemAttr[3:2] == 0b00
00	Region is Device-nGnRnE memory
01	Region is Device-nGnRE memory
10	Region is Device-nGRE memory
11	Region is Device-GRE memory

- When MemAttr[3:2] != 0b00, indicating Normal memory, Table D5-39 on page D5-2779 shows the encoding of MemAttr[1:0].

Table D5-39 MemAttr[1:0] encoding for Normal memory

MemAttr[1:0]	Meaning when MemAttr[3:2] != 0b00
00	Reserved, CONSTRAINED UNPREDICTABLE ^a
01	Inner Non-cacheable
10	Inner Write-Through Cacheable
11	Inner Write-Back Cacheable

- a. See *Reserved values in System and memory-mapped registers and translation table entries* on page K1-8423 for the permitted CONSTRAINED UNPREDICTABLE behavior.

Note

- The stage 2 translation does not assign any allocation hints.
- The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:
 - MemAttr[3:2] == 0b11, Normal memory, Outer Write-Back Cacheable.
 - MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

D5.5.4 Stage 2 Shareability attribute, for Normal memory

If the *Effective value* of `VTCCR_EL2.DS` is 0, when using the VMSAv8-64 translation table format, the `SH[1:0]` field in a block or page Translation Table descriptor specifies the Shareability attributes of the corresponding memory region. [Table D5-40 on page D5-2780](#) shows the encoding of this field.

Table D5-40 SH[1:0] field encoding for Normal memory, VMSAv8-64 translation table format

SH[1:0]	Normal memory
00	Non-shareable
01	Reserved, CONSTRAINED UNPREDICTABLE ^a
10	Outer Shareable
11	Inner Shareable

- a. See *Reserved values in System and memory-mapped registers and translation table entries on page K1-8423* for the permitted CONSTRAINED UNPREDICTABLE behavior.

Note

- [VMSAv8-64 Translation Table format descriptors on page D5-2739](#) This encoding is the same as the shareability encoding described in [Stage 1 Shareability attribute, for Normal memory on page D5-2777](#).
- The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes.

If `FEAT_LPA2` is implemented, when `VTCCR_EL2.DS`==1, `OA[51:50]` replaces the `SH[1:0]` field in the Block or Page descriptor for the stage 2 translation regime. In that case, the Shareability of normal cacheable locations determined by a Block or Page descriptor is taken from `VTCCR_EL2.SH0`.

See [Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D5-2786](#) for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

D5.5.5 Stage 2 memory region type and Cacheability attributes when FEAT_S2FWB is implemented

When `FEAT_S2FWB` is implemented and `HCR_EL2.FWB` is set to 1, the `MemAttr[3:0]` field is encoded in bits[5:2] of the Stage 2 Page or Block descriptor as follows:

- Bit[5] is RES0.
- Bit[4] determines the interpretation of bits [3:2].

When bit[4] is one the effects of bits [3:2] are defined in [Table D5-41 on page D5-2780](#).

Table D5-41 Effect of bit[4] == 1 on Cacheability and Memory Type

Stage 1 Memory Type and Inner or Outer Cacheability attribute	Stage 2 Block/ Descriptor Bits[3:2]	Resultant Memory type and Cacheability attribute
Normal Write-Back	0b11	Normal Write-Back
Normal Write-Through		Normal Write-Through
Normal Non-cacheable		Normal Non-cacheable
Device<attr>		Device<attr>

Table D5-41 Effect of bit[4] == 1 on Cacheability and Memory Type (continued)

Stage 1 Memory Type and Inner or Outer Cacheability attribute	Stage 2 Block/ Descriptor Bits[3:2]	Resultant Memory type and Cacheability attribute
Normal Write-Back	0b10	Normal Write-Back
Normal Write-Through		
Normal Non-cacheable		
Device<attr>		
Normal Write-Back	0b01	Normal Non-cacheable
Normal Write-Through		
Normal Non-cacheable		
Device<attr>		
-	0b00	RESERVED

When [HCR_EL2.FWB](#) is set to 1 and Bit[4] is 0, then the stage 2 memory type is Device. Bits[3:2] of the Stage 2 Page or Block descriptor define the stage 2 Device memory attributes. The stage 2 Device Memory attributes are defined in [Table D5-42 on page D5-2781](#).

Table D5-42 Device Memory Attributes when Bit[4] == 0

Stage 2 Page/Block descriptor bits [3:2]	Device Memory Attribute
0b00	Device-nGnRnE
0b01	Device-nGnRE
0b10	Device-nGRE
0b11	Device-GRE

When [FEAT_XS](#) is implemented, [HCR_EL2.FWB](#) is set to 1, and the resultant memory attributes become Normal Inner Write-back, Outer Write-back Cacheable, the XS attribute is set to 0 on the resultant memory translation.

The following are unaffected by the value of [HCR_EL2.FWB](#):

- The way that Shareability attributes from stage 1 and stage 2 are combined.
- The way that stage 1 memory types and attributes are combined with stage 2 Device type and attributes.

D5.5.6 Other fields in the VMSAv8-64 Translation Table format descriptors

The following subsections describe the other fields in the Translation Table Block and Page descriptors:

- [The Contiguous bit on page D5-2782](#).
- [IGNORED fields on page D5-2783](#).
- [Field reserved for software use on page D5-2783](#).

The Contiguous bit

When the value of the Contiguous bit is 1, it indicates that the entry is one of a number of adjacent translation table entries that point to a *contiguous output address range*. The required number of adjacent entries depends on the current translation granule size, as follows:

4KB granule 16 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 16 entries must be aligned in the translation table. If accessing a full-sized 4KB translation table, this means that the top 5 of the 9 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

16KB granule This bit indicates that adjacent translation table entries point to contiguous output address range that has the same permissions and attributes. With the 16KB granule, the number of contiguous entries indicated by setting this bit to 1 depends on the lookup level of the translation table:

Level 2 lookup The bit indicates 32 contiguous entries, giving a 1GB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 6 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

Level 3 lookup The bit indicates 128 contiguous entries, giving a 2MB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 4 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 128 translation table entries at the same translation table level.

64KB granule 32 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 32 entries must be aligned in the translation table. If accessing a full-sized 64KB translation table, this means that the top 8 of the 13 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

Setting this bit to 1 means that the TLB can cache a single entry to cover the contiguous translation table entries.

This section defines the requirements for programming the Contiguous bit. [Possible errors in programming the translation table registers on page D5-2726](#) describes the effect of not meeting these requirements.

The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of the Contiguous bit.

TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues.

[Use of the Contiguous bit with hardware updates of the translation table entries on page D5-2774](#) describes the effect of hardware management of the Access flag and dirty state on the Contiguous bit.

————— Note —————

When [FEAT_LVA](#) is implemented, the level 1 block size for the 64KB granule does not support the Contiguous bit, and that field is RES0.

If the [Effective value](#) of [TCR_ELx.DS](#) or [VTCR_EL2.DS](#) is 1, level 0 Block descriptors for the 4KB granule and level 1 Block descriptors for the 16KB granule do not support the Contiguous bit, and that field is RES0.

IGNORED fields

In the VMSAv8-64 Translation Table descriptors, the following fields are identified as IGNORED, meaning the architecture guarantees that a PE makes no use of these fields:

- In the stage 1 and stage 2 Table descriptors, bits[58:51] and bits[11:2].
- In the stage 1 and stage 2 Block and Page descriptors, bit[63] and bits[58:55].
- In the stage 1 and stage 2 Block and Page descriptors in an implementation that does not include [FEAT_HPDS2](#), bits[62:59].

Of these fields:

- In the stage 1 and stage 2 Block and Page descriptors, bits[58:55] are reserved for software use, see [Field reserved for software use on page D5-2783](#).
- In the stage 2 Block and Page descriptors:
 - Bit[63] is reserved for use by a System MMU.
 - In an implementation that does not include [FEAT_HPDS2](#), bits[62:59] are reserved for use by a System MMU.

Field reserved for software use

The architecture reserves a 4-bit IGNORED field in the Block and Translation Table descriptors, bits[58:55], for software use. The definition of IGNORED means the architecture guarantees that hardware makes no use of this field.

———— Note —————

This means there is no need to invalidate the TLB if these bits are changed.

D5.5.7 Combining the stage 1 and stage 2 attributes, EL1&0 translation regime

When EL2 is enabled, the Secure or Non-secure EL1&0 translation regime comprises two stages of translation, each of which can be enabled independently:

- Stage 1 translation is configured and controlled from EL1. When enabled, stage 1 translation can define access permissions independently for access from EL0 and for accesses from EL1.

Stage 1 MMU faults are taken to EL1.

- When stage 2 translation is enabled, the stage 2 access controls defined at EL2:
 - Affect the stage 1 access permissions settings.
 - Take no account of whether the accesses are at EL1 or EL0.
 - Permit software executing at EL2 to assign a write-only attribute to a memory region.Stage 2 MMU faults are taken to EL2.

———— Note —————

In an implementation of virtualization, the attributes defined in the stage 2 translation tables mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The effects of the combination of attributes defined by the Hypervisor are functionally transparent to the Guest OS.

When [HCR_EL2.FWB](#) is 1 and the final memory type is Normal Cacheable:

- If the stage 1 Page or Block descriptor specifies a cacheable memory type, then the final cache allocation hint is the stage 1 cache allocation hint.
- If the stage 1 Page or Block descriptor does not specify a cacheable memory type, then the final cache allocation hint is Read Allocate, Write Allocate.

The effects of [HCR_EL2.FWB](#) apply to both Secure and Non-secure stage 2 translation regime.

When [FEAT_S2FWB](#) is implemented, the architecture requires that [CLIDR_EL1](#).{LoUU, LoIUS} are zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

When [HCR_EL2.FWB](#) is set to 1, and the stage 2 Page or Block descriptor [4:2] is set to 0b110, the resultant memory type is Normal Write-Back Cacheable regardless of the value of the stage 1 memory type.

When [FEAT_XS](#) is implemented, [HCR_EL2.FWB](#) is set to 1, and the resultant memory type becomes Normal Write-Back Cacheable, the XS attribute is set to 0 on the resultant memory translation.

If the stage 1 translation is treated as Tagged, the final memory type is Tagged only if the final cacheable memory type is Inner and Outer Write-back Cacheable and the final allocation hints are Read-Allocate, Write-Allocate.

Combining the stage 1 and stage 2 data access permissions

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in [The AP\[2:1\] data access permissions, for stage 1 translations on page D5-2758](#).
- The stage 2 permissions described in [The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime on page D5-2759](#).

The stage 1 and stage 2 permissions are combined as follows:

1. If an access is not permitted by the stage 1 permissions, then it generates a stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an access is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a stage 2 Permission fault.
3. If an access is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

Combining the stage 1 and stage 2 instruction execution permissions

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in [Stage 1 instruction access and execution permissions on page D5-2762](#).
- The stage 2 permissions described in [Stage 2 instruction execution permissions on page D5-2764](#).

The stage 1 and stage 2 permissions are combined as follows:

1. If an instruction fetch is not permitted by the stage 1 permissions, then it generates a stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an instruction fetch is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a stage 2 Permission fault.
3. If an instruction fetch is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

Combining the stage 1 and stage 2 memory type attributes

The combining of memory type attributes from the two stages of translation applies only if [HCR_EL2.FWB](#) is set to 0.

Table D5-43 on page D5-2785 shows the rules for combining the stage 1 and stage 2 memory type assignments.

Table D5-43 Combining the stage 1 and stage 2 memory type assignments

Rule	If either stage of translation assigns:	The resultant memory type is:
Device has precedence over Normal	Any Device memory type	A Device memory type
non-Gathering has precedence over Gathering	A Device-nGxx memory type	A Device-nGxx memory type
non-Reordering has precedence over Reordering	A Device-nGnRx memory type	A Device-nGnRx memory type
No Early write acknowledge has precedence over Early write acknowledge	The Device-nGnRnE memory type	The Device-nGnRnE memory type

Regardless of any shareability attribute obtained as described in [Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D5-2786](#):

- Any location for which the resultant memory type is any type of Device memory is always treated as Outer Shareable.
- Any location for which the resultant memory type is Normal Inner Non-cacheable, Outer Non-cacheable is always treated as Outer Shareable.

For information about how the cacheability attribute is obtained from the attributes assigned at each stage of translation, see [Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D5-2785](#).

The combining of the memory type attributes from the two stages of translation means a translation table walk for stage 1 translation can be made to a type of Device memory. If this occurs, then:

- If the value of `HCR_EL2.PTW` is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be done speculatively.
- If the value of `HCR_EL2.PTW` is 1, then the memory access generates a stage 2 Permission fault.

When the first stage of the translation regime specifies Device memory, `HCR_EL2.FWB` is set to 1, and the stage 2 Page or Block descriptor [4:2] is set to 0b110:

- Instruction fetches from Device memory are not prevented from being a CONstrained UNPREDICTABLE choice between:
 - Generating a prefetch abort.
 - Accessing memory as the resultant memory type of Normal Write-Back cacheable.
- It is IMPLEMENTATION DEFINED whether Atomic memory accesses or Exclusives are supported, in the same way as it is for accesses to memory locations whose resultant memory type is Device memory.
- It is CONstrained UNPREDICTABLE whether a misaligned access can generate a stage 1 alignment fault as a result of the memory type described in the stage 1 translation.
- It is CONstrained UNPREDICTABLE whether a DC ZVA, DC GZVA, or DC GVA instruction can generate a stage 1 alignment fault as a result of the memory type described in the stage 1 translation.

Combining the stage 1 and stage 2 cacheability attributes for Normal memory

The combining of cacheability attributes from the two stages of translation applies only if `HCR_EL2.FWB` is set to 0.

For a Normal memory region, [Table D5-44 on page D5-2786](#) shows how the stage 1 and stage 2 cacheability assignments are combined. This combination applies, independently, for the Inner cacheability and Outer cacheability attributes.

Table D5-44 Combining the stage 1 and stage 2 cacheability assignments for Normal memory

Assignment in stage 1	Assignment in stage 2	Resultant cacheability
Non-cacheable	Any	Non-cacheable
Any	Non-cacheable	Non-cacheable
Write-Through Cacheable	Write-Through or Write-Back Cacheable	Write-Through Cacheable
Write-Through or Write-Back Cacheable	Write-Through Cacheable	Write-Through Cacheable
Write-Back Cacheable	Write-Back Cacheable	Write-Back Cacheable

Combining the stage 1 and stage 2 shareability attributes for Normal memory

A memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation, if either:

- The resultant memory type attribute, described in [Combining the stage 1 and stage 2 memory type attributes on page D5-2784](#), is any type of Device memory.
- The resultant memory type attribute, described in [Combining the stage 1 and stage 2 memory type attributes on page D5-2784](#), is Normal memory, and the resultant cacheability, described in [Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D5-2785](#), is Inner Non-cacheable, Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal, that is not Inner Non-cacheable, Outer Non-cacheable, [Table D5-45 on page D5-2786](#) shows how the stage 1 and stage 2 shareability assignments are combined.

Table D5-45 Combining the stage 1 and stage 2 Shareability assignments for Normal memory^a

Assignment in stage 1	Assignment in stage 2	Resultant shareability
Outer Shareable	Any	Outer Shareable
Inner Shareable	Outer Shareable	Outer Shareable
Inner Shareable	Inner Shareable	Inner Shareable
Inner Shareable	Non-shareable	Inner Shareable
Non-shareable	Outer Shareable	Outer Shareable
Non-shareable	Inner Shareable	Inner Shareable
Non-shareable	Non-shareable	Non-shareable

a. Applies only if the Normal memory is not Inner Non-cacheable, Outer Non-cacheable, see text.

D5.6 Virtualization Host Extensions

Armv8.1 introduces the Virtualization Host Extensions that provide enhanced support for a Type 2 virtualization solution, where there is a Host OS, which is either more privileged than the hypervisor, or is a peer of the hypervisor.

The Virtualization Host Extensions only apply to an implementation that includes EL2 using AArch64.

D5.6.1 State added by the Virtualization Host Extensions

The following state is added as part of FEAT_VHE:

- A configuration bit, E2H, is added to HCR_EL2.
- New registers:
 - CONTEXTIDR_EL2, which has the same format and contents as CONTEXTIDR_EL1.
 - TTBR1_EL2, which has the same format and contents as TTBR1_EL1.
- An EL2 virtual timer which is accessed using the registers CNTHV_CTL_EL2, CNTHV_CVAL_EL2, and CNTHV_TVAL_EL2. The registers take the same format as CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0 respectively. The virtual offset is treated as 0 for this timer.

D5.6.2 Behavior of HCR_EL2.E2H

When the value of HCR_EL2.E2H is 0:

- There are no changes to the Armv8 functionality other than the new state described in *State added by the Virtualization Host Extensions on page D5-2787*.

————— **Note** —————

This means the translation regime controlled by TCR_EL2 is called the EL2 translation regime.

- The contents of TTBR1_EL2 are ignored by hardware, other than reads by an MRS instruction and writes by an MSR instruction.
- The Context ID matching breakpoint is disabled at EL2, and uses the value of CONTEXTIDR_EL1 at EL0 and EL1.

When the value of HCR_EL2.E2H is 1, and EL2 is enabled for the current Security state:

- The translation regime controlled by TCR_EL2 is the EL2&0 translation regime, and the behaviors of this translation regime differ from those of the EL2 translation regime.
- The EL2&0 translation regime behaves in the same way as stage 1 of the EL1&0 translation regime, with an upper address range translated by tables pointed to by TTBR1_EL2. The existing TTBR0_EL2 translates the lower address range of the EL2&0 translation regime and is extended to have the same contents and format as the TTBR0_EL1.
- The translation tables used in the EL2&0 translation regime take the same format as the EL1&0 translation regime. EL2 accesses are treated as privileged in this format.
- Context ID matching can occur at EL2. When executing at EL2, a Context ID matching breakpoint uses CONTEXTIDR_EL2.
- VMID and VMID + Context ID matching breakpoints do not match at EL2.
- The virtual offset is treated as 0 when CNTVCT_EL0 is read from EL2.
- The Privileged Access Never mechanism applies to accesses from EL2 to a virtual address which has access permitted in the EL2&0 translation regime.
- The following registers are redefined:
 - CNTHCTL_EL2.
 - CPTR_EL2.
 - TCR_EL2.

If HCR_EL2.{E2H, TGE} = {1, 0}, then all accesses from EL1 and EL0 are not included in the EL2&0 translation regime.

If `HCR_EL2.{E2H, TGE} == {1, 1}`:

- The EL2&0 translation regime is used when executing at EL0 as well as when executing at EL2, where EL0 accesses are treated as unprivileged.

———— **Note** —————

Accesses from EL1 are not possible under this configuration.

- In EL2, the unprivileged instructions LDTR, LDTRB, LDTRH, LDTRSB, LDTRSH, LDTRSW, STTR, STTRB, and STTRH act as if they are executing at EL0 for permission and watchpoint checking.
- Except for the purpose of reading the value held in the register, some fields in `HCR_EL2` and all fields in `HSTR_EL2` are treated as having a specific value.
- `SCTLR_EL2` is redefined to include additional fields from `SCTLR_EL1`, and to apply to execution at EL0.
- The following timer registers, and their equivalent AArch32 registers, are redefined to access the associated EL2 register, rather than accessing the EL0 register when in EL0:
 - `CNTP_CTL_EL0`.
 - `CNTP_CVAL_EL0`.
 - `CNTP_TVAL_EL0`.
 - `CNTV_CTL_EL0`.
 - `CNTV_CVAL_EL0`.
 - `CNTV_TVAL_EL0`.

For some information on registers that are redirected, see *System and Special-purpose register redirection on page D5-2788*.

- When executing at EL0, a Context ID matching breakpoint uses `CONTEXTIDR_EL2`.
- `VMID` and `VMID` + Context ID matching breakpoints do not match at EL0.
- The `CPACR_EL1` register does not cause any instructions to be trapped to EL1, regardless of the contents of `CPACR_EL1`.
- The `CNTKCTL_EL1` register does not cause any instructions to be trapped to EL1, and the event stream event caused by the `CNTKCTL_EL1` is disabled, regardless of the contents of `CNTKCTL_EL1`.
- The virtual offset is treated as 0 when `CNTVCT_EL0` is read from EL0 or EL2.
- The TLB maintenance and address translation instructions that apply to the EL1&0 translation regime are redefined to apply to the EL2&0 translation regime. See *A64 System instructions for address translation on page C5-567* and *A64 System instructions for TLB maintenance on page C5-592*.
- When executing at EL2 or EL0, any physical interrupt that is configured to be taken at EL2 is subject to the `PSTATE.{D, A, I, F}` interrupt masks. If the mask bit is set, then the corresponding interrupt will not be taken. If the mask bit is not set, then the corresponding interrupt will be taken. See *Asynchronous exception masking on page D1-2504*.
- When an exception is taken from EL0 to EL2, the value of the `HCR_EL2.RW` bit is not considered when determining the exception vector offset to use. [Table D1-5 on page D1-2477](#) lists the vector offsets used when an exception is taken from EL0.

D5.6.3 System and Special-purpose register redirection

When `FEAT_VHE` is implemented, and `HCR_EL2.E2H` is set to 1, when executing at EL2, some EL1 System register access instructions are redefined to access the equivalent EL2 register.

Table D5-46 on page D5-2789 shows the System register access instruction encodings that are redirected to the equivalent EL2 register when the named mnemonic is used.

Table D5-46 System register redirection

System register access instruction encoding					Mnemonic	Equivalent register accessed at EL2
op0	op1	CRn	CRm	op2		
3	0	1	0	0	SCTLR_EL1	SCTLR_EL2
				2	CPACR_EL1	CPTR_EL2
				2	1	TRFCR_EL1
	2	0	0	0	TTBR0_EL1	TTBR0_EL2
				1	TTBR1_EL1	TTBR1_EL2
				2	TCR_EL1	TCR_EL2
	5	1	0	0	AFSR0_EL1	AFSR0_EL2
				1	AFSR1_EL1	AFSR1_EL2
				2	0	ESR_EL1
	6	0	0	FAR_EL1	FAR_EL2	
	10	2	0	0	MAIR_EL1	MAIR_EL2
				3	0	AMAIR_EL1
	12	0	0	VBAR_EL1	VBAR_EL2	
	13	0	1	CONTEXTIDR_EL1	CONTEXTIDR_EL2	
14	1	0	CNTKCTL_EL1	CNTHCTL_EL2		
3	14	2	0	0	CNTP_TVAL_EL0	CNTHP_TVAL_EL2 CNTHPS_TVAL_EL2 ^a
				1	CNTP_CTL_EL0	CNTHP_CTL_EL2 CNTHPS_CTL_EL2 ^a
				2	CNTP_CVAL_EL0	CNTHP_CVAL_EL2 CNTHPS_CVAL_EL2 ^a
				0	CNTV_TVAL_EL0	CNTHV_TVAL_EL2 CNTHVS_TVAL_EL2 ^a
				1	CNTV_CTL_EL0	CNTHV_CTL_EL2 CNTHVS_CTL_EL2 ^a
				2	CNTV_CVAL_EL0	CNTHV_CVAL_EL2 CNTHVS_CVAL_EL2 ^a

a. This register is accessed when FEAT_SEL2 is implemented and enabled, when the value of SCR_EL3.EEL2 is 1.

Table D5-47 on page D5-2790 shows the Special-purpose register access instruction encodings that are redirected to the equivalent EL2 register when the named mnemonic is used.

Table D5-47 Special-purpose register redirection

Special-purpose register access instruction encoding			Mnemonic	Equivalent register accessed at EL2
op1	CRm	op2		
0	0	0	SPSR_EL1	SPSR_EL2
		1	ELR_EL1	ELR_EL2

D5.6.4 System and Special-purpose register aliasing

New register encodings, and aliases, are provided so that software executing at EL2 can access the EL1 registers for which accesses from EL2 are redirected as described in [System and Special-purpose register redirection on page D5-2788](#). These aliases can also be used at EL3, but are UNDEFINED at EL1 and EL0.

Table D5-48 on page D5-2791 shows the System register access instruction encodings that are aliased.

Table D5-48 System register aliases

System register access instruction encoding					Mnemonic	Register accessed	
op0	op1	CRn	CRm	op2			
3	5	1	0	0	SCTLR_EL12	SCTLR_EL1	
				2	CPACR_EL12	CPACR_EL1	
				2	0	ZCR_EL12	ZCR_EL1 ^a
					1	TRFCR_EL12	TRFCR_EL1
		2	0	0	TTBR0_EL12	TTBR0_EL1	
				1	TTBR1_EL12	TTBR1_EL1	
				2	TCR_EL12	TCR_EL1	
		5	1	0	0	AFSR0_EL12	AFSR0_EL1
					1	AFSR1_EL12	AFSR1_EL1
					2	ESR_EL12	ESR_EL1
		6	0	0	FAR_EL12	FAR_EL1	
		9	9	0	PMSCR_EL12	PMSCR_EL1	
		10	2	0	0	MAIR_EL12	MAIR_EL1
					3	AMAIR_EL12	AMAIR_EL1
12	0	0	VBAR_EL12	VBAR_EL1			
13	0	1	CONTEXTIDR_EL12	CONTEXTIDR_EL1			
14	1	0	0	CNTKCTL_EL12	CNTKCTL_EL1		
			2	0	CNTP_TVAL_EL02	CNTP_TVAL_EL0	
				1	CNTP_CTL_EL02	CNTP_CTL_EL0	
				2	CNTP_CVAL_EL02	CNTP_CVAL_EL0	
3	5	14	3	0	CNTV_TVAL_EL02	CNTV_TVAL_EL0	
				1	CNTV_CTL_EL02	CNTV_CTL_EL0	
				2	CNTV_CVAL_EL02	CNTV_CVAL_EL0	

a. Scalable Vector Extension System register, see *The Scalable Vector Extension (SVE)* on page A2-110.

Table D5-49 on page D5-2792 shows the Special-purpose register aliasing.

Table D5-49 Special-purpose register aliases

Special-purpose register access instruction encoding					Register name	Register accessed
op0	op1	CRn	CRm	op2		
3	5	4	0	0	SPSR_EL12	SPSR_EL1
				1	ELR_EL12	ELR_EL1

D5.7 Nested virtualization

From Armv8.3, nested virtualization is supported in AArch64 state:

- If [FEAT_NV](#) is implemented, a Host hypervisor executing at EL2 can run a Guest hypervisor at EL1, see [Armv8.3 nested virtualization functionality on page D5-2793](#).
- If [FEAT_NV2](#) is implemented, the PE further transforms System register accesses into memory accesses, see [Enhanced support for nested virtualization on page D5-2795](#).

D5.7.1 Armv8.3 nested virtualization functionality

Note

- When running a Guest hypervisor with [HCR_EL2.E2H](#) == 0, the Host hypervisor must set [HCR_EL2.TVM](#) and [CPTR_EL2.TCPAC](#) to trap any Guest hypervisor accesses to the EL1 System registers that would be accesses from any Guest OS running under the Guest hypervisor.
 - [FEAT_NV](#) does not introduce any changes to either debug or to the Performance Monitors. Arm assumes that the Host hypervisor will trap accesses to the Breakpoint and Performance Monitors registers to EL2, so that it can process any accesses to these registers made by a Guest hypervisor or by a Guest OS running under the Guest hypervisor.
-

[FEAT_NV](#) adds the fields [HCR_EL2.{NV, NV1, AT}](#), see:

- [Effect of HCR_EL2.{NV, NV1} on page D5-2793](#).
- [Effect of HCR_EL2.AT on page D5-2794](#).

Effect of [HCR_EL2.{NV, NV1}](#)

The following subsections describe the effect of [HCR_EL2.{NV, NV1}](#):

- [Behavior when \[HCR_EL2.NV\]\(#\) == 1 on page D5-2793](#).
- [Additional behavior when \[HCR_EL2.NV\]\(#\) == 1 and \[HCR_EL2.NV1\]\(#\) == 0 on page D5-2794](#).
- [Additional behaviors when \[HCR_EL2.NV\]\(#\) == 1 and \[HCR_EL2.NV1\]\(#\) == 1 on page D5-2794](#).
- [Behavior when \[HCR_EL2.NV\]\(#\) == 0 and \[HCR_EL2.NV1\]\(#\) == 1 on page D5-2794](#).

[HCR_EL2.{NV, NV1}](#) are both permitted to be cached in a TLB.

Behavior when [HCR_EL2.NV](#) == 1

The following behaviors apply when the value of [HCR_EL2.NV](#) is 1, regardless of the value of [HCR_EL2.NV1](#).
At EL1:

- Reads or writes to any allocated and implemented System register or Special-purpose register named [*_EL2](#), [*_EL02](#), or [*_EL12](#) in the MRS or MSR instruction, other than [SP_EL2](#), are trapped to EL2 rather than being UNDEFINED. In this case, [ESR_EL2](#) uses the EC code of 0x18.

Only accesses that are permitted at EL2 are trapped. This means that, for example, if the register is a read-only register at EL2, then an MSR from Non-secure EL1 to the register is not trapped by this mechanism. Instead the register access remains UNDEFINED.

Note

The priority of this trapping relative to other configurable traps follows the standard hierarchy of exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2490](#).

- Reads or writes to [SPSR_irq](#), [SPSR_abt](#), [SPSR_und](#), or [SPSR_fiq](#) using MRS and MSR instructions are trapped to EL2 rather than being UNDEFINED. In this case the exception is reported in [ESR_EL2](#) using the EC code 0x18.
- Reads or writes to [SP_EL1](#) using the dedicated MRS and MSR instruction for accessing that register are trapped to EL2 rather than being UNDEFINED. In this case the exception is reported in [ESR_EL2](#) using the EC code 0x18.
- Execution of the EL2 translation regime Address translation instructions and TLB maintenance instructions are trapped to EL2 rather than being UNDEFINED. In this case the exception is reported in [ESR_EL2](#) using the EC code 0x18.

- Execution of the EL1 translation regime Address translation instructions and TLB maintenance instructions that are only accessible from EL2 and above are trapped to EL2 rather than being UNDEFINED. In this case the exception is reported in [ESR_EL2](#) using the EC code 0x18.
- The [ERETAA](#), [ERETAB](#), and [ERET](#) instructions are trapped to EL2. In this case the exception is reported in [ESR_EL2](#) using the EC code 0x1A.

———— **Note** —————

The [ERETAA](#) and [ERETAB](#) instructions are only available when [FEAT_PAuth](#) is implemented.

- A read of [CurrentEL](#) returns the value 0x2 in bits[3:2].
- If EL3 is not implemented and [HCR_EL2.TSC](#) == 1, an SMC instruction executed at EL1 is trapped to EL2 rather than being UNDEFINED, and [HCR_EL2.TSC](#) is not RES0. In this case the exception is reported in [ESR_EL2](#) using the EC code 0x17.

Additional behavior when [HCR_EL2.NV](#) == 1 and [HCR_EL2.NV1](#) == 0

At EL1, all the behaviors described in [Behavior when \[HCR_EL2.NV\]\(#\)==1 on page D5-2793](#) apply.

In addition, when [HCR_EL2](#).{NV, NV1} == {1, 0}, any exception taken from EL1 to EL1 causes [SPSR_EL1.M](#)[3:2] to be set to 0b10 rather than 0b01.

Additional behaviors when [HCR_EL2.NV](#) == 1 and [HCR_EL2.NV1](#) == 1

At Non-secure EL1, all the behaviors described in [Behavior when \[HCR_EL2.NV\]\(#\)==1 on page D5-2793](#) apply.

In addition, when [HCR_EL2](#).{NV, NV1} == {1, 1}:

- Accesses to [VBAR_EL1](#), [ELR_EL1](#), [SPSR_EL1](#), and, if implemented, [SCXTNUM_EL1](#), from EL1 are trapped to EL2. In this case the exception is reported in [ESR_EL2](#) using the EC code 0x18.
- In the EL1 translation table Block and Page descriptors:
 - Bit[54] holds PXN, not UXN.
 - Bit[53] is RES0.
 - Bit[6] is treated as 0 regardless of the actual value.
- If Hierarchical permissions are enabled, then in the EL1 Translation Table descriptor:
 - Bit[61] is treated as 0 regardless of the actual value.
 - Bit[60] holds PXNTable, not UXNTable.
 - Bit[59] is RES0.
- When in EL1, [PSTATE.PAN](#) is treated as 0 for all purposes except reading the value of the bit.
- When executed at EL1, the LDTR* behave as the corresponding LDR* instructions, and the STTR* instructions behave as the equivalent STR* instructions.

Behavior when [HCR_EL2.NV](#) == 0 and [HCR_EL2.NV1](#) == 1

When [HCR_EL2](#).{NV, NV1} == {0, 1}, the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- Behaving as if [HCR_EL2.NV](#)==1 and [HCR_EL2.NV1](#)==1 for all purposes other than reading back the value of the [HCR_EL2.NV](#) bit.
- Behaving as if [HCR_EL2.NV](#)==0 and [HCR_EL2.NV1](#)==0 for all purposes other than reading back the value of the [HCR_EL2.NV1](#) bit.
- Behaving as defined for [HCR_EL2.NV](#)==0, with [HCR_EL2.NV1](#)==1 having the effect of causing accesses to [VBAR_EL1](#), [ELR_EL1](#), and [SPSR_EL1](#) from EL1 to be trapped to EL2.

Effect of [HCR_EL2.AT](#)

When [FEAT_NV](#) is implemented, if [HCR_EL2.AT](#) is 1, then EL1 accesses to [AT S1E0R](#), [AT S1E0W](#), [AT S1E1R](#), [AT S1E1W](#), [AT S1E1RP](#), and [AT S1E1WP](#), are trapped to EL2. In this case the exception is reported in [ESR_EL2](#) using the EC code 0x18.

D5.7.2 Enhanced support for nested virtualization

If [FEAT_NV2](#) is implemented, the PE can access the [VNCR_EL2](#) register and the control bit [HCR_EL2.NV2](#).

When [HCR_EL2.NV2](#) is 1:

- When in EL1, the PE redirects EL2 register accesses to EL1 register accesses, see [Redirection of register accesses from EL2 to EL1 on page D5-2795](#).
- When a Guest hypervisor issues System register access instructions to a Guest OS, the PE transforms the System register access instructions into memory access instructions, see [Loads and stores generated by transforming register accesses on page D5-2795](#).

When [HCR_EL2.NV2](#) is 0, the behavior of [HCR_EL2.NV](#) and [HCR_EL2.NV1](#) are as described in [Armv8.3 nested virtualization functionality on page D5-2793](#).

Redirection of register accesses from EL2 to EL1

When [HCR_EL2.NV](#) and [HCR_EL2.NV2](#) are set to 1, instructions accessing certain Special-purpose EL2 registers executed at EL1 are redefined to access the corresponding EL1 register:

Table D5-50 Redirection of accesses to special-purpose registers at EL2

Special register access instruction ^a	Named EL2 register	Actual register accessed
op1 = 4, CRm=0, op2=0	SPSR_EL2	SPSR_EL1
op1 = 4, CRm=0, op2=1	ELR_EL2	ELR_EL1

a. For further information, see [op0=0b11, Moves to and from Special-purpose registers on page C5-405](#).

When [HCR_EL2.NV](#) and [HCR_EL2.NV2](#) are set to 1, instructions accessing certain System registers executed at EL1 are redefined to access the corresponding EL1 register:

Table D5-51 Redirection of accesses to System registers at EL2

System register access instruction ^a	Named EL2 register	Actual register accessed
op0 = 3, op1=4, CRn=5, CRm=2, op2=0	ESR_EL2	ESR_EL1
op0 = 3, op1=4, CRn=6, CRm=0, op2=0	FAR_EL2	FAR_EL1

a. For further information, see [Instructions for accessing non-debug System registers on page D12-3023](#).

Loads and stores generated by transforming register accesses

When an MRS or MSR instruction is executed at EL1 and is accessing a register listed in [Table D5-52 on page D5-2796](#), the PE transforms that access into a load or store, respectively.

When the PE transforms a System register access into a memory access, the address of the resulting memory access is defined using a combination of a base address and an offset according to the formula $\text{SignExtend}(\text{VNCR_EL2.BADDR} : \text{Offset}\langle 11:0 \rangle, 64)$:

- [VNCR_EL2](#) holds the base memory address used for memory redirection of System register accesses.

- Each register which supports redirection to memory has a unique offset value, see [Table D5-52](#) on page D5-2796.

Table D5-52 Memory address offsets associated with each transformed register access

Register access		Offset
If HCR_EL2.{NV, NV1, NV2} == {1, 0, 1}	If HCR_EL2.{NV, NV1, NV2} == {1, 1, 1}

TRFCR_EL12	TRFCR_EL1	0x880
AMEVCNTVOFF0<n>_EL2	AMEVCNTVOFF0<n>_EL2	0xA00+8*n
AMEVCNTVOFF1<n>_EL2	AMEVCNTVOFF1<n>_EL2	0xA80+8*n

Note

Software should assume that future expansion of the architecture will allocate offset values up to but not including 0x1000.

Registers that affect hypervisor execution by controlling the event stream are not included in [Table D5-52 on page D5-2796](#):

- CNTHCTL_EL2
- When $HCR_EL2.NV1$ is 0, CNTKCTL_EL12.
- When $HCR_EL2.NV1$ is 1, CNTKCTL_EL1.

When a System register access is transformed into a memory access, that memory access has a defined format:

- The addressee the memory access is translated by the EL2 translation regime.
- The endianness of the memory access is defined by $SCTLR_EL2.EE$.
- The memory access is 64-bit single-copy atomic aligned to 64 bits.
- The memory access does not have acquire or release semantics.

Note

The value of the transformed System register access is not affected by fields that are defined to be RES0 or RES1 in the associated System register.

- When there is no context synchronizing operation between the read or write of the register and the load or store instruction accessing the address, the PE is permitted, but not required, to reorder the memory accesses with respect to any EL1 reads or writes generated by load or store instructions to the same address.
- The memory accesses behave as if $PSTATE.PAN == 0$ regardless of the value of $PSTATE.PAN$.

When a register access instruction targets a register that is not implemented, the PE treats access to that register as UNALLOCATED.

Any attempt to trap a register access instruction is subject to the exception prioritization rules, unless it is trapped by either or both of $HCR_EL2.\{NV, NV1\}$. When a System register access instruction is trapped by either or both of $HCR_EL2.\{NV, NV1\}$, then the instruction is transformed into a memory access instruction instead of creating a trap, see [Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2490](#).

Exceptions from transformed register accesses

When $HCR_EL2.\{NV2, NV\} == \{1, 1\}$ any exception taken from EL1 and taken to EL1 causes the $SPSR_EL1.M[3:2]$ to be set to 0b10 and not 0b01.

When the memory access generates a Data Abort, then the resulting fault has a defined format:

- The fault is taken to EL2, using the standard vector offset for exceptions from EL1 to EL2.
- The fault is reported as a Data Abort from the current exception level with the $ESR_EL2.EC$ code 0x25, see [ISS encoding for an exception from a Data Abort on page D13-3219](#).
- FAR_EL2 is updated to hold the faulting address.

When the memory access generates a synchronous External abort, and when External aborts are not configured to be taken to EL3, then the resulting fault has a defined format:

- The fault is taken to EL2 using the standard vector offset for exceptions from EL1 to EL2.
- The fault is reported as a Data Abort from the current Exception level with [ESR_EL2.EC](#) code 0x25, see [ISS encoding for an exception from a Data Abort on page D13-3219](#).

The VNCR field in [ESR_EL2](#) and [ESR_EL3](#) identifies whether the fault came from use of [VNCR_EL2](#) by EL1, see [ISS encoding for an exception from a Data Abort on page D13-3219](#).

Interaction with self-hosted and External debug

When a register access is transformed into a memory access, the PE:

- Treats the instruction as an instruction executed at EL1.
- Treats the loads and stores generated by the transformation of reads and writes of registers as an EL2 access.

This means that:

- When filtering PMU events by Exception level, filtering instructions by Exception level for trace or Statistical Profiling, and when checking the instruction address against breakpoint registers or trace resources, the operation is checked as an instruction executed at EL1.
- When checking the memory access against the watchpoint registers, or recording the address in a Statistical Profiling record, the PE treats the access as an EL2 access.

When the memory access matches an EL2 access in the watchpoint registers, while a watchpoint is linked to a context-aware breakpoint that is programmed to match the value held in [CONTEXTIDR_EL1](#) or VMID, then it is CONSTRAINED UNPREDICTABLE whether there is a watchpoint match.

When there is a watchpoint match, while [EDSCR.HDE](#) is set to 1 and halting is allowed, the watchpoint match generates a Watchpoint debug event.

When there is a watchpoint match, while [EDSCR.HDE](#) is set to 0 and debug exceptions are enabled at EL2, then the watchpoint match generates a Watchpoint exception.

When the watchpoint match generates a Watchpoint exception, the resulting exception has a defined format:

- The exception is taken to EL2.
- The exception is reported as a Watchpoint from the current Exception level with the [ESR_EL2.EC](#) code 0x35, see [ISS encoding for an exception from a Watchpoint exception on page D13-3231](#).
- [FAR_EL2](#) is updated to hold the watchpointed address.

The VNCR field in [ESR_EL2](#) identifies whether the Watchpoint exception came from use of [VNCR_EL2](#) by EL1, see [ISS encoding for an exception from a Watchpoint exception on page D13-3231](#).

The loads and stores generated by the transformation of reads and writes of registers are treated by the Performance Monitors as Memory-read operations and Memory-write operations. For more information, see [Memory-read operation on page D7-2872](#) and [Memory-write operation on page D7-2872](#).

When the Statistical Profiling Unit (SPU) selects the instruction generating the memory access for profiling, it records the operation as a load/store operation. For more information, see [Operation Type packet payload \(load/store\) on page D10-3000](#).

When the SPU selects the instruction generating the memory access for profiling while Statistical Profiling is disabled at EL2, the virtual address for the memory access is not recorded.

D5.8 VMSAv8-64 memory aborts

In a VMSAv8-64 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

Debug exception	An exception caused by the debug configuration, see Chapter D2 AArch64 Self-hosted Debug .
Alignment fault	An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information, see Alignment support on page B2-160 .
MMU fault	An MMU fault is a fault generated by the fault checking sequence for the current translation regime. See Types of MMU faults on page D5-2800 .
External abort	Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault.

Collectively, these mechanisms are called *aborts*. [Chapter D2 AArch64 Self-hosted Debug](#) and [on page H3-7377](#) describe Debug exceptions, and the remainder of this section describes Alignment faults, MMU faults, and External aborts.

An access that causes an abort is said to be aborted, and uses the *Fault Address Registers* (FARs) and *Exception Syndrome Registers* (ESRs) to record context information.

In AArch64 state MMU faults are synchronous exceptions that are reported as either:

- Data Aborts.
- Instruction Aborts

———— **Note** ————

Instruction Aborts report any synchronous memory abort on an instruction fetch.

The Exception level that an MMU fault is taken to depends on the translation regime and stage that generated the fault. The fault context saved in the appropriate `ESR_ELx`, where ELx is the Exception level that the fault is taken to, is dependent on whether:

- The MMU fault is reported as an Instruction or as a Data Abort.
- The exception is taken from the same or a lower Exception level.

For more information, see [Synchronous exception types, routing and priorities on page D1-2489](#).

External aborts can be reported synchronously or asynchronously. Asynchronous External aborts are reported using the SError interrupt. For more information, see [External aborts on page D4-2666](#).

Software stepping, which is a debug feature, and a PC alignment fault exception are the only exceptions that are higher priority than an Instruction Abort. Only watchpoints are at a lower priority than Data Aborts in the exception priority hierarchy. For more information, see [Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2490](#).

The following sections describe the abort mechanisms:

- [Types of MMU faults on page D5-2800](#).
- [The MMU fault-checking sequence on page D5-2803](#).
- [AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D5-2807](#).

D5.8.1 Types of MMU faults

This section describes the faults that might be detected during one of the fault-checking sequences described in [The MMU fault-checking sequence on page D5-2803](#). The following list includes all the types of exceptions that can occur:

- Alignment fault on a data access, see [Alignment support on page B2-160](#).
- Permission fault.

- [Translation fault](#).
- [Address size fault](#).
- Synchronous [External abort on a translation table walk](#).
- [Access flag fault](#).
- [TLB conflict abort](#).

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as Device.

The following subsections describe the MMU faults that are not described elsewhere in this Manual.

Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See [About access permissions on page D5-2754](#) for information about conditions that cause a Permission fault.

A TLB might hold a translation table entry that causes a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access.

This maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache maintenance instructions cannot generate Permission faults, except that:

- A stage 1 translation table walk performed as part of a cache maintenance instruction can generate a stage 2 Permission fault as described in [Stage 2 fault on a stage 1 translation table walk](#).
- When the value of `SCTLR_EL1.UCI` is 1, enabling EL0 execution of the `DC CVAU`, `DC CVAC`, `DC CVAP`, `DC CIVAC`, and `IC IVAU` instructions:
 - Executing a `DC CVAU`, `DC CVAC`, `DC CVAP`, or `DC CIVAC` instruction at EL0 to a location that does not have read permission at EL0 generates a Permission fault, subject to the constraints described in this section.
 - It is IMPLEMENTATION DEFINED whether executing an `IC IVAU` instruction at EL0 to a location that does not have read permission at EL0 generates a Permission fault.
- A `DC IVAC` instruction requires write permission to the address it invalidates, otherwise it generates a Permission fault, subject to the constraints described in this section.

Note

- Execution of the `DCIMVAC` instruction in AArch32 state does not have this write permission requirement.
- When EL1&0 stage 2 address translation is enabled, a `DC IVAC` instruction executed in Non-secure state performs a cache clean and invalidate, meaning it performs the same invalidation as a `DC CIVAC` instruction, as described in [Effects of virtualization and Security state on the cache maintenance instructions on page D4-2654](#).

In all cases where the execution of a cache maintenance instruction might generate a Permission fault:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by VA to the Point of Coherency instruction can generate a Permission fault.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Permission fault.

The Data Cache Zero instruction, `DC ZVA`, operates as set of stores to each byte within the block being accessed, and therefore it generates a Permission fault if the translation system does not permit writes to these locations.

Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a Translation Table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information, see [VMSAv8-64 Translation Table format descriptors on page D5-2739](#).

In addition, a Translation fault is generated if the input address for a translation either does not map onto an address range of a `TTBR_ELx`, or the `TTBR_ELx` range that it maps onto is disabled. In these cases, the fault is reported as a level 0 Translation fault on the translation stage at which the mapping to a region described by a `TTBR_ELx` failed.

A data or unified cache maintenance by `VA` instruction can generate a Translation fault, except that:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by `VA` instruction can generate a Translation fault.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by `VA` to the Point of Unification instruction can generate a Translation fault.

It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by `VA` operation can generate a Translation fault.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

If `FEAT_EOPD` is implemented and enabled, the `TCR_ELx`.{E0D0, E0D1} fields can prevent unprivileged access to the addresses translated by `TTBR0_ELx` or `TTBR1_ELx`. If access is prevented, the fault is reported as a level 0 Translation fault, and should take the same time to generate, whether the address is present in the TLB or not, to mitigate attacks that use fault timing.

Address size fault

An Address size fault can be generated at any level of lookup.

An Address size fault is generated if one of the following has nonzero address bits above the output address size, for the current stage of translation:

- The `TTBR_ELx` used for the translation.
- A translation table entry.
- The output address of the translation.

For an Address size fault generated because the `TTBR_ELx` used for the translation has nonzero address bits above the output address size, the reported fault code indicates a fault at level 0. Otherwise, the reported fault code indicates the lookup level at which the fault occurred.

A data or unified cache maintenance by `VA` instruction can generate an Address size fault, except that:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by `VA` instruction can generate an Address size fault.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by `VA` to the Point of Unification instruction can generate an Address size fault.

It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by `VA` operation can generate an Address size fault.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

For more information on Address size faults, see [Output address size on page D5-2690](#).

External abort on a translation table walk

An External abort on a translation table walk can be either synchronous or asynchronous. An External abort on a translation table walk is reported:

- If the External abort is synchronous, using:
 - A synchronous Instruction Abort exception if the translation table walk is for an instruction fetch.
 - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the External abort is asynchronous, using the SError interrupt exception.

Behavior of External aborts on a translation table walk caused by address translation instructions

The address translation instructions summarized in [Address translation instructions on page C5-401](#) require translation table walks. An External abort can occur in the translation table walk. This is reported as follows:

- If the External abort is synchronous, using a synchronous Data Abort exception.
- If the External abort is asynchronous, using the SError interrupt exception.

For more information, see [Synchronous faults generated by address translation instructions on page D5-2737](#).

Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if a Translation Table descriptor with the Access flag bit set to 0 is used.

For more information about the Access flag bit, see [VMSAv8-64 Translation Table format descriptors on page D5-2739](#).

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to execute any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance by VA instructions can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see [The Access flag on page D5-2765](#).

D5.8.2 The MMU fault-checking sequence

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory effects:

- If an instruction fetch faults, it generates an Instruction Abort.
- If a data memory access faults, it generates a Data Abort.

MMU fault checking is performed for each stage of address translation.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see [About address translation and supported input address ranges on page D5-2686](#).

Note

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in [TLB conflict aborts on page D5-2814](#).

[Types of MMU faults on page D5-2800](#) describes the faults that an MMU fault-checking sequence can report.

[Figure D5-18 on page D5-2804](#) shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, if the translation is stage 1 of the Secure or Non-secure EL1&0 translation regime, when EL2 is enabled, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

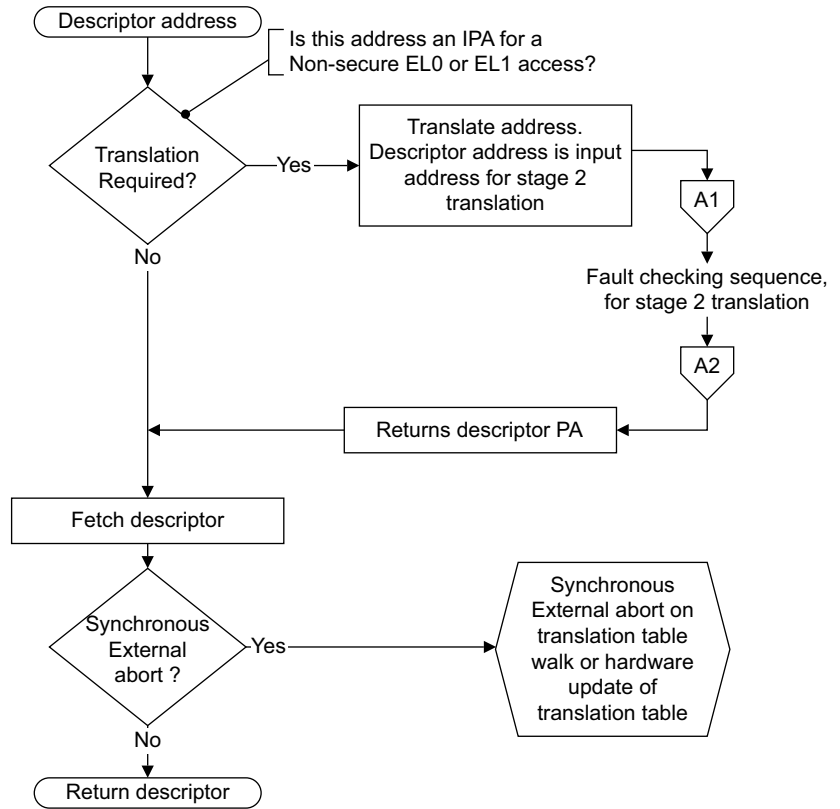

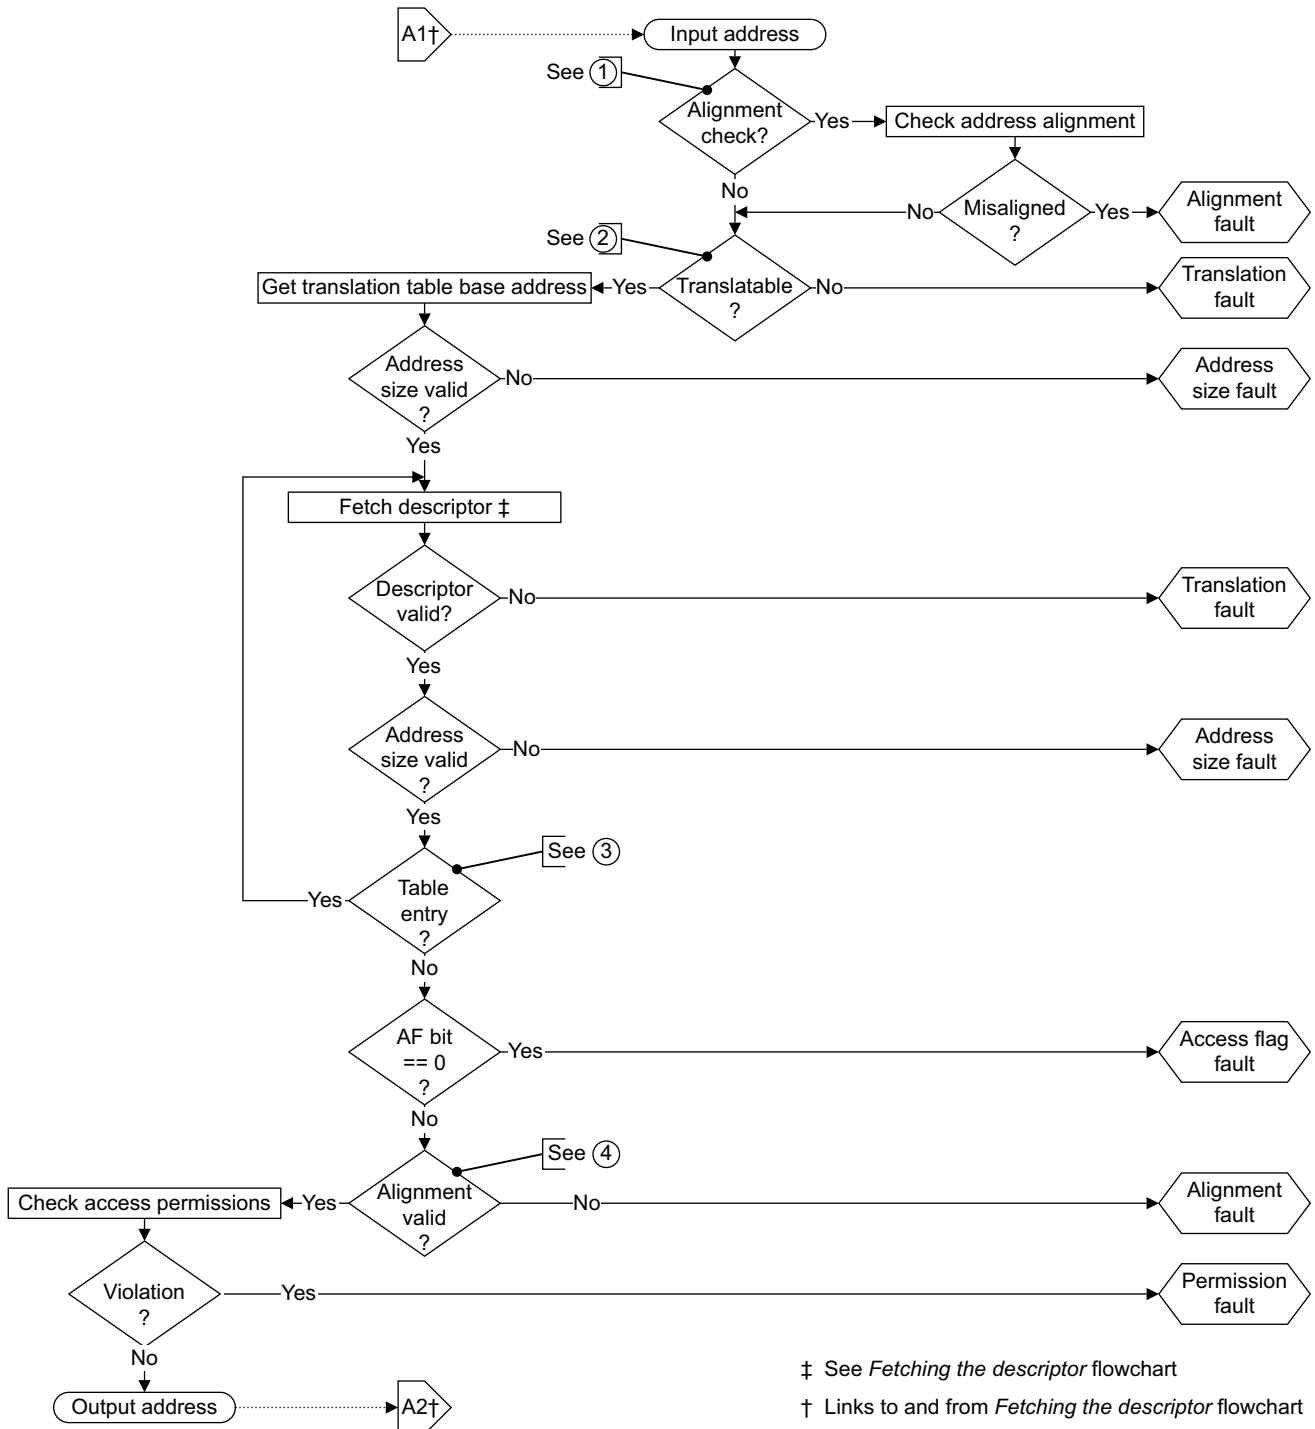

Figure D5-18 Fetching the descriptor in a VMSAv8-64 translation table walk

Figure D5-19 on page D5-2805 shows the full VMSA fault checking sequence, including the alignment check on the initial access.

- ‡ See *Fetching the descriptor* flowchart
- † Links to and from *Fetching the descriptor* flowchart
- ① Is the access subject to an alignment check?
- ② Does the address map to a TTBR?
- ③ Not permitted at the lowest lookup level
- ④ Fault any unaligned access to Device memory

Figure D5-19 VMSAv8-64 fault checking sequence

Stage 2 fault on a stage 1 translation table walk

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous External abort on the memory access.

If `SCR_EL3.EA` is set to 1, a synchronous External abort is taken to EL3. Otherwise, these faults are reported as stage 2 memory aborts. `ESR_EL2.ISS[7]` is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information, see *Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-2478*.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the Device attribute assigned on the stage 2 translation of the address accessed. When the `HCR_EL2.PTW` bit is set to 1, such an access generates a stage 2 Permission fault.

———— Note —————

On most systems, such a mapping to Device memory on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of `HCR_EL2.PTW`. Therefore, if `HCR_EL2.PTW` is changed without changing the current VMID, the TLBs must be invalidated before executing in EL1 or EL0 state.

A cache maintenance instruction executed at EL1 or EL0 can cause a stage 1 translation table walk that might generate a stage 2 Permission fault as described in this section. However:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by VA instruction can generate a Permission fault in this way.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Permission fault in this way.
- It is IMPLEMENTATION DEFINED whether an instruction cache invalidation by VA instruction can generate a Permission fault in this way.

———— Note —————

This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.

The level associated with MMU faults

For MMU faults, [Table D5-53 on page D5-2806](#) shows how the LL bits in the `ESR_ELx.STATUS` fields encode the lookup level associated with the fault.

Table D5-53 Use of LL bits to encode the lookup level at which the fault occurred

LL bits	Meaning
00	Level 0 of translation or translation table base register.
01	Level 1.
10	Level 2.
11	Level 3. When xFSR.STATUS indicates a Domain fault, this value is reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.

- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, or because FEAT_E0PD is enabled and prevents access to the translation table, the fault is reported as a level 0 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see [Synchronous External aborts from address translation caching structures on page D5-2809](#)

D5.8.3 AArch64 state prioritization of synchronous aborts from a single stage of address translation

[Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2490](#) describes the prioritization of exceptions taken to an Exception level that is using AArch64. This section gives additional information about the prioritization of MMU faults from VMSAv8-64 translation regimes.

————— Note —————

The priority numbering in this list only shows the relative priorities of aborts from a single stage of address translation in a VMSAv8-64 translation regime. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-6364](#).

For a single stage of translation in a VMSAv8-64 translation regime, the following numbered list shows the priority of the possible memory management faults on a memory access. In this list:

- For memory accesses that undergo two stages of translation, the *italic entries show where the faults from the stage 2 translation can occur*. A stage 2 fault within a stage 1 translation table walk follows the same prioritization of faults:
- For synchronous External aborts from translation table walks, see also [Synchronous External aborts from address translation caching structures on page D5-2809](#).

The prioritization between the stage 2 permission failure on the stage 1 translation table walk and the stage 1 abort generated by the stage 1 translation table entry is IMPLEMENTATION DEFINED if all the following are true:

- Stage 1 hardware updating of either access or dirty information is enabled.
- A stage 1 translation table entry results in the stage 1 translation table entry having the access or dirty bit updated.
- The stage 1 translation table entry has stage 2 read permission but not stage 2 write permission.
- The stage 1 translation entry generates an abort (which might be one of an address size fault, an alignment fault caused by memory type or a Permission fault).

The priority order, from highest priority to lowest priority, is:

1. Alignment fault not caused by memory type. This is possible for a stage 1 translation only.
2. Translation fault due to the input address being out of the address range to be translated or requiring a TTBR_ELx that is disabled. This includes VTCCR_EL2.SL0 being inconsistent with VTCCR_EL2.T0SZ, VSTCCR_EL2.SL0 being inconsistent with VSTCCR_EL2.T0SZ, or SL0 programmed to a reserved value. If the *Effective value* of VTCCR_EL2.DS is 1, this includes VTCCR_EL2.SL2 being inconsistent with VTCCR_EL2.T0SZ, VSTCCR_EL2.SL2 being inconsistent with VSTCCR_EL2.T0SZ, or SL2 programmed to a reserved value.
3. Address size fault on a TTBR_ELx caused by either:
 - The check on TCR_EL1.IPS, TCR_EL2.{I}PS, TCR_EL3.PS, or VTCCR_EL2.PS.
 - The PA being out of the range implemented.
4. *Second stage abort on a level -1 memory access of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented.* This is a second stage abort during a first stage translation table walk.
5. Synchronous parity or ECC error on a level -1 lookup of a translation table walk.
6. Synchronous External abort on a level -1 lookup level of a translation table walk.
7. Translation fault on a level -1 translation table entry.

8. Address size fault a level -1 lookup translation table entry caused by either:
 - The check on [TCR_EL1.IPS](#), [TCR_EL2.{I}PS](#), [TCR_EL3.PS](#), or [VTCCR_EL2.PS](#).
 - The output address being out of the range implemented.
9. *Second stage abort on a level 0 memory access of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is a second stage abort during a first stage translation table walk.*
10. Synchronous parity or ECC error on a level 0 lookup of a translation table walk.
11. Synchronous External abort on a level 0 lookup level of a translation table walk.
12. Translation fault on a level 0 translation table entry.
13. Address size fault a level 0 lookup translation table entry caused by either:
 - The check on [TCR_EL1.IPS](#), [TCR_EL2.{I}PS](#), [TCR_EL3.PS](#), or [VTCCR_EL2.PS](#).
 - The output address being out of the range implemented.
14. *Second stage abort on a level 1 memory access of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is a second stage abort during a first stage translation table walk.*
15. Synchronous parity or ECC error on a level 1 lookup of a translation table walk.
16. Synchronous External abort on a level 1 lookup level of a translation table walk.
17. Translation fault on a level 1 translation table entry.
18. Address size fault on a level 1 lookup translation table entry caused by either:
 - The check on [TCR_EL1.IPS](#), [TCR_EL2.{I}PS](#), [TCR_EL3.PS](#), or [VTCCR_EL2.PS](#).
 - The output address being out of the range implemented.
19. *Second stage abort on a level 2 memory access of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is a second stage abort during a first stage translation table walk.*
20. Synchronous parity or ECC error on a level 2 lookup of a translation table walk.
21. Synchronous External abort on a level 2 lookup level of a translation table walk.
22. Translation fault on a level 2 translation table entry.
23. Address size fault on a level 2 lookup translation table entry caused by either:
 - The check on [TCR_EL1.IPS](#), [TCR_EL2.{I}PS](#), [TCR_EL3.PS](#), or [VTCCR_EL2.PS](#).
 - The output address being out of the range implemented.
24. *Second stage abort on a level 3 memory access of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is a second stage abort during a first stage translation table walk.*
25. Synchronous parity or ECC error on a level 3 lookup of a translation table walk.
26. Synchronous External abort on a level 3 lookup level of a translation table walk.
27. Translation fault on a level 3 translation table entry.
28. Address size fault on a level 3 lookup translation table entry caused by either:
 - The check on [TCR_EL1.IPS](#), [TCR_EL2.{I}PS](#), [TCR_EL3.PS](#), or [VTCCR_EL2.PS](#).
 - The output address being out of the range implemented.
29. Access Flag fault.
30. Alignment fault caused by the memory type.
31. Permission fault.
32. *A fault from the stage 2 translation of the memory access. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented.*
33. Synchronous parity or ECC error on the memory access.
34. Synchronous External abort on the memory access.

———— **Note** —————

- The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.
- The prioritization of IMPLEMENTATION DEFINED MMU faults for a Load-Exclusive or Store-Exclusive to an unsupported memory type is IMPLEMENTATION DEFINED.

- The prioritization of an unsupported atomic hardware update MMU fault is IMPLEMENTATION DEFINED to be at a point between immediately before the priority of an Access Flag fault generated by the same stage of translation as the stage of this MMU fault, and immediately after the priority of a Permission fault generated by the same stage of translation as the stage of this MMU fault.
-

Synchronous External aborts from address translation caching structures

A caching structure used for caching translation table walks might support:

- An arbitrary number of levels of translation table lookup.
- One or more stages of translation, that might not correspond to the stages of an address translation lookup.

This might mean that, on a synchronous External aborts arising from the caching structure, including parity or ECC errors, the PE cannot precisely determine one or both of the translation stage and level of lookup at which the error occurred. In this case:

- If the PE cannot determine precisely the translation stage at which the error occurred, it is reported and prioritized as a stage 1 error.
- If the PE cannot determine precisely the lookup level at which the error occurred, the level is reported and prioritized as either:
 - The lowest-numbered level that could have given rise to the error.
 - Level 0 if it the PE cannot determine any information about the level.

D5.9 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and the VMSA provides TLB maintenance instructions for the management of TLB contents.

———— **Note** —————

The Arm architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

The following sections describe the architectural requirements for Translation Lookaside Buffers (TLBs) and their maintenance:

- [Use of ASIDs and VMIDs to reduce TLB maintenance requirements on page D5-2810.](#)
- [About Armv8 Translation Lookaside Buffers \(TLBs\) on page D5-2812.](#)
- [TLB maintenance requirements and the TLB maintenance instructions on page D5-2816.](#)

In these descriptions, TLB entries for a translation regime for a particular Exception level are *out of context* when executing at a higher Exception level.

———— **Note** —————

In addition to the functions described in this section, the TLB might cache information from control registers that are described as being “permitted to be cached in a TLB”, even when any or all of the stages of translation are disabled. This caching of information gives rise to the maintenance requirements described in [General TLB maintenance requirements on page D5-2816.](#)

D5.9.1 Use of ASIDs and VMIDs to reduce TLB maintenance requirements

To reduce the need for TLB maintenance on context switches, the lookups from some translation regimes can be associated with an ASID, or with an ASID and a VMID, as follows:

ASID For stage 1 of a translation regime that can support two VA ranges the VMSA can distinguish between *Global pages* and *Process-specific pages*. The ASID identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

For these stage 1 translations, each of `TTBR0_ELx` and `TTBR1_ELx` has a valid ASID field, and `TCR_ELx.A1` determines which of these holds the current ASID.

———— **Note** —————

The selected ASID applies regardless of which set of translation tables are used. For example, when the value of `TCR_ELx.A1` is 0, any translation table lookup using this stage of translation is associated with the ASID from `TTBR0_ELx.ASID`, regardless of whether the translation lookup uses `TTBR0_ELx` or `TTBR1_ELx`.

See also [ASID size on page D5-2811](#) and [Global and process-specific translation table entries on page D5-2813](#).

For a symmetric multiprocessor cluster where a single operating system is running on the set of processing elements, the Arm architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all processing elements in the system.

VMID For the Secure or Non-secure EL1&0 translation regime, when EL2 is enabled, the VMID identifies the current virtual machine, with its own independent [ASID](#) space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another if the virtual machines have different VMIDs.

`VTBR_EL2.VMID` holds the current VMID.

Common not private translations

In an implementation that includes [FEAT_TTCNP](#), multiple PEs in the same Inner Shareable domain can use the same translation table entries for a given stage of translation in a particular translation regime. This sharing is enabled by the [TTBR_ELx.CnP](#) field for the stage of address translation.

When the value of a [TTBR_ELx.CnP](#) field is 1, translation table entries pointed to by that [TTBR_ELx](#) are shared with all other PEs in the Inner Shareable domain for which the following conditions are met:

- The corresponding [TTBR_ELx.CnP](#) field has the value 1.
- That [TTBR_ELx](#) relates to the same translation regime.

Note

- For [TTBR0_EL1](#) the current Security state determines whether the register relates to the Secure EL1&0, when EL2 is disabled, translation regime, or to the Non-secure EL1&0, when EL2 is enabled, translation regime.
- For [TTBR0_EL2](#) the value of [HCR_EL2.E2H](#) determines whether the register relates to the EL2 translation regime, or to the EL2&0 translation regime.

- If an ASID applies to the stage of translation corresponding to that [TTBR_ELx](#) then the current ASID value must be the same for all of the PEs that are sharing entries for any translation table entry that is not global or not leaf level.
- If a VMID applies to the stage of translation corresponding to that [TTBR_ELx](#) then the current VMID value must be the same for all of the PEs that are sharing entries.

For all PEs that are sharing translation table entries for a stage of translation, all system registers bits that apply to that stage of translation and that are described as being permitted to be cached in a TLB must be the same for all the PEs that are sharing the translation table entry. If this condition is not met by software then it is **CONSTRAINED UNPREDICTABLE** whether or not the value of such a control bit that has a different value between PEs, interpreted by a PE, called PE1 here, takes the value configured for:

- The system register bit of PE1.
- The system register bit of one of the PEs that is sharing the translation table entry.

For a translation regime with both stage 1 and stage 2 translations, where a TLB holds only stage 1 translation tables or where a TLB combines information from stage 1 and stage 2 translation table entries into a single entry, this entry can be shared between different PEs only if the value of the [TTBR_ELx.CnP](#) bit is 1 for both stage 1 and stage 2 of the translation table walk.

The [TTBR_ELx.CnP](#) bit can be cached in a TLB.

For a given [TTBR_ELx](#), if the value of [TTBR_ELx.CnP](#) is 1 on multiple PEs in the same Inner Shareable domain, and those PEs meet the other conditions for sharing translation table entries as defined in this section, but those [TTBR_ELx](#)s do not point to the same translation table entries, then the system is misconfigured, and performing an address translation using that [TTBR_ELx](#):

- Might generate multiple hits in the TLB, and as a result generate an exception that is reported using the TLB conflict fault code, see [TLB conflict aborts on page D5-2814](#).
- Otherwise, has a **CONSTRAINED UNPREDICTABLE** result, as described in [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-8409](#).

ASID size

In VMSAv8-64, the **ASID** size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and [ID_AA64MMFR0_EL1.ASIDBits](#) identifies the supported size.

When an implementation supports a 16-bit **ASID**, [TCR_ELx.AS](#) selects whether the top 8 bits of the **ASID** are used.

When the value of [TCR_ELx.AS](#) is 0, **ASID**[15:8]:

- Are ignored by hardware for every purpose other than direct reads of [TTBR0_ELx.ASID](#) and [TTBR1_ELx.ASID](#).
- Are treated as if they are all zeros when used for allocating and matching entries in the TLB.

Note

VMSAv8-32 uses an 8-bit **ASID**. For backwards compatibility, when executing using translations controlled from an Exception level that is using AArch32, the **ASID** size remains at 8 bits. If the implementation supports 16-bit **ASIDs**, the 8-bit **ASID** used is zero-extended to 16 bits.

VMID size

From Armv8.1, the **VMID** size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and **ID_AA64MMFR1_EL1.VMIDBits** identifies the supported size.

When **FEAT_VMID16** is implemented, **VTTBR_EL2[63:48]** contains the 16-bit **VMID**.

When an implementation supports a 16-bit **VMID**, **VTTCR_EL2.VS** selects whether the top 8 bits of the **VMID** are used.

When the value of **VTTCR_EL2.VS** is 0, **VMID[63:56]**:

- Are ignored by hardware for every purpose other than reads of **ID_AA64MMFR1_EL1**.
- Are treated as if they are all zeros when used for allocating and matching entries in the TLB.

FEAT_VMID16 is only supported when EL2 is using AArch64.

D5.9.2 About Armv8 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement for every memory access to perform a translation table walk in memory. The Arm architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Permission fault might be held in the TLB.
- When address translation is enabled, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not from a translation regime for an Exception level that is lower than the current Exception level can be allocated to a TLB at any time. The only translation table entries guaranteed not to be held in a TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

Note

A TLB can hold a translation table entry that does not itself generate a Translation fault but that points to a subsequent table in the translation table walk. This is referred to as *intermediate caching* of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not have been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- [Global and process-specific translation table entries on page D5-2813.](#)
- [TLB matching on page D5-2813.](#)
- [TLB behavior at reset on page D5-2814.](#)
- [TLB lockdown on page D5-2814.](#)
- [TLB conflict aborts on page D5-2814.](#)

See also [TLB maintenance requirements and the TLB maintenance instructions on page D5-2816.](#)

Global and process-specific translation table entries

In a VMSA implementation, system software can divide the virtual memory map used by a stage of translation that can support two VA ranges into global and non-global regions, indicated by the nG bit in the Translation Table descriptors:

- nG == 0** The translation is global, meaning the region is available for all processes.
- nG == 1** The translation is non-global, or process-specific, meaning it relates to the current [ASID](#), as defined by:
- [TTBR0_ELx.ASID](#), if the value of [TCR_ELx.A1](#) is 0.
 - [TTBR1_ELx.ASID](#), if the value of [TCR_ELx.A1](#) is 1.

As indicated by the nG field definitions, each non-global region has an associated [ASID](#). These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

Note

- The selected [ASID](#) applies to the translation of any address for which the value of the nG bit is 1, regardless of whether the address is translated based on [TTBR0_ELx](#) or on [TTBR1_ELx](#).
 - In an implementation that does not include [FEAT_VHE](#), the only stage of translation that can support two VA ranges is stage 1 of the EL1&0 translation regime. In an implementation that includes [FEAT_VHE](#) stage 1 of the EL2&0 translation regime also can support two VA ranges.
-

[ASIDs](#) are supported only when stage 1 translations can support two VA ranges. Stage 2 translations, and stage 1 translations that can support only a single VA range do not support [ASIDs](#), and all descriptors in these regimes are treated as global.

In a translation regime that supports global and non-global translations, translation table entries from lookup levels other than the final level of lookup are treated as being non-global, regardless of the value of the nG bit.

When a PE is using the VMSAv8-64 translation table format which supports both global and non-global entries, and is in Secure state, a stage 1 translation must be treated as non-global, regardless of the value of the nG bit, if [NSTable](#) is set to 1 at any level of the translation table walk.

For more information, see [Control of Secure or Non-secure memory access on page D5-2753](#).

TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in [TLB maintenance requirements and the TLB maintenance instructions on page D5-2816](#) can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular [ASID](#) and [VMID](#) are changed without suitable invalidation of the TLB. This can occur only if the architecturally-required break-before-make sequence described in [Using break-before-make when updating translation table entries on page D5-2818](#) is not used. If the break-before make sequence is not used, the TLB can hold two mappings for the same address, and this:

- Might generate an exception that is reported using the TLB conflict fault code, see [TLB conflict aborts on page D5-2814](#).
- Might lead to [CONSTRAINED UNPREDICTABLE](#) behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for access. In addition, where all the entries being amalgamated come from Non-secure memory, the amalgamation cannot give rise to an output address that accesses Secure memory. For more information, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-8409](#).

TLB behavior at reset

The Arm architecture does not require a reset to invalidate the TLBs. The architecture recognizes that an implementation might require caches, including TLBs, to maintain their contents over a system reset. Possible reasons for doing so include power management and debug requirements.

Therefore, for Armv8:

- All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
- All TLBs are disabled from reset. All stages of address translation are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information, see [Controlling address translation stages on page D5-2688](#).
- An implementation can require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device. Arm recommends that if an invalidation routine is required for this purpose, the routine is based on the TLB maintenance instructions described in [TLB maintenance instructions on page D5-2819](#).

Similar rules apply to cache behavior, see [Behavior of caches at reset on page D4-2643](#).

TLB lockdown

The Arm architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- VMSAv8-64 does not require TLB lockdown support.
- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that a region of the System instruction encoding space is reserved for IMPLEMENTATION DEFINED functions, see [Reserved encodings for IMPLEMENTATION DEFINED registers on page D12-3038](#). An implementation might use some of these encodings to implement TLB lockdown functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the PLI and PLD hint instructions.

In an implementation that includes EL2, exceptions generated as a result of TLB lockdown when executing in EL1 or EL0 state can be routed to either:

- EL1, as a Data Abort exception.
- EL2, as a Hyp Trap exception.

For more information, see [Traps to EL2 of EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-2523](#).

TLB conflict aborts

If an address matches multiple entries in the TLB, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.

———— Note —————

An address can hit multiple entries in the TLB if the TLB has been invalidated inappropriately, for example if TLB invalidation required by the architecture has not been performed.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses. A TLB conflict abort:

- On an instruction fetch is reported as an Instruction Abort, see [ISS encoding for an exception from an Instruction Abort on page D13-3170](#).
- On a data access is reported as a Data Abort, see [ISS encoding for an exception from a Data Abort on page D13-3219](#).

Armv8 defines the Fault status encoding of 0b110000 for TLB conflict aborts. On a TLB conflict abort, the returned syndrome includes the address that generated the fault. That is, it includes the address that was being looked up in the TLB.

It is IMPLEMENTATION DEFINED whether a TLB conflict abort is a stage 1 abort or a stage 2 abort.

———— **Note** —————

A stage 2 abort cannot be generated if stage 2 of the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime is disabled.

—————

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of a TLB that can generate the abort. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

If an address matches multiple entries in the TLB and no TLB conflict abort is generated, the resulting behavior is CONSTRAINED UNPREDICTABLE, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-8409](#). The CONSTRAINED UNPREDICTABLE behavior must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Exception level.

D5.10 TLB maintenance requirements and the TLB maintenance instructions

Translation Lookaside Buffers (TLBs) are an implementation mechanism that caches translations or translation table entries. The Arm architecture does not specify the form of any TLB structures, but defines the mechanisms by which TLBs can be maintained. The following sections describe the VMSA TLB maintenance instructions:

- [General TLB maintenance requirements on page D5-2816](#).
- [TLB maintenance instructions on page D5-2819](#).

See also [Atomicity of register changes on changing virtual machine on page D5-2697](#).

D5.10.1 General TLB maintenance requirements

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures to ensure that changes to the translation tables are reflected correctly in those TLB caching structures.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault, provided that the entry does not, itself, cause a Translation fault, an Address size fault, or an Access Flag fault. This means that the entries that can be cached include:

- Entries in translation tables that point to subsequent tables to be used in that stage of translation.
- Stage 2 translation table entries used as part of a stage 1 translation table walk.
- Stage 2 translation table entries used to translate the output address of the stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are used during a translation table walk and that are distinct from the data caches in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction on the form of these intermediate TLB caching structures when these caches are indexed by their input address. The architecture does not restrict having either:

- Translation table entry caching that is indexed by the physical address of the location holding the translation table entry.
- Translation table entry caching that is used for stage 1 translations and is indexed by the intermediate physical address of the location holding the translation table entry. However, [FEAT_nTLBPA](#) allows software discoverability of whether such caches exist, such that if [FEAT_nTLBPA](#) is implemented, such caching is not implemented.

If all of the following are true, a TLB maintenance instruction will ensure that any physical address or intermediate physical address indexed cached copies of translation table entries are invalidated for a PE:

- The TLB maintenance instruction applies to that PE with the context information that is relevant to translation table entry caching that is either:
 - Indexed by the physical address of the location holding the translation table entry.
 - Stage 1 translation information that is indexed by the intermediate physical address of the location holding the translation table entry.
- [FEAT_nTLBPA](#) is not implemented.

———— **Note** ————

Any TLB caching based on the physical address or intermediate physical address obeys the other rules regarding the caching to TLB entries described in this manner, including restrictions on types of entries that cannot be held in a TLB, and a requirement that entries held in a TLB are distinguished by context information such as translation regime, [VMID](#), and [ASID](#).

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries, and in particular for a translation regime that involves two stages of translation, it is recognized that such caching structures might contain:

- Entries containing information from stage 1 translation table entries, at any level of the translation table walk.
- Entries containing information from stage 2 translation table entries, at any level of the translation table walk.
- Entries that combine information from stage 1 and stage 2 translation table entries, at any level of the translation table walk.

Note

For the purpose of TLB maintenance, the term *TLB entry* denotes any structure, including temporary working registers in translation table walk hardware, that holds a translation table entry.

Where a TLB maintenance instruction is:

- Required to apply to stage 1 entries, then it must apply to any cached entries in caching structures that include any stage 1 information that are used to translate the address being invalidated.

Note

- Where stage 1 information has been cached in multiple TLB entries, as could occur from splintering a page when caching in the TLB, then the invalidation must apply to each cached entry containing stage 1 information from the page that is used to translate the address being invalidated, regardless of whether or not that cached entry would be used to translate the address being invalidated.
 - As stated in [Global and process-specific translation table entries on page D5-2813](#), translation table entries from levels of translation other than the final level are treated as being non-global. Arm expects that, in at least some implementations, cached copies of levels of the translation table walk other than the last level are tagged with their [ASID](#), regardless of whether the final level is global. This means that TLB invalidations that involve the [ASID](#) require the [ASID](#) to match such entries to perform the required invalidation.
-

- Required to apply to stage 2 entries only, then:
 - It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
 - It must apply to caching structures that contain information only from stage 2 translation table entries.
- Required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Whenever translation tables entries associated with a particular [VMID](#) or [ASID](#) are changed, the corresponding entries must be invalidated from the TLB to ensure that these changes are visible to subsequent execution, including speculative execution, that uses the changed translation table entries.

Some System register field descriptions state that the effect of the field is permitted to be cached in a TLB. This means that all TLB entries that might be affected by a change of the field must be invalidated whenever that field is changed, to ensure that the effect of the change of that control field is visible to subsequent execution, including speculative execution, that uses that control field. This invalidation is required in addition to, and after, the normal synchronization of the System registers described in [Synchronization requirements for AArch64 System registers on page D13-3041](#), and applies to any stage of address translation that is implemented for the translation regime, and [VMID](#) and [ASID](#) as appropriate, that is affected by that control field. A control field that is permitted to be cached in a TLB requires this maintenance even when all stages of address translation are disabled.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information, see [Cache maintenance requirement created by changing translation table attributes on page D5-2837](#).

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access Flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB invalidation. However, a [Context synchronization event](#) is required to ensure that instruction fetches are affected by a completed change to translation table entries that, before the change, generated a Translation, Address size, or Access flag fault.

Special considerations apply to translation table updates that change the memory type, cacheability, or output address of an entry, see [Using break-before-make when updating translation table entries on page D5-2818](#).

Using break-before-make when updating translation table entries

To avoid possibly creating multiple TLB entries for the same address, and to avoid the effects of TLB caching possibly breaking coherency, single-copy atomicity properties, ordering guarantees or uniprocessor semantics, or possibly failing to clear the Exclusives monitors, the architecture requires the use of a break-before-make sequence when changing translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation table entries involves any of:

- A change of the memory type, including shareability.
- A change of the cacheability attributes.
- A change of the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable, including if the DBM bit is set and hardware updates to the dirty bits are enabled.
- A change to the size of block used by the translation system. This applies both:
 - When changing from a smaller size to a larger size, for example by replacing a table mapping with a block mapping in a stage 2 translation table.
 - When changing from a larger size to a smaller size, for example by replacing a block mapping with a table mapping in a stage 2 translation table.
- A change of the output address (OA), if the contents of memory at the new OA do not match the contents of memory at the previous OA.
- Creating a global entry when there might be non-global entries in a TLB that overlap with that global entry.

Note

Changes to the output address (OA) include changing between Secure and Non-secure output addresses.

A break-before-make sequence on changing from an old translation table entry to a new translation table entry requires the following steps:

1. Replace the old translation table entry with an invalid entry, and execute a DSB instruction.
2. Invalidate the translation table entry with a broadcast TLB invalidation instruction, and execute a DSB instruction to ensure the completion of that invalidation.
3. Write the new translation table entry, and execute a DSB instruction to ensure that the new entry is visible.

This sequence ensures that at no time are both the old and new entries simultaneously visible to different threads of execution, and therefore the problems described at the start of this subsection cannot arise.

In Armv8.1, with the introduction of hardware updates to the translation table entries, the effects of not following the break-before-make rules are extended.

If the break-before-make rules are not followed for changing the translation table entries, the Armv8.1 architecture permits that the following failures associated with the hardware updates of the translation table entries could occur:

- The Access flag is not set on such a translation table entry despite the fact that the memory location associated with that entry was accessed.
- The AP[2] or S2AP[1] bit is modified by the hardware on such a translation table entry despite the fact that the memory location associated with that entry was not written to.
- The AP[2] or S2AP[1] bit is not modified by the hardware on such a translation table entry despite the fact that the memory location associated with that entry was written to.
- The ordering required between hardware updates to such a translation table entry and stores appearing later in program order is not followed.

Support levels for changing block size

If [FEAT_BBM](#) is implemented, the PE provides three levels of support when changing block size, without changing any other parameters that require break-before-make:

- Level 0** Software must use break-before-make to avoid breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors when changing block size. See [Using break-before-make when updating translation table entries on page D5-2818](#).

- Level 1** Software can use the level 0 approach, or software can use the nT block translation entry to avoid breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors when changing block size. See [Block translation entry on page D5-2766](#).
- Level 2** Software can use the level 0 or level 1 approach and, in addition, changing block size does not break coherency, ordering guarantees or uniprocessor semantics, or fail to clear the Exclusives monitors. If there has not been a TLB invalidation of the entries that have changed since the writes that changed those entries were completed, this change might cause Conflict aborts. This is because multiple translation entries might exist within the TLB for the same input address.

In addition, an implementation that uses the level 1 or level 2 approach supports the following without breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors:

- A change to a set of blocks or pages from having the Contiguous bit set to having the Contiguous bit not set.
- A change to a set of blocks or pages from having the Contiguous bit not set to having the Contiguous bit set.

If multiple translation entries exist within the TLB for the same input address, this change might cause Conflict aborts when translating the address.

For level 1 or level 2 support, if the change of block size or contiguous bit gives rise to a Conflict abort, then in a translation regime for which stage 2 translations are enabled, the Conflict abort is reported to EL2.

Clearing entries associated with a Conflict abort

While using level 1 or level 2 support, on a Conflict abort, the following instructions are guaranteed to clear the entries associated with the conflict:

- For the EL1&0 translation regime, while stage 2 translations are in use: TLBI VMALLS12E1, TLBI ALLE1.
- For the EL1&0 translation regime, while stage 2 translations are not in use: TLBI VMALLE1, TLBI ALLE1.
- For the EL2&0 translation regime: TLBI VMALLE1, TLBI ALLE1.
- For the EL2 translation regime: TLBI ALLE2.
- For the EL3 translation regime: TLBI ALLE3.

D5.10.2 TLB maintenance instructions

The architecture defines TLB maintenance instructions, which provide the following:

- Invalidate all entries in the TLB.
- Invalidate a single TLB entry by [ASID](#) for a non-global entry.
- Invalidate all TLB entries that match a specified [ASID](#).
- Invalidate all TLB entries that match a specified [VA](#), regardless of the [ASID](#).
- Invalidate all TLB entries within a range of addresses.

Each instruction can be specified as applying only to the PE that executes the instruction, or as applying to all PEs in the same shareability domain as the PE that executes the instruction.

The following subsections describe these instructions:

- [TLB maintenance instruction syntax on page D5-2820](#).
- [Operation of the TLB maintenance instructions on page D5-2823](#).
- [Scope of the A64 TLB maintenance instructions on page D5-2824](#).
- [TLB range maintenance instructions on page D5-2828](#).
- [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).
- [Broadcast TLB maintenance between AArch32 and AArch64 on page D5-2830](#).
- [Broadcast TLB maintenance with different translation granule sizes on page D5-2831](#).
- [Ordering and completion of TLB maintenance instructions on page D5-2831](#).
- [TLB maintenance in the event of TLB conflict on page D5-2833](#).
- [The interaction of TLB lockdown with TLB maintenance instructions on page D5-2833](#).

[TLB maintenance instructions on page C5-401](#) describes the encoding of the TLB maintenance instructions.

TLB maintenance instruction syntax

The A64 syntax for TLB maintenance instructions is:

```
TLBI <operation>{, <Xt>}
```

Where:

<operation> Is one of ALLE1{NXS}, ALLE2{NXS}, ALLE3{NXS}, ALLE1IS{NXS}, ALLE2IS{NXS}, ALLE3IS{NXS}, ALLE10S{NXS}, ALLE20S{NXS}, ALLE30S{NXS}, VMALLE1{NXS}, VMALLE1IS{NXS}, VMALLE10S{NXS}, VMALLS12E1{NXS}, VMALLS12E1IS{NXS}, VMALLS12E10S{NXS}, ASIDE1{NXS}, ASIDE1IS{NXS}, ASIDE10S{NXS}, {R}VA{L}E1{NXS}, {R}VA{L}E2{NXS}, {R}VA{L}E3{NXS}, {R}VA{L}E1IS{NXS}, {R}VA{L}E2IS{NXS}, {R}VA{L}E3IS{NXS}, {R}VA{L}E10S{NXS}, {R}VA{L}E20S{NXS}, {R}VA{L}E30S{NXS}, {R}VAA{L}E1{NXS}, {R}VAA{L}E1IS{NXS}, {R}VAA{L}E10S{NXS}, {R}IPAS2{L}E1{NXS}, {R}IPAS2{L}E1IS{NXS}, or {R}IPAS2{L}E10S{NXS}.

<operation> has a structure of {R}<type><level><shareability>{NXS} where:

R When present, indicates that the function applies to all TLBs that are within a determined address range, see [TLB range maintenance instructions on page D5-2828](#). When not present, indicates that the function applies to all TLBs at a single address that contain entries that could be used by the PE that executes the TLBI instruction.

<type> Is one of:

ALL All translations used at <level>.

For the scope of ALL instructions, see [ALL on page D5-2824](#).

The ALL instructions are valid for all values of <level>.

VMALL All stage 1 translations used at <level> with the current VMID, if appropriate.

For the scope of the VMALL instructions, see [VMALL on page D5-2825](#).

The VMALL instructions are valid only when level == E1.

VMALLS12 All stage 1 and stage 2 translations used at EL1 with the current VMID, if appropriate.

For the scope of the VMALLS12 instructions, see [VMALLS12 on page D5-2825](#).

The VMALLS12 instructions are valid only when level == E1.

ASID All translations used at EL1 with the supplied ASID.

For the scope of the ASID instructions, see [ASID on page D5-2825](#).

The ASID instructions are valid only when level == E1.

VA{L} Translations used at <level> for the specified address and, if appropriate, the specified ASID.

For the scope of the VA instructions, see [VA on page D5-2826](#). For the scope of the VAL instructions, see [VAL on page D5-2826](#).

The VA{L} instructions are valid for all values of <level>.

VAA{L} Translations used at <level> for the specified address, for all ASID values, if appropriate.

For the scope of the VAA instructions, see [VAA on page D5-2826](#). For the scope of the VAAL instructions, see [VAAL on page D5-2826](#).

The VAA{L} instructions are valid only when level == E1.

IPAS2{L} Translations used at <level> for the specified IPA that are held in stage 2 only caching structures.

For the scope of the IPAS2 instructions, see [IPAS2 on page D5-2827](#). For the scope of the IPAS2L instructions, see [IPAS2L on page D5-2827](#).

The IPAS2{L} instructions are valid only when level == E1.

In the VA{L}, VAA{L}, and IPAS2{L} types:

L An optional parameter that indicates that the invalidation only applies to caching of entries returned from the final lookup level of the translation table walk.

<level> Defines the Exception level of the translation regime that the invalidation applies to. Is one of:

- E1 EL1.
- E2 EL2.
- E3 EL3.

An instruction that applies to the translation regime of an Exception level higher than the Exception level at which the instruction is executed is UNDEFINED.

TLBI ALLE1{NXS}, TLBI ALLE1IS{NXS}, TLBI ALLE1OS{NXS}, TLBI {R}IPAS2{L}E1{NXS}, TLBI {R}IPAS2{L}E1IS{NXS}, TLBI {R}IPAS2{L}E1OS{NXS}, TLBI VMALLS12E1{NXS}, TLBI VMALLS12E1IS{NXS}, and TLBI VMALLS12E1OS{NXS} are UNDEFINED at EL1.

———— **Note** ————

All TLB maintenance instructions are UNDEFINED at EL0.

<shareability>

Is one of:

- IS When present, it indicates that the function applies to all TLBs in the Inner Shareable shareability domain.
- OS When present, it indicates that the function applies to all TLBs in the Outer Shareable shareability domain.
- <blank> When no Shareability is present, it indicates that the function applies to all TLBs that contain entries that could be used by the PE that executes the TLBI instruction.

———— **Note** ————

When a TLB entry has been invalidated for one PE, it is not consistent with the architecture to allow another PE to refill that TLB entry where the new entry might give the appearance to software that the invalidation has not occurred.

NXS When present, indicates that the scope of the TLB maintenance instruction does not apply to memory transactions with the XS attribute. This parameter is optional and applies only when FEAT_XS is implemented.

<Xt> Passes one or both of an address and an ASID as an argument, where required. <Xt> is required for the TLB ASID, TLB VA{L}, TLB VAA{L}, and TLB IPAS2{L} instructions.

If EL2 is not implemented, the TLBI VA{L}E2{NXS}, TLBI VA{L}E2IS{NXS}, TLBI VA{L}E2OS{NXS}, TLBI ALLE2{NXS}, TLBI ALLE2IS{NXS}, TLBI ALLE2OS{NXS}, TLBI RVA{L}E2{NXS}, TLBI RVA{L}E2IS{NXS}, and TLBI RVA{L}E2OS{NXS} instructions are UNDEFINED.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds a VA, an ASID, or both, and that do not apply to a range of addresses, use the register argument format:

- Bits[63:48]** ASID. These bits are RES0 if the instruction does not require an ASID argument.
 - Bits[47:44]** TTL. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated, see *Translation table level hints on page D5-2822*. This field is RES0 if the instruction does not require an VA argument, or if FEAT_TTL is not implemented.
 - Bits[43:0]** VA[55:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:
 - 4KB granule size** All bits are valid and used for the invalidation.
 - 16KB granule size** Bits[1:0] RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
 - 64KB granule size** Bits[3:0] are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.
- These bits are RES0 if the instruction does not require a VA argument.

For TLB maintenance instructions that take an address argument, hardware interprets VA[63:56] as each having the same value as VA[55].

If a TLB maintenance instruction targets a translation regime that is using AArch32, meaning the VA is only 32-bit, then software must treat VA[55:32] as RES0, and these bits are ignored when the instruction is executed.

If the implementation supports 16 bits of ASID then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds an IPA, and that do not apply to a range of addresses, use the register argument format:

- Bit[63]** NS. Specifies the Secure or Non-secure IPA space. This field is RES0 if the instruction is executed in Non-secure state, or when FEAT_SEL2 is not implemented or is disabled in the current Security state.
- Bits[62:48]** RES0.
- Bits[47:44]** TTL. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated, see [Translation table level hints on page D5-2822](#). This field is RES0 if the instruction does not require an IPA argument, or if FEAT_TTL is not implemented.
- Bits[43:40]** RES0.
- Bits[39:36]** IPA[51:48]. Extension to IPA[47:12]. When 52-bit addresses are in use, forms the upper part of the address value. This field is RES0 if 52-bit addresses are not in use.
- Bits[35:0]** IPA[47:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:
 - 4KB granule size** All bits are valid and used for the invalidation.
 - 16KB granule size** Bits[1:0] RES0 and ignored when the instruction is executed, because IPA[13:12] have no effect on the operation of the instruction.
 - 64KB granule size** Bits[3:0] are RES0 and ignored when the instruction is executed, because IPA[15:12] have no effect on the operation of the instruction.

For the register argument format of TLB instructions that apply to a range of addresses, see [TLB range maintenance instructions on page D5-2828](#).

Translation table level hints

When FEAT_TTL is implemented, the TTL field indicates the level of translation table walk holding the leaf entry for the address being invalidated. Hardware can use this information to determine if there was a risk of splintering.

If an incorrect value for the entry being invalidated by the instruction is specified in the TTL field, then no entries are required by the architecture to be invalidated from the TLB.

The TTL field in TLB maintenance instructions that take a register argument that holds a VA or an IPA, and that do not apply to a range of addresses, use the encodings in [Table D5-54 on page D5-2822](#).

Table D5-54 TTL field encodings in TLB instructions that apply to a single address

TTL[3:2]	TTL[1:0]	Information supplied
00	RES0	No information supplied about the translation level. Hardware must assume that the entry can be from any level.
01	00	The entry comes from a 4KB translation granule. If FEAT_LPA2 is not implemented, this value is reserved, and hardware should treat this as if TTL[3:2] is 0b00. If FEAT_LPA2 is implemented, the leaf entry for the address being invalidated is on level 0 of the translation table walk.
	01	The entry comes from a 4KB translation granule. The leaf entry for the address being invalidated is on level 1 of the translation table walk.
	10	The entry comes from a 4KB translation granule. The leaf entry for the address being invalidated is on level 2 of the translation table walk.

Table D5-54 TTL field encodings in TLB instructions that apply to a single address (continued)

TTL[3:2]	TTL[1:0]	Information supplied
	11	The entry comes from a 4KB translation granule. The leaf entry for the address being invalidated is on level 3 of the translation table walk.
10	00	The entry comes from a 16KB translation granule. This value is reserved, and hardware should treat this as if TTL[3:2] is 0b00.
	01	The entry comes from a 16KB translation granule. If FEAT_LPA2 is not implemented, this value is reserved, and hardware should treat this as if TTL[3:2] is 0b00. If FEAT_LPA2 is implemented, the leaf entry for the address being invalidated is on level 1 of the translation table walk.
	10	The entry comes from a 16KB translation granule. The leaf entry for the address being invalidated is on level 2 of the translation table walk.
	11	The entry comes from a 16KB translation granule. The leaf entry for the address being invalidated is on level 3 of the translation table walk.
11	00	The entry comes from a 64KB translation granule. This value is reserved, and hardware should treat this as if TTL[3:2] is 0b00.
	01	The entry comes from a 64KB translation granule. The leaf entry for the address being invalidated is on level 1 of the translation table walk.
	10	The entry comes from a 64KB translation granule. The leaf entry for the address being invalidated is on level 2 of the translation table walk.
	11	The entry comes from a 64KB translation granule. The leaf entry for the address being invalidated is on level 3 of the translation table walk.

The TTL field in TLB maintenance instructions that take a register argument that holds a VA or an IPA, and apply to a range of addresses, use the encodings in [Table D5-55 on page D5-2823](#).

Table D5-55 TTL field encodings in TLB instructions that apply to multiple addresses

TTL	Information supplied
00	The entries in the range can be using any level for the translation table entries.
01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved, and hardware should treat the TTL field as 0b00. If FEAT_LPA2 is implemented, when using a 16KB translation granule, all entries to invalidate are Level 1 translation table entries.
10	All entries to invalidate are Level 2 translation table entries.
11	All entries to invalidate are Level 3 translation table entries.

Operation of the TLB maintenance instructions

Any TLB maintenance instruction can affect any TLB entries that are not locked down.

The TLB maintenance instructions specify the Exception level of the translation regime to which they apply.

Note

Because there is no guarantee that an unlocked TLB entry remains in the cache, architecturally it is not possible to tell whether a TLB maintenance instruction has affected any TLB entries that were not specified by the instruction.

If a TLB maintenance instruction specifies a VA, and a data or instruction access to that VA would generate an MMU abort, the TLB maintenance instruction does not generate an abort. VAs for which a TLB maintenance instruction does not generate an abort include VAs that are not in the range of VAs that can be translated.

When EL3 is implemented:

- The TLB maintenance instructions that apply to the EL1&0 translation regime take account of the current Security state, as part of the address translation required for the TLB operation.
- SCR_EL3.NS modifies the effect of the TLB maintenance instructions as follows:
 - For instructions that apply to the EL1&0 translation regime, the SCR_EL3.NS bit identifies whether the maintenance instructions apply to the Secure or Non-secure EL1&0 translation regime.

Note

If EL3 is not implemented, then there is only a single EL1&0 translation regime.

- When SCR_EL3.EEL2 is 0 instructions that apply to the EL2 translation regime, or to the EL2&0 translation regime, the SCR_EL3.NS bit must be 1 or the instruction is UNDEFINED.
- For instructions that apply to the EL3 translation regime, the SCR_EL3.NS bit has no effect.

Note

- An address-based TLB maintenance instruction that applies to the Inner Shareable domain or the Outer Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the instruction.
- Previous versions of the Arm architecture included TLB maintenance instructions that operated only on instruction TLBs, or only on data TLBs. From the introduction of Armv7, Arm deprecated any use of these instructions. In Armv8:
 - AArch64 state does not include any of these instructions.
 - AArch32 state includes some of these instructions, but Arm deprecates their use.

The Arm architecture does not dictate the form in which the TLB stores translation table entries. However, when a TLB maintenance instruction is executed, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

Note

The Contiguous bit does not affect the minimum size of entry that must be invalidated from the TLB.

Scope of the A64 TLB maintenance instructions

The TLB invalidation instruction <type> affects the different possible cached entries in the TLB as follows:

ALL The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with the state specified by SCR_EL3.NS and SCR_EL3.EEL2.

For entries from the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, ALL applies to entries with any VMID.

For entries from a translation regime for which an ASID is valid, the invalidation applies to:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

Note

This means the invalidation applies to both:

- Global entries.

— Non-global entries with any [ASID](#).

VMALL The invalidation applies to all cached copies of the stage 1 translation table entries, from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:

- The Security state specified by [SCR_EL3.NS](#) and [SCR_EL3.EEL2](#).
- For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the current [VMID](#).

For entries from a translation regime for which an [ASID](#) is valid that meet the other specified conditions, the invalidation applies to:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

———— **Note** —————

This means the invalidation applies to both:

- Global entries.
 - Non-global entries with any [ASID](#).
-

VMALL is valid for:

- EL1.
- EL2, when [HCR_EL2](#).{E2H, TGE} is {1, 1}.

VMALLS12 The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:

- The Security state specified by [SCR_EL3.NS](#) and [SCR_EL3.EEL2](#).
- For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the current [VMID](#).

For entries from a translation regime for which an [ASID](#) is valid that meet the other specified conditions, the invalidation applies to:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

———— **Note** —————

This means the invalidation applies to both:

- Global entries.
 - Non-global entries with any [ASID](#).
-

VMALLS12 is valid for EL1.

If EL2 is not implemented, or if the TLBI **VMALLS12** instruction is executed when the value of [SCR_EL3.NS](#) is 0 and EL2 is disabled, the instruction is not UNDEFINED but it has the same effect as TLBI **VMALL**. This is because there are no stage 2 translations to invalidate.

ASID The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:

- The Security state specified by [SCR_EL3.NS](#) and [SCR_EL3.EEL2](#).
- For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the current [VMID](#).

For entries from a translation regime for which an [ASID](#) is valid that meet the other specified conditions, the invalidation applies only if either:

- The entry is from a level of lookup above the final level and matches the specified [ASID](#).
- The entry is a non-global entry from the final level of lookup and matches the specified [ASID](#).

ASID is valid for:

- EL1.
- EL2, when `HCR_EL2.{E2H, TGE}` is {1, 1}.

VA The invalidation applies to all cached copies of the stage 1 translation table entries, from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level, that would be used with the following:

- The Security state specified by `SCR_EL3.NS` and `SCR_EL3.EEL2`.
- The current `VMID`, for the Secure or Non-secure EL1&0 translation regime, when EL2 is enabled.
- The current translation regime. For EL2&0 translation regimes, this is determined by `HCR_EL2.E2H`.

For entries from a translation regime which has a valid `ASID`, one of the following must also apply:

- The entry is from a level of lookup above the final level and matches the specified `ASID`.
- The entry is a global entry from the final level of lookup.
- The entry is a non-global entry from the final level of lookup that matches the specified `ASID`.

VAL The invalidation applies to all cached copies of the stage 1 translation table entry, from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level, that would be used with the following:

- The Security state specified by `SCR_EL3.NS` and `SCR_EL3.EEL2`.
- The current `VMID`, for the Secure or Non-secure EL1&0 translation regime, when EL2 is enabled.
- The current translation regime. For EL2&0 translation regimes, this is determined by `HCR_EL2.E2H`.

For entries from a translation regime which has a valid `ASID`, either of the following must also apply:

- The entry is a global entry from the final level of lookup.
- The entry is a non-global entry from the final level of lookup that matches the specified `ASID`.

VAA The invalidation applies to all cached copies of the stage 1 translation table entries, from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with the following:

- The Security state specified by `SCR_EL3.NS` and `SCR_EL3.EEL2`.
- The current `VMID`, for the Secure or Non-secure EL1&0 translation regime, when EL2 is enabled.
- The current translation regime. For EL2&0 translation regimes, this is determined by `HCR_EL2.E2H`.

For entries from a translation regime which has a valid `ASID`, the invalidation applies to all of the following:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

———— **Note** —————

This means the invalidation applies to both:

- Global entries.
- Non-global entries with any `ASID`.

VAA The invalidation applies to all cached copies of the stage 1 translation table entry, from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with the following:

- The Security state specified by `SCR_EL3.NS` and `SCR_EL3.EEL2`.

- The current **VMID**, for the Secure or Non-secure EL1&0 translation regime, when EL2 is enabled.
- The current translation regime. For EL2&0 translation regimes, this is determined by **HCR_EL2.E2H**.

For entries from a translation regime which has a valid **ASID**, the invalidation applies to all entries at the final level of lookup.

———— **Note** ————

This means the invalidation applies to both:

- Global entries.
- Non-global entries with any **ASID**.

- IPAS2 The invalidation applies to all cached copies of the stage 2 translation table entries from any level of the translation table walk required to translate the specified **IPA**, that both:
- Are held in TLB caching structures holding stage 2 only entries.
 - Would be used with the current **VMID**.

It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.

The only translation regime to which this instruction can apply is the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime.

When executed with the **SCR_EL3.NS** = 0, or in an implementation that does not implement EL2, this instruction is a NOP.

For more information about the architectural requirements for the IPAS2 instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

- IPAS2L The invalidation applies to cached copies of the stage 2 translation table entry from the final level of the stage 2 translation table walk required to translate the specified **IPA**, that both:
- Are held in TLB caching structures holding stage 2 only entries.
 - Would be used with the current **VMID**.

It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.

The only translation regime to which this instruction can apply is the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime.

When executed with the **SCR_EL3.NS** = 0, or in an implementation that does not implement EL2, this instruction is a NOP.

For more information about the architectural requirements for the IPAS2L instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

The entries that the invalidations apply to are not affected by the state of any other control bits involved in the translation process.

———— **Note** ————

In particular, in response to a commonly asked question, TLB maintenance applies when memory translation is disabled.

In AArch64 state

SCTLR_EL1.M, **SCTLR_EL2.M**, **SCTLR_EL3**.{M, RW}, **HCR_EL2**.{VM, RW},
TCR_EL1.{TG1, EPD1, T1SZ, TG0, EPD0, T0SZ, AS, A1}, **TCR_EL2**.{TG0, T0SZ},
TCR_EL3.{TG0, T0SZ}, **VTCR_EL2**.{SL0, T0SZ}, **TTBR0_EL1.ASID**, **TTBR1_EL1.ASID**.

In AArch32 state

SCTLR.M, **HCR.VM**, **TTBCR**.{EAE, PD1, PD0, N, EPD1, T1SZ, EPD0, T0SZ, A1},
HTCR.T0SZ, **VTCR**.{SL0, T0SZ}, **TTBR0.ASID**, **TTBR1.ASID**, **CONTEXTIDR.ASID**.

Note

- Arm expects most TLB maintenance performed by an operating system to occur to the last level entries of the stage 1 translation table walks, and the purpose of the address-based TLB invalidation instructions where the invalidation need only apply to caching of entries returned from the last level of translation table walk of stage 1 translation is to avoid unnecessary loss of the intermediate caching of the translation table entries. Similarly, for stage 2 translations, Arm expects that most TLB maintenance performed by a hypervisor for a given Guest operation system will affect only the last level entries of the stage 2 translations. Therefore, similar capability is provided for instructions that invalidate single stage 2 entries.
 - The architecture permits the invalidation of entries in TLB caching structures at any time, so for each of these instructions the definition is in terms of the minimum set of entries that must be invalidated from TLB caching structures, and an implementation might choose to invalidate more entries. In general, for best performance, Arm recommends not invalidating entries that are not required to be invalidated.
 - Dependencies on the **VMID** for the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime apply even when the value of **HCR_EL2.VM** is 0. The **VTTBR_EL2.VMID** field resets to a value that is architecturally UNKNOWN, and therefore **VTTBR_EL2.VMID[7:0]** must be set to a known value, that might be zero, as part of the PE initialization sequence, even if stage 2 translation is not in use.
-

TLB range maintenance instructions

Specific TLB invalidation instructions apply to a range of input addresses rather than a single address. All TLB range maintenance instructions invalidate TLB entries translating addresses that are within the address range determined by the formula: $[BaseADDR \leq input_address < BaseADDR + ((NUM + 1) * 2^{(5 * SCALE + 1)} * Translation_Granule_Size)]$.

Note

The set of Requesters containing TLBs that can be affected by the TLB range maintenance instructions are defined by the system architecture. In some systems, there might be Requesters containing TLBs that are not affected by the TLB range maintenance instructions within the defined Shareability domains.

Within an Inner Shareable domain, it is expected that all PEs are similarly affected by broadcast TLB range maintenance instructions.

VMSAv8-64 TLB range maintenance instructions that take a register argument that holds a **VA**, or a **VA** and an **ASID**, use the following register argument format:

- Bits[63:48]** ASID. These bits are RES0 if the instruction does not require an **ASID** argument.
- Bits[47:46]** TG. This field gives the translation granule size for the translations that are being invalidated. If the translations use a different translation granule size than the one specified, then the architecture does not require that the instruction invalidates any entries.
- Bits[45:44]** SCALE. This field gives the exponent element of the calculation that is used to produce the upper range.
- Bits[43:39]** NUM. This field gives the base element of the calculation that is used to produce the upper range.
- Bits[38:37]** TTL level hint, see *Translation table level hints on page D5-2822*. This field is RES0 if the instruction does not require a **VA** argument, or if **FEAT_TTL** is not implemented.
- Bits[36:0]** BaseADDR. This field gives the starting address for the range of the maintenance instruction.
- If the *Effective value* of **TCR_EL1.DS** is 0:
- | | |
|--------------------------|------------------|
| 4KB granule size | BaseADDR[48:12]. |
| 16KB granule size | BaseADDR[50:14]. |
| 64KB granule size | BaseADDR[52:16]. |
- If **FEAT_LPA2** is implemented and **TCR_EL1.DS** is 1:
- | | |
|--------------------------|--|
| 4KB granule size | BaseADDR[52:16], BaseADDR[15:12] is treated as 0b0000. |
| 16KB granule size | BaseADDR[52:16], BaseADDR[15:14] is treated as 0b00. |

64KB granule size BaseADDR[52:16].

VMSAv8-64 TLB range maintenance instructions that take a register argument that holds an [IPA](#), use the following register argument format:

- Bits[63]** NS. This bit is RES0 if the instruction is executed in Non-secure state.
- Bits[62:48]** RES0.
- Bits[47:46]** TG. This field gives the translation granule size for the translations that are being invalidated. If the translations use a different translation granule size than the one specified, then the architecture does not require that the instruction invalidates any entries.
- Bits[45:44]** SCALE. This field gives the exponent element of the calculation that is used to produce the upper range.
- Bits[43:39]** NUM. This field gives the base element of the calculation that is used to produce the upper range.
- Bits[38:37]** TTL level hint, see [Translation table level hints on page D5-2822](#). This field is RES0 if the instruction does not require a [VA](#) argument, or if [FEAT_TTL](#) is not implemented.
- Bits[36:0]** BaseADDR. This field gives the starting address for the range of the maintenance instruction.
 - If the [Effective value](#) of [TCR_EL1.DS](#) is 0:
 - 4KB granule size** BaseADDR[48:12].
 - 16KB granule size** BaseADDR[50:14].
 - 64KB granule size** BaseADDR[52:16].
 - If [FEAT_LPA2](#) is implemented and [TCR_EL1.DS](#) is 1:
 - 4KB granule size** BaseADDR[52:16], BaseADDR[15:12] is treated as 0b0000.
 - 16KB granule size** BaseADDR[52:16], BaseADDR[15:14] is treated as 0b00.
 - 64KB granule size** BaseADDR[52:16].

The range of addresses invalidated is UNPREDICTABLE when:

- When a 4K translation granule used, if [FEAT_LPA2](#) is implemented, [TCR_EL1.DS](#) is 1, the TTL field is 0b00, and BaseADDR[38:12] does not equal 0b000000000000000000000000.
- When a 4K translation granule used, if the TTL field is 0b01 and BaseADDR[29:12] does not equal 0b000000000000000000000000.
- When a 4K translation granule used, if the TTL field is 0b10 and BaseADDR[20:12] does not equal 0b000000000000000000000000.
- When a 16K translation granule used, if [FEAT_LPA2](#) is implemented, [TCR_EL1.DS](#) is 1, the TTL field is 0b01, and BaseADDR[35:14] does not equal 0b000000000000000000000000.
- When a 16K translation granule used, if the TTL field is 0b10 and BaseADDR[24:14] does not equal 0b000000000000000000000000.
- When a 64K translation granule used, if the TTL field is 0b01 and BaseADDR[41:16] does not equal 0b00000000000000000000000000000000.
- When a 64K translation granule used, if the TTL field is 0b10 and BaseADDR[28:16] does not equal 0b000000000000000000000000.

Invalidation of TLB entries from stage 2 translations

The architectural requirements of the IPAS2 instruction are that:

1. The following code is sufficient to invalidate all cached copies of the stage 2 translation of the [IPA](#) held in Xt for the current [VMID](#), with the corresponding requirement for the broadcast versions of the instructions:

```

TLBI IPAS2E1, Xt
DSB
TLBI VMALLE1

```
2. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the [IPA](#) held in Xt used to translate the [VA](#) (and the specified [ASID](#) when executing [TLBI VAE1](#)) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:

- TLBI IPAS2E1, Xt
DSB
TLBI VAE1, Xt2 ; or TLBI VAAE1, Xt2
3. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the [IPA](#) held in Xt used to translate the [IPA](#) produced by the last level of stage 1 translation table lookup for the [VA](#) (and [ASID](#) when executing TLBI VAE1) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:
- TLBI IPAS2E1, Xt
DSB
TLBI VAE1, Xt2 ; or TLBI VAAE1, Xt2

———— **Note** ————

Software must use these entire sequences for an EL1&0 translation regime with stage 2 translation enabled, even if stage 1 translation is disabled.

Equivalent architectural requirements apply to the IPAS2L instruction, except that the only TLB entries that must be invalidated by an IPAS2L instruction are those that come from the final level of the translation table lookup.

Broadcast TLB maintenance between AArch32 and AArch64

In most cases, a TLB maintenance instruction affecting the shareability domain executed by a PE in an Exception level that is using AArch64 also affects any other PE in the same shareability domain that is executing at the same Exception level and is using AArch32, provided that the address, qualify the scope of the [ASID](#) and [VMID](#) matching requirements of the original instruction are met, as specified in [Scope of the A64 TLB maintenance instructions on page D5-2824](#).

———— **Note** ————

The requirement to match means that the invalidation only occurs on the PE that is using AArch32 if, for the PE that executed the TLB maintenance instruction at an Exception level that is using AArch64, both of the following apply:

- If [VA](#) matching is required, the [VA](#) is 0x0000FFFFFFFF or lower in the memory map.
- If [ASID](#) matching is required and the PE is using a 16-bit [ASID](#), then the top 8 bits of the [ASID](#) are zero.

Except for the cases identified here, a TLB maintenance instruction affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch32 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch64, provided that the address, [ASID](#), and [VMID](#) matching requirements of the original instruction are met, as specified in [Scope of the A64 TLB maintenance instructions on page D5-2824](#). In addition, for the instruction executed in AArch32 state:

- For a TLBIMVAAIS, TLBIMVAALIS, TLBIMVAHIS, TLBIMVAIS, TLBIMVALHIS, or TLBIMVALIS instruction, the [VA](#) supplied as an argument is zero-extended.
- For a TLBIIPAS2IS or TLBIIPAS2LIS instruction, the [IPA](#) supplied as an argument is zero-extended.
- For a TLBIASIDIS, TLBIMVAIS, or TLBIMVALIS instruction, the [ASID](#) supplied as an argument is zero-extended if the PE executing in AArch64 state is using a 16-bit [ASID](#).

The [VA](#) from the instruction executed in AArch32 state is zero-extended, and the [ASID](#) is zero-extended if the PE executing in AArch64 state is using a 16-bit [ASID](#).

The exceptions to these general rules are as follows:

1. An Armv7 PE in the same Inner Shareable domain is treated in the same way as an Armv8 PE for which EL3 is using AArch32, except that if an Armv8 PE issues a broadcast instruction that is not defined in Armv7, then that instruction is not required to have an effect on the TLBs of the Armv7 PE. The instructions that do not exist in Armv7 include the following TLB maintenance instructions that Armv8 adds to the T32 and A32 instruction sets:
 - The following instructions that operate on TLB entries for the final level of translation table walk for stage 1 translations:
TLBIMVALIS, TLBIMVAALIS, TLBIMVALHIS, TLBIMVAL, TLBIMVAAL, and TLBIMVALH.
 - The following instructions that operate by [IPA](#) on TLB entries for stage 2 translations:

TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, and TLBIIPAS2L.

2. The number of Exception levels in Secure state depends on whether EL3 is using AArch32 or EL3 is using AArch64. This means that, within the Inner Shareable domain, there might be PEs with different numbers of Exception levels in Secure state. Therefore, the following exceptions are made to the general rules:
 - If a PE with EL3 using AArch32 issues a broadcast AArch32 TLB maintenance instruction affecting Secure entries, and the Inner Shareable domain also contains PEs with EL3 using AArch64, then the architecture does not require that the broadcast AArch32 TLB maintenance instruction has any effect on either:
 - The EL3 translation regime of the PEs with EL3 using AArch64.
 - The Secure or Non-secure EL1&0, when EL2 is disabled, translation regime of the PEs with EL3 using AArch64, regardless of whether the Secure or Non-secure EL1&0, when EL2 is disabled, translation regime is using AArch64 or AArch32.
 - If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting EL3 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32, then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.
 - If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting Secure EL1 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32 then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.

———— **Note** ————

While the exceptions to the general rule mean the architecture does not require the specified TLB invalidations, the architecture also does not require that entries in the TLB remain in the TLB at any time, and so it is permissible that such broadcast instructions affect these translation regimes.

Broadcast TLB maintenance with different translation granule sizes

In the following cases, a broadcast TLB maintenance instruction is not required to perform any invalidation on the recipient PE:

- The TLB maintenance instruction specifying a **VA** and affecting the EL2 translation regime, the EL2&0 translation regime, or the EL3 translation regime is broadcast from a PE using one translation granule size for that translation regime to a PE using a different translation granule size for that same translation regime.
- The TLB maintenance instruction specifying a **VA** and affecting the EL1&0 translation regime is broadcast from a PE using one stage 1 translation granule size for that translation regime for a particular **ASID** (if applicable), **VMID** (if applicable), and Security state, to a PE where EL1 for the same **ASID** (if applicable), **VMID** (if applicable), and Security state, is using a different stage 1 translation granule size.
- The TLB maintenance instruction specifying a **VA** and affecting the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime is broadcast from a PE using one stage 2 translation granule size for a particular **ASID** (if applicable) and **VMID**, to a PE where EL1 for the same **ASID** (if applicable) and **VMID** is using a different stage 2 translation granule size.
- The TLB maintenance instruction specifying an **IPA** and affecting the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime is broadcast from a PE using one stage 2 translation granule size for a particular **VMID** to a PE where EL1 for the same **VMID** is using a different stage 2 translation granule size.

Ordering and completion of TLB maintenance instructions

For AArch64 execution, a TLB maintenance instruction can be executed in any order relative to:

- Any load or store instruction, unless a DSB is executed between the load or store and the TLB maintenance instruction.

———— **Note** ————

In the Arm architecture, a translation table walk is considered to be a separate observer, and a store to the translation tables can be observed by that separate observer at any time after the instruction has been executed, but is only guaranteed to be observable after the execution of a DSB instruction by the PE that executed the store to the translation tables.

- Another TLB maintenance instruction, unless a DSB is executed between the instructions.
- A data or instruction cache maintenance instruction, unless a DSB is executed between the instructions.

For AArch64 execution, the completion rules are:

- A TLB maintenance instruction executed by a PE, PEE, causes a TLB maintenance operation to be generated on each PE within the shareability domain of PEE that is specified by the instruction. If the TLB maintenance instruction has the nXS qualifier, the associated TLB maintenance operations have the nXS qualifier. If the TLB maintenance instruction does not have the nXS qualifier:
 - At EL2 or EL3, or at EL1 when the *Effective value* of HCRX_EL2.FnXS is 0, the associated TLB maintenance operations do not have the nXS qualifier.
 - At EL1, when the *Effective value* of HCRX_EL2.FnXS is 1, the associated TLB maintenance operations have the nXS qualifier.

———— **Note** —————

When FEAT_XS is not implemented, all TLB maintenance instructions do not have the nXS qualifier and the *Effective value* of HCRX_EL2.FnXS is 0.

- A TLB maintenance operation without the nXS qualifier generated by a TLB maintenance instruction is finished for a PE when:
 - All memory accesses generated by that PE using in-scope old translation information are complete.
 - All memory accesses RWx generated by that PE are complete.RWx is the set of all memory accesses generated by instructions for that PE that appear in program order before an instruction I₁ executed by that PE where all of the following apply:
 - I₁ uses the in-scope old translation information.
 - The use of the in-scope old translation information generates a synchronous Data Abort.
 - If I₁ did not generate an abort from use of the in-scope old translation information, I₁ would generate a memory access that RWx would be locally-ordered-before.

A TLB maintenance operation with the nXS qualifier generated by a TLB maintenance instruction is finished for a PE when:

- All memory accesses with the XS attribute set to 0 generated by that PE using in-scope old translation information are complete.
 - All memory accesses RWx generated by that PE are complete.
- RWx is the set of all memory accesses generated by instructions for that PE that appear in program order before an instruction I
- ₁
- executed by that PE where all of the following apply:
- I₁ uses the in-scope old translation information.
 - The use of the in-scope old translation information generates a synchronous Data Abort.
 - If I₁ did not generate an abort from use of the in-scope old translation information, I₁ would generate a memory access with the XS attribute set to 0 that RWx would be locally-ordered-before.

In-scope old translation information is any translation information, for addresses that are in the scope of the TLB maintenance instruction, that is not consistent with either:

- The architectural translation information held in the translation tables at the time that the TLB maintenance instruction is executed by PEE.
- Any architecture translation information that is *Coherence-after* the information held in the translation tables at the time that the TLB maintenance instruction is executed by PEE.

———— **Note** —————

- Old translation information of this type might be held in TLBs or other non-coherent caching structures.
- In a translation regime using two stages of translation, the XS attribute used to determine the behavior of the TLB maintenance instruction with the nXS qualifier is the attribute determined after both stages of translation have been applied.

- For best real-time performance, Arm recommends that the completion of a TLB maintenance instruction with the nXS qualifier executed by a PE should not be dependent on the completion of any memory accesses with the XS attribute set to 1 generated by a second PE.

A TLB maintenance instruction is complete when the TLB maintenance operations specified by the TLB maintenance instruction are finished for all PEs.

After the TLB maintenance instruction is complete, no new memory accesses using the in-scope old translation information will be architecturally performed by any observer that is affected by the TLB maintenance instruction.

Note

Speculative memory accesses can be performed using those entries if it is impossible for software running on any observer to tell that those memory accesses have been performed.

- A TLB maintenance instruction executed by a PE, PEx, can complete at any time after it is issued, but is only guaranteed to be finished for a PE other than PEx after the execution of DSB by the PEx.
- In an implementation that does not implement [FEAT_ETS](#), a TLB maintenance instruction executed by a PE, PEx, can complete at any time after it is issued, but is only guaranteed to be finished for a PE, PEx, after the execution of DSB by the PEx followed by a [Context synchronization event](#).
- In an implementation that implements [FEAT_ETS](#):
 - A TLB maintenance instruction that applies only to translations without execute permission and where the later translations also do not have execute permission, executed by a PE, PEx, can complete at any time after it is issued, but is only guaranteed to be finished for a PE, PEx, after the execution of DSB.
 - A TLB maintenance instruction that applies to any translations with execute permission executed by a PE, PEx, can complete at any time after it is issued, but is only guaranteed to be finished for a PE, PEx, after the execution of DSB by the PEx followed by a [Context synchronization event](#).

In all cases in this section where a DMB or DSB is referred to, it refers to a DMB or DSB whose required access type is both loads and stores. A DSB NSH is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE. A DSB ISH is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

TLB maintenance in the event of TLB conflict

In the event that multiple entries in the TLB are being used to translate a given address (which implies that an attempt to access the given address might give rise to a TLB Conflict abort), it is IMPLEMENTATION DEFINED as to the form of TLB maintenance operation that the software must perform in order to be guaranteed that all TLB entries associated with the given address and translation regime have been invalidated. In all cases, an ALL or VMALL form of TLB maintenance operation that targets the given translation regime is guaranteed to remove all entries within that regime, even if there are multiple, conflicting TLB entries for any given address within that regime.

The interaction of TLB lockdown with TLB maintenance instructions

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

- The effect on a locked TLB entry of a TLB invalidate all operation that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
 - The operation has no effect on entries that are locked down.
 - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down.Any such exceptions taken from Non-secure EL1 can be trapped to EL2, see [Traps to EL2 of EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-2523](#).

Note

These options permit a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.

- The effect on a locked TLB entry of a TLB invalidate by [VA](#) or invalidate by [ASID](#) match operation that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
 - The locked entry is invalidated in the TLB.
 - The operation has no effect on any locked entry in the TLB. In the case of an invalidate single entry by [VA](#), this means the PE treats the operation as a NOP.
 - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down.

The exception syndrome definitions include a fault code for cache and TLB lockdown faults, see [ESR_EL1](#), [Exception Syndrome Register \(EL1\)](#) on page D13-3145.

———— **Note** —————

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other specified alternatives for the locked entries.

Arm recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined operations. This minimizes the number of customized operations required.

In addition, an implementation that uses an abort mechanism for handling the effect of TLB maintenance instructions on entries that can be locked down but are not actually locked down must provide an IMPLEMENTATION DEFINED mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see [The interaction of cache lockdown with cache maintenance instructions](#) on page D4-2662.

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side effect of any TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

D5.11 Caches in a VMSAv8-64 implementation

The Arm architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

In particular, maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

- Summarizes the architectural requirements for the interaction between caches and address translation.
- Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

- [Data and unified caches on page D5-2835](#).
- [Instruction caches on page D5-2835](#).

In addition, [Cache maintenance requirement created by changing translation table attributes on page D5-2837](#) describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance, see [A64 Cache maintenance instructions on page D4-2648](#), that describes the cache maintenance instructions in the A64 instruction set.

D5.11.1 Data and unified caches

For data and unified caches, the use of address translation is entirely transparent to any data access other than as described in [Mismatched memory attributes on page B2-176](#).

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as *Physically-indexed, physically-tagged* (PIPT) caches.

D5.11.2 Instruction caches

In the Arm architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The Arm architecture permits different behaviors for instruction caches. These are identified by descriptions of the associated expected implementation. The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of address translation transparent to the instruction cache:

- [PIPT \(Physically-indexed, physically-tagged\) instruction caches on page D5-2836](#).
- [VPIPT \(VMID-aware PIPT\) instruction caches on page D5-2836](#).
- [VIPT \(Virtually-indexed, physically-tagged\) instruction caches on page D5-2836](#).
- [The IVIPT Extension on page D5-2837](#).

The `CTR_EL0.L1Ip` field identifies the form of the instruction caches.

Note

For software to be portable between implementations that might use any of PIPT instruction caches, VPIPT instruction caches, or VIPT instruction caches, software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

PIPT (*Physically-indexed, physically-tagged*) instruction caches

For a PIPT instruction cache:

- The use of memory address translation is entirely transparent to all instruction fetches other than as described in [Mismatched memory attributes on page B2-176](#).
- If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see [The IVIPT Extension on page D5-2837](#).

VPIPT (*VMID-aware PIPT*) instruction caches

An Armv8.2 implementation can implement VPIPT instruction caches. If it does so then it is described as implementing [FEAT_VPIPT](#).

The [CTR_EL0.L1Ip](#) field identifies the implemented cache type, meaning it identifies whether [FEAT_VPIPT](#) is implemented.

For a VPIPT instruction cache:

- If VMIDs are being used for the current Security state, instruction fetches from EL1 and EL0 are only permitted to hit in the cache if the instruction fetch is made using the VMID that was used when the entry in the instruction cache was fetched.
- If VMIDs are being used for the current Security state, an instruction cache maintenance instruction executed at EL0 or at EL1 is required to have an effect on entries in the instruction cache only if those entries were fetched using the VMID that is current when the cache maintenance instruction is executed.

All other requirements for the use of cache maintenance instructions are the same as for [PIPT \(*Physically-indexed, physically-tagged*\) instruction caches on page D5-2836](#).

An implementation that provides VPIPT instruction caches implements the IVIPT Extension, see [The IVIPT Extension on page D5-2837](#).

VIPT (*Virtually-indexed, physically-tagged*) instruction caches

For a VIPT instruction cache:

- The use of memory address translation is transparent to all instruction fetches other than for the effect of memory address translation on instruction cache invalidate by address operations or as described in [Mismatched memory attributes on page B2-176](#).

Note

Cache invalidation is the only cache maintenance that can be performed on an instruction cache.

- If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the [VA](#) supplied with the operation. The effect of the invalidation might not be visible to any other aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a [PA](#) from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see [The IVIPT Extension on page D5-2837](#).

The IVIPT Extension

In Armv8, any permitted instruction cache implementation can be described as implementing the *IVIPT Extension* to the Arm architecture.

The formal definition of the Arm IVIPT Extension is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a [PA](#) that holds an instruction.

Note

Previous versions of the Arm architecture have permitted an instruction cache option that does not implement the Arm IVIPT Extension.

D5.11.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in [General TLB maintenance requirements on page D5-2816](#). If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through.
- Write-Back to Non-cacheable.
- Write-Through to Non-cacheable.
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the shareability attributes to the required new values.

Chapter D6

Memory Tagging Extension

This chapter describes the Memory Tagging Extension. It contains the following sections:

- *Introduction* on page D6-2840.
- *Allocation Tags* on page D6-2841.
- *Tag checking* on page D6-2842.
- *Tagged and Untagged Addresses* on page D6-2843.
- *PE access to Allocation Tags* on page D6-2844.
- *Enabling the Memory Tagging Extension* on page D6-2845.
- *PE handling of Tag Check Fault* on page D6-2846.
- *PE generation of Tag Checked and Tag Unchecked accesses* on page D6-2848.

D6.1 Introduction

There are three versions of the Memory tagging extension:

FEAT_MTE

FEAT_MTE supports the Memory tagging instructions accessible in EL0.

When **FEAT_MTE** is implemented:

- A set of tag load and tag store instructions are provided.
- Instructions to generate and insert Logical Tags in addresses are provided.
- System instructions to Clean, and Clean and Invalidate Allocation Tags from caches are provided.
- If **FEAT_MTE2** is not implemented, all System instructions defined by the Memory Tagging Extension are UNDEFINED.
- If **FEAT_MTE2** is not implemented, all operations which read Allocation Tags treat the Allocation Tag as zero, and any traps or permission checks continue to apply.
- If **FEAT_MTE2** is not implemented, instructions which insert Allocation Tags into addresses treat the Allocation Tag as zero.
- If **FEAT_MTE2** is not implemented, the Tagged memory type encoding in the Memory Attribute Indirection Registers are UNPREDICTABLE.

FEAT_MTE2

FEAT_MTE2 supports all instructions and System registers defined by the extension, Allocation Tags in memory, and Tag Checking of accesses to tagged memory.

When **FEAT_MTE2** is implemented:

- All **FEAT_MTE** functionalities are available for use.
- System register and page level control over access to Allocation Tags in memory is provided.
- Allocation Tags are provided for each 16-byte granule of *Conventional memory*.
- The tag PA space is separate to the data physical address (data PA) space accessed by data load and store instructions to access data in normal memory and devices.
- Any associated fields in System control registers are available for use.
- All System registers defined by the extension become available for use.
- All System instructions and instructions defined by the extension become available for use.

FEAT_MTE3

FEAT_MTE3 adds support for asymmetric Tag Check Fault handling.

When **FEAT_MTE3** is implemented:

- All **FEAT_MTE** and **FEAT_MTE2** functionalities are available for use.
- Tag Check Faults can be configured to cause a synchronous exception on reads, and be asynchronously accumulated on writes.
- Any Tag Check Fault on an access that performs both a read and a write can be configured to cause a synchronous exception.

D6.2 Allocation Tags

The tag PA space provides access to Allocation Tags stored in memory. The data PA space provides access to data held in memory.

An Allocation Tag is 4-bits wide.

Each naturally-aligned set of 16 tag PA space locations is a Tag Granule. Each Tag Granule is associated with one Allocation Tag.

———— **Note** ————

The value `0b1111` may incur a higher performance overhead than other Allocation Tag encodings.

If FEAT_MTE2 is implemented, storage is provided for Allocation Tags at each tag PA where *Conventional memory* exists at the same physical address in the data PA space.

———— **Note** ————

Arm recommends that software does not use instructions which write `0b1111` as an Allocation Tag to memory.

The result of an access to the tag PA where Allocation Tag storage is not provided is IMPLEMENTATION DEFINED.

It is IMPLEMENTATION DEFINED whether Allocation Tags are permitted to be accessed through regions of the data PA space. If Allocation Tags are accessible through the data PA space, then the layout of Allocation Tags is IMPLEMENTATION DEFINED.

It is not architecturally required for an Allocation Tag accessed via the tag PA space to be coherent with the same Allocation Tag accessed via the data PA space. A write to one location can be made visible at the other location by the use of the cache maintenance operations.

Unless otherwise stated, the definitions in [Chapter B2 The AArch64 Application Level Memory Model](#) and [Chapter D4 The AArch64 System Level Memory Model](#) that apply to data accesses and data, apply separately to Allocation Tag accesses and Allocation Tags.

It is IMPLEMENTATION DEFINED whether accesses to the tag PA space are monitored by the global monitor.

D6.2.1 Cache activity and Allocation Tags

When data is evicted from a cache entry at a cache level, the evicted data can overwrite data in memory that has been written by another observer if either, or any of the following are true:

- The data has been written by an observer in the Shareability domain of that memory location, where the maximum size of the memory that can be overwritten is defined by the Cache Write-Back Granule in [CTR_EL0](#).
- The associated Allocation Tags have been written to by an observer in the Shareability domain of that memory location, where the maximum size of the memory that can be overwritten is defined by the Cache Write-Back Granule in [CTR_EL0](#).

When Allocation Tags are evicted from a cache entry at a cache level, the evicted Allocation Tags can overwrite Allocation Tags in memory that have been written by another observer only if the following are true:

- The entry contains a memory location where the Allocation Tags have been written to by an observer in the Shareability domain of that memory location.
- The maximum size of the memory that can be overwritten is defined by the Cache Write-Back Granule in [CTR_EL0](#).

For more information on DC operations that affect Allocation Tags see [A64 System instructions for cache maintenance on page C5-506](#).

D6.3 Tag checking

A memory access that is a read or write can be either Tag Checked or Tag Unchecked.

An access to the data PA space can be either Tag Checked or Tag Unchecked.

An access to the tag PA space is always Tag Unchecked.

A data access which is performed as part of a prefetch operation is Tag Unchecked.

When the value of [PSTATE.TCO](#) is 1, all loads and stores are Tag Unchecked.

A Tag Checked memory access includes a Physical Address Tag.

A Tag Checked access causes a Tag Check operation to be performed.

If the Allocation Tag and Physical Address Tag in a Tag Check operation do not match, the Tag Check operation generates a Tag Check Fault.

The read of an Allocation Tag due to a Tag Check operation, and the dependent data access, are not required to form an atomic operation.

Software cannot rely on a Load-Exclusive/Store-Exclusive pair to eventually succeed if the Tag Checked properties of the following in a Load-Exclusive/Store-Exclusive instruction pair accessing the same location from the same PE do not match:

- A memory access due to a Store-Exclusive instruction.
- A memory access due to the preceding Load-Exclusive instruction.

D6.3.1 Tag Check Faults

A Tag Check Fault can be configured to cause one of the following:

- A synchronous exception.
- A bit to be asynchronously set in [TFSR_ELx](#).
- To be ignored.

If a store causes a synchronous Tag Check Fault exception, the faulting memory locations being written to by the store that caused the fault are unchanged.

If a Tag Check Fault is not configured to cause a synchronous exception then the following are true:

- There is no effect on the data access, that is the load or store completes unless another exception is taken.
- There is no effect on any of the side effects caused by the completion of the data access.

If [FEAT_MTE2](#) is implemented, a synchronous exception due to a Tag Check Fault is reported as a Data Abort with a Data Fault Status Code of Synchronous Tag Check Fault and the faulting virtual address is reported in [FAR_ELx](#). For more information, see [PE handling of Tag Check Fault on page D6-2846](#).

D6.4 Tagged and Untagged Addresses

Virtual addresses can either be Tagged or Untagged.

An access to memory at:

- An Untagged virtual address generates a Tag Unchecked access.
- A Tagged virtual address permits the generation of a Tag Checked or Tag Unchecked access.

A read of an Allocation Tag from an Untagged virtual address returns the value `0b0000`.

A write of an Allocation Tag to an Untagged address is IGNORED.

Accesses of Allocation Tags at Tagged virtual addresses are permitted.

All virtual addresses in AArch32 state are Untagged.

D6.4.1 Virtual address translation

If stage 1 translation at the current Exception level is enabled, stage 1 translations are Tagged or Untagged depending on the Memory Attributes for the memory location being accessed.

If stage 1 translation at the current Exception level is disabled:

- When the value of `HCR_EL2.DC` is 1, stage 1 translations are Tagged or Untagged depending on the value of `HCR_EL2.DCT`.
- When the value of `HCR_EL2.DC` is 0, stage 1 translations are treated as Untagged.

Memory locations are treated as Tagged where all of the following is true:

- The combined effects of stage 1 and stage 2 translations define the memory attributes as:
 - Normal memory.
 - Inner, and Outer Write-Back Non-Transient Read-Allocate Write-Allocate.
- The stage 1 translation is treated as Tagged.

Otherwise memory locations are Untagged.

If a memory location is marked as Untagged, a data cache invalidation operation that would invalidate Allocation Tags at that location cleans and invalidates the Allocation Tags.

———— **Note** —————

If a memory location is marked as both Tagged and Non-shared, it is IMPLEMENTATION DEFINED whether the memory location is treated as Tagged or Untagged.

When the EL1&0 stage 1 translation regime is disabled and `HCR_EL2.DC` is 1, in the current Security state, the execution of any of the AT S1E0, AT S1E1, AT S12E0, AT S12E1 address translation instructions will reflect the effect of `HCR_EL2.DCT` in `PAR_EL1.ATTR`.

If `SCTLR_ELx.C` is 0 for a stage 1 translation regime, it is CONSTRAINED UNPREDICTABLE between:

- The stage 1 translation is treated as Untagged.
- `SCTLR_ELx.C` has no effect on whether the stage 1 translation is treated as Tagged or Untagged.

———— **Note** —————

To ensure consistent behavior, software can set `SCTLR_ELx.ATA` to 0 when `SCTLR_ELx.C` is 0.

For more information on Virtual address translation, see [The VMSAv8-64 address translation system on page D5-2682](#).

D6.5 PE access to Allocation Tags

Instructions that load or store Allocation Tags apply the same address translation and permission checks as a load or store of data to a virtual address.

Instructions that load or store Allocation Tags at a virtual address have the same effect on the Access flag and dirty state as instructions that load or store data at the same virtual address.

An instruction that loads or stores an Allocation Tag:

- Is considered a load or store of data to each location associated with the Allocation Tag for the purpose of triggering Watchpoints and PMU events, other than for events which count bytes of data transferred.
- Is treated as a load or store for the purpose of Statistical profiling.
- Generates a tag PA with the same physical address as a load or store of data to a virtual address.

Instructions that store Allocation Tags to memory locations marked as Device memory result in a CONSTRAINED UNPREDICTABLE choice between:

- Storing the data, if any, to the specified locations.
- Generating an Alignment Fault, which is prioritized in the same way as other alignment faults that are determined by the memory type.

[DC GZVA](#) and [DC GVA](#) are instructions that store Allocation tags.

Instructions which load or store Allocation tags are considered to perform the access, irrespective of whether access to Allocation tags in memory is disabled due to Allocation tag access controls in [HCR_EL2](#), [SCR_EL3](#) and [SCTLR_ELx](#), or due to the absence of the Tagged attribute on the locations being accessed, for the purpose of:

- Address translation.
- Triggering watchpoints.
- Generating PMU events.
- Statistical profiling.

A read of an Allocation Tag that returns zero due to access to Allocation tags being disabled by [HCR_EL2.ATA](#), [SCR_EL3.ATA](#) or [SCTLR_ELx.{ATA, ATA0}](#), or due to the memory type not having the Tagged attribute, is permitted to generate an External abort if a read of data from the same address would generate an External abort.

For more information on which instructions can be used to access an Allocation tag, see:

- [Loads and stores on page C3-224](#), for load and store instructions.
- [Branches, Exception generating, and System instructions on page C3-216](#), for System instructions.

D6.6 Enabling the Memory Tagging Extension

Access to Allocation Tags in memory can be enabled by use of the following controls:

- [SCR_EL3.ATA](#).
- [HCR_EL2.ATA](#).
- [SCTLR_ELx.ATA](#).
- [SCTLR_ELx.ATA0](#).

When executed at an exception level where accesses to Allocation Tags are disabled, instructions that:

- Load or store data, are Unchecked.
- Load or store Allocation Tags treat the Allocation Tag as RAZ/WI.
- Insert Logical Address Tags into addresses treat the Allocation Tag used to generate the Logical Address Tag as zero,
- Invalidate Allocation Tags from caches, behave as the equivalent Clean and Invalidate operation on Allocation Tags.

For the purpose of determining Allocation Tag access, unprivileged load and store instructions are treated as if executed at EL0 when executed at either:

- EL1, when the Effective value of PSTATE.UAO is 0.
- EL2, when both the Effective value of HCR_EL2.{E2H, TGE} is {1, 1} and the Effective value of PSTATE.UAO is 0.

———— **Note** —————

Arm recommends that:

- When software requires access to Allocation Tags in a context but Tag Checking is not required, the [SCTLR_ELx.TCF](#) or [SCTLR_ELx.TCF0](#) affecting that context is set to 0.
- When software does not require access to Allocation Tags in a context, one or more [SCTLR_ELx.ATA](#) affecting that context are set to 0.

D6.7 PE handling of Tag Check Fault

If `SCTLR_ELx.TCF` has the value of `0b00`, a Tag Check Fault due to a load or store at ELx has no effect on the PE.

A Tag Check Fault due to a load or store at EL0 has no effect on the PE if either of the following conditions are true:

- `SCTLR_EL1.TCF0` has the value of `0b00`, and `HCR_EL2.{E2H, TGE}` does not have the value of `{1,1}`.
- `SCTLR_EL2.TCF0` has the value of `0b00`, and `HCR_EL2.{E2H, TGE}` has the value of `{1,1}`.

If `SCTLR_ELx.TCF` has the value of `0b01`, a Tag Check Fault due to a load or store at ELx generates a synchronous exception.

If `SCTLR_ELx.TCF` has the value of `0b10`, a Tag Check Fault due to a load or store at ELy using `TTBR_ELx` causes `TFSR_ELy.TFx` to be asynchronously set to 1.

If `FEAT_MTE3` is implemented, and `SCTLR_ELx.TCF` has the value of `0b11`, a Tag Check Fault due to a load, or an atomic operation, generates a synchronous exception.

If `FEAT_MTE3` is implemented, and `SCTLR_ELx.TCF` has the value of `0b11`, a Tag Check Fault due to a store at ELy using `TTBR_ELx` causes `TFSR_ELy.TFx` to be asynchronously set to 1.

A Tag Check Fault due to a load or store at EL0 has no effect on the PE if either of the following conditions are true:

- `SCTLR_EL1.TCF0` has the value of `0b00`, and `HCR_EL2.{E2H, TGE}` does not have the value of `{1,1}`.
- `SCTLR_EL2.TCF0` has the value of `0b00`, and `HCR_EL2.{E2H, TGE}` has the value of `{1,1}`.

A Tag Check Fault due to a load or store at EL0 generates a synchronous exception if either of the following conditions are true:

- `SCTLR_EL1.TCF0` has the value of `0b01`, and `HCR_EL2.{E2H, TGE}` does not have the value of `{1,1}`.
- `SCTLR_EL2.TCF0` has the value of `0b01`, and `HCR_EL2.{E2H, TGE}` has the value of `{1,1}`.

A Tag Check Fault due to a load or store at EL0 using `TTBRy_EL1` or `TTBRy_EL2`, causes `TFSRE0_EL1.TFy` to be set to 1 if either of the following conditions are true:

- `SCTLR_EL1.TCF0` has the value of `0b10`, and `HCR_EL2.{E2H, TGE}` does not have the value of `{1,1}`.
- `SCTLR_EL2.TCF0` has the value of `0b10`, and `HCR_EL2.{E2H, TGE}` has the value of `{1,1}`.

If `FEAT_MTE3` is implemented, a Tag Check Fault due to a load, or an atomic operation, at EL0 generates a synchronous exception, if either of the following conditions are true:

- `SCTLR_EL1.TCF0` has the value of `0b11`, and `HCR_EL2.{E2H, TGE}` does not have the value of `{1,1}`.
- `SCTLR_EL2.TCF0` has the value of `0b11`, and `HCR_EL2.{E2H, TGE}` has the value of `{1,1}`.

If `FEAT_MTE3` is implemented, a Tag Check Fault due to a store at EL0 using `TTBRy_EL1` or `TTBRy_EL2` causes `TFSRE0_EL1.TFy` to be set to 1, if either of the following conditions are true:

- `SCTLR_EL1.TCF0` has the value of `0b11`, and `HCR_EL2.{E2H, TGE}` does not have the value of `{1,1}`.
- `SCTLR_EL2.TCF0` has the value of `0b11`, and `HCR_EL2.{E2H, TGE}` has the value of `{1,1}`.

`TFSR_ELx` and `TFSRE0_EL1` are unchanged by a memory data access causing a Tag Check pass.

A synchronous exception due to a Tag Check Fault is reported as a Data Abort, with a Data Fault status code of Synchronous Tag Check Fault, and the faulting virtual address is reported in `FAR_ELx`.

A Data Abort due to a Tag Check Fault is taken from EL0 to one of the following exception levels:

- EL1 if `HCR_EL2.TGE` is 0.
- EL2 if `HCR_EL2.TGE` is 1.

A Data Abort due to a Tag Check Fault is taken from ELx to ELx where x is 1, 2 or 3.

A Data Abort due to a Tag Check Fault is prioritized as a Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk.

If an access generates both a Data Abort due to a Synchronous Tag Check Fault, and a Data Abort due to a synchronous External abort that was not generated by a translation table walk, it is IMPLEMENTATION DEFINED which abort is reported. For more information on prioritization of exceptions see *Synchronous exception types, routing and priorities* on page D1-2489.

If an instruction that stores to memory generates a Data Abort that is a Synchronous Tag Check Fault, the value of each memory location that the instruction stores to is UNKNOWN for any location for which no exceptions, and no Debug event is generated. The size of a memory location is defined as being the size for which a memory access is single-copy atomic.

For the purpose of determining Tag Check Fault handling, unprivileged load and store instructions are treated as if executed at EL0 when executed at either:

- EL1, when the Effective value of PSTATE.UAO is 0.
- EL2, when both the Effective value of HCR_EL2.{E2H, TGE} is {1, 1} and the Effective value of PSTATE.UAO is 0.

Indirect writes to [TFSRE0_EL1](#) and any [TFSR_ELx](#) accessible at ELy that are caused by a Tag Check Fault are synchronized by any of:

- An exception entry to ELy, if SCTLR_ELy.ITFSB has the value of 0b1.
- A DSB over the Non-shareable domain at ELy in program order, after the instruction causing the Tag Check Fault.

When [FEAT_SVE](#) is implemented, if a load of an element in a SVE Non-faulting or First-faulting load instruction causes a Tag Check Fault, and is not the First active element in a First-faulting instruction, the Tag Check Fault:

- Is recorded in the corresponding FFR register.
- Does not generate a Synchronous Tag Check Fault exception.
- Does not cause any bit in any [TFSR_ELx](#) or [TFSRE0_EL1](#) registers to be set.
- The value loaded into the element is UNKNOWN.

When [FEAT_SVE](#) is implemented, if a load of an element in a SVE Non-faulting or First-faulting load instruction causes a Tag Check Fault, and is the First active element in a First-faulting instruction, the Tag Check Fault:

- Is not recorded in the corresponding FFR register.
- Generates a Synchronous Tag Check Fault exception if configured to do so.
- Sets a bit in [TFSR_ELx](#) or [TFSRE0_EL1](#) registers if configured to do so.
- If a synchronous Tag Check Fault is generated, the value loaded into the element is UNKNOWN.

It is CONSTRAINED UNPREDICTABLE whether the FFR element associated with the read of an Active element in an SVE Non-fault load, or an Active element which is not the First active element in an SVE First-fault load, R₂, to location X, is set to FALSE if all of the following are true:

- Tag Check Faults are configured as asynchronous for both reads and writes.
- A read or write RW₁ to location Y causes a Tag Check Fault.
- Tag Check Faults for locations X and Y are reported in the same status bit, either:
 - [TFSR_ELx.TFy](#).
 - [TFSRE0_EL1.TFy](#).
- RW₁ is in program order before R₂, or is the First active element in the first-fault load instruction causing R₂.
- There are no other faults caused by R₂ that are reported in FFR.
- There is not a DSB and a direct write of 0b0 to that status bit appearing in program order between the instruction causing RW₁ and the instruction causing R₂.

D6.8 PE generation of Tag Checked and Tag Unchecked accesses

A Logical Address Tag is formed by bits [59:56] of the 64-bit address that is used for a load or store instruction. The PE generates a Physical Address Tag from the Logical Address Tag for each Tag Checked access to memory. Unless an access is explicitly defined as a Tag Unchecked access, it is a Tag Checked access.

D6.8.1 Tag Unchecked accesses

The following operations generate a Tag Unchecked access:

- An instruction fetch.
- A load instruction that loads an Allocation Tag.
- A store instruction that stores an Allocation Tag.

When `PSTATE.TCO` is 1, all loads and stores generate Tag Unchecked accesses.

A cache maintenance by virtual address operation other than `DC ZVA`, `Data Cache Zero by VA`, generates a Tag Unchecked access.

An access due to a translation table walk generates a Tag Unchecked access.

If `FEAT_NV2` is implemented, loads and stores relative to `VNCR_EL2` generate a Tag Unchecked access.

If the Statistical Profiling Extension is implemented, all accesses to the Profiling Buffer are Tag Unchecked accesses. See [Chapter D9 The Statistical Profiling Extension](#) for more information.

Data accesses by an external Debugger may generate Tag Checked accesses. See [Chapter H2 Debug State](#) for more information.

An access which would be translated using `TTBR0_ELx` is Tag Unchecked, irrespective of whether the stage 1 address translation for the ELx translation regime is enabled or not, where either of the following conditions apply:

- `TCR_ELx.TBI` is 0.
- `TCR_ELx.TBI0` is 0.

If `TCR_ELx.TBI1` has the value of zero, an access which would be translated using `TTBR1_ELx` is Tag Unchecked, irrespective of whether the stage 1 address translation for the ELx translation regime is enabled or not.

An access will be Tag Unchecked, irrespective of whether the stage 1 address translation for the ELx translation regime is enabled or not, where all of the following conditions apply:

- The access would be translated using `TTBR0_ELx`.
- The Logical Address Tag is `0b0000`.
- `TCR_ELx.TCMA` is 1, or `TCR_ELx.TCMA0` is 1.

An access will be Tag Unchecked, irrespective of whether the stage 1 address translation for the ELx translation regime is enabled or not, when all of the following conditions apply:

- The access would be translated using `TTBR1_ELx`.
- The Logical Address Tag is `0b1111`.
- `TCR_ELx.TCMA1` is 1.

A Tag Unchecked access will be generated for a load or store that uses either of the following:

- A base register only, with the SP as the base register.
- A base register plus immediate offset addressing form, with the SP as the base register.

Literal (PC-relative) loads generate a Tag Unchecked access.

D6.8.2 Constrained Unpredictable behavior

When executing a Store-Exclusive instruction, that if Tag Unchecked would not perform the store, and would return a status value of one, it is `CONSTRAINED UNPREDICTABLE` whether:

- The instruction generates a Tag Checked access.
- The instruction generates a Tag Unchecked access.

Chapter D7

The Performance Monitors Extension

This chapter describes the Armv8 implementation of the Arm Performance Monitors, that are an optional non-invasive debug component. It describes version 3 of the *Performance Monitor Unit* (PMU) architecture, [FEAT_PMUv3](#). It contains the following sections:

- [About the Performance Monitors](#) on page D7-2850.
- [Accuracy of the Performance Monitors](#) on page D7-2853.
- [Behavior on overflow](#) on page D7-2855.
- [Attributability](#) on page D7-2857.
- [Controlling the PMU counters](#) on page D7-2859.
- [Event filtering](#) on page D7-2865
- [Performance Monitors and Debug state](#) on page D7-2867.
- [Enabling event counters](#) on page D7-2859.
- [Counter access](#) on page D7-2868.
- [PMU events and event numbers](#) on page D7-2869.
- [Performance Monitors Extension registers](#) on page D7-2940.

Note

[Table K15-2](#) on page K15-8604 disambiguates the general register references used in this chapter.

D7.1 About the Performance Monitors

In Armv8-A, the Performance Monitors Extension is an OPTIONAL feature of an implementation, but Arm strongly recommends that Armv8-A implementations include version 3 of the Performance Monitors Extension, [FEAT_PMUv3](#).

———— **Note** —————

No previous versions of the Performance Monitors Extension can be implemented in Armv8.

The basic form of the Performance Monitors is:

- A 64-bit cycle counter, see [Time as measured by the Performance Monitors cycle counter on page D7-2852](#).
- A number of 64-bit or 32-bit event counters. If [FEAT_PMUv3p5](#) is implemented and the highest Exception level is using AArch64, the event counters are 64-bit. If [FEAT_PMUv3p5](#) is not implemented, the event counters are 32-bit.
- The event counted by each event counter is programmable. Armv8 provides space for up to 31 event counters. The actual number of event counters is IMPLEMENTATION DEFINED, and the specification includes an identification mechanism.

———— **Note** —————

The Performance Monitors Extension permits an implementation with no event counters ([PMCR_ELO.N==0](#)). However, Arm recommends that at least two event counters are implemented, and that hypervisors provide at least this many event counters to guest operating systems.

- When EL2 is implemented, the required controls to partition the implemented event counters into the following sets:
 - A set which is available for use by the guest operating system accessible at all Exception levels.
 - A set which is available for use by the hypervisor accessible at EL3 and EL2, and, if [FEAT_SEL2](#) is not implemented or if Secure EL2 is disabled, in Secure state.
- Controls for:
 - Enabling and resetting counters.
 - Flagging overflows.
 - Enabling interrupts on overflow.
 - Disabling or freezing counters.

The PMU architecture uses event numbers to identify an event. It:

- Defines event numbers for common events, for use across many architectures and microarchitectures.

———— **Note** —————

Implementations that include [FEAT_PMUv3](#) must, as a minimum requirement, implement a subset of the common events. See [Common event numbers on page D7-2876](#).

- Reserves a large event number space for IMPLEMENTATION DEFINED events.

The full set of events for an implementation is IMPLEMENTATION DEFINED. Arm recommends that implementations include all of the events that are appropriate to the architecture profile and microarchitecture of the implementation.

When an implementation includes the Performance Monitors Extension, Armv8 defines the following possible interfaces to the Performance Monitors Extension registers:

- A System register interface. This interface is mandatory.

———— **Note** —————

In AArch32 state, the interface is in the (coproc==0b1111) encoding space.

- An external debug interface which optionally supports memory-mapped accesses. Implementation of this interface is OPTIONAL. See [Chapter 13 Recommended External Interface to the Performance Monitors](#).

An operating system can use the System registers to access the counters.

Also, if required, the operating system can enable application software to access the counters. This enables an application to monitor its own performance with fine-grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

To enable interaction with external monitoring, an implementation might consider additional enhancements, such as providing:

- A set of events, from which a selection can be exported onto a bus for use as external events.
- The ability to count external events. This enhancement requires the implementation to include a set of external event input signals.

The Performance Monitors Extension is common to AArch64 operation and AArch32 operation. This means the Armv8 architecture defines both AArch64 and AArch32 System registers to access the Performance Monitors. For example, the Performance Monitors Cycle Count Register is accessible as:

- When executing in AArch64 state, [PMCCNTR_EL0](#).
- When executing in AArch32 state, [PMCCNTR](#).

When executing in AArch32 state, if [FEAT_PMUv3p5](#) is implemented, bits [63:32] of the event counters are not accessible. If the implementation does not support AArch64 at any Exception level, 64-bit event counters are not required to be implemented.

D7.1.1 Interaction with EL3

Software executing at EL3 can trap attempts by lower Exception levels to access the PMU. This means that the Secure monitor can identify any software which is using the PMU and switch contexts, if required.

Software executing at EL3 can:

- Prohibit counting of events [Attributable](#) to Secure state.
- If [FEAT_PMUv3p5](#) is implemented, prohibit counting of cycles in Secure state, see [Controlling the PMU counters on page D7-2859](#).
- If [FEAT_PMUv3p7](#) is implemented:
 - Prohibit event counters from counting events at EL3 without affecting the rest of Secure state.
 - Prohibit the cycle counter from counting cycles at EL3 without affecting the rest of Secure state.For more information, see [Controlling the PMU counters on page D7-2859](#) and [Freezing event counters on page D7-2860](#).

In AArch32 state, the Performance Monitors registers are Common registers, see [Classification of System registers on page G5-6396](#).

If [FEAT_MTPMU](#) is implemented and EL3 is implemented, [MDCR_EL3.MTPME](#) and [SDCR.MTPME](#) enable and disable the [PMEVTYPEPER<n>.MT](#) bit.

D7.1.2 Interaction with EL2

Software can program [HDCR.HPMN](#) to reserve the highest-numbered event counters by partitioning the event counters into two sets. This does not depend on whether EL2 is enabled in the current Security state. Each set of event counters has its own global controls.

Software executing at EL3, and when EL2 is implemented and enabled in the current Security state, software executing at EL2 can:

- Trap an access at EL0 or EL1 to the PMU. This means the hypervisor can identify which Guest OSs are using the PMU and intelligently employ switching of the PMU state. There is a separate trap for the [PMCR](#) register, and if [FEAT_FGT](#) is implemented and enabled, fine-grained traps are provided.
- If [FEAT_PMUv3p1](#) is implemented, prohibit counting of events [Attributable](#) to EL2 by the counters accessible to EL1 and EL0.

- If [FEAT_PMUv3p5](#) is implemented, prohibit counting of cycles at EL2.

When EL2 is implemented and enabled in the current Security state, software executing at EL1 and, if enabled by [PMUSERENR](#), EL0:

- Will read the value of [HDCR.HPMN](#) for [PMCR.N](#).
- Cannot access the highest-numbered event counters, or the controls associated with them.

If [FEAT_MTPMU](#) is implemented, EL3 is not implemented, and EL2 is implemented, [MDCR_EL2.MTPME](#) and [HDCR.MTPME](#) enable and disable the [PMEVTYPEPER<n>.MT](#) bit.

For more information, see:

- [Enabling event counters on page D7-2859](#).
- [Counter access on page D7-2868](#).
- [Controlling the PMU counters on page D7-2859](#).
- [Multithreaded implementations on page D7-2863](#).

D7.1.3 Time as measured by the Performance Monitors cycle counter

The Performance Monitors cycle counter, accessed through [PMCCNTR_EL0](#) or [PMCCNTR](#), increments from the hardware processor clock, not PE clock cycles.

The relationship between the count recorded by the Performance Monitors cycle counter and the passage of real time is IMPLEMENTATION DEFINED.

See [Controlling the PMU counters on page D7-2859](#) for information about when the cycle counter does not increment.

———— Note —————

- This means that, in an implementation where PEs are multithreaded, when enabled, the cycle counter continues to increment across all PEs, rather than only counting cycles for which the current PE is active.
- Although the architecture requires that direct reads of [PMCCNTR_EL0](#) or [PMCCNTR](#) occur in program order, there is no requirement that the count increments between two such reads. Even when the counter is incrementing on every clock cycle, software might need check that the difference between two reads of the counter is nonzero.

The architecture requires that an indirect write to the [PMCCNTR_EL0](#) or [PMCCNTR](#) is observable to direct reads of the register in finite time. The counter increments from the hardware processor clock are indirect writes to these registers.

D7.1.4 Interaction with trace

It is IMPLEMENTATION DEFINED whether the implementation exports counter events to a PE Trace Unit, or other external monitoring agent, to provide triggering information. The form of any exporting is also IMPLEMENTATION DEFINED. If implemented, this exporting might be enabled as part of the performance monitoring control functionality.

Arm recommends system designers include a mechanism for importing a set of external events to be counted, but such a feature is IMPLEMENTATION DEFINED. When implemented, this feature enables the PE Trace Unit to pass in events to be counted.

Exporting PMU events to the ETM is prohibited for some Exception levels when `SelfHostedTraceEnabled() == TRUE`. For more information, see [Controls to prohibit trace at Exception levels on page D3-2629](#).

D7.2 Accuracy of the Performance Monitors

The Performance Monitors:

- Are a non-invasive debug component. See *Non-invasive behavior* on page D7-2853.
- Must provide broadly accurate and statistically useful count information.

However, the Performance Monitors allow for:

- A reasonable degree of inaccuracy in the counts to keep the implementation and validation cost low. See *A reasonable degree of inaccuracy* on page D7-2853.
- IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to put the PE in an operating state that might do one or both of the following:
 - Change the level of non-invasiveness of the Performance Monitors so that enabling an event counter can impact the performance or behavior of the PE.
 - Allow inaccurate counts. This includes, but is not limited to, cycle counts.

D7.2.1 Non-invasive behavior

The Performance Monitors are a non-invasive debug feature. A non-invasive debug feature permits the observation of data and program flow. Performance Monitors, PC Sample-based Profiling and Trace are non-invasive debug features.

Non-invasive debug components do not guarantee that they do not make any changes to the behavior or performance of the processor. Any changes that do occur must not be severe however, as this will reduce the usefulness of event counters for performance measurement and profiling. This does not include any change to program behavior that results from the same program being instrumented to use the Performance Monitors, or from some other performance monitoring process being run concurrently with the process being profiled in a multitasking operating system. As such, a reasonable variation in performance is permissible.

———— **Note** —————

Power consumption is one measure of performance. Therefore, a reasonable variation in power consumption is permissible.

Arm does not define a *reasonable variation in performance*, but recommends that such a variation is kept within 5% of normal operating performance, when averaged across a suite of code that is representative of the application workload.

———— **Note** —————

For profiles other than A-profile, there is the potential for stronger requirements. Ultimately, performance requirements are determined by end-users, and not set by the architecture.

For some common architectural events, this requirement to be non-invasive can conflict with the requirement to present an accurate value of the count under normal operating conditions. Should an implementation require more performance-invasive techniques to accurately count an event, there are the following options:

- If the event is optional, define an alternative implementation defined event that accurately counts the event and document the impact on performance of enabling the event.
- Provide an implementation defined control that disables accurate counting of the event to restore broadly accurate performance, and document the impact on performance of accurate counting.

D7.2.2 A reasonable degree of inaccuracy

The Performance Monitors provide broadly accurate and statistically useful count information. To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the counts is acceptable. Arm does not define a *reasonable degree of inaccuracy* but recommends the following guidelines:

- Under normal operating conditions, the counters must present an accurate value of the count.

- In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the count to be inaccurate.
- Under very unusual, non-repeating pathological cases, the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

———— **Note** —————

An implementation must not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. For example, it is not reasonable for the count of branch behavior to be inaccurate when caused by a systematic error generated by the loop structure producing a dropping in branch count.

However, dropping a single branch count as the result of a rare interaction with an interrupt is acceptable.

The permitted inaccuracy limits the possible uses of the Performance Monitors. In particular, the architecture does not define the points in a pipeline where the event is generated and where it is counted, relative to the point where a read of the counters is made. This means that pipelining effects can cause some imprecision.

Where a direct write to a Performance Monitors control register disables a counter, and is followed by a *Context synchronization event*, any subsequent indirect read of the control register by the Performance Monitors to determine whether the counter is enabled will return the updated value. Any subsequent direct read of the counter will return the value at the point the counter was disabled.

———— **Note** —————

The imprecision means that the counter might have counted an event around the time the counter was disabled, but does not allow the event to be observed as counted after the counter was disabled.

A change of Security state can also affect the accuracy of the Performance Monitors, see *Interaction with EL3* on page D7-2851.

In addition to this, entry to and exit from Debug state can disturb the normal running of the PE, causing further inaccuracy in the Performance Monitors. Disabling the counters while in Debug state limits the extent of this inaccuracy. An implementation can employ methods to limit this inaccuracy, for example by promptly disabling the counters during the Debug state entry sequence.

An implementation must document any particular scenarios where significant inaccuracies are expected.

D7.3 Behavior on overflow

The event counters, `PMEVCNTR<n>` are either 32-bit or 64-bit unsigned counters that overflow in the following situations:

- If `FEAT_PMUv3p5` is not implemented, 32-bit event counters are implemented, and if incrementing `PMEVCNTR<n>` causes an unsigned overflow of an event counter, the PE sets `PMOVSLR[n]` to 1.
- If `FEAT_PMUv3p5` is implemented, 64-bit event counters are implemented, and either n is in the range `[0 .. (HDCR.HPMN-1)]` or EL2 is not implemented, then event counter overflow is configured by `PMCR.LP`:
 - When `PMCR.LP` is set to 0, if incrementing `PMEVCNTR<n>` causes an unsigned overflow of bits `[31:0]` of the event counter, the PE sets `PMOVSLR[n]` to 1.
 - When `PMCR.LP` is set to 1, if incrementing `PMEVCNTR<n>` causes an unsigned overflow of bits `[63:0]` of the event counter, the PE sets `PMOVSLR[n]` to 1.
- If `FEAT_PMUv3p5` is implemented, 64-bit event counters are implemented, and EL2 is implemented, when n is in the range `[HDCR.HPMN .. (PMCR.N-1)]`, event counter overflow is configured by `HDCR.HLP`:
 - When `HDCR.HLP` is set to 0, if incrementing `PMEVCNTR<n>` causes an unsigned overflow of bits `[31:0]` of the event counter, the PE sets `PMOVSLR[n]` to 1.
 - When `HDCR.HLP` is set to 1, if incrementing `PMEVCNTR<n>` causes an unsigned overflow of bits `[63:0]` of the event counter, the PE sets `PMOVSLR[n]` to 1.

The cycle counter, `PMCCNTR`, is a 64-bit unsigned counter, that is configured by `PMCR.LC`:

- If `PMCR.LC` is set to 0, if incrementing `PMCCNTR` causes an unsigned overflow of bits `[31:0]` of the cycle counter, the PE sets `PMOVSLR[31]` to 1.
- If `PMCR.LC` is set to 1, if incrementing `PMCCNTR` causes an unsigned overflow of bits `[63:0]` of the cycle counter, the PE sets `PMOVSLR[31]` to 1.

For all 64-bit counters, incrementing the counter is the same whether an unsigned overflow occurs at `[31:0]` or `[63:0]`. If the counter increments for an event, bits `[63:0]` are always incremented,

When any overflow occurs, an interrupt request is generated if the PE is configured to generate counter overflow interrupts. For more information, see [Generating overflow interrupt requests on page D7-2855](#).

If `FEAT_PMUv3p7` is implemented, event counting can be frozen after an unsigned overflow is detected, see [Freezing event counters on page D7-2860](#).

———— Note —————

Software executing at EL1 or higher must take care that setting `PMCR.LP` or `HDCR.HLP` does not cause software executing at lower Exception levels to malfunction. If legacy software accesses the PMU at lower Exception levels, software at the higher Exception levels should not set the `PMCR.LP` or `HDCR.HLP` fields to 1. However, if the legacy software does not use the counter overflow, it is not affected by setting the `PMCR.LP` or `HDCR.HLP` to 1.

D7.3.1 Generating overflow interrupt requests

Software can program the Performance Monitors so that an overflow interrupt request is generated when a counter overflows. See `PMINTENSET` and `PMINTENCLR`.

———— Note —————

- The mechanism by which an interrupt request from the Performance Monitors generates an FIQ or IRQ exception is IMPLEMENTATION DEFINED.
- Arm recommends that the overflow interrupt requests:
 - Translate into a `PMUIRQ` signal, so that they are observable to external devices.
 - Connect to inputs on an IMPLEMENTATION DEFINED Generic Interrupt Controller as a *Private Peripheral Interrupt* (PPI) for the originating processor. See the *ARM Generic Interrupt Controller Architecture Specification* for information about PPIs.
 - Connect to a *Cross Trigger Interface* (CTI), see [Chapter H5 The Embedded Cross-Trigger Interface](#).

- Arm strongly discourages implementations from connecting overflow interrupt requests from multiple PEs to the same *System Peripheral Interrupt* (SPI) identifier.
- From GICv3, the *ARM® Generic Interrupt Controller Architecture Specification* recommends that the *Private Peripheral Interrupt* (PPI) with ID 23 is used for overflow interrupt requests.

Software can write to the counters to control the frequency at which interrupt requests occur. For example, software might set a 32-bit counter to `0xFFFF0000`, to generate another counter overflow after 65536 increments, and reset it to this value every time an overflow interrupt occurs.

Note

If an event can occur multiple times in a single clock cycle, then counter overflow can occur without the counter registering a value of zero.

The overflow interrupt request is a level-sensitive request. The PE signals a request for:

- Any given `PMEVCNTR<n>` counter, when the value of `PMOVSSET[n]` is 1, the value of `PMINTENSET[n]` is 1, and one of the following is true:
 - EL2 is not implemented and the value of `PMCR.E` is 1.
 - EL2 is implemented, n is less than the value of `HDCR.HPMN`, and the value of `PMCR.E` is 1.
 - EL2 is implemented, n is greater than or equal to the value of `HDCR.HPMN`, and the value of `HDCR.HPME` is 1.
- The cycle counter, when the values of `PMOVSSET[31]`, `PMINTENSET[31]`, and `PMCR.E` are all 1.

The overflow interrupt request is active in both Secure and Non-secure states. In particular, if EL3 and EL2 are both implemented, overflow events from `PMEVCNTR<n>` where n is greater than or equal to the value of `HDCR.HPMN` can be signaled from all modes and states but only if the value of `HDCR.HPME` is 1.

The interrupt handler for the counter overflow request must cancel the interrupt request, by writing 1 to `PMOVSCLR[n]` to clear the overflow bit to 0.

Pseudocode description of overflow interrupt requests

See [Chapter J1 Armv8 Pseudocode](#) for a pseudocode description of overflow interrupt requests. The `AArch64.CheckForPMUOverflow()` and `AArch32.CheckForPMUOverflow()` pseudocode functions signal PMU overflow interrupt requests to an interrupt controller and PMU overflow trigger events to the cross-trigger interface.

D7.4 Attributability

An event caused by the PE counting the event is *Attributable*. If an agent other than the PE that is counting the events causes an event, these events are Unattributable.

An event is defined as being either Attributable or Unattributable. If the event is Attributable, it is further defined whether it is Attributable to:

- The current Security state of the PE.
- The current Exception level of the PE.
- When the PE is in Debug state, operations issued to the PE by the debugger through the external debug interface.

In a multithreaded implementation, an event might be generated by another PE with the same values for [affinity level 1](#) and higher. This event is further defined as Attributable to:

- The current Security state of that PE.
- The current Exception level of that PE.
- When that PE is in Debug state, operations issued to that PE by the debugger through the external debug interface.

See [Multithreaded implementations on page D7-2863](#) for information about enabling and restricting counting events in a multithreaded implementation.

Note

- In an implementation containing multiple PEs, each PE is identified by a unique *affinity* value reported by [MPIDR_EL1](#) {Aff3, Aff2, Aff1, Aff0}, where the value of affinity level 0 is the most significant for determining the PE behavior, and the values of higher affinity levels are less significant. Affinity level 3 is only supported in AArch64 state.
- An implementation is described as multithreaded when the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. In this section, when referring to a multithreaded implementation, *thread* is used to mean processing elements with:
 - [MPIDR_EL1.MT](#) or [MPIDR.MT](#) set to 1,
 - Different values for affinity level 0.
 - The same values for affinity level 1 and higher.

An event can be defined as the combination of multiple subevents, which can be either Attributable or Unattributable.

All architecturally defined events are [Attributable](#), unless otherwise stated.

Unattributable events might be counted when Attributable events are not counted. See:

- [Interaction with EL3 on page D7-2851](#).
- [Event filtering on page D7-2865](#).
- [Performance Monitors and Debug state on page D7-2867](#).

These sections are summarized by [Table D7-1 on page D7-2858](#) for events Attributable to the processor, and Unattributable events. [Table D7-1 on page D7-2858](#) entries apply when the counter and PMU are enabled and not frozen. Otherwise, events are not counted.

Table D7-1 Counting events

State	Allowed or prohibited	Filtered	Event type		
			If Attributable to:	Then	Else
Non-debug	Allowed	Not filtered	X	Count	Count
		Filtered	Current Exception level	Do not count	IMPLEMENTATION DEFINED
	Prohibited	X	Current Security state	Do not count	IMPLEMENTATION DEFINED
Debug	X	X	Debugger operations or raw cycles	Do not count	IMPLEMENTATION DEFINED

D7.5 Controlling the PMU counters

This section describes the mechanisms available for controlling the PMU event and cycle counters. The following sections describe those mechanisms:

- [Enabling event counters on page D7-2859](#).
- [Freezing event counters on page D7-2860](#).
- [Prohibiting event and cycle counting on page D7-2861](#).

D7.5.1 Enabling event counters

[Table D7-2 on page D7-2859](#) shows an implementation that does not include EL2, where the `PMCR.E` bit is a global counter enable bit, and `PMCNTENSET` provides an enable bit for each counter.

Table D7-2 Event counter enables when an implementation does not include EL2

<code>PMCR.E</code>	<code>PMCNTENSET[n] == 0</code>	<code>PMCNTENSET[n] == 1</code>
0	<code>PMEVCNTR<n></code> disabled	<code>PMEVCNTR<n></code> disabled
1	<code>PMEVCNTR<n></code> disabled	<code>PMEVCNTR<n></code> enabled

If the implementation includes EL2, then in addition to the `PMCR.E` and `PMCNTENSET` enable bits:

- `HDCR.HPME` overrides the value of `PMCR.E` for counters configured for access in EL2.
- `HDCR.HPMN` specifies the number of performance counters that the Guest OS can access. The minimum permitted value of `HDCR.HPMN` is 1, meaning there must be at least one counter that the Guest OS can access.

[Table D7-3 on page D7-2859](#) shows the combined effect of all the counter enable controls.

Table D7-3 Event counter enables when an implementation includes EL2

<code>HDCR.HPME</code>	<code>PMCR.E</code>	<code>PMCNTENSET[n] == 0</code>	<code>PMCNTENSET[n] == 1</code>	
			$n < \text{HDCR.HPMN}$	$n \geq \text{HDCR.HPMN}$
0	0	<code>PMEVCNTR<n></code> disabled	<code>PMEVCNTR<n></code> disabled	<code>PMEVCNTR<n></code> disabled
0	1	<code>PMEVCNTR<n></code> disabled	<code>PMEVCNTR<n></code> enabled	<code>PMEVCNTR<n></code> disabled
1	0	<code>PMEVCNTR<n></code> disabled	<code>PMEVCNTR<n></code> disabled	<code>PMEVCNTR<n></code> enabled
1	1	<code>PMEVCNTR<n></code> disabled	<code>PMEVCNTR<n></code> enabled	<code>PMEVCNTR<n></code> enabled

———— **Note** ————

- The effect of `HDCR.{HPME, HPMN}` on the counter enables applies at all Exception levels and in both Security states.
- The value returned for `PMCR.N` is not affected by `HDCR.HPMN` at:
 - EL3.
 - EL2.
 - Secure EL1, if `FEAT_SEL2` is not implemented or Secure EL2 is disabled.
 - Secure EL0, if `FEAT_SEL2` is not implemented or Secure EL2 is disabled.

———— **Note** ————

The cycle counter, `PMCCNTR`, counts unless disabled or prohibited as described in *Prohibiting event and cycle counting* on page D7-2861.

D7.5.2 Freezing event counters

When `FEAT_SPEv1p2` is implemented, the PMU can be configured to freeze event counters when an SPE buffer management event occurs. A counter is disabled under the following conditions:

- If EL2 is implemented, n is in the range $[0 .. (\text{MDCR_EL2.HPMN}-1)]$, when `PMBSR_EL1.S` is 1, and `PMBLIMITR_EL1.E` is 1, indicating an SPE buffer management event occurred, event counter n does not count if all the following are true:
 - `PMBLIMITR_EL1.PMFZ` is 1.
 - `PMCR_EL0.FZS` is 1.
- If EL2 is not implemented, n is in the range $[0 .. (\text{PMCR_EL0.N}-1)]$, when `PMBSR_EL1.S` is 1 and `PMBLIMITR_EL1.E` is 1, indicating an SPE buffer management event occurred, event counter n does not count if all the following are true:
 - `PMBLIMITR_EL1.PMFZ` is 1.
 - `PMCR_EL0.FZS` is 1.
- If EL2 is implemented, n is in the range $[\text{MDCR_EL2.HPMN} .. (\text{PMCR_EL0.N}-1)]$, when `PMBSR_EL1.S` is 1 and `PMBLIMITR_EL1.E` is 1, indicating an SPE buffer management event occurred, event counter n does not count if all the following are true:
 - `PMBLIMITR_EL1.PMFZ` is 1.
 - `MDCR_EL2.HPMFZS` is 1.

———— **Note** ————

This also applies when EL2 is disabled in the current Security state.

If the highest implemented Exception level is using AArch32, then the *Effective value* of `PMBLIMITR_EL1.E` is 0 and `FEAT_SPEv1p2` does not affect the PMU event counters. Otherwise, the effect of `FEAT_SPEv1p2` on PMU event counters applies in AArch32 state.

When `FEAT_PMUv3p7` is implemented, the PMU can be configured to freeze event counters when an unsigned overflow of a counter occurs. A counter is disabled under the following conditions:

- If EL2 is implemented, n is in the range $[0 .. (\text{MDCR_EL2.HPMN}-1)]$, when `PMOVSLR_EL0[(MDCR_EL2.HPMN-1):0]` is non-zero, indicating an unsigned overflow in one of the event counters in the range, event counter n does not count when `PMCR_EL0.FZO` is 1.
- If EL2 is implemented, `MDCR_EL2.HPMN` is less than `PMCR_EL0.N` and n is in the range $[\text{MDCR_EL2.HPMN} .. (\text{PMCR_EL0.N}-1)]$, when `PMOVSLR_EL0[(PMCR_EL0.N-1):MDCR_EL2.HPMN]` is non-zero, indicating an unsigned overflow in one of the event counters in the range, event counter n does not count when `PMCR_EL0.FZO` is 1.
- If EL2 is not implemented and n is in the range $[0 .. (\text{PMCR_EL0.N}-1)]$, when `PMOVSLR_EL0[(PMCR_EL0.N-1):0]` is non-zero, indicating an unsigned overflow in one of the event counters in the range, event counter n does not count when `PMCR_EL0.FZO` is 1.

When the applicable `PMCR_EL0.FZO` or `MDCR_EL2.HPMFZO` bit is 1, it is CONstrained UNpredictable whether any event happening at or about the same time as the event that caused the overflow is counted. This includes other instances of the same event.

———— **Note** ————

The architecture does not define when PMU events are counted relative to the instructions that caused the event. Events caused by an instruction might be counted before or after the instruction becomes architecturally executed, and events might be counted for operations that are not architecturally executed. Events can be counted speculatively, out-of-order, or both with respect to the simple sequential execution of the program. Events might also be counted simultaneously by other event counters when the overflow occurs, including events from different instructions. Multiple instances of an event might occur simultaneously, thus an event counter unsigned overflow can yield a nonzero value in the event counter.

Arm recommends that such counting anomalies are minimized when software uses the freeze on overflow feature. When the freeze on overflow feature is being used, software cannot assume that the event counter stops counting at zero when an overflow occurs.

If an event counter $\langle n \rangle$ overflows, where n is even and event counter $\langle n+1 \rangle$ is configured to count the [CHAIN](#) event, it is [CONSTRAINED UNPREDICTABLE](#) whether the [CHAIN](#) event observes the overflow event when the applicable [PMCR_EL0.FZO](#) or [MDCR_EL2.HPMFZO](#) bit is 1 and the corresponding [PMCR_EL0.LP](#) or [MDCR_EL2.HLP](#) bit is 0.

D7.5.3 Prohibiting event and cycle counting

Counting [Attributable](#) events in Secure state is prohibited unless any one of the following is true:

- [EL3](#) is not implemented.
- [FEAT_PMUv3p7](#) is not implemented, [EL3](#) is implemented, is using [AArch64](#), and the value of [MDCR_EL3.SPME](#) is 1.
- [FEAT_PMUv3p7](#) is implemented, [EL3](#) is implemented, [EL3](#) is using [AArch64](#), the value of [MDCR_EL3.SPME](#) is 1. and the value of [MDCR_EL3.MPMX](#) is 0.
- [FEAT_PMUv3p7](#) is implemented, [EL3](#) is implemented, the PE is not at [EL3](#), [EL3](#) is using [AArch64](#), and the value of [MDCR_EL3.MPMX](#) is 1
- [EL3](#) is implemented, is using [AArch32](#), and the value of [SDCR.SPME](#) is 1.
- [EL3](#) is implemented, [EL3](#) or [EL1](#) is using [AArch32](#), executing at [EL0](#), and the value of [SDER32_EL3.SUNIDEN](#) is 1.
- If [FEAT_Debugv8p2](#) is not implemented, [EL3](#) is implemented, and counting is permitted by an [IMPLEMENTATION DEFINED](#) authentication interface, `ExternalSecureNoninvasiveDebugEnabled() == TRUE`.

Note

Software can read the Authentication Status register, [DBGAUTHSTATUS](#) to determine the state of an [IMPLEMENTATION DEFINED](#) authentication interface.

If a direct read of [PMOVSLR_EL0](#) returns a non-zero value for a subset of the overflow flags, which means an event counter $\langle n \rangle$ should not count, then a sequence of direct reads of [PMEVCNTR<n>_EL0](#) ordered after the read of [PMOVSLR_EL0](#) and before the [PMOVSLR_EL0](#) flags are cleared to zero, will return the same value for each read, because the event counter has stopped counting.

Note

Direct reads of System registers require explicit synchronization for following direct reads of other System registers to be ordered after the first direct read.

If [FEAT_PMUv3p7](#) is implemented and [MDCR_EL3.MPMX](#) is 1, counting [Attributable](#) events at [EL3](#) for event counter n is prohibited if any of the following are true:

- [EL2](#) is not implemented, and n is in the range $[0 .. (\text{PMCR_EL0.N}-1)]$.
- [EL2](#) is implemented, [MDCR_EL3.SPME](#) is 0, and n is in the range $[0 .. (\text{PMCR_EL0.N}-1)]$.
- [EL2](#) is implemented, [MDCR_EL3.SPME](#) is 1, and n is in the range $[0 .. (\text{MDCR_EL2.HPMN}-1)]$.

If [EL2](#) is implemented and [MDCR_EL3](#).{[SPME](#), [MPMX](#)} is {1, 1}, when [MDCR_EL2.HPMN](#) is less than [PMCR_EL0.N](#) and n is in the range $[\text{MDCR_EL2.HPMN} .. (\text{PMCR_EL0.N}-1)]$, counting [Attributable](#) events at [EL3](#) for event counter n is allowed.

Counting [Attributable](#) events at [EL2](#) is prohibited unless any of the following are true:

- [FEAT_PMUv3p1](#) is not implemented.
- [HDCR.HPMD](#) is 0.

- `MDCR_EL2.HPMN` is less than `PMCR_EL0.N` and event counter n is in the range [`MDCR_EL2.HPMN` .. (`PMCR_EL0.N`-1)].

If `FEAT_SEL2` is implemented, counting `Attributable` events at Secure EL2 is allowed if and only if counting events is allowed in Secure state, and counting events is allowed at EL2.

The accessibility of Performance Monitors registers is unaffected by whether event counting is enabled or prohibited.

The cycle counter, `PMCCNTR`, counts unless any of the following is true:

- The cycle counter is disabled by `PMCR_EL0.E` or `PMCNTENSET_EL0`[31].
- Event counting is prohibited and `PMCR.DP` is set to 1.
- The PE is in Debug state.
- `FEAT_PMUv3p5` is implemented, EL3 is implemented, the PE is in Secure state, and `SDCR.SCCD` is set to 1.
- `FEAT_PMUv3p5` is implemented, EL2 is implemented, the PE is executing at EL2, and `HDCR.HCCD` is set to 1.
- `FEAT_PMUv3p7` is implemented, the PE is at EL3, EL3 is using AArch64, and `MDCR_EL3.MCCD` is set to 1.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when counting `Attributable` events is prohibited.

See `AArch64.CountEvents()` and `AArch32.CountEvents()` in [Chapter J1 Armv8 Pseudocode](#) for more information. The `CountEvents(n)` functions return TRUE if `PMEVCNTR<n>` is enabled and allowed to count events at the current Exception level or state, and FALSE otherwise. The function `CountEvents(31)` returns TRUE if the cycle counter is enabled and allowed to count cycles at the current Exception level and state and FALSE otherwise. However, these functions do not completely describe the behavior for Unattributable events.

The Performance Monitors are intended to be broadly accurate and statistically useful, see [Accuracy of the Performance Monitors on page D7-2853](#). Some inaccuracy is permitted at the point of changing between a state where counting is prohibited and a state where counting is allowed, however. To avoid the leaking of information, the permitted inaccuracy is that transactions that are not prohibited can be uncounted. Where possible, prohibited transactions must not be counted, but if they are counted, then that counting must not degrade security.

D7.6 Multithreaded implementations

If an implementation is multithreaded and the *Effective value* of `PMEVTYPER<n>.MT == 1`, events on other PEs with the same level 1 Affinity are also counted. A pair of PEs have the same level 1 Affinity if they have the same values for all fields in `MPIDR_EL1` or `MPIDR` except the `Aff0` field.

Events on other PEs are not counted when the *Effective value* of `PMEVTYPER<n>.MT` is 0.

If the CPU implements multithreading, and `FEAT_MTPMU` is not implemented, for Armv8.5 and earlier, it is IMPLEMENTATION DEFINED whether `PMEVTYPER<n>.MT` is implemented as RW or RES0. From Armv8.6, if the OPTIONAL `FEAT_MTPMU` feature is not implemented, the *Effective value* of `PMEVTYPER<n>.MT` is RES0.

If `FEAT_MTPMU` is implemented, EL3 is implemented, and `MDCR_EL3.MTPME` is 0 or `SDCR.MTPME` is 0, `FEAT_MTPMU` is disabled and the *Effective value* of `PMEVTYPER<n>.MT` is 0.

If `FEAT_MTPMU` is implemented, EL3 is not implemented, EL2 is implemented, and `MDCR_EL2.MTPME` is 0 or `HDCR.MTPME` is 0, `FEAT_MTPMU` is disabled and the *Effective value* of `PMEVTYPER<n>.MT` is 0.

If `FEAT_MTPMU` is disabled on a Processing Element PE_A , it is IMPLEMENTATION DEFINED whether `FEAT_MTPMU` is disabled on another Processing Element PE_B , if all the following are true:

- `FEAT_MTPMU` is implemented on PE_A and PE_B .
- PE_A and PE_B have the same values for Affinity level 1 and higher.
- PE_A and PE_B both have `MPIDR_EL1.MT` or `MPIDR.MT` set to 1.

However, even when the *Effective value* of `PMEVTYPER<n>.MT` is 1, PE_A does not count an event that is *Attributable* to Secure state on PE_B if counting events *Attributable* to Secure state is prohibited on PE_A . Similarly, PE_A does not count an event that is *Attributable* to EL2 on PE_B if counting events *Attributable* to EL2 is prohibited on PE_A .

Example D7-1 The effect of having `PMEVTYPER<n>.MT == 1`

If the value of `MDCR_EL3.SPME` is 0, and `<n>` is less than `PMCR.N` on PE_A , then event counter `<n>` on PE_A does not count events *Attributable* to Secure state on PE_B , even if one or both of the following applies:

- PE_A is in Non-secure state.
 - `MDCR_EL3.SPME == 1` on PE_B .
-

Example D7-2 The effect of having `PMEVTYPER<n>.MT == 1`

If the value of `MDCR_EL2.HPMD` is 1 and `<n>` is less than `MDCR_EL2.HPMN` on PE_A , then event counter `<n>` on PE_A does not count events *Attributable* to EL2 on PE_B , even if one of the following applies:

- `MDCR_EL2.HPMD == 0` on PE_B .
 - PE_A is not executing at EL2.
-

When the current configuration is not multithreaded, and PE_A prohibits counting of events *Attributable* to Secure state when PE_A is in Secure state, it is IMPLEMENTATION DEFINED whether:

- Counting events *Attributable* to Secure state when PE_A is in Non-secure state is permitted.
- Counting Unattributable events related to other Secure operations in the system when PE_A is in Non-secure state is permitted.

Otherwise, counting events in Non-secure state is permitted.

When the current configuration is not multithreaded, and PE_A prohibits counting of events *Attributable* to EL2 when PE_A is at EL2, it is IMPLEMENTATION DEFINED whether:

- Counting events *Attributable* to EL2 when PE_A is using another Exception level is permitted.
- Counting Unattributable events related to EL2 when PE_A is using another Exception level is permitted.

Otherwise, counting events at another Exception level is permitted.

D7.7 Event filtering

The PMU can filter events by various combinations of Exception level and Security state. This gives software the flexibility to count events across multiple processes.

D7.7.1 Filtering by Exception level and Security state

In AArch64 state:

- For each event counter, `PMEVTYPER<n>_EL0` specifies the Exception levels in which the counter counts events [Attributable](#) to Exception levels.
- `PMCCFILTR_EL0` specifies the Exception levels in which the cycle counter counts.

For an event that is [Attributable](#) to an Exception level, in a multithreaded implementation:

- When the *Effective value* of `PMEVTYPER<n>_EL0.MT` is 1, the specified filtering is evaluated using the current Exception level and Security state of the thread to which the event is [Attributable](#). See [Example D7-3 on page D7-2865](#).
- When the *Effective value* of `PMEVTYPER<n>_EL0.MT` is 0, the event is only counted if it is [Attributable](#) to the counting thread, and the filtering is evaluated using the Exception level and Security state of the counting thread.

Example D7-3 Example of the effect of the `PMEVTYPER<n>_EL0.MT` control

In a multithreaded implementation, if the *Effective value* of `PMEVTYPER<n>_EL0.MT` is 1 and the value of `PMEVTYPER<n>_EL0.U` is 1 on the counting thread, then event counter `<n>` does not count events [Attributable](#) to EL0 on another thread, even if the counting thread is not executing at EL0.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether the filtering applies. In a multithreaded implementation, if the filtering applies to an Unattributable event, then the filtering is evaluated using the Exception level and Security state of the counting thread.

In AArch32 state, the filtering controls are provided by the `PMEVTYPER<n>` and `PMCCFILTR` registers.

For more information, see the individual register descriptions and [Multithreaded implementations on page D7-2863](#).

D7.7.2 Accuracy of event filtering

For most events, it is acceptable that, during a transition between states, events generated by instructions executed in one state are counted in the other state. The following sections describe the cases where event counts must not be counted in the wrong state:

- [Exception-related events on page D7-2865](#).
- [Software increment events on page D7-2866](#).

Exception-related events

The PMU must filter events related to exceptions and exception handling according to the Exception level in which the event occurred. These events are:

- `EXC_TAKEN`, Exception taken.
- `EXC_RETURN`, Instruction architecturally executed, Condition code check pass, exception return.
- `CID_WRITE_RETIRED`, Instruction architecturally executed, Condition code check pass, write to `CONTEXTIDR`.

- [TTBR_WRITE_RETIRED](#), [Instruction architecturally executed](#), [Condition code check pass](#), write to translation table base.

The PMU must not count an exception after it has been taken because this could systematically report a result of zero exceptions at EL0. Similarly, it is not acceptable for the PMU to count exception returns or writes to [CONTEXTIDR](#) after the return from the exception.

Software increment events

The PMU must filter software increment events according to the Exception level in which the software increment occurred. Software increment counting must also be precise, meaning the PMU must count every architecturally executed software increment event, and must not count any [Speculatively executed](#) software increment.

Software increment events must also be counted without the need for explicit synchronization. For example, two software increments executed without an intervening [Context synchronization event](#) must increment the event counter twice.

For more information, see [SW_INCR](#), [Instruction architecturally executed](#), [Condition code check pass](#), software increment.

D7.7.3 Pseudocode description of event filtering

See [AArch64.CountEvents\(\)](#) and [AArch32.CountEvents\(\)](#) in [Chapter J1 Armv8 Pseudocode](#) for a pseudocode description of event filtering. However, this function does not completely describe the behavior for Unattributable events.

D7.8 Performance Monitors and Debug state

Events that count cycles are not counted in Debug state.

Events [Attributable](#) to the operations issued by the debugger through the external debug interface are not counted in Debug state.

In an implementation that supports multithreading, when the *Effective value* of `PMEVTYPER<n>_EL0.MT` is 1, if an event is Attributable to an operation issued by the debugger through the external debug interface to another thread that is in Debug state, then the event is not counted, and it is IMPLEMENTATION DEFINED whether the event is counted when the counting thread is in Debug state.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when the counting PE is in Debug state. If the event might be counted, then the rules in [Filtering by Exception level and Security state on page D7-2865](#) apply for the current Security state in Debug state.

D7.9 Counter access

All implemented event counters are accessible in EL3 and EL2. If EL2 is implemented the hypervisor uses [HDCR.HPMN](#) to reserve an event counter, with the effect that if EL2 is enabled in the current Security state, software cannot access that counter and its associated state from EL0 or EL1.

If [FEAT_FGT](#) is implemented, if [PMSELR.SEL](#) or n indicates an unimplemented event counter, access to [PMXEVTYPER](#), [PMXVCNTR](#), [PMEVTYPER<n>](#), or [PMEVCNTR<n>](#) is UNDEFINED.

———— Note —————

Whether software can access an event counter at an Exception level does not affect whether the counter counts events at that Exception level. For more information, see [Controlling the PMU counters on page D7-2859](#) and [Enabling event counters on page D7-2859](#).

D7.9.1 PMEVCNTR<n> event counters

[Table D7-4 on page D7-2868](#) shows how the number of implemented event counters, [PMCR.N](#), and if EL2 is implemented, the value of the [HDCR.HPMN](#) field affects the behavior of permitted accesses to the [PMEVCNTR<n>](#) event counter registers for values of n from 0 to 30.

Table D7-4 Result of [PMEVCNTR<n>](#) event counter accesses

Condition	Access at Exception level			
	EL3	EL2	EL1	EL0
$n < \text{PMCR.N}$ and either EL2 is not implemented or EL2 is disabled in the current Security state	Succeeds	n/a	Succeeds	Succeeds
$n < \text{HDCR.HPMN}$ and EL2 is implemented and enabled in the current Security state	Succeeds	Succeeds	Succeeds	Succeeds
$n \geq \text{HDCR.HPMN}$ and $n < \text{PMCR.N}$ and EL2 is implemented and enabled in the current Security state	Succeeds	Succeeds	No access	No access
$n \geq \text{PMCR.N}$	No access	No access	No access	No access

Where [Table D7-4 on page D7-2868](#) shows access succeeds for an event counter $\langle n \rangle$, the access might be UNDEFINED or generate a trap exception. See the descriptions of [PMEVCNTR<n>](#) and [PMXVCNTR](#) for details.

Where [Table D7-4 on page D7-2868](#) shows no access for an event counter $\langle n \rangle$:

- When [PMSELR.SEL](#) is n , the PE prevents direct reads and direct writes of [PMXEVTYPER](#) or [PMXVCNTR](#). See the register descriptions for more information.
- The PE prevents direct reads and direct writes of [PMEVTYPER<n>](#) or [PMEVCNTR<n>](#). See the register descriptions for more information.
- Direct reads and direct writes of the following registers are RAZ/WI. [PMOVSCLR\[n\]](#), [PMOVSSSET\[n\]](#), [PMCNTENSET\[n\]](#), [PMCNTENCLR\[n\]](#), [PMINTENSET\[n\]](#), and [PMINTENCLR\[n\]](#).
- Direct writes to [PMSWINC\[n\]](#) are ignored.
- A direct write of 1 to [PMCR.P](#) does not reset [PMEVCNTR<n>](#).

D7.9.2 Cycle counter

The PMU does not provide any control that a hypervisor can use to reserve the cycle counter for its own use. However, access to the PMU registers are subject to the access permissions described in [Configurable instruction enables and disables, and trap controls on page D1-2510](#).

D7.10 PMU events and event numbers

The following sections describe the events that can be counted and their associated event numbers, and the mnemonics for the events:

- [Definitions on page D7-2869.](#)
- [The PMU event number space and common events on page D7-2875.](#)
- [Common event numbers on page D7-2876.](#)
- [Cycle event counting on page D7-2936.](#)
- [Meaningful ratios between common microarchitectural events on page D7-2937.](#)
- [Required events on page D7-2937.](#)
- [IMPLEMENTATION DEFINED event numbers on page D7-2939.](#)

D7.10.1 Definitions

The following subsections give more information about terms used in the event definitions:

- [Definition of terms on page D7-2869.](#)
- [Levels of caches and TLBs on page D7-2874.](#)
- [Shared caches and buses on page D7-2875.](#)

Definition of terms

ALU operation counts

The PMU events 0x80C0 to 0x80CF count the number of arithmetic logic unit operations performed by each instruction.

[Table D7-5 on page D7-2870](#) gives the ALU operation counts for accumulator instruction PMU events.

In this table:

Input size The element size of input operands other than the accumulator.

Acc size The element size of the accumulator operand.

Count The number of addition and multiply operations per 128 bits of input:

- Scalable vector operations increment the counter by the Count value for an applicable *_SCALE_OPS_SPEC event.
- Advanced SIMD operations operating on a 128-bit register increment the counter by the Count value for an applicable *_FIXED_OPS_SPEC event.
- Advanced SIMD operations operating on a 64-bit register increment the counter by half the Count value for an applicable *_FIXED_OPS_SPEC event.

Type The data type classification for the operations. This determines for which events the event counter counts the operation.

Predicated operations are counted even if the Governing predicate for the element is FALSE.

Note

The FP64 FMMLA instruction works on 256-bit segments, and performs 16 operations per 256-bit segment. The table represents counts per 128 bits of input, so the counter increments by 8.

Table D7-5 ALU operation counts

Operation	Input size	Acc size	Count	Type
SDOT, UDOT, USDOT, SUDOT	8 bits	32 bits	32	Integer
SDOT, UDOT	16 bits	64 bits	16	Integer
BFDOT	16 bits	32 bits	16	Single-precision floating point
BFMMLA	16 bits	32 bits	32	Single-precision floating point
BFMLAL, FMLAL, and FMLSL	16 bits	32 bits	8	Single-precision floating point
SMMLA, UMMLA, or USMMLA	8 bits	32 bits	64	Integer
FMMLA	32 bits	32 bits	16	Single-precision floating point
FMMLA	64 bits	64 bits	8	Double-precision floating point

Note

Predicated operations are counted even if the governing predicate for the element is FALSE.

For other instructions, the PMU events that count ALU operations are incremented as follows:

- Multiply-add, multiply-subtract, fused multiply-add, and fused multiply-subtract instructions generate two ALU operations of the specified type per input element. For floating-point operations, these are the instructions counted by [FP_FMA_SPEC](#).
- All other data processing operations generate one ALU operation of the specified type per input element.

For example, ALU operation counters are incremented as follows:

- Non-SVE load and store of a single register instructions increment the counter by 1. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Non-SVE load and store of a pair of registers instructions increment the counter by 2. This includes loads and stores of pairs of Sx, Dx, and Qx SIMD&FP registers.
- AArch32 load and store multiple registers instructions increment the counter by the number of registers transferred.
- Atomic store instructions increment the counter by 1. These are instructions that atomically update a value in memory without returning a value to a register.
- Atomic load, compare and swap of a single register, and swap instructions increment the counter by 2. Atomic load instructions are instructions that atomically update a value in memory, returning a value to a register.
- Compare and swap of a pair of registers increment the counter by 4.
- SVE and Advanced SIMD LD1R instructions increment the counter by 1.
- SVE LD1RQ instructions increment the counter by $(128 \div \text{CSIZE})$.
- Advanced SIMD LD[1-4] and ST[1-4] instructions increment the counter by the number of elements transferred per vector multiplied by the number of transferred registers.
- DC ZVA and DC GZVA instructions increment by the counter by an IMPLEMENTATION DEFINED amount

CSIZE

Container size, in bits, that corresponds to the largest non-overlapping SVE or Advanced SIMD vector element size or scalar register size that is encoded in the instruction opcode. This excludes the 64-bit elements of the wide element variants of the SVE bitwise shift and integer compare instructions that overlap the narrower source and destination elements.

Instruction architecturally executed

Instruction architecturally executed is a class of event that counts for each instruction of the specified type. Architecturally executed means that the program flow is such that the counted instruction would be executed in a *Simple sequential execution* of the program. Therefore an instruction that has been executed and retired is defined to be *architecturally executed*. When a PE can perform speculative execution, an instruction is not architecturally executed if the PE discards the results of the speculative execution.

If an instruction that would be executed in a *Simple sequential execution* of the program generates a synchronous exception, it is IMPLEMENTATION DEFINED whether the instruction is counted.

Each architecturally executed instruction is counted once, even if the implementation splits the instruction into multiple operations. Instructions that have no visible effect on the architectural state of the PE are architecturally executed if they form part of the architecturally executed program flow. The point where such instructions are retired is IMPLEMENTATION DEFINED.

Examples of instructions that have no visible effect are:

- A NOP.
- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.

The point at which an event causes an event counter to be updated is not defined.

Unless otherwise stated, all instructions of the specified type are counted even if they have no visible effect on the architectural state of the PE. This includes a conditional instruction that fails its Condition code check.

For events that count only the execution of instructions that update context state, such as writes to the `CONTEXTIDR`, if such an instruction is executed twice without an intervening *Context synchronization event*, it is CONSTRAINED UNPREDICTABLE whether the first instruction is counted.

Instruction architecturally executed, Condition code check pass

Instruction architecturally executed, Condition code check pass is a class of events that explicitly do not occur for:

- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.
- A Test and Branch on Zero, TBZ, instruction that does not branch.
- A Test and Branch on Nonzero, TBNZ, instruction that does not branch.
- A Store-Exclusive instruction that does not write to memory.

Otherwise, the definition of architecturally executed is the same as for [Instruction architecturally executed](#).

A branch that is architecturally executed, with condition code check pass is also described as a branch taken.

Instruction memory access

A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:

- Fetching instructions that are architecturally executed.
- The result of the execution of an instruction preload instruction, PLI.
- Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is IMPLEMENTATION DEFINED. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

Memory-read operations

A PE accesses memory through memory-read operations and [Memory-write operations](#). A memory-read operation might be due to:

- The result of an architecturally executed memory-reading instructions.
- The result of a [Speculatively executed](#) memory-reading instructions.
- A translation table walk.

For levels of cache hierarchy beyond the Level 1 caches, memory-read operations also include accesses made as part of a refill of another cache closer to the PE. Such refills might be due to:

- Memory-read operations or [Memory-write operations](#) that miss in the cache
- The execution of a data preload instruction.
- The execution of an instruction preload instruction on a unified cache.
- The execution of a cache maintenance instruction.

———— **Note** —————

A preload instruction or cache maintenance instruction is not, in itself, an access to that cache. However, it might generate cache refills which are then treated as memory-read operations beyond that cache.

- Speculation that a future instruction might access the memory location.
- Instruction memory accesses.

This list is not exhaustive.

The relationship between memory-read instructions and memory-read operations is IMPLEMENTATION DEFINED. For example, for some implementations an LDP instruction that reads two 64-bit registers might generate one memory-read operation if the address is quadword-aligned, but for other addresses it generates two or more memory-read operations.

Memory-write operations

Memory-write operations might be due to:

- The result of an architecturally executed memory-writing instructions.
- The result of a [Speculatively executed](#) memory-writing instructions.

———— **Note** —————

[Speculatively executed](#) memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a memory-write operation that is later undone in some implementation specific way.

For levels of cache hierarchy beyond the Level 1 caches, memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. Such write-backs might be due to:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill, see [Memory-read operations](#).
- The execution of a cache maintenance instruction.

———— **Note** —————

A cache maintenance instruction is not in itself an access to that cache. However, it might generate write-backs which are then treated as memory-write operations beyond that cache.

- The result of a coherency request from another PE.

This list is not exhaustive.

DC ZVA is counted as a [Memory-write operation](#).

The relationship between memory-writing instructions and memory-write operations is IMPLEMENTATION DEFINED. For example, for some implementations an STP instruction that writes two 64-bit registers might generate one memory-write operation if the address is quadword-aligned,

but for other addresses it generates two or more memory-write operations. In some implementations, the result of two STR instructions that write to adjacent memory might be merged into a single memory-write operation.

———— **Note** —————

The data written back from a cache that is shared with other PEs might not be data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

Microarchitectural operation

It is permissible for an implementation of a PE to break down instructions into separate, smaller, operations. The use of Microarchitectural operations (micro-ops) is IMPLEMENTATION DEFINED.

An instruction might create one or more micro-ops at any point in the execution pipeline. For the purpose of event counting, the micro-ops are counted. The definition of a micro-op is implementation specific. An architecture instruction might create more than one micro-op for each instruction. micro-ops might also be removed or merged in the execution stream, so an architecture instruction might create no micro-ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of micro-ops is permitted.

The counting of operations can indicate the workload on the PE. However, there is no requirement for operations to represent similar amounts of work, and direct comparisons between different microarchitectures are not meaningful.

For example, an implementation might split an A32 or T32 LDM instruction of six registers into six micro-ops, one for each load, and a seventh address-generation operation to determine the base address or writeback address. Also, for doubleword alignment, the six load micro-ops might combine into four operations, that is, a word load, two doubleword loads, and a second word load. This single instruction can then be counted as five, or possibly six, events:

- Four ([Operations speculatively executed - Load](#)) events.
- One ([Operations speculatively executed - Integer data processing](#)) event.
- One ([Operations speculatively executed - Software change of the PC](#)) event if the PC was one of the six registers in the LDM instruction.

MSIZE Memory element access size, in bits, that corresponds to a load or store instruction mnemonic suffix, where B=8, H=16, W=32 and D=64. When an instruction mnemonic does not end with B, H, W or D, the memory access size is implied by the scalar transfer register size or SIMD transfer register element size.

non-SIMD SVE instructions

These are instructions listed in the non-SIMD SVE instruction category in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

Operations speculatively executed

A [Microarchitectural operation](#) that is [Speculatively executed](#).

There is no architecturally guaranteed relationship between a [Speculatively executed](#) micro-op and an architecturally executed instruction.

The results of such an operation can also be discarded, if it transpires that the operation was not required, following a mispredicted branch. Therefore, Armv8-A defines these events as *operations speculatively executed*, where appropriate.

———— **Note** —————

In some events, operation has a more specific meaning described in the event. See [ALU operation counts on page D7-2869](#).

Processor cycle

For a non-multithreaded implementation, this means a cycle of the processor. For a multithreaded implementation, processor cycle means each cycle of the multithreaded processor, not just those cycles for which the PE counting the event is active.

Slot

An implementation of a PE might be able to execute multiple micro-ops in a single processor cycle. The maximum number of micro-ops that can be executed might vary at different points in the execution pipeline.

To allow profiling of the utilization of the resource of the PE, an implementation specific point in the execution pipeline is chosen where the maximum number of micro-ops that can be executed is an IMPLEMENTATION DEFINED fixed value.

Each possible micro-op that can be executed at that point in a cycle is called a Slot. The maximum number of micro-ops that can be executed is defined by [PMMIR.SLOTS](#).

Software change of the PC

Some events relate to instructions that cause a software change of the PC. This includes all:

- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data-processing instructions that explicitly write to the PC.
- Exception return instructions.

It is IMPLEMENTATION DEFINED whether any or all of the following are treated as software changes of the PC:

- BRK and BKPT instructions.
- An exception generated because an instruction is UNDEFINED.
- The exception-generating instructions, SVC, HVC, and SMC.
- Context synchronization barrier ISB instructions.

Speculatively executed

Many events relate to speculatively executed operations. Here, speculatively executed means the PE did some work associated with one or more instructions but the instructions were not necessarily architecturally executed.

See [Operations speculatively executed](#) for speculation of micro-ops.

————— Note —————

The definition of *speculatively executed* does not mean only those operations that are executed speculatively and later abandoned, for example due to a branch misprediction or fault. That is, speculatively executed operations must count operations on both false and correct execution paths.

Different groups of events can have different IMPLEMENTATION DEFINED definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example is of the base type, operation speculatively executed.

For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

Within these groups, events are commonly defined with reference to a particular architecture instruction or group of instructions. In the case of speculatively executed operations this means operations with semantics that map to that type of instruction.

VL The current SVE vector length, in bits.

Levels of caches and TLBs

The mapping of levels of cache and TLB to the PMU events is IMPLEMENTATION DEFINED. Although [CLIDR_EL1](#) and [CLIDR](#) define the implemented levels of cache, these are not required to correspond with the levels of cache defined for PMU events. The architecture does not provide any way of determining implemented levels of TLB.

Also, many implementations include structures that provide some caching at a higher level than the level 1 caches or TLBs. Typically, these structures, that might be called Level 0 caches, or mini caches, or microcaches, are invisible to software. The implementation-specific nature of cache and TLB implementations mean that, in general, PMU event counts cannot be used reliably to make direct comparisons between different implementations.

Shared caches and buses

There is no architectural concept of a *shared* component. However, when a cache, a bus, or any other system component that might generate countable events is implemented, and:

- The extent of the first-order effects due to an event from that component are only applicable to a single PE, then the event is not shared.
- Otherwise, the event is shared.

Second-order effects are not considered when determining if an event is shared.

Example D7-4 First and second order effects of a cache miss in a multiple-PE implementation

In an implementation that consists of two PEs, each with its own L1 cache, a cache miss by one of the PEs is a first-order effect of an access to its cache. Any snoop that is performed on the L1 cache of the other PE in the implementation as a result of that cache miss is a second order effect.

Note

Shared events are inherently linked to microarchitectures and so the implementer must make an informed decision about how such events are implemented.

D7.10.2 The PMU event number space and common events

In Armv8.0, the event number space is 10 bits. Armv8.1 extends the event number space, and therefore the `PMEVTYPER<n>_EL0.evtCount` field to 16 bits, and is allocated as [Table D7-6 on page D7-2875](#) shows. For more information about the entries in the [Allocation on page D7-2875](#) column see the text that follows this table:

Table D7-6 Allocation of the PMU event number space

Event numbers	Allocation
In all versions of Armv8	
0x0000-0x003F	Common architectural and microarchitectural events.
0x0040-0x00BF	Arm-recommended common architectural and microarchitectural events.
0x00C0-0x03FF	IMPLEMENTATION DEFINED events.
From Armv8.1	
0x0400-0x3FFF	IMPLEMENTATION DEFINED events.
0x4000-0x403F	Common architectural and microarchitectural events.
0x4040-0x40BF	Arm-recommended common architectural and microarchitectural events.
0x40C0-0x7FFF	IMPLEMENTATION DEFINED events.
0x8000-0x80FF	Common architectural and microarchitectural events.
0x8100-0x8124	Previously reserved. From Armv8.6, common architectural and microarchitectural events.

Table D7-6 Allocation of the PMU event number space (continued)

Event numbers	Allocation
0x8125-0x8127	Reserved.
0x8128-0x81FF	Previously reserved. From Armv8.6, common architectural and microarchitectural events.
0x8200-0xC0BF	Reserved.
0xC0C0-0xFFFF	IMPLEMENTATION DEFINED events.

The meaning of the entries in the *Allocation* on page D7-2875 column of Table D7-6 on page D7-2875 is as follows:

Common architectural and microarchitectural events

Arm defines the use of these event numbers. For more information see [Common event numbers on page D7-2876](#).

Arm-recommended common architectural and microarchitectural events

The use of these event numbers is IMPLEMENTATION DEFINED. For more information see:

- [IMPLEMENTATION DEFINED event numbers on page D7-2939](#).
- [Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events](#).

IMPLEMENTATION DEFINED event numbers

For more information about the use of these event numbers see [IMPLEMENTATION DEFINED event numbers on page D7-2939](#).

D7.10.3 Common event numbers

The event numbers of the common architectural and microarchitectural events are reserved for the specified events. Each of these event numbers must either:

- Be used for its assigned event.
- Not be used.

However, see [Required events on page D7-2937](#).

When an implementation supports monitoring of an event that is assigned a common architectural or microarchitectural event number, Arm strongly recommends that it uses that number for the event. However, software might encounter implementations where an event assigned a number in this range is monitored using an event number from an IMPLEMENTATION DEFINED range.

———— Note —————

Arm might define other common architectural and microarchitectural event numbers. This is one reason why software must not assume that an event with an assigned common architectural or microarchitectural event number is never monitored using an event number from the IMPLEMENTATION DEFINED range.

It is IMPLEMENTATION DEFINED which events, including Common events, are generated by IMPLEMENTATION DEFINED extensions to the architecture, including accesses to IMPLEMENTATION DEFINED System registers and IMPLEMENTATION DEFINED System instructions. However, the functionality of the IMPLEMENTATION DEFINED extension must be appropriate for the generated events.

The common events are described in the following sections:

- [Common architectural events on page D7-2877](#).
- [Common microarchitectural events on page D7-2884](#).

The supported common architectural and microarchitectural events in the ranges 0x0000-0x003F and 0x4000-0x403F are discoverable to software through:

- The `PMCEID0_EL0` and `PMCEID1_EL0` registers in AArch64 state.
- The `PMCEID0`, `PMCEID1`, `PMCEID2`, and `PMCEID3` registers in AArch32 state.

Arm recommends that the value of 0 is used for the `PMCEID0_EL0` or `PMCEID1_EL0` bit corresponding to any event that an implementation never generates, even if the implementation is considered to support but never count the event.

———— **Note** ————

- For example, if an implementation never generates the `L1D_CACHE_ALLOCATE` event, event 31, Arm recommends that `PMCEID0_EL0[31]` is RAZ.
- In an implementation that supports both Execution states, each bit in the AArch64 `PMCEID0_EL0` and `PMCEID1_EL0` registers corresponds to a single bit in the AArch32 `PMCEID0`, `PMCEID1`, `PMCEID2`, and `PMCEID3` registers, and corresponding bits must have the same behavior.

However, for some implementations, an event in the common events range might be generated by the system, meaning behavior can vary between systems. In such a case, the corresponding `PMCEIDn_EL0` bit might be RAO.

Event numbers that [Table D7-6 on page D7-2875](#) shows as allocated for common architectural and microarchitectural events that are not described in [Common architectural events on page D7-2877](#) and [Common microarchitectural events on page D7-2884](#) are reserved. Future revisions of this Manual, or of the architecture, might assign these reserved values to additional common events. Events that do not require additional features in the PMU can be implemented retrospectively, meaning an implementation of a particular version of the PMU specification might support common events that are first defined in a later version of the PMU specification.

———— **Note** ————

- The requirement that an event that is implemented retrospectively *does not require additional features in the PMU* means that it must be possible to represent the event *n* the `PMEVTYPER<n>_EL0.evtCount` field. This means, for example, that an implementation with a 10-bit `PMEVTYPER<n>_EL0.evtCount` field can only implement events with event numbers 0x0000-0x03FF.
- This means that, for example, an Armv7 PMUv2 implementation, for which the `evtCount` field is 8 bits, can include support for any of the event numbers that are described in [Common architectural events on page D7-2877](#) and [Common microarchitectural events on page D7-2884](#) define in the range 0x00-0xFF.

Common architectural events

This section describes the use of the defined common architectural event numbers.

For the common features, normally the counters must increment only once for each event. The event descriptions include any exceptions to this rule.

In these definitions, the term *architecturally executed* means that the instruction flow is such that the counted instruction would have been executed in a [Simple sequential execution](#) model.

The events corresponding to the common architectural event numbers are:

0x0000, **SW_INCR**, **Instruction architecturally executed**, **Condition code check pass**, **software increment**

The counter increments on writes to the `PMSWINC` register.

If the PE performs two architecturally executed writes to the `PMSWINC` register without an intervening [Context synchronization event](#), then the counter is incremented twice.

If `PMEVTYPER<n>_EL0.evtCount` is set to 0x0000, then in AArch64 state, counts MSR writes to `PMSWINC_EL0` with bit `[n]` set to 1.

If the value of `PMEVTYPER<n>_EL0.MT` is 1 then, in a multithreaded implementation, this counts writes by all PEs that have the same [affinity](#) at level 1 and above.

0x0006, LD_RETIRED, **Instruction architecturally executed, Condition code check pass, load**

The counter increments for every executed memory-reading instruction.

———— **Note** —————

The counter 0x0006 does not count the return status value of a Store-Exclusive instruction.

Whether the preload instructions PRFM, PLD, PLDW, PLI, count as memory-reading instructions is IMPLEMENTATION DEFINED. Arm recommends that if the instruction is not implemented as a NOP then it is counted as a memory-reading instruction.

If **FEAT_MTE** is implemented, the counter increments for every executed Allocation tag load instruction.

0x0007, ST_RETIRED, **Instruction architecturally executed, Condition code check pass, store**

The counter increments for every executed memory-writing instruction.

DC ZVA is counted as a store.

The counter does not increment for a Store-Exclusive instruction that fails.

If **FEAT_MTE** is implemented, the counter increments for every executed Allocation tag store instruction.

0x0008, INST_RETIRED, **Instruction architecturally executed**

The counter increments for every architecturally executed instruction.

It is IMPLEMENTATION DEFINED whether the counter increments for the MOVPRFX instruction.

0x0009, EXC_TAKEN, **Exception taken**

The counter increments for each exception taken. See [Exception-related events on page D7-2865](#).

———— **Note** —————

The counter counts the PE exceptions described in:

- For exceptions taken to an Exception level using AArch64, [Exception entry on page D1-2475](#).
- For exceptions taken to an Exception level using AArch32, [AArch32 state exception descriptions on page G1-6078](#).

0x000A, EXC_RETURN, **Instruction architecturally executed, Condition code check pass, exception return**

The counter increments for each executed exception return instruction. See also [Exception-related events on page D7-2865](#). The following sections define the counted instructions:

- For an exception return from an Exception level using AArch64, [Exception return on page D1-2485](#).
- For an exception return from an Exception level using AArch32, [Exception return instructions on page G1-6065](#).

However, is CONSTRAINED UNPREDICTABLE whether this event counts the execution of an exception return instruction if either:

- Execution of the instruction is, itself, CONSTRAINED UNPREDICTABLE.

———— **Note** —————

Examples of when an exception return instruction is CONSTRAINED UNPREDICTABLE are if the instruction is executed at EL0, or in AArch32 state in System mode.

- Execution of the instruction sets **PSTATE**.IL and does not generate an exception return.

Note

A particular consequence of this CONSTRAINED UNPREDICTABLE behavior is that an implementation that does not support AArch32 state at EL1 or higher does not have to treat AArch32 MOVN, MOVN, LR instructions, and related instructions, as exception return instructions.

0x000B, CID_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR

The counter increments for every write to `CONTEXTIDR`. See [Exception-related events on page D7-2865](#).

If the PE performs two architecturally-executed writes to `CONTEXTIDR` without an intervening [Context synchronization event](#), it is CONSTRAINED UNPREDICTABLE whether the first write is counted.

When `FEAT_VHE` is implemented, the counter is:

- Incremented as a result of the retirement of an instruction accessing the named register `CONTEXTIDR_EL1`, even when executing at EL2.
- Not incremented as a result of the retirement of an instruction accessing the named register `CONTEXTIDR_EL12`.

Note

The event is defined by the name used to access the register. The counter does not count writes to the named register `CONTEXTIDR_EL2`.

0x000C, PC_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, software change of the PC

The counter increments for every [Software change of the PC](#).

The counter does not increment for exceptions other than those explicitly identified as a [Software change of the PC](#).

If `PC_WRITE_RETIRED` and `BR_SKIP_RETIRED` events are both implemented, the PE must have a consistent definition of [Software change of the PC](#) instructions. This means the definition must treat the following instructions in the same way for both events:

- BRK and BKPT instructions.
- An exception generated because an instruction is UNDEFINED.
- The exception-generating instructions, SVC, HVC, and SMC.
- Context synchronization barrier instructions.

From Armv8.6, when `BR_RETIRED` is also implemented, the PE must treat these instructions in the same way for `BR_RETIRED`, `PC_WRITE_RETIRED`, and `BR_SKIP_RETIRED`.

Note

Conditional branches are only counted if the branch is taken.

0x000D, BR_IMMED_RETIRED, Instruction architecturally executed, immediate branch

The counter counts all immediate branch instructions on the architecturally executed path.

In AArch32 state, the counter increments each time the PE executes one of the following instructions:

- B{<c>} <label>.
- BL{<c>} <label>.
- BLX{<c>} <label>.
- CBZ <Rn>, <label>.
- CBNZ <label>.

In AArch64 state, the counter increments each time the PE executes one of the following instructions:

- B <label>.
- B.cond <label>.
- BL <label>.
- CBZ <Rn>, <label>.
- CBNZ <Rn>, <label>.
- TBZ <Rn>, <label>.
- TBNZ <Rn>, <label>.

Note

Conditional branches are always counted, regardless of whether the branch is taken.

If an ISB is counted as a software change of the PC instruction, then it is IMPLEMENTATION DEFINED whether an ISB is counted as an immediate branch instruction.

0x000E, BR_RETURN_RETIRED, Instruction architecturally executed, Condition code check pass, procedure return

In AArch32 state, the counter counts the following procedure return instructions:

- BX R14.
- MOV PC, LR.
- POP {..., PC}.
- LDR PC, [SP], #offset.

Note

The counter counts only the listed instructions as procedure returns. For example, it does not count the following as procedure return instructions:

- BX R0, because Rm != R14.
- MOV PC, R0, because Rm != R14.
- LDM SP, {..., PC}, because writeback is not specified.
- LDR PC, [SP, #offset], because this specifies the wrong addressing mode.

In AArch64 state, the counter counts all architecturally executed RET, RETAA, and RETAB instructions.

0x000F, UNALIGNED_LDST_RETIRED, Instruction architecturally executed, Condition code check pass, unaligned load or store

The counter counts each memory-reading instruction or memory-writing instruction access that would generate an Alignment fault when Alignment fault checking is enabled.

The counter does not count accesses that would generate an SP alignment fault exception if the applicable stack pointer alignment check is enabled, unless that access would also generate an Alignment fault Data Abort exception if Alignment fault checking is enabled.

It is IMPLEMENTATION DEFINED whether this event counts accesses that generate an exception, including accesses that do generate Alignment fault Data Abort exceptions.

See *SP alignment checking* on page D1-2469 for more information.

See *Unaligned data access* on page E2-4312 for more information.

0x001C, TTBR_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to TTBR

The counter counts writes to **TTBR0_EL1** and **TTBR1_EL1** in AArch64 state and **TTBR0** and **TTBR1** in AArch32 state. When EL3 is implemented and using AArch32, this includes counting writes to both banked copies of **TTBR0** and **TTBR1**. See *Exception-related events* on page D7-2865.

If the PE executes two writes to the same **TTBR**, without an intervening *Context synchronization event*, it is CONstrained UNPREDICTABLE whether the first write to the **TTBR**, is counted.

If EL3 is implemented and using AArch64, the counter does not count writes to [TTBR0_EL3](#).

If EL2 is implemented and using AArch64, the counter does not count writes to [TTBR0_EL2](#) and to [VTTBR_EL2](#).

If EL2 is implemented and using AArch32, the counter does not count writes to [HTTBR](#) and to [VTTBR](#).

When FEAT_VHE is implemented, the counter is:

- Incremented as a result of the retirement of an instruction accessing the named registers [TTBR0_EL1](#) and [TTBR1_EL1](#).
- Not incremented as a result of the retirement of an instruction accessing the named registers [TTBR0_EL12](#) and [TTBR1_EL12](#).

0x001E, CHAIN

Even-numbered counters never increment as a result of this event. For an odd-numbered counter $n+1$, the odd-numbered event counter $n+1$ increments when an event increments the preceding even-numbered counter n on the same PE causing unsigned overflow of bits [31:0] of event counter n , and any of the following is true:

- [FEAT_PMUv3p5](#) is not implemented.
- EL2 is not implemented and [PMCR.LP](#) is set to 0.
- EL2 is implemented, $\langle n \rangle$ is less than [HDCR.HPMN](#) and [PMCR.LP](#) is set to 0.
- EL2 is implemented, $\langle n+1 \rangle$ is greater than or equal to [HDCR.HPMN](#) and [HDCR.HLP](#) is set to 0.

Otherwise, the odd-numbered event counter $n+1$ increments when an event increments the preceding even-numbered counter n on the same PE and causes an unsigned overflow of bits [31:0] of event counter n .

This means the CHAIN event can be used to link the odd-numbered counter with the preceding even-numbered counter to provide a 64-bit counter.

———— Note —————

When [FEAT_PMUv3p5](#) is not implemented, the CHAIN event can be used by software to provide N 32-bit counters, $N/2$ 64-bit counters, or a mixture of 32-bit counters and 64-bit counters.

The CHAIN event only counts overflows from the preceding even-numbered counter on the same PE. This means it is unaffected by the value of [PMEVTYPER<n>_EL0.MT](#).

To filter the Exception levels and Security states in which the event is counted, software must:

- Program [PMEVTYPER<n>_EL0](#) to count the event in the required conditions.
- Program [PMEVTYPER<n+1>_EL0](#) to count the CHAIN event in all Exception levels and states.

This allows, but does not require, hardware to ignore the filter settings for the CHAIN event and behave as if they are set to count in all Exception levels and states.

If software does not program the event in this way, the count becomes UNPREDICTABLE.

There is no atomic access to a pair of counters, so if software reads a counter-pair that is enabled, it must use a high-low-high read sequence, or employ reasonable heuristics, to avoid tearing.

Similarly, if using CHAIN events, when disabling the counters software must take care that the result is not torn by the low counter overflowing at the same time as the counters are disabled [Example D7-5 on page D7-2882](#) shows suitable sequences for disabling and enabling CHAIN counters.

Example D7-5 Usage examples for 64-bit counters

An example high-low-high read sequence for a 64-bit counter created by a pair of 32-bit counters paired by a CHAIN event is:

```
retry:
MRS W2, PMEVCNTR1_EL0    ;; read high counter, must be odd-numbered
ISB                       ;; force ordering
MRS W0, PMEVCNTR0_EL0    ;; read low counter
                           ;; must return the previous counter to PMEVCNTR1_EL0
ISB                       ;; force ordering
MRS W1, PMEVCNTR1_EL0    ;; read high counter
CMP W1, W2
BNE retry                 ;; if the high counter has changed, then retry
```

When disabling a pair of counters that are paired by a CHAIN event, software must:

1. Disable the low counter, by setting `PMCNTENCLR_EL0[n]` to 1.
2. Execute an ISB instruction, or perform another *Context synchronization event*.
3. Disable the high counter, by setting `PMCNTENCLR_EL0[n+1]` to 1, or setting `PMCR_EL0.E` to 0.

When enabling a pair of counters that are paired by a CHAIN event, software must:

1. Enable the high counter, by setting `PMCNTENSET_EL0[n+1]` to 1 and, if necessary, setting `PMCR_EL0.E` to 1.
2. Execute an ISB instruction, or perform another *Context synchronization event*.
3. Enable the low counter by setting `PMCNTENSET_EL0[n]` to 1.

When using 64-bit counters created by a pair of 32-bit counters paired by a CHAIN event, the architecture does not define the latency between the first counter overflowing and the second counter incrementing the CHAIN event. There is no requirement for updates to occur synchronously, but software reading or enabling the counter pair using a *low-ISB-high* sequence, as shown in [Example D7-5 on page D7-2882](#), must not observe the low counter incrementing and overflowing for the event and the high counter not incrementing for the resulting CHAIN event. This means that the ISB executed after reading the low counter must ensure the completion of the update of the high counter by the CHAIN event.

`0x0021`, **BR_RETIRED**, **Instruction architecturally executed**, **branch**

The counter counts all branches on the architecturally executed path that would incur cost if mispredicted.

Counts all branch instructions, memory-reading and data-processing instructions that explicitly write to the PC, at retirement.

———— **Note** ————

Conditional branches are always counted, whether the branch is taken or not taken.

It is IMPLEMENTATION DEFINED whether this includes each of:

- Unconditional direct branch instructions. Arm recommends these are included.
- Exception-generating instructions.
- Exception return instructions. Arm recommends these are included.
- Context synchronization instructions.

From Armv8.6, when `PC_WRITE_RETIRED` and `BR_RETIRED` are both implemented, the PE must treat the following types of instruction in the same way for both events:

- BRK and BKPT instructions.
- UNDEFINED instructions.
- The exception-generating instructions, SVC, HVC, and SMC.

- Context synchronization barrier instructions.

0x8000, SIMD_INST_RETIRED, SIMD Instruction architecturally executed

The counter counts the following architecturally executed SIMD instructions:

- SVE instructions, but not [non-SIMD SVE instructions](#).
- Advanced SIMD instructions, but not Advanced SIMD scalar instructions.

0x8001, ASE_INST_RETIRED, Advanced SIMD Instruction architecturally executed

The counter counts architecturally executed Advanced SIMD instructions. It is IMPLEMENTATION DEFINED whether this event counts Advanced SIMD scalar instructions.

0x8002, SVE_INST_RETIRED, Instruction architecturally executed, SVE

The counter counts architecturally executed SVE instructions. It is IMPLEMENTATION DEFINED whether this event counts [non-SIMD SVE instructions](#).

0x8003, ASE_SVE_INST_RETIRED, Advanced SIMD and SVE Instruction architecturally executed

The counter counts architecturally executed instructions that are counted by [ASE_INST_RETIRED](#) or [SVE_INST_RETIRED](#).

0x8107, BR_SKIP_RETIRED, Instruction architecturally executed, branch not taken

The counter counts the each conditional [Software change of the PC](#) instruction, on the architecturally executed path, that is not taken.

———— **Note** —————

Many of these instructions can only be conditional in the AArch32 instruction sets.

The counter does not increment for exceptions not listed as a [Software change of the PC](#).

If [PC_WRITE_RETIRED](#) and [BR_SKIP_RETIRED](#) events are both implemented, the PE must have a consistent definition of [Software change of the PC](#) instructions. This means the definition must treat the following instructions in the same way for both events:

- BRK and BKPT instructions.
- UNDEFINED instructions.
- The exception-generating instructions, SVC, HVC, and SMC.
- Context synchronization barrier instructions.

From Armv8.6, when the [BR_RETIRED](#) event is implemented, the PE must treat these instructions in the same way for the [BR_RETIRED](#) event.

0x8108, BR_IMMED_TAKEN_RETIRED, Instruction architecturally executed, immediate branch taken

The counter counts the instructions, on the architecturally executed path, counted by both [BR_IMMED_RETIRED](#) and [PC_WRITE_RETIRED](#). These are all immediate branch instructions where the branch is taken.

0x8109, BR_IMMED_SKIP_RETIRED, Instruction architecturally executed, immediate branch not taken

The counter counts the instructions on the architecturally executed path, counted by both [BR_IMMED_RETIRED](#), and [BR_SKIP_RETIRED](#). These are all immediate branch instructions where the branch is not taken.

0x810A, BR_IND_TAKEN_RETIRED, Instruction architecturally executed, indirect branch taken

The counter counts the instructions, on the architecturally executed path, counted by both [BR_IND_RETIRED](#) and [PC_WRITE_RETIRED](#). These are branch instructions where the branch is taken, but do not include immediate instructions.

A64 does not include conditional indirect branches. If AArch32 is not supported at any Exception level, this event is not implemented because [BR_IND_RETIRED](#) counts the same events.

0x810B, BR_IND_SKIP_RETIRED, Instruction architecturally executed, indirect branch not taken

The counter counts the instructions on the architecturally executed path, counted by both [BR_IND_RETIRED](#), and [BR_SKIP_RETIRED](#). These are branch instructions, where the branch is not taken, but do not include immediate instructions.

A64 does not include conditional indirect branches. If AArch32 is not supported at any Exception level, this event is not implemented.

0x810C, BR_INDNR_TAKEN_RETIRED, Instruction architecturally executed, indirect branch taken excluding returns

The counter counts the instructions, on the architecturally executed path, counted by both [BR_IND_RETIRED](#) and [PC_WRITE_RETIRED](#), but not [BR_RETURN_RETIRED](#). These are branch instructions, where the branch is taken, but do not include returns or immediate instructions.

0x810D, BR_INDNR_SKIP_RETIRED, Instruction architecturally executed, indirect branch not taken excluding returns

The counter counts the instructions, on the architecturally executed path, counted by both [BR_INDNR_RETIRED](#) and [BR_SKIP_RETIRED](#). These are branch instructions, where the branch is not taken, but do not include returns or immediate instructions.

A64 does not include conditional indirect branches. If AArch32 is not supported at any Exception level, this event is not implemented.

0x810E, BR_RETURN_ANY_RETIRED, Instruction architecturally executed, procedure return

The counter counts the instructions counted on the architecturally executed path by [BR_IND_RETIRED](#) where, if taken, the branch would be counted by [BR_RETURN_RETIRED](#).

A64 does not include conditional indirect branches. If AArch32 is not supported at any Exception level, this event is not implemented, because [BR_RETURN_RETIRED](#) counts the same events.

0x810F, BR_RETURN_SKIP_RETIRED, Instruction architecturally executed, procedure return not taken

The counter counts the instructions on the architecturally executed path, counted by both [BR_RETURN_ANY_RETIRED](#) and [BR_SKIP_RETIRED](#). These are branch return instructions, where the branch is not taken.

A64 does not include conditional indirect branches. If AArch32 is not supported at any Exception level, this event is not implemented.

0x811D, BR_IND_RETIRED, Instruction architecturally executed, indirect branch

The counter counts each [Software change of the PC](#) on the architecturally executed path that is not counted by [BR_IMMED_RETIRED](#). These are all branch instructions that are not immediate branch instructions.

———— **Note** —————

Conditional branches are always counted, whether the branch is taken or not taken.

0x811E, BR_INDNR_RETIRED, Instruction architecturally executed, indirect branch excluding procedure return

The counter counts the instructions on the architecturally executed path counted by [BR_IND_RETIRED](#), but not counted by [BR_RETURN_ANY_RETIRED](#). These are branch instructions but do not include returns or immediate instructions.

If AArch32 is not supported at any Exception level, this event is not implemented, because [BR_INDNR_TAKEN_RETIRED](#) counts the same events.

Common microarchitectural events

This section describes the use of the defined common microarchitectural event numbers.

The common microarchitectural events are features that are likely to be implemented across a wide range of implementations. Unlike the common architectural events, there can be some IMPLEMENTATION DEFINED variation between definitions on different implementations.

Unless otherwise stated, the common microarchitectural features relate only to events resulting from the operation of the PE counting the events. Events resulting from the operation of other PEs that might share a resource must not be counted. Where a resource can be subject to events that do not result from the operation of any of the PEs that share it, Arm recommends that the resource implements its own event counters. An example of a resource that might require its own event counters is a shared Level 2 cache that is subject to accesses from a system coherency port on that cache.

The event definitions relating to Level 2 caches generally assume the Level 2 cache is shared. The event definitions relating to Level 1 caches generally assume the Level 1 cache is not shared.

The events corresponding to the common microarchitectural event numbers are:

0x0001, L1I_CACHE_REFILL, Level 1 instruction cache refill

The counter counts each access counted by [L1I_CACHE](#) that causes a refill of any of the Level 1 caches outside the Level 1 caches of this PE.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted. If [FEAT_PMUv3p4](#) is not implemented, the counter does not count cache maintenance instructions. If [FEAT_PMUv3p4](#) is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x0002, L1I_TLB_REFILL, Level 1 instruction TLB refill

The counter counts each [Instruction memory access](#) counted by [L1I_TLB](#) that causes a TLB refill of the Level 1 instruction TLB. This includes an access that causes memory system accesses due to a translation table walk or an access to another TLB level.

The counter does not count an access if any of the following are true:

- [FEAT_E0PD](#) is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- The access is due to a TLB maintenance instruction.
- The access misses in the TLB and generates a translation table walk but does not cause a refill of the TLB.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A refill for any other reason that results in a Translation fault, other than for those cases where the event must not be counted.
- A refill that is not allocated in the TLB.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x0003, L1D_CACHE_REFILL, Level 1 data cache refill

The counter counts each access counted by [L1D_CACHE](#) that causes a refill of at least the Level 1 data or unified cache from outside the Level 1 cache. Each access to a cache line that causes a new linefill is counted, including those from instructions that generate multiple accesses, such as load or store multiples, and PUSH and POP instructions. In particular, the counter counts accesses to the Level 1 cache that cause a refill that is satisfied by another Level 1 data or unified cache, or a Level 2 cache, or memory.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count:

- A miss that does not cause a new refill but is satisfied by the refill of a previous miss, even if that previous refill is not complete at the time of the miss.
- A miss that does not generate a refill, such as a write through the cache.
- If `FEAT_PMUv3p4` is not implemented, cache maintenance instructions.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted. If `FEAT_PMUv3p4` is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x0004, `L1D_CACHE`, Level 1 data cache access

The counter counts each [Memory-read operation](#) or [Memory-write operation](#) that causes a cache access to at least the Level 1 data or unified cache.

Each cache line access is counted, including multiple accesses caused by single instructions, such as LDM and STM. Accesses to other level 1 data or unified cache structures, such as refill buffers, write buffers, and write-back buffers, are also counted.

If `FEAT_PMUv3p4` is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted. An example of cache status information is whether the cached data is held in an exclusive or shared state.

If `FEAT_PMUv3p4` is not implemented, it is IMPLEMENTATION DEFINED whether updates to cache status information are counted.

If `FEAT_PMUv3p4` is implemented, it is IMPLEMENTATION DEFINED whether accesses caused by cache maintenance instructions are counted.

If `FEAT_PMUv3p4` is not implemented, the counter does not count cache maintenance instructions.

When the `L1D_CACHE_PRFM` and `L1D_CACHE_RW` events are implemented, accesses to the Level 1 data or unified cache due to a preload or prefetch instruction are counted. Otherwise, it is IMPLEMENTATION DEFINED whether accesses to the Level 1 data or unified cache due to a preload or prefetch instruction are counted.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0005, `L1D_TLB_REFILL`, Level 1 data or unified TLB refill

The counter counts each access counted by `L1D_TLB` that causes a TLB refill of the Level 1 data or unified TLB. This includes an access that causes memory system accesses due to a translation table walk or an access to another TLB level.

The counter does not count an access if any of the following are true:

- `FEAT_EOPD` is implemented and the access is an unprivileged access that generates a Translation fault because the applicable `TCR_ELx.EOPDy` bit is 1.
- `FEAT_SVE` is implemented and the access is a non-fault access that fails because the applicable `TCR_ELx.NFDy` bit is 1.
- The access generates a Translation fault because the applicable `TCR_ELx.EPDy` bit is 1.
- The access is due to a TLB maintenance instruction.
- The access misses in the TLB and generates a translation table walk but does not cause a refill of the TLB.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A refill for any other reason that results in a Translation fault, other than for those cases where the event must not be counted.
- A refill that is not allocated in the TLB.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

See also:

- [Attributability](#) on page D7-2857.
- [Meaningful ratios between common microarchitectural events](#) on page D7-2937.

0x0010, BR_MIS_PRED, Mispredicted or not predicted branch [Speculatively executed](#)

The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources and that relates to instructions that the branch prediction resources are capable of predicting.

If no program-flow prediction resources are implemented, Arm recommends that the counter counts all branches that are not taken.

0x0011, CPU_CYCLES, Cycle

The counter increments on every cycle.

All counters are subject to changes in clock frequency. It is CONSTRAINED UNPREDICTABLE whether or not CPU_CYCLES continues to increment when the PE is in WFI or WFE state.

————— **Note** —————

Unlike [PMCCNTR](#), this count is not affected by [PMCR.DP](#), [PMCR.D](#), [PMCR.C](#), [SDCR.SCCD](#) or [HDCR.HCCD](#):

- The counter is not incremented in prohibited regions, so is not affected by [PMCR.DP](#).
- The counter increments on every cycle, regardless of the setting of [PMCR.D](#).
- The counter is reset when event counters are reset by [PMCR.P](#), never by [PMCR.C](#).
- The counter is not disabled when [FEAT_PMUv3p5](#) is implemented, EL3 is implemented, the PE is in Secure state, and [SDCR.SCCD](#) is set to 1.
- The counter is not disabled when [FEAT_PMUv3p5](#) is implemented, EL2 is implemented, the PE is executing at EL2, and [HDCR.HCCD](#) is set to 1.

In a multithreaded implementation, CPU_CYCLES counts each cycle for the processor for which this PE thread is active and can issue an instruction. For more information, see [Cycle event counting](#) on page D7-2936.

0x0012, BR_PRED, Predictable branch [Speculatively executed](#)

The counter counts every branch or other change in the program flow that the branch prediction resources are capable of predicting.

If all branches are subject to prediction, for example a BTB or BTAC, then all branches are predictable branches.

If branches are decoded before the predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is IMPLEMENTATION DEFINED whether other branches are counted as predictable branches. Arm recommends that all branches are counted.

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by [BR_MIS_PRED](#).

If no program-flow prediction resources are implemented, this event is optional, but Arm recommends that BR_PRED counts all branches.

0x0013, MEM_ACCESS, Data memory access

The counter counts [Memory-read operations](#) and [Memory-write operations](#) that the PE made. The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these.

The counter does not increment as a result of:

- Instruction memory accesses, see [Definition of terms on page D7-2869](#).
- Translation table walks.
- Write-back from any cache.
- Refilling of any cache.

The number of accesses generated by each instruction is IMPLEMENTATION DEFINED.

If [FEAT_PMUv3p4](#) is not implemented, the counter does not count cache maintenance instructions. If [FEAT_PMUv3p4](#) is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

0x0014, L1I_CACHE, Level 1 instruction cache access

The counter counts each [Instruction memory access](#) to at least the Level 1 instruction cache.

Each access to other Level 1 instruction memory structures, such as refill buffers, is also counted.

If [FEAT_PMUv3p4](#) is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted. An example of cache status information is whether the cached data is held in an exclusive or shared state.

If [FEAT_PMUv3p4](#) is not implemented, it is IMPLEMENTATION DEFINED whether updates to cache status information are counted.

When the [L1I_CACHE_PRFM](#) and [L1I_CACHE_RD](#) events are implemented, accesses to the Level 1 instruction cache due to a preload or prefetch instruction are counted. Otherwise, it is IMPLEMENTATION DEFINED whether accesses to the Level 1 instruction cache due to a preload or prefetch instruction are counted.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0015, L1D_CACHE_WB, Attributable Level 1 data cache write-back

The counter counts every write-back of data from the Level 1 data or unified cache. The counter counts each write-back that causes data to be written from the Level 1 cache to outside of the Level 1 cache. For example, the counter counts the following cases:

- A write-back that causes data to be written to a Level 2 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 1 cache.
- Transfer of data from the Level 1 cache to outside of this cache made as a result of a coherency request. The conditions determining which of these are counted for transfers to other Level 1 caches within the same multiprocessor cluster are IMPLEMENTATION DEFINED.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

Whether write-backs made as a result of cache maintenance instructions are counted is IMPLEMENTATION DEFINED.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 2 cache or memory.
- Writes from the PE that write through the Level 1 cache to outside of the Level 1 cache.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted. See [Attributability on page D7-2857](#).

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also [Attributability on page D7-2857](#).

0x0016, L2D_CACHE, Level 2 data cache access

The counter counts each [Memory-read operation](#) or [Memory-write operation](#) that causes a cache access to at least the Level 2 data or unified cache.

Each cache line access is counted, including multiple accesses caused by single instructions, such as LDM and STM. Accesses to other level 2 data or unified cache structures, such as refill buffers, write buffers, and write-back buffers, are also counted.

If [FEAT_PMUv3p4](#) is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted. An example of cache status information is whether the cached data is held in an exclusive or shared state.

If [FEAT_PMUv3p4](#) is not implemented, it is IMPLEMENTATION DEFINED whether updates to cache status information are counted.

If [FEAT_PMUv3p4](#) is implemented, it is IMPLEMENTATION DEFINED whether accesses caused by cache maintenance instructions are counted.

If [FEAT_PMUv3p4](#) is not implemented, the counter does not count cache maintenance instructions.

When the [L2D_CACHE_PRFM](#) and [L2D_CACHE_RW](#) events are implemented, accesses to the Level 2 data or unified cache due to a preload or prefetch instruction, or a prefetch to another cache, are counted. Otherwise, it is IMPLEMENTATION DEFINED whether accesses to the Level 2 data or unified cache due to a preload or prefetch instruction, or a prefetch to another cache, are counted.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0017, L2D_CACHE_REFILL, Level 2 data cache refill

The counter counts each access counted by [L2D_CACHE](#) that causes a refill of a refill of any of the Level 1 or Level 2 caches from outside the Level 1 and Level 2 caches of the PE.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 cache that cause a refill that is satisfied by another Level 2 cache, a Level 3 cache, or memory.
- Refills of and write-backs from any Level 1 data, instruction or unified cache that cause a refill from outside the Level 1 and Level 2 caches.
- Accesses to the Level 2 cache that cause a refill of a Level 1 cache from outside of the Level 1 and Level 2 caches, even if there is no refill of the Level 2 cache.

The counter does not count, as events on this PE:

- A miss that does not cause a new refill but is satisfied by the refill of a previous miss, even if that previous refill is not complete at the time of the miss.
- A miss that does not generate a refill, such as a write through the cache.
- If [FEAT_PMUv3p4](#) is not implemented, cache maintenance instructions.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted. If [FEAT_PMUv3p4](#) is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x0018, L2D_CACHE_WB, Attributable Level 2 data cache write-back

The counter counts every write-back of data from the Level 2 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 2 cache to outside the Level 1 and Level 2 caches. For example, the counter counts:

- A write-back that causes data to be written to a Level 3 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 2 cache.

Each write-back is counted once, even if it requires multiple accesses to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of data from the Level 2 cache to outside the Level 1 and Level 2 cache made as a result of a coherency request.
- Write-backs made as a result of Cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 3 cache or memory.
- Writes from the PE or Level 1 data or unified cache that write through the Level 2 cache to outside the Level 1 and Level 2 caches.
- Transfers of data from the Level 2 cache to a Level 1 cache, to satisfy a Level 1 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also [Attributability on page D7-2857](#).

0x0019, BUS_ACCESS, Attributable Bus access

The counter counts [Memory-read operations](#) and [Memory-write operations](#) that access outside of the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

The definition of a bus access is IMPLEMENTATION DEFINED but physically is a single beat rather than a burst. That is, for each bus cycle for which the bus is active.

Bus accesses include refills of and write-backs from data, instruction, and unified caches. Whether bus accesses include operations that do use the bus but not explicitly transfer data is IMPLEMENTATION DEFINED.

An Unattributable bus access occurs when a requestor outside the PE makes a request that results in a bus access, for example, a coherency request. If the bus is shared, then an Unattributable bus access is not counted. If the bus is not shared, then the event is counted.

If the bus is shared, then only Attributable bus accesses are counted. If the bus is not shared, then all bus accesses are counted.

Where an implementation has multiple buses at this boundary, this event counts the sum of accesses across all buses.

If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments once for each channel that is active on a cycle, and so it might increment by more than one in any given cycle.

The maximum increment in any given cycle is implementation defined.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x001A, MEMORY_ERROR, Local memory error

The counter counts every occurrence of a memory error signaled by a memory closely coupled to this PE. The definition of local memories is IMPLEMENTATION DEFINED but includes caches, tightly-coupled memories, and TLB arrays.

Memory error refers to a physical error detected by the hardware, such as a parity or ECC error. It includes errors that are correctable and those that are not. It does not include errors as defined in the architecture, such as MMU faults.

0x001B, INST_SPEC, Operation Speculatively executed

The counter counts [Speculatively executed](#) operations. The definition of [Speculatively executed](#) is IMPLEMENTATION DEFINED.

0x001D, BUS_CYCLES, Bus cycle

The counter increments on every cycle of the interface at the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

———— **Note** ————

If the implementation clocks the external memory interface at the same rate as the processor hardware, the counter counts every cycle.

See also [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x001F, L1D_CACHE_ALLOCATE, Level 1 data cache allocation without refill

The counter counts each cache line allocation in the Level 1 data or unified cache that is not a refill counted by [L1D_CACHE_REFILL](#) or [L1D_CACHE_HWPRF](#). The counter increments on every [Attributable](#) write that writes an entire line into the Level 1 cache without fetching from outside the Level 1 cache, for example:

- A write of an entire cache line from a PE coalescing write buffer.
- A DC ZVA operation executed by a PE.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0020, L2D_CACHE_ALLOCATE, Level 2 data cache allocation without refill

The counter counts each cache line allocation in the Level 2 data or unified cache that is not a refill counted by [L2D_CACHE_REFILL](#) or [L2D_CACHE_HWPRF](#). The counter increments on every [Attributable](#) write that writes an entire line into the Level 2 cache without fetching from outside the Level 1 or Level 2 caches, for example:

- A write-back of an entire cache line from another cache.
- A write of an entire cache line from a PE coalescing write buffer.
- A DC ZVA operation executed by a PE.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0022, BR_MIS_PRED_RETIRE, Instruction architecturally executed, mispredicted branch

The counter counts all instructions counted by [BR_RETIRE](#) that were not correctly predicted.

If no program-flow prediction resources are implemented, this event counts all retired not-taken branches.

0x0023, STALL_FRONTEND, No operation issued due to the frontend

The counter counts every cycle counted by the [CPU_CYCLES](#) event on which no operation was issued because there are no operations available to issue for this PE from the frontend.

The division between frontend and backend is IMPLEMENTATION DEFINED. [STALL](#), [STALL_FRONTEND](#), and [STALL_BACKEND](#) events must count at the same point in the pipeline.

———— **Note** ————

- For a simplified pipeline model of Fetch → Decode → Issue → Execute → Retire, Arm recommends that the events are counted when instructions are dispatched from Decode to Issue.
- On a given cycle, both events might be counted if the backend is unable to accept any operations and there are no operations available to issue from the frontend.

For more information, see [Cycle event counting on page D7-2936](#).

0x0024, STALL_BACKEND, No operation issued due to the backend

The counter counts every cycle counted by the [CPU_CYCLES](#) event on which no operation was issued because either:

- The backend is unable to accept any of the operations available for issue for this PE.
- The backend is unable to accept any operations.

For example, the backend might be unable to accept operations because of a resource conflict or non-availability.

The division between frontend and backend is IMPLEMENTATION DEFINED. [STALL](#), [STALL_FRONTEND](#), and [STALL_BACKEND](#) events must count at the same point in the pipeline. See [STALL_FRONTEND](#) for more information.

For more information, see [Cycle event counting on page D7-2936](#).

0x0025, L1D_TLB, Level 1 data or unified TLB access

The counter counts each [Memory-read operation](#) or [Memory-write operation](#) that causes a TLB access to at least the Level 1 data or unified TLB. Each access to a TLB entry is counted, including multiple accesses caused by single instructions, such as LDM or STM.

The counter does not count TLB maintenance instructions.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0026, L1I_TLB, Level 1 instruction TLB access

The counter counts each [Instruction memory access](#) that causes a TLB access to at least the Level 1 instruction TLB.

The counter does not count TLB maintenance instructions.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0027, L2I_CACHE, Level 2 instruction cache access

The counter counts each [Instruction memory access](#) to at least the Level 2 instruction cache.

Each access to other Level 2 instruction memory structures, such as refill buffers, is also counted.

If [FEAT_PMUv3p4](#) is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted. An example of cache status information is whether the cached data is held in an exclusive or shared state.

If [FEAT_PMUv3p4](#) is not implemented, it is IMPLEMENTATION DEFINED whether updates to cache status information are counted.

When the [L2I_CACHE_PRFM](#) and [L2I_CACHE_RD](#) events are implemented, accesses to the Level 2 instruction cache due to a preload or prefetch instruction, or a prefetch to another cache, are counted. Otherwise, it is IMPLEMENTATION DEFINED whether accesses to the Level 2 instruction cache due to a preload or prefetch instruction, or a prefetch to another cache, are counted.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0028, L2I_CACHE_REFILL, [Attributable](#) Level 2 instruction cache refill

The counter counts each access counted by [L2I_CACHE](#) that causes a refill of any of the Level 1 or 2 caches outside the Level 1 or 2 caches of this PE.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted. If [FEAT_PMUv3p4](#) is not implemented, the counter does not count cache maintenance instructions. If [FEAT_PMUv3p4](#) is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x0029, L3D_CACHE_ALLOCATE, Level 3 data cache allocation without refill

The counter counts each cache line allocation in the Level 3 data or unified cache that is not a refill counted by [L3D_CACHE_REFILL](#) or [L3D_CACHE_HWPRF](#). The counter increments on every [Attributable](#) write that writes an entire line into the Level 3 cache without fetching from outside the Level 1, Level 2, or Level 3 cache, for example:

- A write-back of an entire cache line from another cache.
- A write of an entire cache line from a PE coalescing write buffer.
- A DC ZVA operation executed by a PE.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x002A, L3D_CACHE_REFILL, [Attributable](#) Level 3 data cache refill

The counter counts each access counted by [L3D_CACHE](#) which causes a refill of any of the Level 1, Level 2, or Level 3 caches from outside the Level 1, Level 2, and Level 3 caches.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count as events on this PE:

- A miss that does not cause a new refill but is satisfied by the refill of a previous miss, even if that previous refill is not complete at the time of the miss.
- A miss that does not generate a refill, such as a write through the cache.
- If [FEAT_PMUv3p4](#) is not implemented, cache maintenance instructions.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted. If [FEAT_PMUv3p4](#) is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x002B, L3D_CACHE, Level 3 data cache access

The counter counts each [Memory-read operation](#) or [Memory-write operation](#) that causes a cache access to at least the Level 3 data or unified cache.

Each cache line access is counted, including multiple accesses caused by single instructions, such as LDM and STM. Accesses to other level 3 data or unified cache structures, such as refill buffers, write buffers, and write-back buffers, are also counted.

If [FEAT_PMUv3p4](#) is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted. An example of cache status information is whether the cached data is held in an exclusive or shared state.

If [FEAT_PMUv3p4](#) is not implemented, it is IMPLEMENTATION DEFINED whether updates to cache status information are counted.

If [FEAT_PMUv3p4](#) is implemented, it is IMPLEMENTATION DEFINED whether accesses caused by cache maintenance instructions are counted.

If [FEAT_PMUv3p4](#) is not implemented, the counter does not count cache maintenance instructions.

When the [L3D_CACHE_PRFM](#) and [L3D_CACHE_RW](#) events are implemented, accesses to the Level 3 data or unified cache due to a preload or prefetch instruction, or a prefetch to another cache, are counted. Otherwise, it is IMPLEMENTATION DEFINED whether accesses to the Level 3 data or unified cache due to a preload or prefetch instruction, or a prefetch to another cache, are counted.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x002C, L3D_CACHE_WB, Attributable Level 3 data cache write-back

The counter counts every write-back of data from the Level 3 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 3 cache to outside of the Level 1, Level 2, and Level 3 caches. For example, the counter counts the following cases:

- A write-back that causes data to be written to a Level 4 cache, or to memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 3 cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of data from the Level 3 cache to outside the Level 1, Level 2, and Level 3 caches made as a result of a coherency request.
- A write-back made as a result of a Cache maintenance instruction.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 4 cache or memory.
- Writes from the PE, Level 1, or Level 2 data or unified cache, that write through the Level 3 cache to outside of the Level 3 cache.
- Transfers of data from the Level 3 cache to a Level 1 or Level 2 cache, to satisfy a Level 1 or Level 2 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then Unattributable write-back events are not counted. If the cache is not shared, then Unattributable write-back events are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also [Attributability on page D7-2857](#).

0x002D, L2D_TLB_REFILL, Level 2 data or unified TLB refill

The counter counts each access counted by [L2D_TLB](#) that causes a TLB refill of any of the Level 1 to Level 2 data or unified TLB. This includes an access that causes memory system accesses due to a translation table walk or an access to another TLB level.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A refill that results in a Translation fault, other than for those cases where the event must not be counted.

- A refill that is not allocated in the TLB.

The counter does not count an access if any of the following are true:

- [FEAT_E0PD](#) is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.
- [FEAT_SVE](#) is implemented and the access is a non-fault access that fails because the applicable [TCR_ELx.NFDy](#) bit is 1.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- The access is due to a TLB maintenance instruction.
- The access misses in the TLB and generates a translation table walk but does not cause a refill of the TLB.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x002E, L2I_TLB_REFILL, Level 2 instruction TLB refill

The counter counts each access counted by [L2I_TLB](#) that causes a TLB refill of any of the Level 1 to Level 2 instruction TLBs. This includes an access that causes memory system accesses due to a translation table walk or an access to another TLB level.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A refill that results in a Translation fault, other than for those cases where the event must not be counted.
- A refill that is not allocated in the TLB.

The counter does not count an access if any of the following are true:

- [FEAT_E0PD](#) is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- The access is due to a TLB maintenance instruction.
- The access misses in the TLB and generates a translation table walk but does not cause a refill of the TLB.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x002F, L2D_TLB, Level 2 data or unified TLB access

The counter counts each memory read operation or memory write operation that causes a TLB access to at least the Level 2 data or unified TLB. Each access to a TLB entry is counted, including multiple accesses caused by single instructions, such as LDM or STM.

The counter does not count TLB maintenance instructions.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0030, L2I_TLB, Level 2 instruction TLB access

The counter counts each [Instruction memory access](#) that causes a TLB access to at least the Level 2 instruction TLB.

The counter does not count TLB maintenance instructions.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0031, REMOTE_ACCESS, Access to another socket in a multi-socket system

The counter counts each [Attributable](#) memory read operation or memory write operation that causes an access to another socket in a multi-socket system.

It is IMPLEMENTATION DEFINED whether an access that causes a snoop into another socket but does not return data from or pass data to the remote socket is counted.

See also [Attributability on page D7-2857](#).

0x0032, LL_CACHE, Last Level cache access

The counter counts each [Memory-read operation](#) or [Memory-write operation](#) that causes a cache access to at least the Last Level data or unified cache.

Each cache line access is counted, including multiple accesses caused by single instructions, such as LDM and STM. Accesses to other last level data or unified cache structures, such as refill buffers, write buffers, and write-back buffers, are also counted.

If [FEAT_PMUv3p4](#) is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted. An example of cache status information is whether the cached data is held in an exclusive or shared state.

If [FEAT_PMUv3p4](#) is not implemented, it is IMPLEMENTATION DEFINED whether updates to cache status information are counted.

If [FEAT_PMUv3p4](#) is implemented, it is IMPLEMENTATION DEFINED whether accesses caused by cache maintenance instructions are counted.

If [FEAT_PMUv3p4](#) is not implemented, the counter does not count cache maintenance instructions.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x0033, LL_CACHE_MISS, Last Level cache miss

The Counter counts each [Attributable](#) [Memory-read operation](#) or [Memory-write operation](#) that causes a cache access to at least the Last Level data or unified cache, but is not completed by the Last Level cache. That is, either of the following:

- A memory read operation that does not return data from the Last Level cache.
- A memory write operation that does not update the Last Level cache.

The counter does not count operations that are completed by a cache above the Last Level cache.

If [FEAT_PMUv3p4](#) is not implemented, the counter does not count cache maintenance instructions.

If [FEAT_PMUv3p4](#) is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x0034, DTLB_WALK, Access to data or unified TLB causes a translation table walk

The counter counts each access counted by [L1D_TLB](#) that causes a refill of a data or unified TLB involving at least one translation table walk access. This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

If Armv8.7 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that cause a translation table entry update involving at least one translation table walk access and update an existing TLB entry are counted. If Armv8.7 is implemented, these accesses are counted.

The counter does not count if any of the following are true:

- The access is due to a TLB maintenance instruction.
- [FEAT_E0PD](#) is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.

- **FEAT_SVE** is implemented and the access is a non-fault access that fails because the applicable **TCR_ELx.NFDy** bit is 1.
- The access generates a Translation fault because the applicable **TCR_ELx.EPDy** bit is 1.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x0035, **ITLB_WALK**, Access to instruction TLB that causes a translation table walk

The counter counts each access counted by **L1I_TLB** that causes a refill of an instruction TLB, involving at least one translation table walk access. This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

If Armv8.7 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that cause a translation table entry update involving at least one translation table walk access and update an existing TLB entry are counted. If Armv8.7 is implemented, these accesses are counted.

The counter does not count if any of the following are true:

- The access is due to a TLB maintenance instruction.
- **FEAT_E0PD** is implemented and the access is an unprivileged access that generates a Translation fault because the applicable **TCR_ELx.E0PDy** bit is 1.
- The access generates a Translation fault because the applicable **TCR_ELx.EPDy** bit is 1.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x0036, **LL_CACHE_RD**, Last level data cache access, read

The counter counts each access counted by **LL_CACHE** that is a [Memory-read operation](#).

If **FEAT_PMUv3p4** is not implemented, the counter does not count cache maintenance instructions. If **FEAT_PMUv3p4** is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x0037, **LL_CACHE_MISS_RD**, Last level cache miss, read

As **LL_CACHE_MISS**, but counts only memory read operations.

If **FEAT_PMUv3p4** is not implemented, the counter does not count cache maintenance instructions. If **FEAT_PMUv3p4** is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

See also:

- [Attributability on page D7-2857](#).
- [Meaningful ratios between common microarchitectural events on page D7-2937](#).

0x0038, **REMOTE_ACCESS_RD**, Access to another socket in a multi-socket system, read

As **REMOTE_ACCESS**, but counts only memory read operations.

See also:

- [Attributability on page D7-2857](#).

- [Meaningful ratios between common microarchitectural events on page D7-2937.](#)

0x0039, L1D_CACHE_LMISS_RD, Level 1 data cache long-latency read miss

The counter counts each memory read access counted by [L1D_CACHE](#) that incurs additional latency because it returns data from outside the Level 1 data or unified cache of this PE.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted. It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

The event indicates to software that the access missed in the Level 1 data or unified cache and might have a significant performance impact compared to the latency of an access that hits in the Level 1 data or unified cache.

This counter does not count:

- Access where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared against a miss in all Level 1 caches that the access looks up in that results in an access being made to a Level 2 cache or elsewhere beyond the Level 1 data and unified cache.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency nor to track the access to determine whether the additional latency had a performance impact. An implementation can extend the definition of this event with additional scenarios where a memory read access counted by [L1D_CACHE](#) might have a significant performance impact due to additional latency for the address.

See also [Attributability on page D7-2857.](#)

0x003A, OP_RETIRED, Micro-operation architecturally executed

The counter counts each operation counted by [OP_SPEC](#) that would be executed in a [Simple sequential execution](#) of the program.

0x003B, OP_SPEC, Micro-operation Speculatively executed

The counter counts the number of operations executed by the PE, including those that are executed speculatively and would not be executed in a [Simple sequential execution](#) of the program.

0x003C, STALL, No operation sent for execution

The counter counts every [Attributable](#) cycle on which no [Attributable](#) instruction or operation was sent for execution on this PE.

If the PMU supports multi-threading:

- When [PMEVTYPER<n>_EL0.MT](#) = 0b0, the counter counts cycles for which only instructions or operations [Attributable](#) to other PEs are sent for execution when this PE is eligible to execute instructions or operations on that cycle. The counter does not count cycles when this PE of the multi-threaded operation is not eligible to execute instructions or operations.
- When [PMEVTYPER<n>_EL0.MT](#) = 0b1, the counter counts all cycles when no instructions or operations for any PE of the multi-threaded operation are sent for execution.

The division between frontend and backend is IMPLEMENTATION DEFINED. [STALL](#), [STALL_FRONTEND](#), and [STALL_BACKEND](#) events must count at the same point in the pipeline. For more information, see [STALL_FRONTEND](#).

See also:

- [Attributability on page D7-2857.](#)
- [Meaningful ratios between common microarchitectural events on page D7-2937.](#)

0x003D, STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend

Counts each Slot counted by STALL_SLOT where no **Attributable** instruction or operation was sent for execution because the backend is unable to accept one of:

- The instruction operation available for the PE on the Slot.
- Any operations on the Slot.

The division between frontend and backend is IMPLEMENTATION DEFINED. STALL_SLOT, STALL_SLOT_FRONTEND, and STALL_SLOT_BACKEND events must count at the same point in the pipeline. The maximum value that STALL_SLOT_FRONTEND and STALL_SLOT_BACKEND events can count in a single-cycle is IMPLEMENTATION DEFINED. For more information, see STALL_SLOT.

See also *Attributability* on page D7-2857.

0x003E, STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend

Counts each Slot counted by STALL_SLOT where no **Attributable** instruction or operation was sent for execution because there was no **Attributable** instruction or operation available to issue from the PE from the frontend for the Slot.

The division between frontend and backend is IMPLEMENTATION DEFINED. STALL_SLOT, STALL_SLOT_FRONTEND, and STALL_SLOT_BACKEND events must count at the same point in the pipeline. The maximum value that STALL_SLOT_FRONTEND and STALL_SLOT_BACKEND events can count in a single-cycle is implementation defined. For more information, see STALL_SLOT.

———— **Note** —————

Arm recommends that STALL_SLOT_FRONTEND counts instructions that have been decoded and, if applicable, split into micro-operations.

See also *Attributability* on page D7-2857.

0x003F, STALL_SLOT, No operation sent for execution on a Slot

The counter counts on each **Attributable** cycle the number of instruction or operation Slots that were not occupied by an instruction or operation **Attributable** to the PE.

If the PMU supports multi-threading:

- When **PMEVTYPER<n>_EL0.MT** = 0b0, the counter counts instruction or operation Slots for which those Slots are occupied by instructions or operations **Attributable** to other PEs of the multi-threaded implementation only when the PE was eligible to execute instruction or operations in that cycle. The counter does not count any instruction or operation Slots on cycles when this PE was not eligible to execute instructions or operations.
- When **PMEVTYPER<n>_EL0.MT** = 0b1, for every cycle the counter counts all instruction or operation Slots not occupied by any instruction or operation for any PE of the multi-threaded implementation.

If **FEAT_PMUv3p4** is implemented then **PMMIR.SLOTS** defines the largest value by which this event can increment the counter in a single cycle.

See also *Attributability* on page D7-2857.

0x4000, SAMPLE_POP, Statistical Profiling sample population

The counter increments for each operation that might be sampled, whether or not the operation was sampled. Operations that are executed at an Exception level or Security state in which the Statistical Profiling Extension is disabled are not counted.

0x4001, SAMPLE_FEED, Statistical Profiling sample taken

The counter increments each time the sample interval counter reaches zero and is reloaded, and the sample does not collide with the previous sample. Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

0x4002, SAMPLE_FILTRATE, Statistical Profiling sample taken and not removed by filtering

The counter counts each sample counted by [SAMPLE_FEED](#) that is not removed by filtering. Sample records that are not removed by filtering, but are discarded before being written to the Profiling Buffer because of a Profiling Buffer management event or because Discard mode is implemented and enabled, are counted.

0x4003, SAMPLE_COLLISION, Statistical Profiling sample collided with a previous sample

The counter increments for each sample record that is taken when the previous sampled operation has not completed generating its sample record.

0x4004, CNT_CYCLES, Constant frequency cycles

The counter increments at a constant frequency equal to the rate of increment of the System counter, [CNT_PCT_EL0](#).

It is CONSTRAINED UNPREDICTABLE whether or not [CNT_CYCLES](#) continues to increment when the PE is in WFI or WFE state.

In a multithreaded implementation, [CNT_CYCLES](#) counts when this PE thread is active and can issue an instruction. For more information, see [Cycle event counting on page D7-2936](#).

0x4005, STALL_BACKEND_MEM, Memory stall cycles

The counter counts each cycle counted by [STALL_BACKEND](#) where there is a cache miss in the last level of cache within the PE clock domain.

It is IMPLEMENTATION DEFINED whether the counter counts backend stall cycles when a non-cacheable access is in progress.

0x4006, L1I_CACHE_LMISS, Level 1 instruction cache long-latency read miss

If the [L1I_CACHE_RD](#) event is implemented, the counter counts each access counted by [L1I_CACHE_RD](#) that incurs additional latency because it returns instructions from outside of the Level 1 instruction cache of this PE.

If the [L1I_CACHE_RD](#) event is not implemented, the counter counts each access counted by [L1I_CACHE](#) that incurs additional latency because it returns instructions from outside the Level 1 instruction cache of this PE.

The event indicates to software that the access missed in the Level 1 instruction cache and might have a significant performance impact due to the additional latency, compared to the latency of an access that hits in the Level 1 instruction cache.

This counter does not count:

- Access where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared against a miss in all Level 1 caches that the access looks up in that results in instructions being returned from a Level 2 cache or elsewhere beyond the Level 1 instruction cache.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x4009, L2D_CACHE_LMISS_RD, Level 2 data cache long-latency read miss

The counter counts each memory read access counted by [L2D_CACHE](#) that incurs additional latency because it returns data from outside the Level 2 data or unified cache of this PE.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted. It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

The event indicates to software that the access missed in the Level 2 data or unified cache and might have a significant performance impact compared to the latency of an access that hits in the Level 2 data or unified cache.

This counter does not count:

- Access where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared against a miss in all Level 2 caches that the access looks up in that results in an access being made to a Level 3 cache or elsewhere beyond the Level 2 data and unified cache. This might be counted as a Level 1 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency nor to track the access to determine whether the additional latency had a performance impact. An implementation can extend the definition of this event with additional scenarios where a memory read access counted by [L2D_CACHE](#) might have a significant performance impact due to additional latency for the address.

See also [Attributability on page D7-2857](#).

0x400A, [L2I_CACHE_LMISS](#), Level 2 instruction cache long-latency read miss

If the [L2I_CACHE_RD](#) event is implemented, the counter counts each access counted by [L2I_CACHE_RD](#) that incurs additional latency because it returns instructions from outside of the Level 1 to Level 2 instruction cache of this PE.

If the [L2I_CACHE_RD](#) event is not implemented, the counter counts each access counted by [L2I_CACHE](#) that incurs additional latency because it returns instructions from outside the Level 1 to Level 2 instruction cache of this PE.

The event indicates to software that the access missed in the Level 2 instruction cache and might have a significant performance impact due to the additional latency, compared to the latency of an access that hits in the Level 2 instruction cache.

This counter does not count:

- Access where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared against a miss in all Level 2 caches that the access looks up in that results in instructions being returned from a Level 3 cache or elsewhere beyond the Level 2 instruction cache. This might be counted as a Level 1 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted.

See also [Attributability on page D7-2857](#).

0x400B, [L3D_CACHE_LMISS_RD](#), Level 3 data cache long-latency read miss

The counter counts each memory read access counted by [L3D_CACHE](#) that incurs additional latency because it returns data from outside the Level 3 data or unified cache of this PE.

If the cache is shared, only events [Attributable](#) to this PE are counted. If the cache is not shared, all events are counted. It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

The event indicates to software that the access missed in the Level 3 data or unified cache and might have a significant performance impact compared to the latency of an access that hits in the Level 3 data or unified cache.

This counter does not count:

- Access where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared against a miss in all Level 3 caches that the access looks up in that results in an access being made to a Level 4 cache or elsewhere beyond the Level 3 data and unified cache. This might be counted as a Level 2 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency nor to track the access to determine whether the additional latency had a performance impact. An implementation can extend the definition of this event with additional scenarios where a memory read access counted by [L3D_CACHE](#) might have a significant performance impact due to additional latency for the address.

See also [Attributability](#) on page D7-2857.

0x4020, LDST_ALIGN_LAT, Access with additional latency from alignment

The counter counts each access counted by [MEM_ACCESS](#) that, due to the alignment of the address and size of data being accessed, incurred additional latency.

0x4021, LD_ALIGN_LAT, Load with additional latency from alignment

The counter counts each memory-read access counted by [LDST_ALIGN_LAT](#).

0x4022, ST_ALIGN_LAT, Store with additional latency from alignment

The counter counts each memory-write access counted by [LDST_ALIGN_LAT](#).

0x4024, MEM_ACCESS_CHECKED, Checked data memory access

The counter counts each memory access counted by [MEM_ACCESS](#) that is Tag Checked by the Memory Tagging Extension. For more information see [Chapter D6 Memory Tagging Extension](#).

It is IMPLEMENTATION DEFINED whether the counter increments on a Tag Checked access made when Tag Check Faults are configured to be ignored by [SCTLR_ELx.TCF](#) or [SCTLR_ELx.TCF0](#).

0x4025, MEM_ACCESS_CHECKED_RD, Checked data memory access, read

The counter counts each memory-read access counted by [MEM_ACCESS_CHECKED](#).

It is IMPLEMENTATION DEFINED whether the counter increments on a Tag Checked access made when Tag Check Faults are configured to be ignored by [SCTLR_ELx.TCF](#) or [SCTLR_ELx.TCF0](#).

0x4026, MEM_ACCESS_CHECKED_WR, Checked data memory access, write

The counter counts each memory-write access counted by [MEM_ACCESS_CHECKED](#).

It is IMPLEMENTATION DEFINED whether the counter increments on a Tag Checked access made when Tag Check Faults are configured to be ignored by [SCTLR_ELx.TCF](#) or [SCTLR_ELx.TCF0](#).

0x8004, SIMD_INST_SPEC, SIMD Instructions, Operations speculatively executed

The counter counts speculatively executed operations due to the following SIMD instructions:

- SVE instructions, but not [non-SIMD SVE instructions](#).
- Advanced SIMD instructions, but not Advanced SIMD scalar instructions.

0x8005, ASE_INST_SPEC, Advanced SIMD Instructions, Operations speculatively executed

The counter counts speculatively executed operations due to Advanced SIMD instructions. It is IMPLEMENTATION DEFINED whether this event counts operations due to Advanced SIMD scalar instructions.

0x8006, SVE_INST_SPEC, SVE Operations speculatively executed

The counter counts speculatively executed operations due to SVE instructions. It is IMPLEMENTATION DEFINED whether this event counts operations due to [non-SIMD SVE instructions](#)

0x8007, ASE_SVE_INST_SPEC, Advanced SIMD and SVE Operations speculatively executed

The counter counts speculatively executed operations that would be counted by [ASE_INST_SPEC](#) or [SVE_INST_SPEC](#).

0x8008, UOP_SPEC, Microarchitectural operation, Operations speculatively executed

The counter counts all speculatively executed microarchitectural operations, irrespective of the IMPLEMENTATION DEFINED interpretation of [Operations speculatively executed](#).

0x8009, ASE_UOP_SPEC, Advanced SIMD Microarchitectural operation, Operations speculatively executed

The counter counts all speculatively executed microarchitectural operations due to Advanced SIMD instructions, irrespective of the IMPLEMENTATION DEFINED interpretation of [Operations speculatively executed](#). It is IMPLEMENTATION DEFINED whether this event counts microarchitectural operations due to Advanced SIMD scalar instructions.

0x800A, SVE_UOP_SPEC, SVE micro-operation, Speculatively executed

The counter counts all speculatively executed microarchitectural operations due to SVE instructions, irrespective of the IMPLEMENTATION DEFINED interpretation of [Operations speculatively executed](#). It is IMPLEMENTATION DEFINED whether this event counts microarchitectural operations due to [non-SIMD SVE instructions](#).

0x800B, ASE_SVE_UOP_SPEC, Advanced SIMD and SVE Microarchitectural operation, Operations speculatively executed

The counter counts all speculatively executed microarchitectural operations that are counted by [SVE_UOP_SPEC](#) or [ASE_UOP_SPEC](#).

0x800C, SIMD_UOP_SPEC, SIMD micro-operation, Speculatively executed

The counter counts the following speculatively executed microarchitectural operations, irrespective of the IMPLEMENTATION DEFINED interpretation of [Operations speculatively executed](#), due to:

- SVE instructions, but not [non-SIMD SVE instructions](#).
- Advanced SIMD instructions, but not Advanced SIMD scalar instructions.

0x800E, SVE_MATH_SPEC, SVE Math accelerator Operations speculatively executed

The counter counts speculatively executed math function operations due to the SVE FTSMUL, FT MAD, FT SSE L, and FEX PA instructions.

0x8010, FP_SPEC, Floating-point Operations speculatively executed

The counter counts speculatively executed operations due to scalar, Advanced SIMD, and SVE floating-point instructions. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

———— **Note** ————

The IMPLEMENTATION DEFINED event counter [VFP_SPEC](#) is similar to this event counter, but does not count SIMD operations.

0x8011, ASE_FP_SPEC, Advanced SIMD floating-point Operations speculatively executed

The counter counts speculatively executed operations due to Advanced SIMD floating-point instructions. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8012, SVE_FP_SPEC, SVE floating-point Operations speculatively executed

The counter counts speculatively executed operations due to SVE floating-point instructions. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8013, ASE_SVE_FP_SPEC, Advanced SIMD and SVE floating-point Operations speculatively executed

The counter counts speculatively executed operations due to Advanced SIMD and SVE floating-point instructions. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8014, FP_HP_SPEC, Half-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to scalar, Advanced SIMD, and SVE floating-point instructions, where the largest type is half-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8015, ASE_FP_HP_SPEC, Advanced SIMD, Half-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to Advanced SIMD floating-point instructions, where the largest type is half-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8016, SVE_FP_HP_SPEC, SVE Half-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to SVE floating-point instructions, where the largest type is half-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8017, ASE_SVE_FP_HP_SPEC, Advanced SIMD and SVE Half-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to Advanced SIMD and SVE instructions, where the largest type is half-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8018, FP_SP_SPEC, Single-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to scalar, Advanced SIMD, and SVE floating-point instructions, where the largest type is single-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8019, ASE_FP_SP_SPEC, Advanced SIMD Single-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to Advanced SIMD floating-point instructions, where the largest type is single-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x801A, SVE_FP_SP_SPEC, SVE Single-precision floating-point operations, Operations speculatively executed

The counter counts speculatively executed operations due to SVE floating-point instructions, where the largest type is single-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x801B, ASE_SVE_FP_SP_SPEC, Advanced SIMD and SVE Single-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to Advanced SIMD and SVE instructions, where the largest type is single-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x801C, FP_DP_SPEC, Double-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to scalar, Advanced SIMD, and SVE floating-point instructions, where the largest type is double-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x801D, ASE_FP_DP_SPEC, Advanced SIMD Double-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to Advanced SIMD floating-point instructions, where the largest type is double-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x801E, SVE_FP_DP_SPEC, SVE Double-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to SVE floating-point instructions, where the largest type is double-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x801F, ASE_SVE_FP_DP_SPEC, Advanced SIMD and SVE Double-precision floating-point Operations speculatively executed

The counter counts speculatively executed operations due to Advanced SIMD and SVE floating-point instructions, where the largest type is double-precision. These instructions are in the floating point instructions category and optionally the floating-point conversions instructions category and the floating-point or integer instructions category listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8020, FP_DIV_SPEC, Floating-point divide Operations speculatively executed

The counter counts speculatively executed floating-point divide operations.

0x8021, ASE_FP_DIV_SPEC, Advanced SIMD Floating-point divide Operations speculatively executed

The counter counts speculatively executed Advanced SIMD floating point divide operations.

0x8022, SVE_FP_DIV_SPEC, SVE Floating-point divide Operations speculatively executed

The counter counts speculatively executed SVE floating-point divide operations.

0x8023, ASE_SVE_FP_DIV_SPEC, Advanced SIMD and SVE Floating-point divide Operations speculatively executed

The counter counts speculatively executed Advanced SIMD and SVE floating-point divide operations.

0x8024, FP_SQRT_SPEC, Floating-point square-root Operations speculatively executed

The counter counts speculatively executed floating-point square-root operations.

0x8025, ASE_FP_SQRT_SPEC, Advanced SIMD Floating-point square-root Operations speculatively executed

The counter counts speculatively executed Advanced SIMD floating-point square-root operations.

0x8026, SVE_FP_SQRT_SPEC, SVE Floating-point square-root Operations speculatively executed

The counter counts speculatively executed SVE floating-point square-root operations.

0x8027, ASE_SVE_FP_SQRT_SPEC, Advanced SIMD and SVE Floating-point square root Operations speculatively executed

The counter counts speculatively executed Advanced SIMD and SVE floating point square-root operations.

0x8028, FP_FMA_SPEC, Floating-point FMA Operations speculatively executed

The counter counts speculatively executed floating point fused multiply-add and multiply-subtract operations due to the following instructions:

- Scalar: FMADD, FMSUB, FNMADD, FNMSUB.
- Advanced SIMD: FCMLA, FMLA, FMLS.
- SVE: FCMLA, FMAD, FMLA, FMLS, FMSB, FMAD, FNMLA, FNMLS, FNMSB, FTMAD.

0x8029, ASE_FP_FMA_SPEC, Advanced SIMD Floating-point FMA Operations speculatively executed

The counter counts speculatively executed floating point multiply-add and multiply-subtract operations due to the Advanced SIMD FCMLA, FMLA, and FMLS instructions.

0x802A, SVE_FP_FMA_SPEC, SVE Floating-point FMA Operations speculatively executed

The counter counts speculatively executed floating point multiply-add and multiply-subtract operations due to the SVE FCMLA, FMAD, FMLA, FMLS, FMSB, FMAD, FNMLA, FNMLS, FNMSB, FTMAD instructions.

0x802B, ASE_SVE_FP_FMA_SPEC, Advanced SIMD and SVE Floating-point FMA Operations speculatively executed

The counter counts speculatively executed floating-point fused multiply-add and multiply-subtract operations due to the following instructions:

- Advanced SIMD: FCMLA, FMLA, FMLS.
- SVE: FCMLA, FMAD, FMLA, FMLS, FMSB, FMAD, FNMLA, FNMLS, FNMSB, FTMAD.

0x802C, FP_MUL_SPEC, Floating-point multiply Operations speculatively executed

The counter counts speculatively executed floating-point multiply operations due to the scalar, Advanced SIMD, and SVE FMUL and FMULX instructions, and the SVE FTSMUL instruction.

0x802D, ASE_FP_MUL_SPEC, Advanced SIMD Floating-point multiply Operations speculatively executed

The counter counts speculatively executed floating-point multiply operations due to the scalar Advanced SIMD FMUL and FMULX instructions.

0x802E, SVE_FP_MUL_SPEC, SVE Floating-point multiply Operations speculatively executed

The counter counts speculatively executed floating-point multiply operations due to SVE FMUL, FMULX, and FTSMUL instructions.

0x802F, ASE_SVE_FP_MUL_SPEC, Advanced SIMD and SVE Floating-point multiply Operations speculatively executed

The counter counts speculatively executed floating-point multiply operations due to the Advanced SIMD and SVE FMUL and FMULX instructions and the SVE FTSMUL instruction.

0x8030, FP_ADDSUB_SPEC, floating-point add or subtract Operations speculatively executed

The counter counts speculatively executed floating-point add and subtract operations due to the scalar, Advanced SIMD, and SVE FADD and FSUB instructions, and the Advanced SIMD and SVE FABD instructions.

0x8031, ASE_FP_ADDSUB_SPEC, Advanced SIMD floating-point add or subtract Operations speculatively executed

The counter counts speculatively executed floating-point add and subtract operations due to the Advanced SIMD FABD, FADD, and FSUB instructions.

0x8032, SVE_FP_ADDSUB_SPEC, SVE floating-point add or subtract Operations speculatively executed

The counter counts speculatively executed floating-point add and subtract operations due to the SVE FABD, FADD, and FSUB instructions.

0x8033, ASE_SVE_FP_ADDSUB_SPEC, Advanced SIMD and SVE floating-point add and subtract Operations speculatively executed

The counter counts speculatively executed floating-point add and subtract operations due to the Advanced SIMD and SVE FABD, FADD, and FSUB instructions.

0x8034, FP_RECPE_SPEC, Floating-point reciprocal estimate Operations speculatively executed

The counter counts speculatively executed floating-point reciprocal estimate operations due to the Advanced SIMD scalar, Advanced SIMD vector, and SVE FRECPE and FRSQRTE instructions.

0x8035, ASE_FP_RECPE_SPEC, Advanced SIMD floating-point reciprocal estimate Operations speculatively executed

The counter counts speculatively executed floating-point reciprocal estimate operations due to the Advanced SIMD vector FRECPE and FRSQRTE instructions.

0x8036, SVE_FP_RECPE_SPEC, SVE floating-point reciprocal estimate Operations speculatively executed

The counter counts speculatively executed floating-point reciprocal estimate operations due to the SVE FRECPE and FRSQRTE instructions.

0x8037, ASE_SVE_FP_RECPE_SPEC, Advanced SIMD and SVE floating-point reciprocal estimate Operations speculatively executed

The counter counts speculatively executed floating-point reciprocal estimate operations due to Advanced SIMD vector and SVE FRECPE and FRSQRTE instructions.

0x8038, FP_CVT_SPEC, floating-point convert Operations speculatively executed

The counter counts speculatively executed floating-point convert operations due to the scalar, Advanced SIMD, and SVE floating-point conversion instructions. The instructions in the Floating-point conversions category are listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8039, ASE_FP_CVT_SPEC, Advanced SIMD floating-point convert Operations speculatively executed

The counter counts speculatively executed floating-point convert operations due to the Advanced SIMD floating-point conversion instructions. The instructions in the Floating-point conversions category are listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x803A, SVE_FP_CVT_SPEC, SVE floating-point convert Operations speculatively executed

The counter counts speculatively executed floating-point convert operations due to the SVE floating-point conversion instructions. The instructions in the Floating-point conversions category are listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x803B, ASE_SVE_FP_CVT_SPEC, Advanced SIMD and SVE floating-point convert Operations speculatively executed

The counter counts speculatively executed floating-point convert operations due to the Advanced SIMD and SVE floating-point conversion instructions. The instructions in the Floating-point conversions category are listed in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x803C, SVE_FP_AREDUCE_SPEC, SVE floating-point accumulating reduction Operations speculatively executed

The counter counts speculatively executed floating-point accumulating reduction operations due to the SVE FADDA instruction.

0x803D, ASE_FP_PREDUCE_SPEC, Advanced SIMD floating-point pairwise add step Operations speculatively executed

The counter counts speculatively executed floating-point pairwise add operations due to the Advanced SIMD FADDP instruction.

0x803E, SVE_FP_VREDUCE_SPEC, SVE floating-point vector reduction Operations speculatively executed

The counter counts speculatively executed floating-point treewise reduction operations due to the SVE FADDV, FMAXNMV, FMAXV, FMINNMV, and FMINV instructions.

0x803F, ASE_SVE_FP_VREDUCE_SPEC, Advanced SIMD and SVE floating-point vector reduction Operations speculatively executed

The counter counts speculatively executed floating-point reduction operations due to the Advanced SIMD and SVE FMAXNMV, FMAXV, FMINNMV, and FMINV instructions, the Advanced SIMD FADDP instruction, and the SVE FADDV instruction.

0x8040, INT_SPEC, integer Operations speculatively executed

The counter counts speculatively executed integer arithmetic operations due to scalar, Advanced SIMD, and SVE data-processing instructions. These instructions are listed in the integer instructions category and optionally the floating-point conversions category and the floating-point or integer category in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8041, ASE_INT_SPEC, Advanced SIMD integer Operations speculatively executed

The counter counts speculatively executed integer arithmetic operations due to Advanced SIMD data-processing instructions. These instructions are listed in the integer instructions category and optionally the floating-point conversions category and the floating-point or integer category in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8042, SVE_INT_SPEC, SVE integer Operations speculatively executed

The counter counts speculatively executed integer arithmetic operations due to SVE data-processing instructions. These instructions are listed in the integer instructions category and optionally the floating-point conversions category and the floating-point or integer category in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8043, ASE_SVE_INT_SPEC, Advanced SIMD and SVE integer Operations speculatively executed

The counter counts speculatively executed integer arithmetic operations due to Advanced SIMD and SVE data-processing instructions. These instructions are listed in the integer instructions category and optionally the floating-point conversions category and the floating-point or integer category in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

0x8044, INT_DIV_SPEC, integer divide Operations speculatively executed

The counter counts speculatively executed scalar and SVE integer divide operations due to the SDIV and UDIV instructions.

0x8045, INT_DIV64_SPEC, 64-bit integer divide Operations speculatively executed

The counter counts speculatively executed scalar and SVE integer divide operations due to the SDIV and UDIV instructions with 64-bit operands or vector elements.

0x8046, SVE_INT_DIV_SPEC, SVE integer divide Operations speculatively executed

The counter counts speculatively executed SVE integer divide operations due to the SVE SDIV and UDIV instructions.

0x8047, SVE_INT_DIV64_SPEC, SVE 64-bit integer divide Operations speculatively executed

The counter counts speculatively executed SVE integer divide operations due to the SVE SDIV and UDIV instructions with 64-bit vector elements.

0x8048, INT_MUL_SPEC, integer multiply Operations speculatively executed

The counter counts speculatively executed integer multiply operations due to the following instructions:

- Scalar: MADD, MSUB, MUL, SMADDL, SMULH, UMADDL, UMLH.
- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, SMLAL, SMLS, SMULL, SQMLAL, SQMLSL, SQDMULH, SQDMULL, SQRDLAH, SQRDLAH, SQRDLAH, SQRDLAH, UMLAL, UMLSL, UMULL.
- SVE: MAD, MLA, MLS, MSB, MUL, SMULH, UMLH.

0x8049, ASE_INT_MUL_SPEC, Advanced SIMD integer multiply Operations speculatively executed

The counter counts speculatively executed integer multiply operations due to the following Advanced SIMD instructions: MLA, MLS, MUL, PMUL, PMULL, SMLAL, SMLS, SMULL, SQMLAL, SQMLSL, SQDMULH, SQDMULL, SQRDLAH, SQRDLAH, SQRDLAH, UMLAL, UMLSL, UMULL.

0x804A, SVE_INT_MUL_SPEC, SVE integer multiply Operations speculatively executed

The counter counts speculatively executed integer multiply operations due to the following SVE instructions: MAD, MLA, MLS, MSB, MUL, SMULH, UMLH.

0x804B, ASE_SVE_INT_MUL_SPEC, Advanced SIMD and SVE integer multiply Operations speculatively executed

The counter counts speculatively executed integer multiply operations due to the following instructions:

- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, SMLAL, SMLS, SMULL, SQMLAL, SQMLSL, SQDMULH, SQDMULL, SQRDLAH, SQRDLAH, SQRDLAH, UMLAL, UMLSL, UMULL.
- SVE: MAD, MLA, MLS, MSB, MUL, SMULH, UMLH.

0x804C, INT_MUL64_SPEC, integer 64x64 multiply Operations speculatively executed

The counter counts speculatively executed integer multiply operations returning a 64-bit result for the following instructions:

- Scalar: MADD, MSUB, MUL, SMADDL, SMULH, UMADDL, UMLH.
- SVE: MAD, MLS, MLA, MSB, MUL, SMULH, UMLH.

0x804D, SVE_INT_MUL64_SPEC, SVE integer 64-bit multiply Operations speculatively executed

The counter counts speculatively executed integer multiply operations returning a 64-bit result for the following SVE instructions: MAD, MLA, MLS, MSB, MUL, SMULH, UMLH.

0x804E, INT_MULH64_SPEC, integer 64-bit multiply returning high part Operations speculatively executed

The counter counts speculatively executed widening integer multiply operations returning a 64-bit result for the scalar and SVE SMULH and UMLH instructions.

0x804F, SVE_INT_MULH64_SPEC, SVE integer 64-bit multiply high part Operations speculatively executed

The counter counts speculatively executed widening integer multiply operations returning a 64-bit result for the SVE SMULH and UMLH instructions.

0x8058, NONFP_SPEC, Non floating-point Operations speculatively executed

The counter counts speculatively executed operations due to the following instructions:

- Scalar instructions that would be counted by the DP_SPEC event.
- Advanced SIMD data processing instructions defined in *Data processing - SIMD and floating-point on page C3-255* that would not be counted by FP_SPEC.
- SVE instructions with vector source or destination registers that would not be counted by FP_SPEC.

0x8059, ASE_NONFP_SPEC, Advanced SIMD non-floating-point Operations speculatively executed

The counter counts speculatively executed operations due to Advanced SIMD data processing instructions defined in the section titled *Data processing - SIMD and floating-point on page C3-255* that would not be counted by ASE_FP_SPEC.

0x805A, SVE_NONFP_SPEC, SVE non-floating-point Operations speculatively executed

The counter counts speculatively executed operations due to SVE instructions with vector source or destination registers that would not be counted by SVE_FP_SPEC.

0x805B, ASE_SVE_NONFP_SPEC, Advanced SIMD and SVE non-floating-point Operations speculatively executed

The counter counts speculatively executed operations due to the following instructions:

- Advanced SIMD data-processing instructions defined in *Data processing - SIMD and floating-point on page C3-255* that would not be counted by ASE_SVE_FP_SPEC.
- SVE instructions with vector source or destination registers that would not be counted by ASE_SVE_FP_SPEC.

0x805D, ASE_INT_VREDUCE_SPEC, Advanced SIMD integer reduction Operations speculatively executed

The counter counts speculatively executed across-vector and pairwise integer reduction operations due to the Advanced SIMD SADDLP, SADDLV, SMAXP, SMAXV, SMINP, SMINV, UADDVL, UMAXV, and UMINV instructions.

0x805E, SVE_INT_VREDUCE_SPEC, SVE integer reduction Operations speculatively executed

The counter counts speculatively executed across-vector integer reduction operations due to the following SVE instructions: ANDV, EORV, ORV, SADDV, SMAXV, SMINV, UADDV, UMAXV, and UMINV instructions.

0x805F, ASE_SVE_INT_VREDUCE_SPEC, Advanced SIMD and SVE integer reduction Operations speculatively executed

The counter counts speculatively executed across-vector and pairwise integer reduction operations due to the following instructions:

- Advanced SIMD: SADDLP, SADDLV, SMAXP, SMAXV, SMINP, SMINV, UADDVL, UMAXV, and UMINV.
- SVE: ANDV, EORV, ORV, SADDV, SMAXV, SMINV, UADDV, UMAXV, UMINV.

0x8060, SVE_PERM_SPEC, SVE permute Operations speculatively executed

The counter counts speculatively executed vector or predicate permute operations due to the following SVE instructions: CLASTA, CLASTB, CPY, COMPACT, DUP, EXT, INSR, LASTA, LASTB, PUNPKHI, PUNPKLO, REV, REV16, REV32, REV64, SPLICE, SUNPKHI, SUNPKLO, TBL, TRN1, TRN2, UUNPKHI, UUNPKLO, UZP1, UZP2, ZIP1, and ZIP2.

0x8061, SVE_PERM_IGRANULE_SPEC, SVE intra-granule permute Operations speculatively executed

The counter counts speculatively executed vector or predicate permute operations within a 128-bit vector granule or 16-bit predicate granule for the following SVE instructions: REV16, REV32, REV64, TRN1, TRN2.

0x8062, SVE_PERM_XGRANULE_SPEC, SVE cross-granule permute Operations speculatively executed

The counter counts speculatively executed vector or predicate permute operations that can cross between 128-bit vector granules or 16-bit predicate granules for the following SVE instructions: CLASTA, CLASTB, CPY, COMPACT, DUP, EXT, INSR, LASTA, LASTB, PUNPKHI, PUNPKLO, REV, SPLICE, SUNPKHI, SUNPKLO, TBL, UNPKHI, UNPKLO, UZP1, UZP2, ZIP1, and ZIP2.

0x8063, SVE_PERM_VARIABLE_SPEC, SVE programmable permute Operations speculatively executed

The counter counts speculatively executed variable vector permute operations due to the following SVE instructions: CLASTA, CLASTB, COMPACT, LASTA, LASTB, SPLICE, and TBL.

0x8064, SVE_XPIPE_SPEC, SVE cross-pipe Operations speculatively executed

The counter counts speculatively executed cross-pipeline transfer operations due to the following SVE instructions: CLASTA (scalar), CLASTB (scalar), CNTP, CPY (scalar), DECP (scalar), DUP (scalar), INCP (scalar), INDEX (immediate, scalar), INDEX (scalar, immediate), INDEX (scalar, scalar), INSR (scalar), LASTA (scalar), LASTB (scalar), SQDECP (scalar), SQINCP (scalar), UQDECP (scalar), UQDECP (scalar), WHILE<cc>.

0x8065, SVE_XPIPE_Z2R_SPEC, SVE vector to scalar cross-pipe Operations speculatively executed

The counter counts speculatively executed vector to general-purpose scalar cross-pipeline transfer operations due to the following SVE instructions: CLASTA (scalar), CLASTB (scalar), CNTP, DECP (scalar), INCP (scalar), LASTA (scalar), LASTB (scalar), SQDECP (scalar), SQINCP (scalar), UQDECP (scalar), UQDECP (scalar).

0x8066, SVE_XPIPE_R2Z_SPEC, SVE scalar to vector cross-pipe Operations speculatively executed

The counter counts speculatively executed general-purpose scalar to vector cross-pipeline transfer operations due to the following SVE instructions: CPY (scalar), DUP (scalar), INDEX (immediate, scalar), INDEX (scalar, immediate), INDEX (scalar, scalar), INSR (scalar), WHILE<cc>.

0x8067, SVE_PGEN_NVEC_SPEC, SVE predicate-only Operations speculatively executed

The counter counts speculatively executed predicate-generating operations that do not read vector registers due to the following SVE instructions: AND (predicates), ANDS, BIC (predicates), BICS, BRKA, BRKAS, BRKB, BRKBS, BRKN, BRKNS, BRKPA, BRKPAS, BRKPB, BRKPBS, EOR (predicates), EORS, NAND, NANDS, NOR, NORNS, ORN (predicates), ORNS, ORR (predicates), ORRS, PFALSE, PFIRST, PNEXT, PTRUE, PTRUES, PUNPKHI, PUNPKLO, RDIFFR, RDIFFRS, REV (predicate), SEL (predicates), TRN1 (predicates), TRN2 (predicates), UZP1 (predicates), UZP2 (predicates), WHILE<cc>, ZIP1 (predicates), ZIP2 (predicates).

0x8068, SVE_PGEN_SPEC, SVE predicate generating Operations speculatively executed

The counter counts speculatively executed predicate-generating operations due to the following SVE instructions: AND (predicates), ANDS, BIC (predicates), BICS, BRKA, BRKAS, BRKB, BRKBS, BRKN, BRKNS, BRKPA, BRKPAS, BRKPB, BRKPBS, CMP<cc>, EOR (predicates), EORS, FAC<cc>, FCM<cc>, NAND, NANDS, NOR, NORNS, ORN (predicates), ORNS, ORR (predicates), ORRS, PFALSE, PFIRST, PNEXT, PTRUE, PTRUES, PUNPKHI, PUNPKLO, RDIFFR, RDIFFRS, REV (predicate), SEL (predicates), TRN1 (predicates), TRN2 (predicates), UZP1 (predicates), UZP2 (predicates), WHILE<cc>, ZIP1 (predicates), ZIP2 (predicates).

0x8069, SVE_PGEN_FLG_SPEC, SVE predicate flag setting Operations speculatively executed

The counter counts speculatively executed predicate-generating operations that set condition flags, due to the following SVE instructions: ANDS, BICS, BRKAS, BRKBS, BRKNS, BRKPAS, BRKPBS, CMP<cc>, EORS, NANDS, NORNS, ORNS, ORRS, PFIRST, PNEXT, PTRUES, RDIFFRS, WHILE<cc>.

0x806A, SVE_PGEN_CMP_SPEC, SVE vector compare Operations speculatively executed

The counter counts speculatively executed vector compare operations due to the following SVE instructions: CMP<cc>, FAC<cc>, FCM<cc>.

0x806B, SVE_PGEN_FCM_SPEC, SVE floating-point vector compare Operations speculatively executed

The counter counts speculatively executed vector floating-point compare operations, due to the following SVE instructions: FAC<cc>, FCM<cc>.

0x806C, SVE_PGEN_LOGIC_SPEC, SVE predicate logical Operations speculatively executed

The counter counts speculatively executed predicate logical operations due to the following SVE instructions: AND (predicates), ANDS, BIC (predicates), BICS, EOR (predicates), EORS, NAND, NANDS, NOR, NORs, ORN (predicates), ORNS, ORR (predicates), ORRS.

0x806D, SVE_PPERM_SPEC, SVE predicate permute Operations speculatively executed

The counter counts speculatively executed predicate permute operations, due to the following SVE instructions: PUNPKHI, PUNPKLO, REV (predicate), TRN1 (predicates), TRN2 (predicates), UZP1 (predicates), UZP2 (predicates), ZIP1 (predicates), ZIP2 (predicates).

0x806E, SVE_PSCAN_SPEC, SVE predicate scan Operations speculatively executed

The counter counts speculatively executed predicate scanning and generation operations, due to the following SVE instructions: BRKA, BRKAS, BRKB, BRKBS, BRKN, BRKNS, BRKPA, BRKPAS, BRKPB, BRKPBS, PFIRST, PNEXT.

0x806F, SVE_PCNT_SPEC, SVE predicate count Operations speculatively executed

The counter counts speculatively executed predicate population count operations, due to the following SVE instructions: CNTP, DECP, INCP, SQDECP, SQINCP, UQDECP, UQINCP.

0x8070, SVE_PLOOP_WHILE_SPEC, SVE predicate loop while Operations speculatively executed

The counter counts speculatively executed counted predicate generation operations, due to the following SVE instructions: WHILELE, WHILELO, WHILELS, WHILELT.

0x8071, SVE_PLOOP_TEST_SPEC, SVE predicate loop test Operations speculatively executed

The counter counts speculatively executed loop predicate test operations, due to the following SVE instructions: BRKAS, BRKBS, BRKNS, BRKPAS, BRKPBS, WHILELE, WHILELO, WHILELS, WHILELT.

0x8072, SVE_PLOOP_ELTS_SPEC, SVE predicate loop elements Operations speculatively executed

The counter counts speculatively executed loop predicate generation operations, due to the following SVE instructions: WHILELE, WHILELO, WHILELS, WHILELT. This event increments the counter by $(128 \div CSIZE)$.

———— **Note** —————

This counter must be multiplied by $(VL \div 128)$ to determine the number of vector elements speculatively processed by while loops.

0x8073, SVE_PLOOP_TERM_SPEC, SVE predicate loop termination, Operations speculatively executed

The counter counts speculatively executed loop-terminating predicate generation operations due to the following SVE instructions:

- WHILELE, WHILELO, WHILELS, WHILELT, which set **PSTATE.N** to 0.
- BRKAS, BRKBS, BRKNS, BRKPAS, BRKPBS, which set **PSTATE.C** to 1.
- CTERMEQ and CTERMNE, which set **PSTATE.N** to 1 and **PSTATE.V** to 0.

0x8074, SVE_PRED_SPEC, SVE predicated Operations speculatively executed

The counter counts speculatively executed SIMD data-processing and load and store operations due to SVE instructions with a Governing predicate operand that determines the Active elements.

0x8075, SVE_PRED_EMPTY_SPEC, SVE predicated operations with no active predicates, Operations speculatively executed

The counter counts speculatively executed SIMD data-processing and load and store operations due to SVE instructions with a Governing predicate in which all elements are FALSE.

0x8076, SVE_PRED_FULL_SPEC, SVE predicated operations with all active predicates, Operations speculatively executed

The counter counts speculatively executed SIMD data-processing and load and store operations due to SVE instructions with a Governing predicate in which all elements are TRUE.

0x8077, SVE_PRED_PARTIAL_SPEC, SVE predicated operations with partially active predicates, Operations speculatively executed

The counter counts speculatively executed SIMD data-processing and load and store operations due to SVE instructions with a Governing predicate in which elements are neither all TRUE nor all FALSE.

0x8078, SVE_UNPRED_SPEC, SVE unpredicated Operations speculatively executed

The counter counts speculatively executed SIMD data-processing and load/store operations due to SVE instructions without a Governing predicate.

0x8079, SVE_PRED_NOT_FULL_SPEC, SVE predicated operations with empty or partially active predicates, Operations speculatively executed

The counter counts speculatively executed SIMD data-processing and load and store operations due to SVE instructions with a Governing predicate in which elements are not all TRUE, but may be all FALSE.

0x807C, SVE_MOVPRFX_SPEC, SVE MOVPRFX Operations speculatively executed

The counter counts speculatively executed operations due to MOVPRFX instructions, whether or not they were fused with the prefixed instruction.

0x807D, SVE_MOVPRFX_Z_SPEC, SVE MOVPRFX zeroing predication Operations speculatively executed

The counter counts speculatively executed operations due to MOVPRFX instructions using zeroing predication, whether or not they were fused with the prefixed instruction.

0x807E, SVE_MOVPRFX_M_SPEC, SVE MOVPRFX merging predication Operations speculatively executed

The counter counts speculatively executed operations due to MOVPRFX instructions using merging predication, whether or not they were fused with the prefixed instruction.

0x807F, SVE_MOVPRFX_U_SPEC, SVE MOVPRFX unfused Operations speculatively executed

The counter counts speculatively executed operations due to MOVPRFX instructions that were not fused with the prefixed instruction.

0x8080, SVE_LDST_SPEC, SVE load, store, and prefetch Operations speculatively executed

The counter counts speculatively executed operations that read from, write to, or prefetch memory due to SVE instructions.

0x8081, SVE_LD_SPEC, SVE load Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to SVE load instructions.

0x8082, SVE_ST_SPEC, SVE store Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to SVE store instructions.

0x8083, SVE_PRF_SPEC, SVE prefetch Operations speculatively executed

The counter counts speculatively executed operations that prefetch memory due to SVE prefetch instructions.

0x8084, ASE_SVE_LDST_SPEC, Advanced SIMD and SVE, load and store Operations speculatively executed

The counter counts speculatively executed operations that read from or write to memory due to SVE and Advanced SIMD instructions, or any instructions that prefetch memory.

0x8085, ASE_SVE_LD_SPEC, Advanced SIMD and SVE load Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to SVE and Advanced SIMD load instructions.

0x8086, ASE_SVE_ST_SPEC, Advanced SIMD and SVE store Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to SVE and Advanced SIMD store instructions.

0x8087, PRF_SPEC, Prefetch Operations speculatively executed

The counter counts speculatively executed prefetch operations due to scalar PRFM and SVE PRF instructions.

0x8088, BASE_LDST_REG_SPEC, General-purpose register load, store and prefetch Operations speculatively executed

The counter counts speculatively executed operations that read from memory to a general-purpose register, write a general-purpose register to memory, or prefetch memory due to the PRFM instruction. It is IMPLEMENTATION DEFINED whether operations due to the DC ZVA instruction are counted.

0x8089, BASE_LD_REG_SPEC, General-purpose register load Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to an instruction that loads a general-purpose register.

0x808A, BASE_ST_REG_SPEC, General-purpose register store Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to an instruction that stores a general-purpose register. It is IMPLEMENTATION DEFINED whether operations due to the DC ZVA instruction are counted.

0x808B, BASE_PRF_SPEC, General-purpose register prefetch Operations speculatively executed

The counter counts speculatively executed operations that prefetch memory due to the PRFM instruction.

0x808C, FPASE_LDST_REG_SPEC, Advanced SIMD and floating-point register load and store Operations speculatively executed

The counter counts speculatively executed operations that read from or write to memory, due to scalar SIMD&FP LDR, LDP, STR, and STP instructions or Advanced SIMD LD1, LD1R, and ST1 instructions.

0x808D, FPASE_LD_REG_SPEC, Advanced SIMD and floating-point register load Operations speculatively executed

The counter counts speculatively executed operations that read from memory, due to scalar SIMD&FP LDR and LDP instructions or Advanced SIMD LD1 and LD1R instructions.

0x808E, FPASE_ST_REG_SPEC, Advanced SIMD and floating-point register store Operations speculatively executed

The counter counts speculatively executed operations that write to memory, due to scalar SIMD&FP STR and STP instructions or Advanced SIMD ST1 instructions.

0x8090, SVE_LDST_REG_SPEC, SVE unpredicated load and store register Operations speculatively executed

The counter counts speculatively executed operations that read from memory or write to memory due to SVE LDR and STR instructions.

0x8091, SVE_LDR_REG_SPEC, SVE unpredicated load register Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to an SVE LDR instruction.

0x8092, SVE_STR_REG_SPEC, SVE unpredicated store register Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to an SVE STR instruction.

0x8094, SVE_LDST_PREG_SPEC, SVE load and store predicate register Operations speculatively executed

The counter counts speculatively executed operations that read from memory or write to memory due to SVE LDR (predicate) and STR (predicate) instructions.

0x8095, SVE_LDR_PREG_SPEC, SVE load predicate register Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to an SVE LDR (predicate) instruction.

0x8096, SVE_STR_PREG_SPEC, SVE store predicate register Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to an SVE STR (predicate) instruction.

0x8098, SVE_LDST_ZREG_SPEC, SVE load and store vector register Operations speculatively executed

The counter counts speculatively executed operations that read from memory or write to memory due to SVE LDR (vector) and STR (vector) instructions.

0x8099, SVE_LDR_ZREG_SPEC, SVE load vector register Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to an SVE LDR (vector) instruction.

0x809A, SVE_STR_ZREG_SPEC, SVE store vector register Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to an SVE STR (vector) instruction.

0x809C, SVE_LDST_CONTIG_SPEC, SVE contiguous load, store, and prefetch element Operations speculatively executed

The counter counts speculatively executed operations that read from, write to, or prefetch memory due to an SVE predicated single vector contiguous element load, store, or prefetch instruction. Operations due to SVE load and replicate LD1R and LD1RQ instructions are also counted.

0x809D, SVE_LD_CONTIG_SPEC, SVE contiguous load element Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to SVE predicated single vector contiguous element load instructions. Operations due to SVE load and replicate LD1R and LD1RQ instructions are also counted.

0x809E, SVE_ST_CONTIG_SPEC, SVE contiguous store element Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to SVE predicated single vector contiguous element store instructions.

0x809F, SVE_PRF_CONTIG_SPEC, SVE contiguous prefetch element Operations speculatively executed

The counter counts speculatively executed operations that prefetch memory due to an SVE predicated single contiguous element prefetch instruction.

0x80A0, SVE_LDSTNT_CONTIG_SPEC, SVE non-temporal contiguous load and store element Operations speculatively executed

The counter counts speculatively executed operations that read from memory or write to memory with a non-temporal hint due to an SVE non-temporal contiguous element load or store instruction.

0x80A1, SVE_LDNT_CONTIG_SPEC, SVE non-temporal contiguous load element Operations speculatively executed

The counter counts speculatively executed operations that read from memory with a non-temporal hint due to an SVE non-temporal contiguous element load instruction.

0x80A2, SVE_STNT_CONTIG_SPEC, SVE non-temporal contiguous store element Operations speculatively executed

The counter counts speculatively executed operations that write to memory with a non-temporal hint due to an SVE non-temporal contiguous element store instruction.

0x80A4, ASE_SVE_LDST_MULTI_SPEC, Advanced SIMD and SVE contiguous load and store multiple vector Operations speculatively executed

The counter counts speculatively executed operations that read from memory or write to memory due to an SVE or Advanced SIMD multiple vector contiguous structure load and store instruction.

0x80A5, ASE_SVE_LD_MULTI_SPEC, Advanced SIMD and SVE contiguous load multiple vector Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to SVE and Advanced SIMD multiple vector contiguous structure load instructions.

0x80A6, ASE_SVE_ST_MULTI_SPEC, Advanced SIMD and SVE contiguous store multiple vector Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to SVE and Advanced SIMD multiple vector contiguous structure store instructions.

0x80A8, SVE_LDST_MULTI_SPEC, SVE contiguous load and store multiple vector Operations speculatively executed

The counter counts speculatively executed operations that read from memory or write to memory due to SVE multiple vector contiguous structure load and store instructions.

0x80A9, SVE_LD_MULTI_SPEC, SVE contiguous load multiple vector Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to SVE multiple vector contiguous structure load instructions.

0x80AA, SVE_ST_MULTI_SPEC, SVE contiguous store multiple vector Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to SVE multiple vector contiguous structure store instructions.

0x80AC, SVE_LDST_NONCONTIG_SPEC, SVE non-contiguous load, store, and prefetch Operations speculatively executed

The counter counts speculatively executed operations that read from, write to, or prefetch memory due to SVE non-contiguous gather-load, scatter-store, and gather-prefetch instructions.

0x80AD, SVE_LD_GATHER_SPEC, SVE gather-load Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to SVE non-contiguous gather-load instructions.

0x80AE, SVE_ST_SCATTER_SPEC, SVE scatter-store Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to SVE non-contiguous scatter-store instructions.

0x80AF, SVE_PRF_GATHER_SPEC, SVE gather-prefetch Operations speculatively executed

The counter counts speculatively executed operations that prefetch memory due to SVE non-contiguous gather-prefetch instructions.

0x80B0, SVE_LDST64_NONCONTIG_SPEC, SVE 64-bit non-contiguous load, store, and prefetch Operations speculatively executed

The counter counts speculatively executed operations that read from, write to, or prefetch memory due to SVE non-contiguous gather-load, scatter-store, and gather-prefetch instructions with 64-bit vector elements in the address.

0x80B1, SVE_LD64_GATHER_SPEC, SVE 64-bit gather-load Operations speculatively executed

The counter counts speculatively executed operations that read from memory due to SVE non-contiguous gather-load instructions with 64-bit vector elements in the address.

0x80B2, SVE_ST64_SCATTER_SPEC, SVE 64-bit scatter-store Operations speculatively executed

The counter counts speculatively executed operations that write to memory due to SVE non-contiguous scatter-store instructions with 64-bit vector elements in the address.

0x80B3, SVE_PRF64_GATHER_SPEC, SVE 64-bit gather-prefetch Operations speculatively executed

The counter counts speculatively executed operations that prefetch memory due to SVE non-contiguous gather-prefetch instructions with 64-bit vector elements in the address.

0x80B4, ASE_SVE_UNALIGNED_LDST_SPEC, Advanced SIMD and SVE unaligned accesses

The counter counts memory read and write accesses due to SVE and Advanced SIMD load and store instructions where:

- A contiguous vector address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.
- A gather, scatter, or single element address is not aligned to the memory element access size, in bytes.

The counter also counts unaligned accesses if they are subsequently converted into multiple aligned accesses.

0x80B5, ASE_SVE_UNALIGNED_LD_SPEC, Advanced SIMD and SVE unaligned read accesses

The counter counts memory read and write accesses due to SVE and Advanced SIMD load instructions where:

- A contiguous vector address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.
- A gather, scatter or single element address is not aligned to the memory element access size, in bytes.

The counter also counts unaligned accesses if they are subsequently converted into multiple aligned accesses.

0x80B6, ASE_SVE_UNALIGNED_ST_SPEC, Advanced SIMD and SVE unaligned write accesses

The counter counts memory read and write accesses due to SVE and Advanced SIMD store instructions where:

- A contiguous vector address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.
- A gather, scatter or single element address is not aligned to the memory element access size, in bytes.

The counter also counts unaligned accesses if they are subsequently converted into multiple aligned accesses.

0x80B8, ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC, Advanced SIMD and SVE unaligned contiguous accesses

The counter counts memory read and write accesses due to SVE and Advanced SIMD contiguous load and store instructions where the address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.

The counter also counts unaligned accesses if they are subsequently converted into multiple aligned accesses.

0x80B9, ASE_SVE_UNALIGNED_CONTIG_LD_SPEC, Advanced SIMD and SVE unaligned contiguous read accesses

The counter counts memory read accesses due to SVE and Advanced SIMD contiguous load instructions where the address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.

The counter also counts unaligned accesses if they are subsequently converted into multiple aligned accesses.

0x80BA, ASE_SVE_UNALIGNED_CONTIG_ST_SPEC, Advanced SIMD and SVE unaligned contiguous write accesses

The counter counts memory write accesses due to SVE and Advanced SIMD contiguous store instructions where the address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.

The counter also counts unaligned accesses if they are subsequently converted into multiple aligned accesses.

0x80BC, SVE_LDFF_SPEC, SVE First-fault load Operations speculatively executed

The counter counts speculatively executed memory read operations due to SVE First-fault and Non-fault load instructions.

0x80BD, SVE_LDFF_FAULT_SPEC, SVE First-fault load operations which set FFR bit to 0, Operations speculatively executed

The counter counts speculatively executed memory read operations due to SVE First-fault and Non-fault load instructions that write 0 to at least one bit in FFR.

0x80C0, FP_SCALE_OPS_SPEC, Scalable floating-point element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed operations that would be counted by **SVE_FP_SPEC**, except that it is IMPLEMENTATION DEFINED whether this includes operations due to instructions other than those listed in the Floating-point arithmetic (SVE) category in the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

See *ALU operation counts on page D7-2869* for information on the counter increment for different types of instruction.

0x80C1, FP_FIXED_OPS_SPEC, Non-scalable floating-point element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed operations that would be counted by **FP_SPEC** but not by **SVE_FP_SPEC**. It does not count operations that are counted by the **FP_SCALE_OPS_SPEC** event. It is IMPLEMENTATION DEFINED whether this includes operations due to instructions other than those listed in the Floating-point arithmetic (scalar) category and the Floating-point arithmetic (Advanced SIMD) category in *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*. See *ALU operation counts on page D7-2869* for information on the counter increment for different types of instruction.

0x80C2, FP_HP_SCALE_OPS_SPEC, Scalable half-precision floating-point element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed operations that would be counted by **SVE_FP_HP_SPEC**, except that is IMPLEMENTATION DEFINED whether this includes operations due to instructions other than those listed in the Floating-point arithmetic (SVE) category in *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*. See *ALU operation counts on page D7-2869* for information on the counter increment for different types of instruction.

0x80C3, FP_HP_FIXED_OPS_SPEC, Non-scalable half-precision floating-point element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed operations that would be counted by **FP_HP_SPEC** but not by **SVE_FP_HP_SPEC**. It does not count operations that are counted by the **FP_HP_SCALE_OPS_SPEC** event. It is IMPLEMENTATION DEFINED whether this includes operations due to instructions other than those listed in the Floating-point arithmetic (scalar) category and the Floating-point arithmetic (Advanced SIMD) category in *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*. See *ALU operation counts on page D7-2869* for information on the counter increment for different types of instruction.

0x80C4, FP_SP_SCALE_OPS_SPEC, Scalable single-precision floating-point element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed operations that would be counted by **SVE_FP_SP_SPEC**, except that is IMPLEMENTATION DEFINED whether this includes operations other than those listed in the Floating-point arithmetic (SVE)

category in *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80C5, FP_SP_FIXED_OPS_SPEC, Non-scalable single-precision floating-point element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed operations that would be counted by `FP_SP_SPEC` but not by `SVE_FP_SP_SPEC`. It does not count operations that are counted by the `FP_SP_SCALE_OPS_SPEC` event. It is IMPLEMENTATION DEFINED whether this includes operations due to instructions other than those listed in the Floating-point arithmetic (scalar) category and the Floating-point arithmetic (Advanced SIMD) category in *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80C6, FP_DP_SCALE_OPS_SPEC, Scalable double-precision floating-point element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed operations that would be counted by `SVE_FP_DP_SPEC`, except that is IMPLEMENTATION DEFINED whether this includes operations due to instructions other than those listed in the Floating-point arithmetic (SVE) category in *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80C7, FP_DP_FIXED_OPS_SPEC, Non-scalable double-precision floating-point element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed operations that would be counted by `FP_DP_SPEC` but not by `SVE_FP_DP_SPEC`. It does not count operations that are counted by the `FP_DP_SCALE_OPS_SPEC` event. It is IMPLEMENTATION DEFINED whether this includes operations due to instructions other than those listed in the Floating-point arithmetic (scalar) category in *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80C8, INT_SCALE_OPS_SPEC, Scalable integer element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed operations that would be counted by `SVE_INT_SPEC`. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80C9, INT_FIXED_OPS_SPEC, Non-scalable integer element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed operations that would be counted by `INT_SPEC` but not by `SVE_INT_SPEC`. It does not count the operations that are counted by the `INT_SCALE_OPS_SPEC` event.

See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80CA, LDST_SCALE_OPS_SPEC, Scalable load and store element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed memory-read and write operations, due to the SVE predicated vector load and store instructions, excluding the replicating `LD1R` and `LD1RQ` instructions. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

This event counter does not count tag loads or tag stores.

0x80CB, LDST_FIXED_OPS_SPEC, Non-scalable load and store element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed memory-read and write operations, due to all non-SVE load, store and atomic operations, all SVE non-vector load and store operations, and SVE replicating LD1R and LD1RQ instructions. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80CC, LD_SCALE_OPS_SPEC, Scalable load element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed memory read operations, due to SVE predicated vector load instructions, excluding the replicating LD1R and LD1RQ instructions. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

This event counter does not count tag loads or tag stores.

0x80CD, LD_FIXED_OPS_SPEC, Non-scalable load element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed [Memory-read operations](#) due to all non-SVE load and atomic operations, all SVE non-vector load operations, and SVE replicating LD1R and LD1RQ instructions. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80CE, ST_SCALE_OPS_SPEC, Scalable store element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed [Memory-write operations](#), due to SVE predicated vector store instructions. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

This event counter does not count tag loads or tag stores.

0x80CF, ST_FIXED_OPS_SPEC, Non-scalable store element ALU operation counts Speculatively executed

The counter counts the number of ALU operation counts generated for speculatively executed [Memory-write operations](#) due to all non-SVE store and atomic operations, and all SVE non-vector store operations. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80DA, LDST_SCALE_BYTES_SPEC, Scalable load and store bytes, Speculatively executed

The counter counts bytes speculatively read or written due to SVE vector load and store instructions, excluding the replicating LD1R and LD1RQ instructions. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

This event counter does not count tag loads or tag stores.

0x80DB, LDST_FIXED_BYTES_SPEC, Non-scalable load and store bytes, Speculatively executed

The counter counts bytes speculatively read or written due to all non-SVE load, store and atomic operations, all SVE non-vector load and store operations, and SVE replicating LD1R and LD1RQ instructions.

- SVE and Advanced SIMD LD1R instructions increment the counter by $(MSIZE \div 8)$.
- SVE LD1RQ instructions increment the counter by 16.
- Advanced SIMD LD[1-4] and ST[1-4] instructions increment the counter by the number of transferred per register multiplied by the number of transferred.

See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80DC, LD_SCALE_BYTES_SPEC, Scalable load bytes, Speculatively executed

The counter counts bytes speculatively read due to SVE vector load instructions, excluding the replicating LD1R and LD1RQ instructions. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

This event counter does not count tag loads or tag stores.

0x80DD, LD_FIXED_BYTES_SPEC, Non-scalable load bytes, Speculatively executed

The counter counts bytes speculatively read due to all non-SVE load and atomic operations, all SVE non-vector load operations, and SVE replicating LD1R and LD1RQ instructions. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80DE, ST_SCALE_BYTES_SPEC, Scalable store bytes, Speculatively executed

The counter counts bytes speculatively written due to SVE vector store instructions. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

This event counter does not count tag loads or tag stores.

0x80DF, ST_FIXED_BYTES_SPEC, Non-scalable store bytes, Speculatively executed

The counter counts bytes written due to all non-SVE store and atomic operations, and all SVE non-vector store operations. See [ALU operation counts on page D7-2869](#) for information on the counter increment for different types of instruction.

0x80E1, ASE_INT8_SPEC, Advanced SIMD 8-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT8_SPEC](#) where the operation is an Advanced SIMD operation.

0x80E2, SVE_INT8_SPEC, SVE 8-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT8_SPEC](#) where the operation is an SVE operation.

0x80E3, ASE_SVE_INT8_SPEC, Advanced SIMD and SVE 8-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT8_SPEC](#) where the largest type is an 8-bit integer.

0x80E5, ASE_INT16_SPEC, Advanced SIMD 16-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT16_SPEC](#) where the operation is an Advanced SIMD operation.

0x80E6, SVE_INT16_SPEC, SVE 16-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT16_SPEC](#) where the operation is an SVE operation.

0x80E7, ASE_SVE_INT16_SPEC, Advanced SIMD and SVE 16-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT16_SPEC](#) where the largest type is an 16-bit integer.

0x80E9, ASE_INT32_SPEC, Advanced SIMD 32-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT32_SPEC](#) where the operation is an Advanced SIMD operation.

0x80EA, SVE_INT32_SPEC, SVE 32-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT32_SPEC](#) where the operation is an SVE operation.

0x80EB, ASE_SVE_INT32_SPEC, Advanced SIMD and SVE 32-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT32_SPEC](#) where the largest type is an 32-bit integer.

0x80ED, ASE_INT64_SPEC, Advanced SIMD 64-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT64_SPEC](#) where the operation is an Advanced SIMD operation.

0x80EE, SVE_INT64_SPEC, SVE 64-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT64_SPEC](#) where the operation is an SVE operation.

0x80EF, ASE_SVE_INT64_SPEC, Advanced SIMD and SVE 64-bit integer Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT_SPEC](#) where the largest type is an 64-bit integer.

0x80F1, ASE_FP_DOT_SPEC, Advanced SIMD floating-point dot-product Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_FP_DOT_SPEC](#) where the operation is an Advanced SIMD dot-product operation.

0x80F2, SVE_FP_DOT_SPEC, SVE floating-point dot-product Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_FP_DOT_SPEC](#) where the operation is an SVE dot-product operation.

0x80F3, ASE_SVE_FP_DOT_SPEC, Advanced SIMD and SVE floating-point dot-product Operations speculatively executed

The counter counts each operation counted by [FP_SPEC](#) where the operation is an Advanced SIMD or SVE dot-product operation.

0x80F5, ASE_FP_MMLA_SPEC, Advanced SIMD floating-point matrix multiply Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_FP_MMLA_SPEC](#) where the operation is an Advanced SIMD matrix multiply operation.

0x80F6, SVE_FP_MMLA_SPEC, SVE floating-point matrix multiply Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_FP_MMLA_SPEC](#) where the operation is an SVE matrix multiply operation.

0x80F7, ASE_SVE_FP_MMLA_SPEC, Advanced SIMD and SVE floating-point matrix multiply Operations speculatively executed

The counter counts each operation counted by [FP_SPEC](#) where the operation is an Advanced SIMD or SVE matrix multiply operation.

0x80F9, ASE_INT_DOT_SPEC, Advanced SIMD integer dot-product Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT_DOT_SPEC](#) where the operation is an Advanced SIMD dot-product operation.

0x80FA, SVE_INT_DOT_SPEC, SVE integer dot-product Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT_DOT_SPEC](#) where the operation is an SVE dot-product operation.

0x80FB, ASE_SVE_INT_DOT_SPEC, Advanced SIMD and SVE integer dot-product Operations speculatively executed

The counter counts each operation counted by [INT_SPEC](#) where the operation is an Advanced SIMD or SVE dot-product operation.

0x80FD, ASE_INT_MMLA_SPEC, Advanced SIMD integer matrix multiply Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT_MMLA_SPEC](#) where the operation is an Advanced SIMD matrix multiply operation.

0x80FE, SVE_INT_MMLA_SPEC, SVE integer matrix multiply Operations speculatively executed

The counter counts each operation counted by [ASE_SVE_INT_MMLA_SPEC](#) where the operation is an SVE matrix multiply operation.

0x80FF, ASE_SVE_INT_MMLA_SPEC, Advanced SIMD and SVE integer matrix multiply Operations speculatively executed

The counter counts each operation counted by [INT_SPEC](#) where the operation is an Advanced SIMD or SVE matrix multiply operation.

0x8110, **BR_IMMED_PRED_RETIRE**D, **Instruction architecturally executed, predicted immediate branch**

The counter counts the instructions on the architecturally executed path counted by both [BR_IMMED_RETIRE](#)D and [BR_PRED_RETIRE](#)D. These are all immediate branch instructions where the branch was correctly predicted.

0x8111, **BR_IMMED_MIS_PRED_RETIRE**D, **Instruction architecturally executed, mispredicted immediate branch**

The counter counts the instructions on the architecturally executed path, counted by both [BR_IMMED_RETIRE](#)D and [BR_MIS_PRED_RETIRE](#)D. These are all immediate branch instructions where the branch was mispredicted.

0x8112, **BR_IND_PRED_RETIRE**D, **Instruction architecturally executed, predicted indirect branch**

The counter counts the instructions on the architecturally executed path counted by both [BR_IND_RETIRE](#)D and [BR_PRED_RETIRE](#)D. These are branch instructions where the branch was correctly predicted, but does not include immediate instructions.

0x8113, **BR_IND_MIS_PRED_RETIRE**D, **Instruction architecturally executed, mispredicted indirect branch**

The counter counts the instructions on the architecturally executed path counted by both [BR_IND_RETIRE](#)D and [BR_MIS_PRED_RETIRE](#)D. These are branch instructions where the branch was mispredicted, but does not include immediate instructions.

0x8114, **BR_RETURN_PRED_RETIRE**D, **Instruction architecturally executed, predicted procedure return**

The counter counts the instructions on the architecturally executed path counted by [BR_IND_PRED_RETIRE](#)D where, if taken, the branch would be counted by [BR_RETURN_RETIRE](#)D. These are branch return instructions, where the branch was correctly predicted.

0x8115, **BR_RETURN_MIS_PRED_RETIRE**D, **Instruction architecturally executed, mispredicted procedure return**

The counter counts the instructions on the architecturally executed path counted by [BR_IND_MIS_PRED_RETIRE](#)D where, if taken, the branch would also be counted by [BR_RETURN_RETIRE](#)D. These are branch return instructions where the branch was mispredicted.

0x8116, **BR_INDNR_PRED_RETIRE**D, **Instruction architecturally executed, predicted indirect branch, excluding return**

The counter counts the instructions on the architecturally executed path counted by [BR_IND_PRED_RETIRE](#)D where, if taken, the branch would not be counted by [BR_RETURN_RETIRE](#)D. These are branch instructions where the branch was correctly predicted, but does not include immediate or return instructions.

0x8117, **BR_INDNR_MIS_PRED_RETIRE**D, **Instruction architecturally executed, mispredicted indirect branch, excluding return**

The counter counts the instructions on the architecturally executed path counted by [BR_IND_MIS_PRED_RETIRE](#)D where, if taken, the branch would not be counted by [BR_RETURN_RETIRE](#)D. These are branch instructions where the branch was mispredicted, but does not include immediate or return instructions.

0x8118, **BR_TAKEN_PRED_RETIRE**D, **Instruction architecturally executed, predicted branch, taken**

The counter counts the instructions on the architecturally executed path counted by both [PC_WRITE_RETIRE](#)D and [BR_PRED_RETIRE](#)D. These are branch instructions, where the branch was correctly predicted and taken.

0x8119, **BR_TAKEN_MIS_PRED_RETIRE**D, **Instruction architecturally executed, mispredicted branch, taken**

The counter counts the instructions on the architecturally executed path counted by both [PC_WRITE_RETIRE](#)D and [BR_MIS_PRED_RETIRE](#)D. These are branch instructions where the branch was mispredicted and taken.

0x811A, **BR_SKIP_PRED_RETIRE**, **Instruction architecturally executed, predicted branch, not taken**

The counter counts the instructions on the architecturally executed path counted by both **BR_SKIP_RETIRE** and **BR_PRED_RETIRE**. These are branch instructions, where the branch was correctly predicted and not taken.

0x811B, **BR_SKIP_MIS_PRED_RETIRE**, **Instruction architecturally executed, mispredicted branch, not taken**

The counter counts the instructions on the architecturally executed path counted by both **BR_SKIP_RETIRE** and **BR_MIS_PRED_RETIRE**. These are branch instructions where the branch was mispredicted and not taken.

0x811C, **BR_PRED_RETIRE**, **Instruction architecturally executed, predicted branch**

The counter counts the instructions on the architecturally executed path counted by **BR_RETIRE** that are not counted by **BR_MIS_PRED_RETIRE**. These are branch instructions, where the branch was correctly predicted.

0x8120, **INST_FETCH_PERCYC**, **Event in progress, INST_FETCH**

The counter counts by the number of **INST_FETCH** events in progress on each **Processor cycle**.

If this event is implemented, the **INST_FETCH** event must be implemented.

See also *Meaningful ratios between common microarchitectural events* on page D7-2937.

0x8121, **MEM_ACCESS_RD_PERCYC**, **Event in progress, MEM_ACCESS_RD**

The counter counts by the number of **MEM_ACCESS_RD** events in progress on each **Processor cycle**.

If this event is implemented, the **MEM_ACCESS_RD** event must be implemented.

See also *Meaningful ratios between common microarchitectural events* on page D7-2937.

0x8122, **MEM_ACCESS_WR_PERCYC**, **Event in progress, MEM_ACCESS_WR**

The counter counts by the number of **MEM_ACCESS_WR** events in progress on each **Processor cycle**.

If this event is implemented, the **MEM_ACCESS_WR** event must be implemented.

See also *Meaningful ratios between common microarchitectural events* on page D7-2937.

0x8123, **MEM_ACCESS_PERCYC**, **Event in progress, MEM_ACCESS**

The counter counts by the number of **MEM_ACCESS** events in progress on each **Processor cycle**.

If this event is implemented, the **MEM_ACCESS** event must be implemented.

See also *Meaningful ratios between common microarchitectural events* on page D7-2937.

0x8124, **INST_FETCH**, **Instruction memory access**

The counter counts each **Instruction memory access** that the PE makes. The counter increments whether the access is to a Level 1 instruction cache, a Level 2 instruction, data or unified cache, or none of these.

The counter does not increment as a result of:

- Data memory accesses.
- Translation table walks.
- Cache refills.
- Cache maintenance instructions.

0x8128, **DTLB_WALK_PERCYC**, **Event in progress, DTLB_WALK**

The counter counts by the number of **DTLB_WALK** events in progress on each **Processor cycle**.

If the TLB is shared, only events **Attributable** to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the **DTLB_WALK** event must be implemented.

See also:

- [Attributability](#) on page D7-2857.
- [Meaningful ratios between common microarchitectural events](#) on page D7-2937.

0x8129, **ITLB_WALK_PERCYC, Event in progress, ITLB_WALK**

The counter counts by the number of **ITLB_WALK** events in progress on each [Processor cycle](#).

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the **ITLB_WALK** event must be implemented.

See also:

- [Attributability](#) on page D7-2857.
- [Meaningful ratios between common microarchitectural events](#) on page D7-2937.

0x812A, **SAMPLE_FEED_BR, Statistical Profiling sample taken, branch**

The counter counts each sample counted by **SAMPLE_FEED** that are branch operations.

The values of **PMSFCR_EL1**.{B, FT} are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

0x812B, **SAMPLE_FEED_LD, Statistical Profiling sample taken, load**

The counter counts each sample counted by **SAMPLE_FEED** that are load or load atomic operations.

The values of **PMSFCR_EL1**.{LD, FT} are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

0x812C, **SAMPLE_FEED_ST, Statistical Profiling sample taken, store**

The counter counts each sample counted by **SAMPLE_FEED** that are store or atomic operations, including load atomic operations.

The values of **PMSFCR_EL1**.{ST, FT} are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

0x812D, **SAMPLE_FEED_OP, Statistical Profiling sample taken, matching operation type**

The counter counts each sample counted by **SAMPLE_FEED** that meets one of the following operation type filter constraints:

- The operation is a branch and **PMSFCR_EL1**.B is 1.
- The operation is a load or load atomic, and **PMSFCR_EL1**.LD is 1.
- The operation is a store or atomic operation, and **PMSFCR_EL1**.ST is 1.

The value of **PMSFCR_EL1**.FT is ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

0x812E, **SAMPLE_FEED_EVENT, Statistical Profiling sample taken, matching events**

The counter counts each sample counted by **SAMPLE_FEED** that meets the Events packet filter constraints defined by **PMSEVFR_EL1** and, if implemented, **PMSNEVFR_EL1**.

The values of **PMSFCR_EL1**.{FnE, FE} are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

0x812F, **SAMPLE_FEED_LAT, Statistical Profiling sample taken, exceeding minimum latency**

The counter counts each sample counted by **SAMPLE_FEED** with a total latency greater than or equal to the minimum latency defined by **PMSLATFR_EL1**.MINLAT.

The value of `PMSFCR_EL1.FL` is ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

0x8130, L1D_TLB_RW, Level 1 data or unified TLB demand access

The counter counts each access counted by `L1D_TLB` that is not counted by `L1D_TLB_PRFM`.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the `L1D_TLB` event must be implemented.

See also [Attributability on page D7-2857](#).

0x8131, L1I_TLB_RD, Level 1 instruction TLB demand access

The counter counts each access counted by `L1I_TLB` that is not counted by `L1I_TLB_PRFM`.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the `L1I_TLB` event must be implemented.

See also [Attributability on page D7-2857](#).

0x8132, L1D_TLB_PRFM, Level 1 data or unified TLB preload or prefetch

The counter counts each access counted by `L1D_TLB` that is due to a preload or prefetch instruction.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the `L1D_TLB` event must be implemented.

See also [Attributability on page D7-2857](#).

0x8133, L1I_TLB_PRFM, Level 1 instruction TLB preload or prefetch

The counter counts each access counted by `L1I_TLB` that is due to a preload or prefetch instruction.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the `L1I_TLB` event must be implemented.

See also [Attributability on page D7-2857](#).

0x8134, DTLB_HWUPD, Data TLB hardware update of translation table

The counter counts each access counted by `L1D_TLB` that causes a hardware update of a translation table entry.

The counter does not count if any of the following are true:

- The access is an unprivileged access that generates a Translation fault because the applicable `TCR_ELx.EOPDy` bit is 1.
- `FEAT_SVE` is implemented and the access is a non-fault access that fails because the applicable `TCR_ELx.NFDy` bit is 1.
- The access generates a Translation fault because the applicable `TCR_ELx.EPDy` bit is 1.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the `L1D_TLB` event must be implemented.

This event can only be implemented if `FEAT_E0PD` is implemented.

See also [Attributability on page D7-2857](#).

0x8135, ITLB_HWUPD, Instruction TLB hardware update of translation table

The counter counts each access counted by `L1I_TLB` that causes a hardware update of a translation table entry.

The counter does not count if any of the following are true:

- The access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the [L1D_TLB](#) event must be implemented.

This event can only be implemented if [FEAT_EOPD](#) is implemented.

See also [Attributability on page D7-2857](#).

0x8136, [DTLB_STEP](#), Data TLB translation table walk, step

The counter counts each translation table walk access made by a refill of the data or unified TLB.

The event is [Attributable](#) to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 or EL2.

The counter does not count if any of the following are true:

- The access that caused the walk is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.
- [FEAT_SVE](#) is implemented and the access that caused the walk is a non-fault access that fails because the applicable [TCR_ELx.NFDy](#) bit is 1.
- The access that caused the walk generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the [DTLB_WALK](#) event must be implemented.

This event can only be implemented if [FEAT_EOPD](#) is implemented.

See also [Attributability on page D7-2857](#).

0x8137, [ITLB_STEP](#), Instruction TLB translation table walk, step

The counter counts each translation table walk access made by a refill of an instruction TLB.

The event is [Attributable](#) to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 or EL2.

The counter does not count if any of the following are true:

- The access that caused the walk is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.
- The access that caused the walk generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the [ITLB_WALK](#) event must be implemented.

This event can only be implemented if [FEAT_EOPD](#) is implemented.

See also [Attributability on page D7-2857](#).

0x8138, [DTLB_WALK_LARGE](#), Data TLB large page translation table walk

The counter counts each translation table walk counted by [DTLB_WALK](#) where the result of the walk yields a large page size.

The set of large page sizes is the complement of the set of small page sizes defined by the [DTLB_WALK_SMALL](#) event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count each translation table walk when the access generates a Translation fault. If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the [DTLB_WALK](#) and [DTLB_WALK_SMALL](#) events must be implemented.

If this event is implemented then [FEAT_E0PD](#) must be implemented.

See also [Attributability on page D7-2857](#).

0x8139, [ITLB_WALK_LARGE](#), Instruction TLB large page translation table walk

The counter counts each translation table walk counted by [ITLB_WALK](#) where the result of the walk yields a large page size.

The set of large page sizes is the complement of the set of small page sizes defined by the [ITLB_WALK_SMALL](#) event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count each translation table walk when the access generates a Translation fault. If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the [ITLB_WALK](#) and [ITLB_WALK_SMALL](#) events must be implemented.

If this event is implemented then [FEAT_E0PD](#) must be implemented.

See also [Attributability on page D7-2857](#).

0x813A, [DTLB_WALK_SMALL](#), Data TLB small page translation table walk

The counter counts each translation table walk counted by [DTLB_WALK](#) where the result of the walk yields a small page size.

The set of small page sizes is the complement of the set of large page sizes defined by the [DTLB_WALK_LARGE](#) event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count each translation table walk when the access generates a Translation fault. If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the [DTLB_WALK](#) and [DTLB_WALK_LARGE](#) events must be implemented.

If this event is implemented then [FEAT_E0PD](#) must be implemented.

See also [Attributability on page D7-2857](#).

0x813B, [ITLB_WALK_SMALL](#), Instruction TLB small page translation table walk

The counter counts each translation table walk counted by [ITLB_WALK](#) where the result of the walk yields a small page size.

The set of small page sizes is the complement of the set of large page sizes defined by the [ITLB_WALK_LARGE](#) event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count each translation table walk when the access generates a Translation fault. If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the [ITLB_WALK](#) and [ITLB_WALK_LARGE](#) events must be implemented.

If this event is implemented then [FEAT_E0PD](#) must be implemented.

See also [Attributability](#) on page D7-2857.

0x813C, [DTLB_WALK_RW](#), Data TLB demand access with at least one translation table walk

The counter counts each access counted by [L1D_TLB_RW](#) that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count each access in the following cases:

- The access is due to a TLB maintenance instruction.
- [FEAT_E0PD](#) is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.
- [FEAT_SVE](#) is implemented and the access is a non-fault access that fails because the applicable [TCR_ELx.NFDy](#) bit is 1.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the following events must be implemented:

- [DTLB_WALK](#).
- [L1D_TLB_RW](#).

See also [Attributability](#) on page D7-2857.

0x813D, [ITLB_WALK_RD](#), Instruction TLB demand access with at least one translation table walk

The counter counts each access counted by [L1I_TLB_RD](#) that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count TLB maintenance instructions.

The counter does not count each access in the following cases:

- [FEAT_E0PD](#) is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the following events must be implemented:

- [ITLB_WALK](#).
- [L1I_TLB_RD](#).

See also [Attributability](#) on page D7-2857.

0x813E, [DTLB_WALK_PRFM](#), Data TLB preload or prefetch with at least one translation table walk

The counter counts each access counted by [L1D_TLB_PRFM](#) that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count each access in the following cases:

- [FEAT_E0PD](#) is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.
- [FEAT_SVE](#) is implemented and the access is a non-fault access that fails because the applicable [TCR_ELx.NFDy](#) bit is 1.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the following events must be implemented:

- [DTLB_WALK](#).
- [L1D_TLB_PRFM](#).

See also [Attributability](#) on page D7-2857.

0x813F, ITLB_WALK_PRFM, Instruction TLB preload or prefetch with at least one translation table walk

The counter counts each access counted by [L1I_TLB_PRFM](#) that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count each access in the following cases:

- [FEAT_EOPD](#) is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.

If the TLB is shared, only events [Attributable](#) to this PE are counted. If the TLB is not shared, all events are counted.

If this event is implemented, the following events must be implemented:

- [ITLB_WALK](#).
- [L1I_TLB_PRFM](#).

See also [Attributability](#) on page D7-2857.

0x8140, L1D_CACHE_RW, Level 1 data or unified cache demand access

The counter counts each access counted by [L1D_CACHE](#) that is not counted by [L1D_CACHE_PRFM](#).

If this event is implemented, the following events must be implemented:

- [L1D_CACHE](#).
- [L1D_CACHE_RD](#).
- [L1D_CACHE_WR](#).

0x8141, L1I_CACHE_RD, Level 1 instruction cache demand access

The counter counts each access counted by [L1I_CACHE](#) that is not counted by [L1I_CACHE_PRFM](#).

If this event is implemented, the [L1I_CACHE](#) event must be implemented.

0x8142, L1D_CACHE_PRFM, Level 1 data or unified cache preload or prefetch

The counter counts each access counted by [L1D_CACHE](#) that is due to a preload or prefetch instruction.

If this event is implemented, the [L1D_CACHE](#) event must be implemented.

0x8143, L1I_CACHE_PRFM, Level 1 instruction cache preload or prefetch

The counter counts each access counted by [L1I_CACHE](#) that is due to a preload or prefetch instruction.

If this event is implemented, the [L1I_CACHE](#) event must be implemented.

0x8144, L1D_CACHE_MISS, Level 1 data or unified cache demand access miss

The counter counts each demand access counted by [L1D_CACHE_RW](#) that misses in the Level 1 data or unified cache, causing an access outside the Level 1 data or unified cache of this PE.

If this event is implemented, the [L1D_CACHE_RW](#) event must be implemented.

0x8145, L1I_CACHE_HWPRF, Level 1 instruction cache hardware prefetch

The counter counts each cache line fetched to the Level 1 instruction cache from outside of the Level 1 instruction cache of this PE that is not counted by [L1I_CACHE_REFILL](#). The cache line fetch can be due to a hardware prefetcher but not due to a cache access.

0x8146, L1D_CACHE_REFILL_PRFM, Level 1 data or unified cache refill, preload or prefetch

The counter counts each preload or prefetch access counted by [L1D_CACHE_PRFM](#) that causes a refill of the Level 1 data or unified cache from outside the Level 1 data or unified cache of this PE.

If this event is implemented, the [L1D_CACHE_PRFM](#) event must be implemented.

0x8147, L1I_CACHE_REFILL_PRFM, Level 1 instruction cache refill, preload or prefetch

The counter counts each preload or prefetch access counted by [L1I_CACHE_PRFM](#) that causes a refill of the Level 1 instruction cache from outside the Level 1 instruction cache of this PE.

If this event is implemented, the [L1I_CACHE_PRFM](#) event must be implemented.

0x8148, L2D_CACHE_RW, Level 2 data or unified cache demand access

The counter counts each access counted by [L2D_CACHE](#) that is not counted by [L2D_CACHE_PRFM](#).

It is IMPLEMENTATION DEFINED whether an access to the Level 2 data or unified cache due to a prefetch to another cache is counted by [L2D_CACHE_RW](#) or [L2D_CACHE_PRFM](#).

0x8149, L2I_CACHE_RD, Level 2 instruction cache demand access

The counter counts each access counted by [L2I_CACHE](#) that is not counted by [L2I_CACHE_PRFM](#).

If this event is implemented, the [L2I_CACHE](#) event must be implemented.

0x814A, L2D_CACHE_PRFM, Level 2 data or unified cache preload or prefetch

The counter counts each access counted by [L2D_CACHE](#) that is due to a preload or prefetch instruction, or a prefetch to another cache.

It is IMPLEMENTATION DEFINED whether a prefetch to another cache is counted by [L2D_CACHE_RW](#) or [L2D_CACHE_PRFM](#).

If this event is implemented, the [L2D_CACHE](#) event must be implemented.

0x814B, L2I_CACHE_PRFM, Level 2 instruction cache preload or prefetch

The counter counts each access counted by [L2I_CACHE](#) that is due to a preload or prefetch instruction, or a prefetch to another cache.

It is IMPLEMENTATION DEFINED whether a prefetch to another cache is counted by [L2I_CACHE_RD](#) or [L2I_CACHE_PRFM](#).

If this event is implemented, the [L2I_CACHE](#) event must be implemented.

0x814C, L2D_CACHE_MISS, Level 2 data or unified cache demand access miss

The counter counts each demand access counted by [L2D_CACHE_RW](#) that misses in the Level 1 to Level 2 data or unified caches, causing an access outside the Level 1 to Level 2 data or unified caches of this PE.

If this event is implemented, the [L2D_CACHE_RW](#) event must be implemented.

0x814D, L2I_CACHE_HWPRF, Level 2 instruction cache hardware prefetch

The counter counts each cache line fetched to the Level 2 instruction cache from outside of the Level 1 to Level 2 instruction cache of this PE that is not counted by [L2I_CACHE_REFILL](#). The cache line fetch can be due to a hardware prefetcher but not due to a cache access.

0x814E, L2D_CACHE_REFILL_PRFM, Level 2 data or unified cache refill, preload or prefetch

The counter counts each preload or prefetch access counted by [L2D_CACHE_PRFM](#) that causes a refill of any of the Level 1 to Level 2 data or unified caches from outside the Level 1 to Level 2 data or unified caches of this PE.

If this event is implemented, the [L2D_CACHE_PRFM](#) event must be implemented.

0x814F, L2I_CACHE_REFILL_PRFM, Level 2 instruction cache refill, preload or prefetch

The counter counts each preload or prefetch access counted by [L2I_CACHE_PRFM](#) that causes a refill of the Level 1 to Level 2 instruction caches from outside the Level 1 to Level 2 instruction caches of this PE.

If this event is implemented, the [L2I_CACHE_PRFM](#) event must be implemented.

0x8150, L3D_CACHE_RW, Level 3 data or unified cache demand access

The counter counts each access counted by [L3D_CACHE](#) that is not counted by [L3D_CACHE_PRFM](#).

It is IMPLEMENTATION DEFINED whether an access to the Level 2 data or unified cache due to a prefetch to another cache is counted by [L3D_CACHE_RW](#) or [L3D_CACHE_PRFM](#).

If this event is implemented, the following events must be implemented:

- [L3D_CACHE](#).
- [L3D_CACHE_RD](#).
- [L3D_CACHE_WR](#).

0x8151, L3D_CACHE_PRFM, Level 3 data or unified cache preload or prefetch

The counter counts each access counted by [L3D_CACHE](#) that is due to a preload or prefetch instruction, or a prefetch to another cache.

It is IMPLEMENTATION DEFINED whether a prefetch to another cache is counted by [L3D_CACHE_RW](#) or [L3D_CACHE_PRFM](#).

If this event is implemented, the [L3D_CACHE](#) event must be implemented.

0x8152, L3D_CACHE_MISS, Level 3 data or unified cache demand access miss

The counter counts each demand access counted by [L3D_CACHE_RW](#) that misses in the Level 1 to Level 3 data or unified caches, causing an access outside the Level 1 to Level 3 data or unified caches of this PE.

If this event is implemented, the [L3D_CACHE_RW](#) event must be implemented.

0x8153, L3D_CACHE_REFILL_PRFM, Level 3 data or unified cache refill, preload or prefetch

The counter counts each preload or prefetch access counted by [L3D_CACHE_PRFM](#) that causes a refill of any of the Level 1 to Level 3 data or unified caches from outside the Level 1 to Level 3 data or unified caches of this PE.

If this event is implemented, the [L3D_CACHE_PRFM](#) event must be implemented.

0x8154, L1D_CACHE_HWPRF, Level 1 data cache hardware prefetch

The counter counts each cache line fetched to the Level 1 data or unified cache from outside of the Level 1 data or unified cache of this PE that is not counted by [L1D_CACHE_REFILL](#). The cache line fetch can be due to a hardware prefetcher but not due to a cache access.

———— **Note** —————

[L1D_CACHE_ALLOCATE](#) also does not count these fetches.

0x8155, L2D_CACHE_HWPRF, Level 2 data cache hardware prefetch

The counter counts each cache line fetched to the Level 2 data or unified cache from outside of the Level 1 to Level 2 data or unified cache of this PE that is not counted by [L2D_CACHE_REFILL](#). The cache line fetch can be due to a hardware prefetcher but not due to a cache access.

———— **Note** —————

[L2D_CACHE_ALLOCATE](#) also does not count these fetches.

0x8156, L3D_CACHE_HWPRF, Level 3 data cache hardware prefetch

The counter counts each cache line fetched to the Level 3 data or unified cache from outside of the Level 1 to Level 3 data or unified cache of this PE that is not counted by [L3D_CACHE_REFILL](#). The cache line fetch can be due to a hardware prefetcher but not due to a cache access.

———— **Note** —————

[L3D_CACHE_ALLOCATE](#) also does not count these fetches.

0x8158, STALL_FRONTEND_MEMBOUND, Frontend stall cycles, memory bound

The counter counts each cycle counted by [STALL_FRONTEND](#) when no instructions are delivered from the memory system.

The counter counts stalls that occur when the frontend interface to memory is busy or stalled. This includes the stalls counted by [STALL_FRONTEND_L1I](#), [STALL_FRONTEND_L2I](#), [STALL_FRONTEND_MEM](#), [STALL_FRONTEND_TLB](#), and any other IMPLEMENTATION DEFINED memory stalls.

It does not include stalls that are counted by [STALL_FRONTEND_CPUBOUND](#). However both events will count the same cycle counted by [STALL_FRONTEND](#) if there are both memory and processor-resource stall conditions active.

If this event is implemented, the following events must be implemented:

- [STALL_FRONTEND](#).
- [STALL_FRONTEND_CPUBOUND](#).

0x8159, STALL_FRONTEND_L1I, Frontend stall cycles, level 1 instruction cache

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand miss in the first level instruction cache.

If the first level instruction cache is the last level of instruction cache within the PE clock domain then this event is an alias for [STALL_FRONTEND_MEM](#) and also counts stalls when there is a non-cacheable access in progress.

0x815A, STALL_FRONTEND_L2I, Frontend stall cycles, level 2 instruction or unified cache

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand miss in the second level instruction or unified cache.

If the second level instruction or unified cache is the last level of instruction or unified cache within the PE clock domain then this event is an alias for [STALL_FRONTEND_MEM](#) and also counts stalls when there is a non-cacheable access in progress.

0x815B, STALL_FRONTEND_MEM, Frontend stall cycles, last level PE cache or memory

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand miss in the last level of cache within the PE clock domain or a non-cacheable access in progress.

0x815C, STALL_FRONTEND_TLB, Frontend stall cycles, TLB

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is an instruction or unified TLB demand miss.

If this event is implemented, the [STALL_FRONTEND_MEMBOUND](#) event must be implemented.

0x8160, STALL_FRONTEND_CPUBOUND, Frontend stall cycles, processor bound

The counter counts each cycle counted by [STALL_FRONTEND](#) when the frontend is stalled on a frontend processor resource, not including memory.

The counter counts stalls that occur when a frontend processor resource is busy. This includes the stalls counted by [STALL_FRONTEND_FLOW](#), [STALL_FRONTEND_FLUSH](#), and [STALL_FRONTEND_RENAME](#), and any other IMPLEMENTATION DEFINED processor resource stalls.

It does not include stalls that are counted by [STALL_FRONTEND_MEMBOUND](#). However both events will count the same cycle counted by [STALL_FRONTEND](#) if there are both memory and processor-resource stall conditions active.

If this event is implemented, the [STALL_FRONTEND](#) event must be implemented.

If this event is implemented, the following events must be implemented:

- [STALL_FRONTEND](#).
- [STALL_FRONTEND_MEMBOUND](#).

0x8161, STALL_FRONTEND_FLOW, Frontend stall cycles, flow control

The counter counts each cycle counted by [STALL_FRONTEND_CPUBOUND](#) when the frontend is stalled on unavailability of prediction flow resources.

———— **Note** —————

This event is not counting stalls due to mispredictions, but rather stalls when the frontend is unable to make a prediction.

If this event is implemented, the [STALL_FRONTEND_CPUBOUND](#) event must be implemented.

0x8162, STALL_FRONTEND_FLUSH, Frontend stall cycles, flush recovery

The counter counts each cycle counted by [STALL_FRONTEND_CPUBOUND](#) when the frontend is recovering from a flush or resteer.

The situations when the frontend is flushed are IMPLEMENTATION DEFINED. For example, the frontend might be flushed on a branch misprediction or on a [Context synchronization event](#).

If this event is implemented, the [STALL_FRONTEND_CPUBOUND](#) event must be implemented.

0x8163, STALL_FRONTEND_RENAME, Frontend stall cycles, rename full

The counter counts each cycle counted by [STALL_FRONTEND_CPUBOUND](#) when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available.

If this event is implemented and counts such stalls then the [STALL_BACKEND_RENAME](#) event counts as zero.

If this event is implemented, the [STALL_FRONTEND_CPUBOUND](#) event must be implemented.

0x8164, STALL_BACKEND_MEMBOUND, Backend stall cycles, memory bound

The counter counts each cycle counted by [STALL_BACKEND](#) when the backend is waiting for a memory access to complete.

The counter counts stalls that occur when a backend memory interface is busy or stalled. This includes the stalls counted by [STALL_BACKEND_L1D](#), [STALL_BACKEND_L2D](#), [STALL_BACKEND_ST](#), [STALL_BACKEND_TLB](#), and any other IMPLEMENTATION DEFINED memory stalls.

It does not include stalls that are counted by [STALL_BACKEND_CPUBOUND](#), although both events might count on the same cycle counted by [STALL_BACKEND](#) if there are both memory and processor resource stall conditions active.

If this event is implemented, the following events must be implemented:

- [STALL_BACKEND](#).
- [STALL_BACKEND_CPUBOUND](#).

0x8165, STALL_BACKEND_L1D, Backend stall cycles, level 1 data cache

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand miss in the first level data cache.

If the first level data cache is the last level of cache within the PE clock domain then this event is an alias for [STALL_BACKEND_MEM](#) and also counts stalls when there is a non-cacheable access in progress.

If this event is implemented, the [STALL_BACKEND_MEMBOUND](#) event must be implemented.

0x8166, STALL_BACKEND_L2D, Backend stall cycles, level 2 data or unified cache

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand miss in the second level data or unified cache.

If the second level data or unified cache is the last level of cache within the PE clock domain then this event is an alias for [STALL_BACKEND_MEM](#) and also counts stalls when there is a non-cacheable access in progress.

If this event is implemented, the [STALL_BACKEND_MEMBOUND](#) event must be implemented.

0x8167, STALL_BACKEND_TLB, Backend stall cycles, TLB

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a data or unified TLB demand miss.

If this event is implemented, the [STALL_BACKEND_MEMBOUND](#) event must be implemented.

0x8168, STALL_BACKEND_ST, Backend stall cycles, store

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when the backend is stalled waiting for a store.

If this event is implemented, the [STALL_BACKEND_MEMBOUND](#) event must be implemented.

0x816A, STALL_BACKEND_CPUBOUND, Backend stall cycles, processor bound

The counter counts each cycle counted by [STALL_BACKEND](#) when the backend is stalled on a processor resource, not including memory.

The counter counts stalls that occur when a backend processor resource is busy. This includes the stalls counted by [STALL_BACKEND_RENAME](#) and any other IMPLEMENTATION DEFINED processor resource stalls.

It does not include stalls that are counted by [STALL_BACKEND_MEMBOUND](#), although both events might count on the same cycle counted by [STALL_BACKEND](#) if there are both memory and processor resource stall conditions active.

If this event is implemented, the following events must be implemented:

- [STALL_BACKEND](#).
- [STALL_BACKEND_MEMBOUND](#).

0x816B, STALL_BACKEND_BUSY, Backend stall cycles, backend busy

The counter counts each cycle counted by [STALL_BACKEND](#) when operations are available from the frontend but the backend is not able to accept an operation because an execution unit is busy.

For example, a complex operation unit such as a divider might be executing a previous operation and cannot accept a new operation.

If this event is implemented, the [STALL_BACKEND](#) event must be implemented.

0x816C, STALL_BACKEND_ILOCK, Backend stall cycles, input dependency

The counter counts each cycle counted by [STALL_BACKEND](#) when operations are available from the frontend but at least one is not ready to be sent to the backend due to an input dependency.

If this event is implemented, the [STALL_BACKEND](#) event must be implemented.

0x816D, STALL_BACKEND_RENAME, Backend stall cycles, rename full

The counter counts each cycle counted by [STALL_BACKEND](#) when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available.

If this event is implemented and counts such stalls then the [STALL_FRONTEND_RENAME](#) event counts as zero.

If this event is implemented, the [STALL_BACKEND_CPUBOUND](#) event must be implemented.

D7.10.4 Cycle event counting

The [CPU_CYCLES](#) event and the cycle counter, [PMCCNTR](#), count cycles. The duration of a cycle is subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions.

It is implementation specific whether [CPU_CYCLES](#) and [PMCCNTR](#) count when the PE is in WFI or WFE state, even if the clocks are not stopped.

In addition, events such as [STALL](#), [STALL_FRONTEND](#) and [STALL_BACKEND](#) that are defined to only count cycles that are counted by the [CPU_CYCLES](#) event have the same limitation.

Multithreaded implementations

Multithreaded implementations can have various forms, some examples of these are:

- *Simultaneous Multithreading* (SMT), where every PE thread is active on every [Processor cycle](#).
- *Fine-grained Multithreading* (FGMT), also known as a Barrel processor, where one PE thread is active on each [Processor cycle](#), and this changes regularly.
- *Switch on Event Multithreading* (SoEMT), also known as *Coarse-grained Multithreading* (CGMT), where high latency events cause the processor to switch the active PE thread.

In the above examples, active means that the PE might execute the instructions. A PE can be active but not executing instructions when no instruction is available or because of limited execution resources.

It is implementation specific whether a thread is active when the thread is in WFE or WFI state. This applies for all forms of multithreaded implementation.

When the PMU implementation supports multithreading, and the *Effective value* of `PMEVTYPER<n>_EL0.MT` bit is 0, the `CPU_CYCLES` event does not count [Processor cycles](#) on which the thread was not active. For the example multithreaded implementations, this means that, if the event counter is enabled, event counting is not prohibited, and the thread is not in WFE or WFI state:

- For an SMT implementation, the `CPU_CYCLES` event counts every [Processor cycle](#).
- For a particular FGMT implementation, that alternates between two threads on each [Processor cycle](#), the `CPU_CYCLES` event counts every other [Processor cycle](#).
- For a particular SoEMT implementation, that is waiting for a long latency operation, the `CPU_CYCLES` event does not count [Processor cycles](#), as the PE thread is not active.

If the *Effective value* of `PMEVTYPER<n>_EL0.MT` bit is 1, the `CPU_CYCLES` event counts each [Processor cycle](#), and can only count a maximum of one each [Processor cycle](#).

Events that only count cycles that are counted by the `CPU_CYCLES` event have the same limitation. For example, in an SMT implementation, if a PE thread cannot issue an instruction because of contention with other PE threads, these are counted as `STALL_BACKEND` cycles.

If the *Effective value* of `PMEVTYPER<n>_EL0.MT` bit is 1, the PE only counts cycles on which no operation is issued from any thread.

———— Note ————

The cycle counter, `PMCCNTR`, is not affected by whether the thread is active or inactive. When enabled, `PMCCNTR` counts every processor cycle.

See [Multithreaded implementations](#) on page D7-2863, `MDCR_EL3.MTPME`, `SDCR.MTPME`, `MDCR_EL2.MTPME`, and `HDCR.MTPME` for more information about when the *Effective value* of `PMEVTYPER<n>_EL0.MT` is 0.

D7.10.5 Meaningful ratios between common microarchitectural events

The architecture highlights some meaningful ratios that can be derived from the common microarchitectural events. [Table D7-7](#) on page D7-2937 lists the highlighted ratios.

Table D7-7 REFILL events and associated access events

Numerator	Denominator	Ratio
0x0001 L1I_CACHE_REFILL	0x0014 L1I_CACHE	Attributable Level 1 instruction cache refill rate
0x0002 L1I_TLB_REFILL	0x0026 L1I_TLB	Attributable Level 1 instruction TLB refill rate
0x0003 L1D_CACHE_REFILL	0x0004 L1D_CACHE	Attributable Level 1 data or unified cache refill rate

Table D7-7 REFILL events and associated access events (continued)

Numerator	Denominator	Ratio
0x0005 L1D_TLB_REFILL	0x0025 L1D_TLB	Attributable Level 1 data or unified TLB refill rate
0x0017 L2D_CACHE_REFILL	0x0016 L2D_CACHE	Attributable Level 2 data or unified cache refill rate
0x0028 L2I_CACHE_REFILL	0x0027 L2I_CACHE	Attributable Level 2 instruction cache refill rate
0x002A L3D_CACHE_REFILL	0x002B L3D_CACHE	Attributable Level 3 data or unified cache refill rate
0x002D L2D_TLB_REFILL	0x002F L2D_TLB	Attributable Level 2 data or unified TLB refill rate
0x002E L2I_TLB_REFILL	0x0030 L2I_TLB	Attributable Level 2 instruction TLB refill rate
0x0019 BUS_ACCESS	0x001D BUS_CYCLES	Attributable Bus accesses per cycle
0x0033 LL_CACHE_MISS	0x0032 LL_CACHE	Attributable Last Level data or unified cache refill rate
0x0034 DTLB_WALK	0x0025 L1D_TLB	Attributable data TLB miss rate
0x0035 ITLB_WALK	0x0026 L1I_TLB	Attributable instruction TLB miss rate
0x0037 LL_CACHE_MISS_RD	0x0036 LL_CACHE_RD	Attributable memory read operation miss rate
0x0038 REMOTE_ACCESS_RD	0x0031 REMOTE_ACCESS	Attributable read accesses to another socket in a multi-socket system
0x8120 INST_FETCH_PERCYC	0x8124 INST_FETCH	Mean duration of instruction fetch events in processor cycles
0x8121 MEM_ACCESS_RD_PERCYC	0x0066 MEM_ACCESS_RD	Mean duration of memory read access events in processor cycles
0x8122 MEM_ACCESS_WR_PERCYC	0x0067 MEM_ACCESS_WR	Mean duration of memory write access events in processor cycles
0x8123 MEM_ACCESS_PERCYC	0x0013 MEM_ACCESS	Mean duration of memory access events in processor cycles
0x8128 DTLB_WALK_PERCYC	0x0034 DTLB_WALK	Mean duration of data or unified TLB walk events in processor cycles
0x8129 ITLB_WALK_PERCYC	0x0035 ITLB_WALK	Mean duration of instruction TLB walk events in processor cycles

D7.10.6 Required events

FEAT_PMUv3 requires that an implementation includes the following common events:

- 0x0000, SW_INCR, Instruction architecturally executed, Condition code check pass, software increment.
- 0x0003, L1D_CACHE_REFILL, Level 1 data cache refill.

———— **Note** —————

Event 0x0003 is only required if the implementation includes a Level 1 data or unified cache.

- 0x0004, L1D_CACHE, Level 1 data cache access.

———— **Note** —————

Event 0x0004 is only required if the implementation includes a Level 1 data or unified cache.

- 0x0010, BR_MIS_PRED, Mispredicted or not predicted branch Speculatively executed.

———— **Note** —————

Event 0x0010 is only required if the implementation includes program-flow prediction. However, Arm strongly recommends that the event is implemented as described in [Common microarchitectural events on page D7-2884](#).

- 0x0011, CPU_CYCLES, Cycle.
- 0x0012, BR_PRED, Predictable branch [Speculatively executed](#).

———— **Note** —————

Event 0x0012 is only required if the implementation includes program-flow prediction. However, Arm recommends that the event is implemented as described in [Common microarchitectural events on page D7-2884](#).

- At least one of:
 - 0x0008, INST_RETIRED, Instruction architecturally executed.
 - 0x001B, INST_SPEC, Operation [Speculatively executed](#).

———— **Note** —————

Arm strongly recommends that event 0x008 is implemented.

- When FEAT_PMUv3p1 is implemented:
 - 0x0023, STALL_FRONTEND, No operation issued due to the frontend.
 - 0x0024, STALL_BACKEND, No operation issued due to the backend.
- When [The Scalable Vector Extension \(SVE\)](#) is implemented, at least one of:
 - 0x8002, SVE_INST_RETIRED, SVE instruction architecturally retired.
 - 0x8006, SVE_INST_SPEC, SVE operation speculatively executed.
- When FEAT_SPE is implemented:
 - 0x4000, SAMPLE_POP, Statistical Profiling sample population.
 - 0x4001, SAMPLE_FEED, Statistical Profiling sample taken.
 - 0x4002, SAMPLE_FILTRATE, Statistical Profiling sample filtered.
 - 0x4003, SAMPLE_COLLISION, Statistical Profiling sample collision.
- When FEAT_PMUv3p4 is implemented:
 - 0x003C, STALL, No operation sent for execution.
 - 0x0039, L1D_CACHE_LMISS_RD, Level 1 data cache long-latency read miss.
 - 0x4006, L1I_CACHE_LMISS, Level 1 instruction cache long-latency miss.
 - 0x0040, L1D_CACHE_RD, Level 1 data cache read.
- When FEAT_SPEv1p2 is implemented:
 - 0x812A, SAMPLE_FEED_BR, Statistical Profiling sample taken, branch.
 - 0x812B, SAMPLE_FEED_LD, Statistical Profiling sample taken, load.
 - 0x812C, SAMPLE_FEED_ST, Statistical Profiling sample taken, store.
 - 0x812D, SAMPLE_FEED_OP, Statistical Profiling sample taken, matching operation type.
 - 0x812E, SAMPLE_FEED_EVENT, Statistical Profiling sample taken, matching events.
 - 0x812F, SAMPLE_FEED_LAT, Statistical Profiling sample taken, exceeding minimum latency.

When any of the following common events are implemented, all three of them are implemented:

- 0x003D, STALL_SLOT_BACKEND, No operation sent for execution on a [Slot](#) due to the backend,
- 0x003E, STALL_SLOT_FRONTEND, No operation sent for execution on a [Slot](#) due to the frontend.
- 0x003F, STALL_SLOT, No operation sent for execution on a [Slot](#).

Arm strongly recommends that the following events are implemented:

- 0x0021, BR_RETIRED.
- 0x0022, BR_MIS_PRED_RETIRED.
- 0x003A, OP_RETIRED.
- 0x003B, OP_SPEC.

- 0x003D, [STALL_SLOT_BACKEND](#).
- 0x003E, [STALL_SLOT_FRONTEND](#).
- 0x003F, [STALL_SLOT](#).

D7.10.7 IMPLEMENTATION DEFINED event numbers

Arm recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common event numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, Arm recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

The Arm architecture guarantees not to define any event prefixed with *IMP_* as part of the standard Arm architecture.

Arm strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINED events:

- Separating each of the [STALL_FRONTEND](#) and [STALL_SLOT_FRONTEND](#) events to count holes in instruction availability.
- Separating each of the [STALL_BACKEND](#) and [STALL_SLOT_BACKEND](#) events, to count, for example, cumulative duration of stalls, unavailability of execution resources, or missed superscalar issue opportunities.
- Miss rates for additional levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative duration of a [PSTATE](#). {A, I, F} interrupt mask set to 1.
- Cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist. An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, for example by specifying a minimum latency for an event to be counted.
- Any other microarchitectural features that the implementer considers are valuable to count.

The range of possible IMPLEMENTATION DEFINED event numbers is described in [The PMU event number space and common events on page D7-2875](#). [Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events](#) lists the Arm recommended standardized numbering scheme for these events.

D7.11 Performance Monitors Extension registers

Further information on the Performance Monitors Extension Registers can be found in the following sections:

- [Table K15-2 on page K15-8604](#) lists the Performance Monitors register names for AArch32 and AArch64 states.
- [Performance monitors registers on page K15-8627](#) summarizes the Performance Monitors Extension registers in AArch64 state.
- [Performance monitors registers on page K15-8652](#) summarizes the Performance Monitors Extension registers in AArch32 state.

Chapter D8

The Activity Monitors Extension

This chapter describes the Armv8 implementation of version 1 of the *Activity Monitor Unit* (AMU) architecture, AMUv1, an optional non-invasive component. It contains the following sections:

- [About the Activity Monitors Extension](#) on page D8-2942.
- [Properties and behavior of the activity monitors](#) on page D8-2943.
- [AMU events and event numbers](#) on page D8-2945.

D8.1 About the Activity Monitors Extension

The Activity Monitors Extension is an OPTIONAL extension to the Armv8.4 architecture.

The Activity Monitors Extension implements version 1 of the Activity Monitors architecture, AMUv1, and interfaces to the registers defined by AMUv1, the Activity Monitors registers.

Version 1 of the Activity Monitors architecture implements:

- A counter group of four architected 64-bit event counters. The events counted by the architected event counter are fixed and architecturally defined.

———— **Note** —————

The Activity Monitors architecture provides space for up to 16 architected event counters. Future versions of the Activity Monitors architecture may use this space to implement additional architected event counters.

- A counter group of up to 16 auxiliary 64-bit event counters. The event counted for each auxiliary event counter may be fixed or programmable, and whether it is fixed or programmable is IMPLEMENTATION DEFINED. When the event counted by an auxiliary event counter is fixed, this event is IMPLEMENTATION DEFINED.
- Controls for enabling and disabling counters.
- When the event counted by an auxiliary event counter is programmable, controls for assigning an event to the counter.
- Controls that determine whether the activity monitor counters continue to count while the PE is halted in Debug state.

The read-only registers [AMCFGR](#) and [AMCGCR](#) provide information about features supported by the Activity Monitors Extension, the number of counter groups implemented, the total number of counters implemented, the number of counters implemented within each group, and the size of the counters.

The Activity Monitors Extension provides:

- A mandatory System register interface to the Activity Monitors registers, for both AArch64 and AArch32 states.
[Base system registers on page K15-8635](#) lists the AArch64 Activity Monitors registers, and [Base system registers on page K15-8660](#) lists the AArch32 Activity Monitors registers. [Table K15-3 on page K15-8605](#) shows the relationship between the AArch64 and the AArch32 Activity Monitors register.
- Controls that allow software to enable or disable access by software running at lower Exception levels to the Activity Monitors registers.
- When [FEAT_AMUv1p1](#) is implemented, and the hypervisor is using AArch64, offset registers that support virtualization of the Activity Monitor event counters.
- An optional external interface providing read-only memory-mapped access to the Activity Monitors registers.
[Alphabetical index of memory-mapped registers on page K15-8662](#) lists the Activity Monitors memory-mapped registers. For more information on the recommended external interface, see [Chapter I4 Recommended External Interface to the Activity Monitors](#).

D8.2 Properties and behavior of the activity monitors

D8.2.1 Basic characteristics of the activity monitor event counters

Every activity monitor event counter is a 64-bit wrapping counter. When an activity monitor event counter wraps, the counter overflows.

———— **Note** ————

The Activity Monitor architecture does not provide support for overflow status indication or interrupts.

The state of the authentication signals do not affect counting.

Any change in clock frequency, including when a WFI and WFE instruction stops the clock, can affect any counter.

If [FEAT_AMUv1p1](#) is implemented, for the architected event counters 0, 2 and 3, and each auxiliary event counter configured to use an offset, there is an offset register which is used to virtualize the count on a read from EL1 or EL0. At EL2, EL3 or from the memory-mapped view, permitted accesses to the counters use the physical view without any offset. See [Virtualization on page D8-2944](#)

D8.2.2 Counter configuration and controls

For each architected event counter [AMEVCNTR0<n>](#), there is a corresponding event type register [AMEVTYPER0<n>](#) which provides information on the event counted by that counter. The event type registers [AMEVTYPER0<n>](#) are read-only.

For each auxiliary event counter [AMEVCNTR1<n>](#), there is a corresponding event type register [AMEVTYPER1<n>](#) which provides information on the event counted by that counter. When the event counted by an auxiliary event counter is fixed, the corresponding event type register [AMEVTYPER1<n>](#) is read-only. When the event counted by an auxiliary event counter is programmable, the corresponding event type register [AMEVTYPER1<n>](#) is read/write.

For each counter group, there is a pair of separate controls to enable and disable the counters in that counter group. [AMCNTENCLR0](#) and [AMCNTENSET0](#) are used to disable and enable the architected event counters. [AMCNTENCLR1](#) and [AMCNTENSET1](#) are used to disable and enable the auxiliary event counters.

While the PE is halted in Debug state, [AMCR.HDBG](#) controls whether activity monitor counting is halted.

[AMUSERENR.EN](#) controls access from EL0 to the Activity Monitor Extension System registers. [CPTR_EL2.TAM](#) and [HCPTR.TAM](#) control access from EL0 and EL1 to the Activity Monitor Extension System registers. [CPTR_EL3.TAM](#) control access from EL0, EL1, and EL2 to the Activity Monitor Extension System registers.

———— **Note** ————

These controls obey the priority order described in [Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2490](#) and [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-6047](#).

[AMUSERENR.EN](#) is configurable at EL1, EL2, and EL3. All other controls, as well as the value of the counters, are configurable only at the highest implemented Exception level.

If [FEAT_AMUv1p1](#) is implemented, [AMCG1HDR_EL0](#) defines which auxiliary counters are implemented, and if virtual offsets are enabled, indicates which of the implemented auxiliary counters have a virtual offset when read from EL0 and EL1.

If [FEAT_AMUv1p1](#) is implemented, [AMCR.CG1RZ](#) controls whether the auxiliary event counters read as zero if they are accessed at an Exception level lower than the highest implemented Exception level.

D8.2.3 Power and reset domains

The power domain of the Activity Monitoring Unit is IMPLEMENTATION DEFINED and named the AMU domain.

The reset domain of the Activity Monitoring Unit is IMPLEMENTATION DEFINED and named the AMU reset.

The AMU power domain may be the Core power domain.

When an AMU reset of the AMU power domain occurs, the Activity Monitoring Unit is reset and the counters are reset to zero.

When the PE is not in reset, the Activity Monitoring Unit is available

D8.2.4 Accuracy and non-invasive behavior

The activity monitors are a non-invasive component which must provide broadly accurate and statistically useful count information.

The implementation of an architecturally required event might create a conflict between the requirement to be non-invasive and the requirement to present an accurate value of the count under normal operating conditions. An implementation might provide an IMPLEMENTATION DEFINED control that disables accurate count of the event to restore performance and document the impact on performance of accurate counting. The expectations for non-invasive behavior and the degree of inaccuracy of the activity monitors are otherwise as described for the Performance Monitors architecture.

———— **Note** —————

For information on the expectations for non-invasive behavior and the degree of inaccuracy of the Performance Monitors, see [Non-invasive behavior on page D7-2853](#) and [A reasonable degree of inaccuracy on page D7-2853](#).

D8.2.5 Virtualization

[FEAT_AMUv1p1](#) supports virtualized access to the Activity Monitors event counters at EL1 and EL0.

The fields [HCR_EL2.AMVOFFEN](#) and [SCR_EL3.AMVOFFEN](#) enable and disable virtualization. When enabled, the architected event counters 0, 2 and 3 have counter offsets. Architected event counter 1 does not have an offset. The register [AMCG1IDR_EL0](#) indicates which of the implemented auxiliary event counters has implemented counter offsets. An implemented event counter that does not have a defined offset has an effective offset of zero. The offset registers can be accessed only at EL2 or EL3, and affect views of the event counters at EL1 and EL0 from the System register interfaces only.

The [AMEVCNTVOFF0<n>_EL2](#) registers hold the offsets for the implemented and enabled architected event counters.

The [AMEVCNTVOFF1<n>_EL2](#) registers hold the offsets for the implemented and enabled auxiliary event counters.

D8.3 AMU events and event numbers

The Activity Monitors architecture uses the event number space defined by the Performance Monitors architecture to identify events.

The Activity Monitors architecture defines additional events and adds them to the event number space defined by the Performance Monitors architecture for common events.

If the event is counting an IMPLEMENTATION DEFINED event, it must use an event number from the IMPLEMENTATION DEFINED event space.

When an implementation supports monitoring of an event that is assigned a common architectural or microarchitectural event number, Arm strongly recommends that it uses that number for the event.

When a common event is available to both the Performance Monitors architecture and the Activity Monitors architecture within one implementation, both architectures use the same event number.

D8.3.1 Architected event counters

Version 1 of the Activity Monitors architecture, AMUv1, requires four events to be counted by the architected activity monitor event counters.

The events required to be counted are:

0x0011, CPU_CYCLES, Processor frequency cycles

The counter increments on every cycle when the PE is not in WFI or WFE state. When the PE is in WFI or WFE state, this counter does not increment.

This event is counted by `AMEVCNTR0<n>`, where n is 0.

0x4004, CNT_CYCLES, Constant frequency cycles

The counter increments at a constant frequency when the PE is not in WFI or WFE state, equal to the rate of increment of the System counter, `CNTPCT_EL0`. When the PE is in WFI or WFE state, this counter does not increment.

This event is counted by `AMEVCNTR0<n>`, where n is 1.

0x0008, INST_RETIRED, Instructions retired

This event is defined identically to `INST_RETIRED` in the `FEAT_PMUv3` architecture.

This event is counted by `AMEVCNTR0<n>`, where n is 2.

0x4005, STALL_BACKEND_MEM, Memory stall cycles

The counter counts cycles in which the PE is unable to dispatch instructions from the frontend to the backend of the PE due to a backend stall caused by a miss in the last level of cache within the PE clock domain or, if Armv8.7 is implemented, non-cacheable access in progress.

If Armv8.7 is not implemented, it is IMPLEMENTATION DEFINED whether the counter counts backend stall cycles when a non-cacheable access is in progress.

This event is counted by `AMEVCNTR0<n>`, where n is 3.

D8.3.2 Auxiliary event counters

Auxiliary event counters can count events defined by the Performance Monitors architecture and IMPLEMENTATION DEFINED events defined specifically for activity monitoring.

Implementations must not reuse an IMPLEMENTATION DEFINED event number for different hardware events across the Performance Monitors architecture and the Activity Monitors architecture.

Chapter D9

The Statistical Profiling Extension

This chapter describes the Statistical Profiling Extension. It contains the following sections:

- *About the Statistical Profiling Extension* on page D9-2948.
- *Defining the sample population* on page D9-2950.
- *Controlling when an operation is sampled* on page D9-2951.
- *Enabling profiling* on page D9-2954.
- *Filtering sample records* on page D9-2956.
- *The profiling data* on page D9-2958.
- *The Profiling Buffer* on page D9-2968.
- *Profiling Buffer management* on page D9-2973.
- *Synchronization and Statistical Profiling* on page D9-2977.

D9.1 About the Statistical Profiling Extension

When the Statistical Profiling Extension is implemented, the PE includes a *Statistical Profiling Unit* (SPU). When profiling is enabled, the SPU does the following:

1. Chooses an operation from a sample population, that can be restricted by Exception level, at a programmable interval that might have some random, or pseudorandom, perturbation.
2. Takes a trace of the sampled operation. This includes the PC, events, timings, and data addresses, related to the sampled operation. This is the profiling operation.
3. If defined, filters out potential sample records generated by the profiling operation by reference to any or all of the following:
 - a. The type of operation.
 - b. Events.
 - c. Latency.
4. Creates a record that contains the traced information. Sample records that meet the criteria of the filter are written to and stored in a memory buffer. These sample records can be processed by software when the memory buffer is full.

D9.1.1 Non-invasive behavior

Statistical Profiling is a non-invasive debug operation:

- While profiling is enabled, the operation and performance of the processing element (PE) must not be significantly impacted between sampled operations, that is, other than for writing out sample records and processing Profiling Buffer management interrupts.
- The performance of the sampled operation and the performance of the PE in general must not be significantly impacted. The sample records are not written to memory until after the sampled operation has finished execution. However, this does not apply if the sample records are physical addresses for data access operations. In this case, the impact is IMPLEMENTATION DEFINED.
- The profiling operation to write sample records must not be excessively impactful on the performance of the sampled operation or the performance of the PE generally.

D9.1.2 PMU extensions

If the Statistical Profiling and Performance Monitors Extensions are implemented, then the following PMU events must be implemented:

- [SAMPLE_POP](#).
- [SAMPLE_FEED](#).
- [SAMPLE_FILTRATE](#).
- [SAMPLE_COLLISION](#).

———— **Note** —————

These events are discoverable through a read of [PMCEID0_ELO](#)[35:32].

If [FEAT_SPEv1p2](#) is implemented, the following PMU events must be implemented:

- [SAMPLE_FEED_BR](#).
- [SAMPLE_FEED_LD](#).
- [SAMPLE_FEED_ST](#).
- [SAMPLE_FEED_OP](#).
- [SAMPLE_FEED_EVENT](#).
- [SAMPLE_FEED_LAT](#).

D9.1.3 Multithreaded implementations

In a multithreaded implementation:

- Statistical Profiling is implemented per-thread.
- The sample interval counter counts only operations for the thread that is being profiled.
- Latency and other cycle counters count each cycle for the PE for which the thread was active and could issue an operation.

The architecture does not define features for inter-thread profiling and does not support sharing the Profiling Buffer between threads.

———— **Note** —————

An implementation is described as multithreaded when the lowest level of [affinity](#) consists of logical processors that are implemented using a multi-threading type approach. That is, the performance of processors at the lowest affinity level is very interdependent.

D9.2 Defining the sample population

All samples are taken from a *population of operations*. The population is dynamic rather than static. That is, if a program executes the same operation multiple times (for example, because of loops and subroutines) then that operation appears multiple times in the population.

The operations are an IMPLEMENTATION DEFINED choice between:

- Architecture instructions.
- IMPLEMENTATION DEFINED microarchitectural operations (micro-ops).

Architecture instruction means a single instruction that is defined by the Armv8 instruction set architecture in AArch64 state.

An architecture instruction might create one or more micro-ops at any point in the execution pipeline. The definition of a micro-op is implementation specific. An architecture instruction might create more than one micro-op for each instruction. A micro-op might also be removed or merged with another micro-op in the execution stream, so an architecture instruction might create no micro-ops for an instruction.

Any arbitrary translation of architecture instructions to an equivalent sequence of micro-ops is permitted. In some implementations, the relationship between architecture instructions and micro-ops might vary over time.

———— **Note** —————

Sampling from architecture instructions does not require that the instruction is architecturally executed.

D9.2.1 Operations that might be excluded from the sample population

It is IMPLEMENTATION DEFINED whether each of the following operations is part of the sample population:

- Operations on misspeculated paths.
- Operations (specifically micro-ops) that do not relate to any architecture instruction.
- Operations that generate non-architectural exceptions.

If the operation is not part of the sample population, the operation does not cause the sample interval counter to decrement, is not counted by the [SAMPLE_POP](#) event and therefore is never sampled.

If the operation is part of the sample population, the operation causes the sample interval counter to decrement, is counted by the [SAMPLE_POP](#) event, and might be sampled and counted by the [SAMPLE_FEED](#) event. However, it is IMPLEMENTATION DEFINED whether the sample record for such a sampled operation is captured in the Profiling Buffer. For more information, see [Sample operation records for misspeculated and non-architectural operations on page D9-2965](#) and [Non-architectural exceptions on page D9-2967](#).

If such a sample record is not captured into the Profiling Buffer, then no packets are output and the sample is not counted by the [SAMPLE_FILTRATE](#) event.

———— **Note** —————

If the owning Exception level passes this data to less privileged software for processing, it can set [PMSFCR_EL1.FE](#) to 1 and [PMSEVFR_EL1\[1\]](#) to 1 to prevent speculative instructions from being recorded in the Profiling Buffer.

D9.3 Controlling when an operation is sampled

The sample interval counter, `PMSICR_EL1.COUNT` controls when an operation is selected for sampling. In some implementations, a secondary sample interval counter, `PMSICR_EL1.ECOUNT`, is also used.

The following sections describe the operation of the sample interval counters.

Details of the random or pseudorandom number generator used when `PMSIRR_EL1.RND` is set to 1 are IMPLEMENTATION DEFINED. See *Generating random numbers for sampling* on page D9-2951.

D9.3.1 Operation sampling

A sample operation is as follows:

1. A sampling interval is written to `PMSICR_EL1.COUNT` by software. The interval is measured in operations.
2. The sample interval counter is decremented by hardware for each operation when sampling is enabled.
3. When the sample interval counter reaches zero, then:
 - a. If random perturbation is enabled, the PE continues to count for a random number of further operations while sampling is enabled.
 - b. An operation is chosen for profiling. The choice of operation around the sampling point is implementation-specific, but does not introduce sampling bias.
4. The sample interval counter is reloaded and the process loops to step 2. It is IMPLEMENTATION DEFINED whether the sample interval counter is reloaded before step 3.a) or at step 3.b). That is, before or after counting the random number of further operations.
5. The chosen operation is marked as the sampled operation. The PE collects information about the sampled operation as it executes by a profiling operation.
6. The sample record is created when the sampled operation has finished execution.

D9.3.2 Generating random numbers for sampling

The random number generator is IMPLEMENTATION DEFINED. Implementations might use a pseudorandom number. The random number generator must be reset into a useable state. An implementation might include IMPLEMENTATION DEFINED registers to further configure the random number generator.

It is IMPLEMENTATION DEFINED whether the PE adds the random number to the sample interval counter prior to counting down the interval, or after the counter reaches zero and the counter has been reloaded.

D9.3.3 Initializing the sample interval counters

When the PE moves from a state where profiling is disabled to a state where profiling is enabled:

- If `PMSICR_EL1` is nonzero, then sampling restarts from the current values in `PMSICR_EL1`.
- If `PMSICR_EL1` is zero, then it is loaded with an initial value. The behavior depends on `PMSIRR_EL1.RND` and an IMPLEMENTATION DEFINED choice discoverable by a read of `PMSIDR_EL1.ERnd`.
 - If `PMSIRR_EL1.RND` is 0:
 - `PMSICR_EL1.COUNT[31:8]` is set to `PMSIRR_EL1.INTERVAL`.
 - `PMSICR_EL1.COUNT[7:0]` is set to `0x00`.
 - If `PMSIRR_EL1.RND` is 1 and `PMSIDR_EL1.ERnd` is 0:
 - `PMSICR_EL1.COUNT[31:8]` is set to `PMSIRR_EL1.INTERVAL`.
 - `PMSICR_EL1.COUNT[7:0]` is set to a random or pseudorandom value in the range `0x00` to `0xFF`.
 - If `PMSIRR_EL1.RND` is 1 and `PMSIDR_EL1.ERnd` is 1:
 - `PMSICR_EL1.COUNT[[31:8]` is set to `PMSIRR_EL1.INTERVAL`.
 - `PMSICR_EL1.COUNT[7:0]` is set to a random or pseudorandom value in the range `0x00` to `0xFF`.

D9.3.4 Behavior of the sample interval counter while profiling is enabled

While profiling is enabled, the counters control when an operation is selected for sampling. The behavior depends on `PMSIRR_EL1.RND` and an `IMPLEMENTATION DEFINED` choice discoverable in `PMSIDR_EL1.ERnd`.

If `PMSIRR_EL1.RND` is 0:

While nonzero, the sample interval counter decrements by 1 for each member of the sample population. When the counter reaches zero:

- A member of the sampling population is selected for sampling.
- The counter is set as follows:
 - `PMSICR_EL1.COUNT[31:8]` is set to `PMSIRR_EL1.INTERVAL`.
 - `PMSICR_EL1.COUNT[7:0]` is set to `0x00`.

———— Note ————

Because the counter counts down to zero, when `PMSIRR_EL1.RND` is 0 the interval between operations being selected for sampling is $(INTERVAL \times 256 + 1)$.

If `PMSIRR_EL1.RND` is 1 and `PMSIDR_EL1.ERnd` is 0

While nonzero, the sample interval counter decrements by 1 for each member of the sample population. When the counter reaches zero:

- A member of the sampling population is selected for sampling.
- The counter is set as follows:
 - `PMSICR_EL1.COUNT[31:8]` is set to `PMSIRR_EL1.INTERVAL`.
 - `PMSICR_EL1.COUNT[7:0]` is set to a random or pseudorandom value in the range `0x00` to `0xFF`.

———— Note ————

When `PMSIRR_EL1.RND` is 1 and `PMSIDR_EL1.ERnd` is 0, the mean interval between operations being selected for sampling is $(INTERVAL \times 256 + 128)$, if the random number generator is uniform.

If `PMSIRR_EL1.RND` is 1 and `PMSIDR_EL1.ERnd` is 1

While nonzero, the primary sample interval counter decrements by 1 for each member of the sample population. When the primary counter reaches zero:

- The primary sample interval counter is set as follows:
 - `PMSICR_EL1.COUNT[31:8]` is set to `PMSIRR_EL1.INTERVAL`.
 - `PMSICR_EL1.COUNT[7:0]` is set to `0x00`.
- The secondary sample interval counter, `PMSICR_EL1.ECOUNT`, is set to a random or pseudorandom value in the range `0x00` to `0xFF`.

While the secondary sample interval counter is nonzero, the secondary sample interval counter decrements by 1 for each member of the sample population. The primary sample interval counter also continues to decrement because it is also nonzero.

When the secondary sample interval counter reaches zero, an operation is selected for sampling.

———— Note ————

When `PMSIRR_EL1.RND` is set to 1 and `PMSIDR_EL1.ERnd` is 1, the mean interval between operations being selected for sampling is $(INTERVAL \times 256 + 1)$, if the random number generator is uniform.

D9.3.5 Behavior of the sample interval counter while profiling is disabled

When profiling is disabled:

- No operations are selected for sampling.
- No sample records are collected.
- The sample interval counters retain their values and do not decrement.

D9.3.6 Where operations are sampled

The exact point in the sampled lifespan of operations at which operations are chosen for profiling is IMPLEMENTATION DEFINED.

———— **Note** —————

Arm recommends that the point at which operations are sampled is linked to the definition of the Performance Monitors Extension (PMU) [STALL_FRONTEND](#) and [STALL_BACKEND](#) events, so that sampling records information for [STALL_BACKEND](#) stalls.

D9.3.7 Sample collisions

The maximum number of sampled operations that a PE can support simultaneously is IMPLEMENTATION DEFINED. If the maximum number of simultaneous sampled operations has been reached at the point when a new operation must be sampled, the new sample is said to have collided with a previous sampled operation.

The PE records the fact that a sampled operation has collided with another sampled operation. Software can also count the number of collisions and gauge the impact of the collisions.

On a sample collision:

- The PMU event [SAMPLE_COLLISION](#) is generated.
- [PMBSR_EL1.COLL](#) is set to 1.
- The new operation is not sampled.

Following a context synchronization event an indirect write to [PMBSR_EL1.COLL](#) is guaranteed to be visible to instructions in program order after the sampled operation that collided. There is no guarantee of visibility without a context synchronization event. For more information, see [Synchronization and Statistical Profiling on page D9-2977](#).

———— **Note** —————

This means that following a context synchronization event [PMBSR_EL1.COLL](#) will not change on entry to a state where profiling is disabled.

D9.4 Enabling profiling

Profiling is enabled when all of the following are true:

- The PE is in AArch64 state.
- `PMBLIMITR_EL1.E` is 1 and `PMBSR_EL1.S` is 0.
- The PE is executing at either the Profiling Buffer owning Exception level or any lower Exception level.
- The PE is executing in the Security state of the Profiling Buffer owning Exception level.
- The PE is in Non-debug state.
- `PMSCR_EL1`.{E1SPE, E0SPE} and `PMSCR_EL2`.{E2SPE, E0HSPE} enable profiling at the current Exception level.

———— **Note** —————

The owning Exception level is controlled by `MDCR_EL3.NSPB` and `MDCR_EL2.E2PB`. See *The owning Exception level on page D9-2969*.

`PMSCR_EL1`.{E1SPE, E0SPE} and `PMSCR_EL2`.{E2SPE, E0HSPE} enable sampling by Exception level:

- In a guest operating system or Secure state, `PMSCR_EL1.E1SPE` enables profiling at EL1 and `PMSCR_EL1.E0SPE` at EL0.
- In a hypervisor or host operating system, `PMSCR_EL2.E2SPE` enables profiling at EL2 and `PMSCR_EL2.E0HSPE` at EL0.
- Sampling is always disabled at EL3.

Table D9-1 on page D9-2954 defines the valid combinations of the Effective values of `SCR_EL3.NS`, `SCR_EL3.EEL2`, `MDCR_EL3.NSPB`, `MDCR_EL2.E2PB`, and `HCR_EL2.TGE` that define when sampling is enabled.

In Table D9-1 on page D9-2954:

- D** Disabled.
- E2SPE** Enabled if `PMSCR_EL2.E2SPE == 1`, disabled otherwise.
- E1SPE** Enabled if `PMSCR_EL1.E1SPE == 1`, disabled otherwise.
- E0HSPE** Enabled if `PMSCR_EL2.E0HSPE == 1`, disabled otherwise.
- E0SPE** Enabled if `PMSCR_EL1.E0SPE == 1`, disabled otherwise.

Table D9-1 Enabling by Exception level and Security state (for all Exception levels using AArch64 state)

	Controls				Sampling enabled at				
	NS	NSPB	E2PB	EEL2	TGE	EL3	EL2	EL1	EL0
1	0b0X	X	X	X	X	D	D	D	D
	0b1X	0b1X	X	X	0	D	D	E1SPE	E0SPE
		0b1X	X	X	1	D	D	n/a	D
		0b00	X	X	0	D	E2SPE	E1SPE	E0SPE
		0b00	X	X	1	D	E2SPE	n/a	E0HSPE

Table D9-1 Enabling by Exception level and Security state (for all Exception levels using AArch64 state) (continued)

Controls					Sampling enabled at			
NS	NSPB	E2PB	EEL2	TGE	EL3	EL2	EL1	EL0
0	0b1X	X	X	X	D	D	D	D
	0b0X	X	0	X	D	n/a	E1SPE	E0SPE
	0b1X		1	0	D	D	E1SPE	E0SPE
	0b1X		1	1	D	D	n/a	D
	0b00		1	0	D	E2SPE	E1SPE	E0SPE
	0b00		1	1	D	E2SPE	n/a	E0HSPE

This is described in the pseudocode function [StatisticalProfilingEnabled\(\)](#).

D9.5 Filtering sample records

[PMSFCR_EL1](#).FT enables filtering by operation type. When enabled [PMSFCR_EL1](#).{ST, LD, B} define the collected types:

- ST enables collection of store sampled operations, including all atomic operations.
- LD enables collection of load sampled operations, including atomic operations that return a value to a register.
- B enables collection of branch sampled operations, including direct and indirect branches and exception returns.

———— **Note** —————

When micro-op sampling is implemented, filtering is based on the micro-op type.

[Table D9-2](#) on [page D9-2956](#) summarizes the controls for filtering by operation type. In this table:

Load Atomic Refers to atomic operations which return a value to a general-purpose register. Other atomic operations are classed as Store.

D Indicates that the operation is discarded.

C Indicates that the operation is collected.

C/D Indicates it is CONSTRAINED UNPREDICTABLE whether the operation is collected or discarded.

Table D9-2 Filtering by Operation type

PMSFCR_EL1 field				Operation type				
FT	LD	ST	B	Load	Load Atomic	Store	Branch	Other
0	X	X	X	C	C	C	C	C
1	0	0	0	C/D	C/D	C/D	C/D	C/D
			1	D	D	D	C	D
		1	0	D	C	C	D	D
			1	D	C	C	C	D
	1	0	0	C	C	D	D	D
			1	C	C	D	C	D
		1	0	C	C	C	D	D
			1	C	C	C	C	D

[PMSFCR_EL1](#).FE enables filtering by a set of events that are defined by [PMSEVFR_EL1](#). When enabled, only sampled operations with all the events in the filter set are recorded and written to the Profiling Buffer.

If [FEAT_SPEv1p2](#) is implemented, [PMSFCR_EL1](#).FnE enables filtering by a set of events that are defined by [PMSNEVFR_EL1](#). When enabled, only sampled operations with all the events in the filter clear are recorded and written to the Profiling Buffer.

[PMSFCR_EL1](#).FL enables filtering by total latency. [PMSLATFR_EL1](#).MINLAT defines the minimum latency. When enabled, only sampled operations with a total latency greater than or equal to the minimum latency are recorded and written to the Profiling Buffer.

These controls combine together as a logical AND.

Example D9-1 Collection of sampled operations

If `PMSFCR_EL1.FE` is 1, `PMSFCR_EL1.FnE` is 0, `PMSFCR_EL1.FT` is 1, and `PMSFCR_EL1.FL` is 1, then only sampled operations that meet all of the following criteria are recorded and written to the Profiling Buffer:

- The sampled operation is one of the selected operation types.
 - The operation has all of the events in the filter set.
 - The total latency is equal to or greater than the minimum latency.
-

This is described in the pseudocode function `SPEColllectRecord()`.

D9.5.1 Discard mode

`FEAT_SPEv1p2` adds an operating mode, Discard mode, that allows all sampled operations to be discarded and not written to the Profiling Buffer. Discard mode is enabled when `PMBLIMITR_EL1.FM` is 0b10, and has all of the following effects:

- All profiling data is discarded after filtering.
- The `PMBLIMITR_EL1.LIMIT` and `PMBPTR_EL1` fields are ignored. `PMBPTR_EL1` does not increment for each sampled operation.
- The restrictions on setting `PMBLIMITR_EL1.LIMIT` and `PMBPTR_EL1` do not apply, see *Restrictions on the current write pointer* on page D9-2968.
- Buffer management events are not generated.

Other profiling behaviors are unchanged, including:

- The discarding of profiling data logically occurs after `SAMPLE_FILTRATE` and other PMU events are counted.
- Sample collisions will still set `PMBSR_EL1.COLL` to 1.

D9.6 The profiling data

Unless otherwise stated, all sample records that are generated by a profiling operation contain:

- A timestamp, if enabled. This is one of:
 - The physical counter, `CNTPCT_EL0`.
 - The offset physical counter, `CNTPCT_EL0 - CNTPOFF_EL2`. When any of the following are true, the *Effective value* of `CNTPOFF_EL2` is 0 for all profiling purposes:
 - EL3 is using AArch32.
 - EL2 is not implemented.
 - `FEAT_ECV` is not implemented.
 - The *Effective value* of `SCR_EL3.{NS,RW}` is {1,0}.
 - `CNTHCTL_EL2.ECV` is 0.
 - `SCR_EL3.ECVEn` is 0.
 - The virtual counter, `CNTVCT_EL0`.

It is IMPLEMENTATION DEFINED how this timestamp relates to the sampled operation. It might be the time when the sampled operation was taken or any later time during the lifetime of the sampled operation, that is, up to the time when the sampled operation finishes execution.

If the Generic Timer system counter is disabled and timestamps are enabled, then it is IMPLEMENTATION DEFINED whether:

- The SPU behaves as if timestamps are disabled.
- The timestamp that is collected in the sample record is UNKNOWN.

———— **Note** —————

This behavior describes when `CNTCR.EN` is 0, the Generic Timer system counter is disabled. This behavior does not apply when the Generic Timer system counter is enabled but not accessible at the current Exception level.

- The context, if enabled, which is one or more of:
 - `CONTEXTIDR_EL1`.
 - `CONTEXTIDR_EL2`.
 - The Exception level.
 - The Security state.
- Information about whether the sampled operation generated an exception:
 - The target address for an exception generating operation is not collected.
- Information about whether the sampled operation was *Architecturally executed*.

If the sampled operation is *Architecturally executed* and does not generate an exception, the sample record also contains:

- The PC virtual address for the sampled operation.
- Information about whether the sampled operation is a branch, a load, a load atomic, a store, or other.
- Information about whether the sampled operation is conditional, conditional select, or not.
- The total latency, a cycle count from the start of the sampled operation up to the point where the operation has finished execution and is no longer capable of stalling any instruction that consumes its output.
- The issue latency, a cycle count from the start of the sampled operation up to the point when at least one part of the sampled operation starts executing. A sampled operation might be delayed, for example, because the input operands were not available.

If the sampled operation is not *Architecturally executed* or generates an exception, it is UNPREDICTABLE whether the record contains all or any of this information and the other information about the operation listed in this section and the following subsections. For information on exceptions being taken in sampled operations, see [Exceptions on page D9-2967](#).

The architecture defines a set of additional data that is collected in the sample record for each sampled operation. This is described in the following subsections, and comprises:

- Events, which are required to be implemented consistently with PMU Events. For more information, see [Chapter D10 Statistical Profiling Extension Sample Record Specification](#) and [Chapter D7 The Performance Monitors Extension](#).
- Cycle counters. Cycle count values as described in this architecture, which, for a particular implementation, are fixed with an IMPLEMENTATION DEFINED value, might be omitted from the sample record.
- Addresses.

In addition, the architecture permits IMPLEMENTATION DEFINED events, counters, and addresses to be collected.

D9.6.1 Information collected for micro-ops

Because architectural instructions might create zero, one, or more micro-ops, micro-ops might have different characteristics from the architectural instructions they are created from. The data collected for each micro-op is IMPLEMENTATION DEFINED. Implementations should collect the subset of data appropriate to the micro-op.

Example D9-2 Sampling of micro-ops

If an architectural load instruction is split into an address generation micro-op and a load micro-op, then when generating the sample record and filtering based on operation type:

- If the address generation micro-op is sampled, the sampled operation is treated as *other*.
 - If the load micro-op is sampled, the sampled operation is treated as a load.
-

D9.6.2 Additional information for each profiled branch or exception return

For an *Architecturally executed* sampled branch or exception return operation that finishes execution, the profiling operation records:

- The sampled operation type as an unconditional branch or a conditional branch. Sampled exception returns are treated as unconditional branches by the Statistical Profiling Extension.
- If the branch is taken, the target virtual address of the branch. The target virtual address of the branch includes the Exception level and Security state of the target. The target virtual address includes the Exception level and Security state of the target. If the sampled operation is an illegal exception return, it is CONSTRAINED UNPREDICTABLE whether the context information recorded in the target virtual address is the actual target context, or the target context that is described by the [SPSR](#).
- If the PE implements branch prediction, whether the branch was correctly predicted or mispredicted.
- Whether the branch was taken or not taken.
- Whether the branch was direct or indirect.
- If the branch is not taken, a target virtual address might be recorded. Software must treat this value if present as UNKNOWN.
- If the optional behavior in [FEAT_SPEv1p2](#) is implemented, the target address of the most recently executed sampled branch that was taken and retired in program order before the sampled operation.

Note

A sampled operation that generates an exception is not treated as a branch.

Last branch target

If [FEAT_SPEv1p2](#) is implemented, [PMSIDR_EL1.PBT](#) optionally adds the capability to record a packet for each event that provides the target address of the previous taken branch.

If enabled, the profiling operation records the target address of the most recently sampled branch that was taken and retired in program order before the sampled operation.

It is IMPLEMENTATION DEFINED whether or not the profiling operation records the target address of the most recently taken branch instruction in the following cases:

- The sampled operation is not a sampled retired taken branch operation.
- The most recently taken branch instruction was a Context synchronization operation, exception-generating instruction, or exception return.
- No branch instruction has been retired, prior to the sampled operation, since the most recent Context synchronization operation or taken exception.

The profiling operation does not record the target address of the most recently taken branch instruction in the following cases:

- The most recently taken branch instruction was executed when profiling was disabled or prohibited.
- Either the most recently taken branch instruction or the sampled operation is still speculative.

D9.6.3 Additional information for each profiled memory access operation

For an *Architecturally executed* sampled load, store, or atomic operation that does not generate an exception, the profiling operation records:

- The data virtual and, if enabled, physical addresses being accessed.
 - If the applicable Top Byte Ignore (TBI) bit is set to one, the virtual address includes any top-byte tag.
 - The physical address is the address the PE accesses in the physical address space, and so includes the Secure address space identifier.
- The sampled operation type, which includes:
 - Whether the sampled operation is a load, store, or atomic.
 - Whether the sampled operation is Load-Exclusive, Store-Exclusive or Load-acquire, Store-release.
 - Whether the sampled operation accesses the general-purpose or SIMD&FP registers.
- The translation latency. Cycle count from a virtual address being passed to the MMU for translation to the result of the translation being available.
- Whether the sampled operation accessed the Level 1 data cache and the result.
- Whether the sampled operation accessed the data TLB and the result.
- An optional record of whether the sampled operation accessed Last Level data cache and the result.
- An optional record of whether the sampled operation accessed *another socket* in a multi-socket system.
- An optional, IMPLEMENTATION DEFINED, indicator of the data source for a load. If the sampled operation makes multiple accesses, it is IMPLEMENTATION DEFINED whether this indicator combines information for all parts of the load or applies only for a chosen part of the load.
- If `FEAT_SPEv1p1` is implemented, an optional indication that the sampled memory operation is non-optimal for the access size. For more information, see [Data Alignment Flag on page D9-2962](#).

For each of the cache and another socket indicators, it is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this information is present for store accesses. The Last level cache and another socket indicators are optional and might not be present.

For more information, see [Events packet on page D10-2993](#).

————— Note —————

A store might be marked as not accessing a cache or another socket because it microarchitecturally finished before doing so. For example, the write was placed into a write buffer. This behavior is IMPLEMENTATION DEFINED and might change from time to time, and such events must be interpreted with care.

If `FEAT_MTE2` is implemented, an instruction which loads or stores an Allocation Tag or multiple Allocation Tags will be treated as a load or store if profiling is enabled. Each Allocation Tag covers multiple locations in a Tag Granule. It is IMPLEMENTATION DEFINED whether the implementation treats each Allocation Tag access as an access to the data location addressed in the operation, or the whole Tag Granule. That is, whether the data virtual address associated with the sampled access or chosen part of the access is the address of the location being accessed, or the lowest address covered by the same Allocation Tag or Allocation Tags. For more information, see [Chapter D6 Memory Tagging Extension](#).

If the sampled load, store, or atomic operation performs multiple accesses, it is IMPLEMENTATION DEFINED whether the implementation chooses to profile all of the access or a chosen part of that access.

If the implementation chooses to profile a chosen part of the access:

- It is IMPLEMENTATION DEFINED how the PE chooses the part of the access. The choice does not introduce any systematic bias.

———— **Note** —————

For an example of inadvertent systematic bias, consider an implementation where a multiple-register load operation is split into multiple accesses. If the PE systematically chooses the first operation at the lower address for sampling translation latency and data source indicator, and the operation is executed in a loop with an incrementing address, then the first access has better spatial locality with preceding accesses than later accesses and is more likely to both:

- Hit in the TLB, giving a shorter translation latency.
- Return data from the Level 1 data cache.

In this case, or if the PE systematically chooses the last access at the higher address, then sampling would be biased.

- If the accesses are architecturally contiguous, it is further IMPLEMENTATION DEFINED whether the recorded data virtual address is the lowest virtual address that is accessed by the sampled operation or applies to the chosen part of the access.
- If the accesses are not architecturally contiguous, the recorded data virtual address applies for the chosen part of the access.
- It is IMPLEMENTATION DEFINED whether the events and total operation latency apply to the whole operation or the chosen part of the operation.
- The translation latency applies to the chosen part of the operation, and is the count of cycles for which the chosen part of the operation is waiting for the MMU to complete an address translation.

Arm recommends that if the implementation chooses to profile a chosen part of the access, then the recorded addresses, events, and total operation latency apply to the chosen access. That is, the PE behaves as if the chosen part of the access is the sampled operation.

If the sampled load, store, or atomic operation performs a single access, or the implementation chooses to profile all parts of a multiple access:

- If the accesses are architecturally contiguous, the recorded data virtual addresses is the lowest virtual address that is accessed by the sampled operation.
- If the accesses are not architecturally contiguous, the recorded data virtual addresses apply for the chosen part of the access.
- The events and total operation latency apply to the whole operation. For example, when recording whether the sampled operation accessed the Level 1 data cache, the PE records whether any part of the access accessed the Level 1 data cache, and the result, and the total operation latency applies from the issue of the operation to the completion of all parts of the operation.
- The translation latency is an IMPLEMENTATION DEFINED choice between:
 - The count of cycles for which at least one part of the operation is waiting for the MMU to complete an address translation, and no part of the operation is accessing memory.
 - The count of cycles for which at least one part of the operation is waiting for the MMU to complete an address translation.

If [FEAT_MTE2](#) is implemented and the operation is an access to an Allocation Tag or multiple Allocation Tags, it is IMPLEMENTATION DEFINED whether the sampled data physical address is the address generated from translating the sampled data virtual address or the address generated from translating the lowest address covered by the same Allocation Tag or Allocation Tags, when these differ. Otherwise, the sampled data physical address is the address generated from translating the sampled data virtual address. The sampled data physical address packet is not output if any of the following are true:

- The PE does not translate the address, for example because it does not perform the access or the address translation generates a Translation fault.
- The sampled data virtual address packet is not output.
- Prohibited by System register controls.

If a sampled virtual address packet is not output:

- It is IMPLEMENTATION DEFINED whether the Translation latency Counter packet for the load or store is either not recorded, or recorded with a value of zero.
- It is IMPLEMENTATION DEFINED whether the bits corresponding to the access in the Events packet are recorded or always zero. If access does not occur, these bits are zero.

When the sampled operation is a System register access transformed into a memory access by the mechanism described in [Enhanced support for nested virtualization on page D5-2795](#), the operation is recorded as a load/store operation. If Statistical Profiling is disabled at EL2, the virtual address for the memory access is not recorded.

Data Alignment Flag

If FEAT_SPEv1p1 is implemented [Events packet.E\[11\]](#) is set to 1 for a sampled memory operation if the address alignment is non-optimal for the access size.

Address alignment is defined as *non-optimal* if that access incurs an additional performance penalty only because of the address alignment, and is unrelated to whether the access is architecturally misaligned for the access size.

Example D9-3 Data Alignment Flag operation

-
- A 32-bit word access that is not word aligned is architecturally misaligned, but (if Alignment faults are disabled) might not incur an additional penalty because of this alignment unless the word also happens to span a cache-line boundary.
 - A contiguous load operation that loads a vector that is the length of two cache lines is optimally aligned if it has cache-line alignment, even though the operation makes two cache line accesses.
 - A non-contiguous SVE load operation that makes a sequence of access is optimal only if all of the access are optimal.
-

The definition of non-optimal is IMPLEMENTATION DEFINED and support for the Alignment Flag is OPTIONAL.

D9.6.4 Additional information for each profiled conditional instruction

For an [Architecturally executed](#) sampled conditional select, conditional move, or conditional increment operation finishes execution, the profiling operation records:

- That the sampled operation was conditional.
- Whether the condition passed or failed.

For conditional branches, see [Additional information for each profiled branch or exception return on page D9-2959](#).

D9.6.5 Additional information for each profiled Scalable Vector Extension operation

When FEAT_SPEv1p1 and [The Scalable Vector Extension \(SVE\)](#) are implemented, SVE operations are sampled as described in this section.

In this section the following terms are used:

Maximum implemented vector length

Means the implemented width of the vector registers. This value is IMPLEMENTATION DEFINED.

Accessible vector length

Means the accessible width of the SVE vector registers at the current Exception level, as constrained by the ZCR_EL1, ZCR_EL2 or ZCR_EL3 System registers. The Accessible vector length is always less-than-or-equal-to the [Maximum implemented vector length](#).

Sampled SVE operation

Means an instruction or micro-operation defined by the *Arm Architecture Reference Manual Supplement: The Scalable Vector Extension (SVE), for Armv8-A* and sampled by the SPU that has a vector or a predicate as an input or output. This includes instructions with scalar outputs, but excludes the Non-SIMD SVE instructions.

If an implementation samples micro-operations, then it is IMPLEMENTATION DEFINED, and might vary between operation types, whether an operation for which all the following are true is treated as a Sampled SVE operation or the equivalent Advanced SIMD operation:

- The Accessible vector length is 128 bits.
- The operation is unpredicated, and does not have a predicate register as an input or output.
- The operation has an equivalent Advanced SIMD operation.

This includes SVE load and store operations where an equivalent Advanced SIMD operation is defined.

Sampled operation vector

Means the portion of the accessible vector operated on by the [Sampled SVE operation](#).

Effective vector length

Is the length of the [Sampled operation vector](#). The Effective vector length is always less-than-or-equal-to the [Accessible vector length](#).

———— **Note** —————

The [Accessible vector length](#) is always quantized into multiples of 128-bits. However, the [Sampled operation vector](#) can be any size down to the element size of the operation.

Sampled predicated SVE operation

Means a [Sampled SVE operation](#) that is one of:

- An SVE operation that writes to a vector destination register under a Governing predicate using either zeroing or merging predication.
- A predicated store of a vector register or registers.

For an implementation that samples micro-operations, an SVE instruction might be split up into one or more micro-operations, some of which are predicated and some of which are not predicated.

———— **Note** —————

[Sampled predicated SVE operation](#) excludes operations that do not write a vector register, or do so but not using zeroing or merging predication, and applies to machine instructions rather than aliases. For example, the following instructions are not predicated SVE instructions under this definition:

- CNTP, LASTA, and PTRUE do not write to vector registers.
- FADDV, and SMAXV write scalar values to SIMD&FP registers.
- COMPACT and SEL (vectors) write to vector registers, and have a predicate operand, but do not use that predicate as a Governing predicate for zeroing or merging predication.
- MOV (vector, predicated) appears to be a predicated SVE instruction because it specifies merging predication through the <PG>/M operand, but it is actually an alias for the SEL (vectors) instruction.

If an implementation samples micro-operations, it is IMPLEMENTATION DEFINED whether individual elements, or groups of elements, are treated as single micro-operations.

The division of instructions into micro-operations must be fixed prior to sampling to guarantee consistently accurate statistical sampling.

Example D9-4 Vector length

For example, to support a vector length of 1024 bits, an implementation might split all instructions into four micro-operations on 256-bit vector paths. The implementation must, however, implement 1024-bit wide vector registers.

This behavior might vary based on operation type. For example, an implementation that has a full-width data-path for most operations might choose to break certain complex operations, such as non-contiguous load or stores, into shorter vectors.

Example D9-5 Accessible vector length less-than the Maximum implemented

To support an [Accessible vector length](#) less-than the [Maximum implemented vector length](#), an implementation might choose to do all operations at the [Maximum implemented vector length](#) and discard the results above the [Accessible vector length](#). Discarded results, arising from difference between [Maximum implemented vector length](#) and [Accessible vector length](#), do not form part of the sampled operation and the [Effective vector length](#) must not include any discarded portions of the vector.

Results discarded because of predication are part of the sampled operation.

For a sampled SVE cache prefetch operation:

- The profiling operation captures an IMPLEMENTATION DEFINED subset of the information captured for an SVE load instruction.
- The profiling operation treats the operation type as Other when generating the sample records and filtering based on operation.
- It is IMPLEMENTATION DEFINED whether the operation is treated as a [Sampled SVE operation](#):
 - If treated as a Sampled SVE operation, the Operation Type packet payload format is the [Operation Type packet](#) on page D10-2998.
 - If not treated as a Sampled SVE operation, the Operation Type packet format is the [Operation Type packet payload \(Other\)](#) on page D10-2998.

For a [Sampled SVE operation](#), the [Operation Type packet](#) is one of:

- The SVE operation format.
- The SVE load or store format.

For a [Sampled SVE operation](#), the [Operation Type packet](#).EVL field records an upper bound on the [Effective vector length](#). The value recorded in the [Operation Type packet](#).EVL field is the [Effective vector length](#) rounded up to a power-of-two value.

For a [Sampled SVE operation](#) that is a [Sampled predicated SVE operation](#);

- [Operation Type packet](#).PRED, Predicated SVE operation, is set to 1.
- If any elements in the [Sampled operation vector](#) are Inactive elements, then [Events packet](#).E[17], Partial predicate, is set to 1.
- If all elements in the [Sampled operation vector](#) are Inactive elements, then [Events packet](#).E[18], Empty predicate, is set to 1 and [Events packet](#).E[17] (Partial predicate) is set to 1.
- If all elements in the [Sampled operation vector](#) are Active elements then [Events packet](#).E[18:17] is set to 0b00.

For a [Sampled SVE operation](#) that is not a [Sampled predicated SVE operation](#):

- [Operation Type packet](#).PRED, Predicated SVE operation, is set to 0.
- [Events packet](#).E[18:17] is set to 0b00.

For a sampled non-contiguous SVE load or store operation that makes multiple memory accesses, the sampled data virtual address is the address accessed by a random one of the load or store operations chosen from the [Sampled operation vector](#). If the chosen load or store operation is for an Inactive element, the data virtual address packet is not output.

For more information on memory access operations, see [Additional information for each profiled memory access operation on page D9-2960](#).

For a sampled contiguous SVE load or store operation that makes multiple memory accesses, the sampled data virtual address is an IMPLEMENTATION DEFINED choice of:

- The address accessed for the lowest element in the [Sampled operation vector](#).
- The address used for the access containing the lowest Active element in the [Sampled operation vector](#).

If the corresponding element is an Inactive element, it is IMPLEMENTATION DEFINED whether the data virtual address packet is output.

D9.6.6 Sample operation records for misspeculated and non-architectural operations

It is IMPLEMENTATION DEFINED whether each of the following operations is part of the sample population:

- Operations on misspeculated paths.
- Operations that do not relate to any architecture instruction.

If the operation is part of the sample population, it is further IMPLEMENTATION DEFINED whether the sample record for the sampled operation is captured in the Profiling Buffer. For more information, see [Operations that might be excluded from the sample population on page D9-2950](#).

If such an operation is part of the sample population and the sample record is captured in the Profiling Buffer, then some information for the operation might not be present. However, the [Events packet](#) and either the [End packet](#) or the [Timestamp packet](#) is always output. Neither event 0 (generated exception) nor event 1 (architecturally retired) will be set in the [Events packet](#).

The record must not contain information that cannot be accessed by privileged software of the owning Exception level.

D9.6.7 Additional information for other operations

For cache maintenance operations by virtual address, cache prefetch, other than SVE cache prefetch, or address translation instructions, the profiling operation:

- Captures an IMPLEMENTATION DEFINED subset of the information captured for a load instruction.
- Treats the operation type as *other* when generating the sample record and filtering based on operation type.

See [Filtering sample records on page D9-2956](#), [Operation Type packet](#) and [Additional information for each profiled Scalable Vector Extension operation on page D9-2962](#).

D9.6.8 Controlling the data that is collected

Certain data in sample records is collected only if permitted by one or both of EL1 and EL2. This is to restrict exposure of data to a lower Exception level or to Non-secure state.

[CONTEXTIDR_EL1](#) is collected only if [PMSCR_EL1.CX](#) is set to 1, the PE is executing at EL1 or EL0 and any of the following are true when an operation is sampled:

- EL2 is not implemented.
- [FEAT_SEL2](#) is implemented and EL2 is disabled for the current Security state.
- The Effective value of [HCR_EL2.TGE](#) is 0.

[CONTEXTIDR_EL2](#) is collected only if the Effective value of [PMSCR_EL2.CX](#) is 1 and EL2 is implemented and enabled for the current Security state.

This is described in the pseudocode functions [CollectContextIDR1\(\)](#) and [CollectContextIDR2\(\)](#).

Timestamps are collected only if one of the following is true:

- [PMSCR_EL1.TS](#) is set to 1 and the Profiling Buffer is owned by EL1.
- [PMSCR_EL2.TS](#) is set to 1 and the Profiling Buffer is owned by EL2.

The timestamp is a choice between:

- Physical time, which is defined by the value of [CNTPCT_EL0](#).

- If `FEAT_ECV` is implemented and enabled, offset physical time, as defined by the value of (`CNTPCT_EL0` - `CNTPOFF_EL2`). That is, the physical time minus the physical offset, `CNTPOFF_EL2`.
- Virtual time, as defined by the value of `CNTVCT_EL0`. That is, the physical time minus the virtual offset, `CNTVOFF_EL2`. However, the virtual offset is treated as zero if a read of `CNTVCT_EL0` at the current Exception level would treat the virtual offset as zero.

Table D9-3 on page D9-2966 summarizes the choice of value for the Timestamp packet when `FEAT_ECV` is implemented and `StatisticalProfilingEnabled()` is TRUE. In Table D9-3 on page D9-2966:

- Owning EL** This is the Exception level that owns the Profiling Buffer. This is returned by the function `ProfilingBufferOwner()`. If EL2 is disabled in the current Security state, this is always EL1.
- EL2 enabled** This is TRUE when EL2 is enabled in the current Security state. When EL2 is disabled in the current Security state, this is FALSE.
- Virtual** This means the timestamp is offset physical time, as returned by a direct read of `CNTVCT_EL0` at the Exception level the sampled operation is executed at.
- Physical** This means the timestamp is physical time, given by the value of `CNTPCT_EL0` at the Exception level the sampled operation is executed at.
- Offset physical** This means the timestamp is offset physical time, as returned by (`CNTPCT_EL0` - `CNTPOFF_EL2`) at the Exception level the sampled operation is executed at. That is, the physical time minus the physical offset. When any of the following are true, the *Effective value* of `CNTPOFF_EL2` is 0 for all profiling purposes:
 - EL2 is not implemented.
 - `FEAT_ECV` is not implemented.
 - `CNTHCTL_EL2.ECV` is 0.
 - `SCR_EL3.ECVEn` is 0.

Table D9-3 Recorded timestamp when `FEAT_ECV` is implemented

EL2 enabled	Owning EL	PMSCR_EL2		PMSCR_EL1		Recorded timestamp		
		PCT[1:0]	TS	PCT[1:0]	TS			
x	EL1	xx	x	xx	0	None		
				0b00	1	Virtual		
FALSE	EL1	xx	x	0b01	1	Physical		
				0b11	1	Offset physical		
TRUE	EL1	0b00	x	xx	1	Virtual		
				0b01	x	0b01	1	Physical
				0b11	1	Offset physical		
				0b11	x	0b01	1	Offset physical
				0b11	1	Offset physical		
				0b11	1	Offset physical		
	EL2	xx	0	xx	x	None		
				0b00	1	xx	x	Virtual
				0b01	1	xx	x	Physical
				0b11	1	xx	x	Offset physical

If EL2 is not implemented, see the register descriptions of `PMSCR_EL1.PCT` and `PMSCR_EL2.PCT` for details of their behavior. This behavior is described by the pseudocode function `CollectTimeStamp()`.

Physical data addresses are collected only if one of the following is true:

- `PMSCR_EL1.PA` is set to 1 and the Profiling Buffer is owned by Secure EL1, and Secure EL2 is disabled or is not implemented.
- `PMSCR_EL2.PA` is set to 1 and the Profiling Buffer is owned by Secure or Non-secure EL2.

- [PMSCR_EL1.PA](#) is set to 1 and [PMSCR_EL2.PA](#) is set to 1 and either the Profiling Buffer is owned by Non-secure EL1, or the Profiling Buffer is owned by Secure EL1 and Secure EL2 is implemented and enabled.

If EL2 is not implemented or is disabled for the current Security state, the PE behaves as if [PMSCR_EL2.PA](#) is set to 1, other than for a direct read of the register.

Physical data address collection is described by the pseudocode function [CollectPhysicalAddress\(\)](#).

Enabling collection of the physical data addresses has an IMPLEMENTATION DEFINED impact on the sampled operation.

D9.6.9 Exceptions

All sample records written to the Profiling Buffer contain the Events packet and either the [End packet](#) or the [Timestamp packet](#).

If the sampled operation generates an exception condition, it is UNPREDICTABLE whether the sample record contains any other information. This includes operations that generate faults or other exception conditions but do not generate exceptions. For example:

- An instruction on a misspeculated path.
- A load operation that is part of a Non-fault load instruction or is not the First active element of a First-fault load instruction that generates an MMU fault or watchpoint.
- An address translation operation or prefetch instruction that generates an MMU fault.

Where a sampled operation generates an exception and the type of exception means that a particular item is not computed by the sampled operation, that information is not collected by the profiling operation. For more information, see [Synchronization and Statistical Profiling on page D9-2977](#).

Example D9-6 Translation Faults

If a sampled operation generates a Translation Fault, the physical address for the sampled operation was not generated by the MMU and cannot be recorded.

Non-architectural exceptions

It is IMPLEMENTATION DEFINED whether operations that generate non-architectural exceptions are part of the sample population. If such an operation is part of the sample population, it is further IMPLEMENTATION DEFINED whether the sample record for a sampled operation that generates a non-architectural exception is captured in the Profiling Buffer. For more information, see [Operations that might be excluded from the sample population on page D9-2950](#).

If such an operation is part of the sample population and the sample record is captured in the Profiling Buffer, then the sample might record handling of the non-architectural exception. If the sample record does not record handling of the non-architectural exception, then the sampled operation is not *Architecturally executed* because of the non-architectural exception and it is recorded using $E[1] = 0$ (operation is not architecturally executed) in the [Events packet](#). Bit $E[0]$ (operation generated an exception) might be used to indicate the operation did not complete because of the non-architectural exception.

D9.7 The Profiling Buffer

The profile data is collected in a memory *Profiling Buffer*. The Profiling Buffer is defined by:

- `PMBPTR_EL1`, the current write pointer.
- `PMBLIMITR_EL1`, the write limit pointer.

The Profiling Buffer starts at the current write pointer and extends to the current limit pointer minus one. The write limit pointer must be aligned to the smallest implemented translation granule size. The alignment of the current write pointer is IMPLEMENTATION DEFINED.

`PMBLIMITR_EL1` and `PMBPTR_EL1` are virtual addresses in the stage 1 translation regime of the owning Exception level. This is called the *owning translation regime*.

———— Note ————

The translation of virtual addresses to physical addresses is identical to that for any other virtual address in the owning Exception level. For example, `PMBPTR_EL1[63:56]` are ignored by address translation if the respective TBI bit is set to 1.

D9.7.1 Restrictions on the current write pointer

This section describes the software rules on setting the current write pointer, `PMBPTR_EL1`. If these rules are not followed, the value returned for a direct read of `PMBPTR_EL1` is UNKNOWN, the behavior is UNPREDICTABLE, and the PE might do any of the following at any point after profiling is enabled:

- Write sample records to any writeable address in memory that is writable at the owning Exception level.
- Generate a Profiling Buffer management event, with or without indicating data loss, for one of the following reasons:
 - The Profiling Buffer is full.
 - Any MMU Fault.

When profiling becomes enabled, all the following must be true:

- The current write pointer must be at least one sample record below the write limit pointer. That is:
$$\text{UInt}(\text{PMBPTR_EL1.PTR}) \leq \text{UInt}(\text{PMBLIMITR_EL1.LIMIT} : \text{Zeros}(12)) - 2^{\text{PMSIDR_EL1.MaxSize}}$$
- `PMBPTR_EL1.PTR[63:56]` must equal `PMBLIMITR_EL1.LIMIT[63:56]`.

When the Profiling Buffer is first configured, `PMBPTR_EL1.PTR` must be aligned to `PMBIDR_EL1.Align`. That is, if `PMBIDR_EL1.Align` is nonzero, `PMBPTR_EL1.PTR [UInt(PMBIDR_EL1.Align)-1:0]` must be all zeros.

However, the current write pointer can usually be restored to the saved write pointer value it had when profiling was disabled, providing a `PSB_CSINC` and a context synchronization event were executed before reading `PMBPTR_EL1`:

- If no Profiling Buffer management event was signaled then profiling can be restarted from the saved write pointer. In this case, the saved write pointer points within one sample record of the write limit pointer.
- If a Profiling Buffer management event was signaled then:
 - If `PMBSR_EL1.S` is restored to 1, then profiling is not being enabled, and there are no constraints on the value written to `PMBPTR_EL1`.
 - If `PMBSR_EL1.S` is restored to 0, and the Profiling Buffer management event was caused by an MMU fault, profiling can be restarted from the saved write pointer; if `PMBSR_EL1.{EA, DL}` did not also indicate an External abort or data loss, and the saved write pointer is at least one sample record below the write limit pointer.

———— Note ————

If a signaled MMU fault has not been corrected, the SPU generates a new MMU fault Profiling Buffer management event when it next tries to write a sample record.

- If `PMBSR_EL1.S` is restored to 0, and the Profiling Buffer management event was caused by a buffer full event, the Profiling Buffer can be extended and profiling restarted from the saved write pointer; if `PMBSR_EL1.{EA, DL}` did not also indicate an External abort or data loss and the saved write pointer is at least one sample record below the extended write limit pointer.

The current write pointer must not be restored from the saved write pointer following a Profiling Buffer management event if `PMBSR_EL1.DL` was set to 1.

The saved write pointer might not be aligned to `2PMBIDR_EL1.Align` and might point to within one sample record of the write limit pointer.

For more information, see *Synchronization and Statistical Profiling* on page D9-2977.

D9.7.2 The owning Exception level

The owning Exception level is:

- Non-secure EL1, if all of the following are true:
 - Either EL3 is not implemented and the PE is executing in Non-Secure state, or `MDCR_EL3.NSPB` is either `0b10` or `0b11`.
 - Either EL2 is not implemented, or `MDCR_EL2.E2PB` is either `0b10` or `0b11`.
- Non-secure EL2, if all of the following are true:
 - EL2 is implemented.
 - Either EL3 is not implemented and the PE is executing in Non-secure state, or `MDCR_EL3.NSPB` is either `0b10` or `0b11`.
 - `MDCR_EL2.E2PB` is `0b00`.
- Secure EL1, if all of the following are true:
 - Either EL3 is not implemented and the PE is executing in Secure state, or `MDCR_EL3.NSPB` is either `0b00` or `0b01`.
 - Either Secure EL2 is not implemented or is disabled, or `MDCR_EL2.E2PB` is either `0b10` or `0b11`.
- Secure EL2, if all of the following are true:
 - Secure EL2 is implemented and enabled.
 - Either EL3 is not implemented and the PE is executing in Secure state, or `MDCR_EL3.NSPB` is either `0b00` or `0b01`.
 - `MDCR_EL2.E2PB` is `0b00`.

When the owning Exception level is Non-secure EL1

The Profiling Buffer addresses are in the Non-secure EL1&0 translation regime using the current ASID from `TTBRx_EL1`. This is a two-stage translation using the current VMID if EL2 is implemented and `HCR_EL2.VM` is 1.

If EL3 is implemented, then profiling is disabled in Secure state.

If EL2 is implemented, then profiling is disabled at EL2 and at Non-secure EL0 when `HCR_EL2.TGE` is 1.

When the owning Exception level is Non-secure EL2

The Profiling Buffer addresses are in the Non-secure EL2 translation regime. If `HCR_EL2.E2H` is 1, this is an EL2&0 translation regime using the current EL2&0 translation regime ASID from `TTBRx_EL2`.

If EL3 is implemented, then profiling is disabled in Secure state.

Note

If either `HCR_EL2.E2H` is 0 or `HCR_EL2.TGE` is 0, and the PE is executing at EL1 or EL0, the EL2 translation regime is not the current stage 1 translation regime because the current stage 1 translation regime is EL1&0.

When the owning Exception level is Secure EL1

The Profiling Buffer addresses are in the Secure EL1&0 translation regime using the current ASID from `TTBRx_EL1`. This is a two-stage translation using the current VMID if Secure EL2 is implemented and enabled and `HCR_EL2.VM` is 1.

If EL3 is implemented, then profiling is disabled in Non-secure state.

If Secure EL2 is implemented and enabled, then profiling is disabled at EL2 and at Secure EL0 when `HCR_EL2.TGE` is 1.

When the owning Exception level is Secure EL2

The Profiling Buffer addresses are in the Secure EL2 translation regime. If `HCR_EL2.E2H` is 1, this is an EL2&0 translation regime using the current EL2&0 translation regime ASID from `TTBRx_EL2`.

If EL3 is implemented, then profiling is disabled in Non-secure state.

Summary of the owning translation regime

Profiling is disabled if any of the following are true:

- The owning Exception level is using AArch32 state.
- `PMBLIMITR_EL1.E` is 0.

Table D9-4 on page D9-2970 summarizes the owning translation regime.

Table D9-4 Summary of owning translation regime (for all Exception levels using AArch64 state)

<code>PMBLIMITR_EL1.E</code>	<code>SCR_EL3.NS</code>	<code>SCR_EL3.EEL2</code>	<code>MDCR_EL3.NSPB</code>	<code>MDCR_EL2.E2PB</code>	Owning translation regime	
0	X	X	X	X	Disabled	
1	1	X	0b1x	0b1x	Non-secure EL1&0	
				0b00	Non-secure EL2 or EL2&0 ^a	
				X	Disabled	
	0	0	0b0x	0b0x	X	Secure EL1&0
					0b1x	Secure EL1&0
						0b00
	X	0b1x	X	Disabled		

a. Depending on the values of `HCR_EL2.{E2H,TGE}`.

D9.7.3 Memory access types and coherency

The SPU acts as a separate observer in the system and is subject to the rules regarding coherency.

Writes to any Device memory type by the SPU occur once.

The memory type and attributes that are used for a write by the SPU to the Profiling Buffer is taken from the translation table entries for the virtual address being written to. That is:

- The writes are treated as coming from an observer that is coherent with all observers in the Shareability domain that is defined by the translation tables.
- There is no requirement to manage coherency for observers in the same Shareability domain but coherency for other observers in the system might require explicit management.

For more information, see *Synchronization and Statistical Profiling* on page D9-2977.

If `FEAT_MTE2` is implemented, a PE will generate a Tag Unchecked access for each access to the Profiling Buffer as part of writing a sample record.

For more information on [FEAT_MTE2](#), see [Chapter D6 Memory Tagging Extension](#).

Writes to the Profiling Buffer are made as privileged writes within the owning translation regime. However, the value of `PSTATE.PAN` is ignored for these writes and treated as zero, see [Faults and watchpoints on page D9-2974](#).

This means that if [FEAT_EOPD](#) is implemented, the values of `TCR_ELx.EOPDy`, where `ELx` is the owning Exception level, do not apply to accesses to the Profiling Buffer made by the SPU.

D9.7.4 Memory access and crossing page boundaries

A memory access from the SPU that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in `CONSTRAINED UNPREDICTABLE` behavior. In this case, the implementation performs one of the following behaviors:

- Each memory access generated by the SPU uses the memory type and Shareability attribute associated with its own address.
- The access generates an Alignment fault caused by the memory type:
 - If only the stage 1 translation generated the mismatch, or there is only one stage of translation in the owning translation regime, the resulting Buffer Management event is a stage 1 Data Abort.
 - If only the stage 2 translation generated the mismatch, the resulting Buffer Management event is a stage 2 Data Abort.
 - If both stages of translation generate the mismatch, the resulting Buffer Management event is either a stage 1 Data Abort or a stage 2 Data Abort.
- Some or all of the data is discarded. The write pointer is either updated by the amount of data written not including the discarded data or the amount of data written including the discarded data.

A memory access from the SPU to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes `CONSTRAINED UNPREDICTABLE` behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the SPU are performed as if the boundary has no effect on the memory accesses.
- All memory accesses generated by the SPU are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
- The access generates an Alignment fault caused by the memory type:
 - If only the stage 1 translation causes the boundary to be crossed, or there is only one stage of translation in the owning translation regime, the resulting Buffer Management event is a stage 1 Data Abort.
 - If only the stage 2 translation causes the boundary to be crossed, the resulting Buffer Management event is a stage 2 Data Abort.
 - If both stages of translation cause the boundary to be crossed, the resulting Buffer Management event is either a stage 1 Data Abort or a stage 2 Data Abort.
- Some or all of the data is discarded. The write pointer is either updated by the amount of data written not including the discarded data or the amount of data written including the discarded data.

————— **Note** —————

The boundary referred to is between two Device memory regions that are both:

- Of the size of the smallest implemented translation granule.
- Aligned to the size of the smallest implemented translation granule.

If `PMSIDR_EL1.MaxSize` indicates the same value as `PMBIDR_EL1.Align`, then records are a fixed power-of-two size and never cross a page boundary.

D9.7.5 Cache and TLB operations

TLB maintenance operations that affect the TLB of the PE also affect any TLB caching translations for the SPU of that PE.

Cache maintenance operations that affect the caches of the PE also affect data caching by the SPU of that PE.

This means that the completion of any cache or TLB maintenance instruction includes its completion on all SPUs for PEs that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction. See [Completion and endpoint ordering on page B2-141](#).

Although the SPU acts as another observer in the system, for determining the Shareability domain of this DSB, or cache, or TLB maintenance operation, the writes of sample records are treated as coming from the PE that is being profiled.

D9.7.6 Effect on the exclusive monitors

If a Load-exclusive instruction or an operation between Load-exclusive and Store-exclusive instructions is sampled, and the sample record is written to an unrelated address, then to avoid a probe effect, Arm recommends that the Store-exclusive does not systematically fail on account of the sampled operation.

If a Store-exclusive instruction is sampled, and the sample record is written to an unrelated address, then the Store-exclusive must not systematically fail on account of the instruction having been sampled.

D9.8 Profiling Buffer management

A Profiling Buffer management event occurs:

- On a fault, see *Faults and watchpoints* on page D9-2974.
- On an External abort, see *External aborts* on page D9-2976.
- When the Profiling Buffer fills, see *Buffer full event* on page D9-2974.

On a Profiling Buffer management event:

- The service bit, `PMBSR_EL1.S`, is set to 1.
- The data loss bit, `PMBSR_EL1.DL`, is set as described in the event description.
- The Profiling Buffer management interrupt request signal, `PMBIRQ`, is asserted:
 - `PMBIRQ` is a level-sensitive interrupt request driven by `PMBSR_EL1.S`. This means that a direct write that sets `PMBSR_EL1.S` to 1 causes the interrupt to be asserted, and `PMBIRQ` remains asserted until software clears `PMBSR_EL1.S` to 0.
 - If a Generic Interrupt Controller (GIC) is implemented, `PMBIRQ` must be configured as a Private Peripheral Interrupt (PPI) in a multiprocessor system. `PMBIRQ` is signaled by the PE that implements the SPU.

———— **Note** —————

A standard PPI number is allocated by the *Arm® Base System Architecture (BSA)*.

- Additional syndrome for the event is written to `PMBSR_EL1.MSS`. Unless otherwise stated in the event description, other `PMBSR_EL1` fields are unchanged.

While `PMBSR_EL1.S` is set to 1:

- The buffer is disabled and profiling is disabled.
- All remaining buffered sample records are discarded.
- The values in `PMBPTR_EL1` are retained and `PMSICR_EL1` does not decrement.

Buffer full events and MMU fault Profiling Buffer management events are reported synchronously.

———— **Note** —————

Reported synchronously means that profiling is disabled before the SPU samples further operations. The interrupt exception resulting from asserting the Profiling Buffer interrupt request is an asynchronous exception.

It is IMPLEMENTATION DEFINED whether External aborts are reported to the SPU synchronously or asynchronously. If External aborts are reported as asynchronous:

- The External abort might not be received until after a first Profiling Buffer management event has set `PMBSR_EL1.S` to 1.
- Writes to the buffer might generate a second Profiling Buffer management event after the External abort has set `PMBSR_EL1.S` to 1.

The architecture does not require that a sample record is written sequentially by the SPU, only that:

- The SPU never writes past the `PMBLIMITR_EL1` limit pointer.
- On a Profiling Buffer management interrupt, `PMBSR_EL1.DL` indicates whether `PMBPTR_EL1` points to the first byte after the last complete sample record.
- On an MMU fault or synchronous External abort, `PMBPTR_EL1` serves as a Fault Address Register.

———— **Note** —————

- This means that it must not be assumed that:
 - There is ever any valid data beyond the current `PMBPTR_EL1` write pointer.
 - The PE has not written a valid sample record between the current `PMBPTR_EL1` write pointer and the `PMBLIMITR_EL1` limit pointer.
 - If `PMBSR_EL1.DL` is set to 1 on a Profiling Buffer management interrupt, that there is any valid data between the end of the last complete sample record and the current `PMBPTR_EL1` write pointer.
 - Any valid data has been written to the Profiling Buffer if an External abort is reported asynchronously to the SPU.

- The last complete sample record must end at most $2^{(PMSIDR_EL1.MaxSize)}$ bytes below [PMBPTR_EL1](#).

D9.8.1 Prioritization of Profiling Buffer management events

Where multiple synchronous Profiling Buffer management events occur on writing a sample record, the PE prioritizes them as follows (from highest to lowest priority):

1. Synchronous fault.
2. Synchronous External abort.
3. Buffer full event.

Asynchronous External aborts are not prioritized with respect to other events.

———— **Note** ————

Prioritization of Profiling Buffer management interrupt requests is managed by the interrupt controller. Profiling Buffer management events are prioritized internally by the PE.

D9.8.2 Buffer full event

If, after writing a sample record, there is not sufficient space in the Profiling Buffer for a sample record of the size indicated by [PMSIDR_EL1.MaxSize](#), and [PMBSR_EL1.S](#) is 0, a Profiling Buffer management event is generated:

- [PMBSR_EL1.EC](#) is set to `0b000000`, other buffer management event.
- The BSC field of [PMBSR_EL1.MSS](#) is set as follows:
 - [PMBSR_EL1.BSC](#) is set to `0b000001`, buffer filled.
- [PMBPTR_EL1](#) is set to the first byte after the last complete sample record. [PMBSR_EL1.DL](#) is unchanged.
- The other [PMBSR_EL1](#) fields are unchanged.
- [PMBSR_EL1.S](#) is set to 1.

That is, the Profiling Buffer management event is generated when the PE writes past the write limit pointer minus $2^{(PMSIDR_EL1.MaxSize)}$. The SPU never writes beyond the write limit pointer.

For more information, see [Restrictions on the current write pointer on page D9-2968](#).

D9.8.3 Faults and watchpoints

[Table D9-5 on page D9-2974](#) lists the faults that might be generated by a write to the Profiling Buffer by the SPU.

Writes to the Profiling Buffer never generate watchpoints.

Table D9-5 Faults

Fault	Conditions
Translation	The translation of a virtual address to a physical address might generate a Translation fault.
Address Size	The translation of a virtual address to a physical address might generate an Address Size fault.
Alignment	If PMBPTR_EL1 is not aligned to an IMPLEMENTATION DEFINED minimum alignment, the behavior is UNPREDICTABLE and a write to the Profiling Buffer by the SPU might generate an Alignment fault. For more information, see Restrictions on the current write pointer on page D9-2968 .

Table D9-5 Faults (continued)

Fault	Conditions
Permission	Writes to the Profiling Buffer are made as privileged writes. If the write does not have write permission, a Permission fault is generated. The value of <code>PSTATE.PAN</code> is ignored and treated as zero. If the SPU does not manage the dirty state in translation tables, then accesses ignore the Dirty Bit Modifier bit in Page and Block descriptors and an access might as a result generate a Permission fault. For more information, see The dirty state on page D5-2766 . ^a
Access flag	If the SPU does not manage the Access flag in translation tables or hardware management of the Access flag state is disabled for the owning translation regime, then any access to a Page or Block with the Access Flag bit set to 0 in a descriptor will generate an Access Flag fault. For more information, see The Access flag on page D5-2765 . ^a
TLB Conflict fault	IMPLEMENTATION DEFINED.
Unsupported atomic hardware update fault	If hardware update of the translation tables is not guaranteed atomic in regard to other agents that access the memory, the translation of a virtual address to a physical address might generate an Unsupported atomic hardware update fault.

a. `PMBIDR_EL1.F` defines whether the SPU manages the Access flag and dirty state in the translation tables.

If a write to the Profiling Buffer generates a fault and `PMBSR_EL1.S` is 0, then a Profiling Buffer management event is generated:

- `PMBSR_EL1.S` is set to 1.
- `PMBSR_EL1.EC` is set to one of:
 - `0b100100`, stage 1 Data Abort on write to the Profiling Buffer.
 - `0b100101`, stage 2 Data Abort on write to the Profiling Buffer.
- The FSC field of `PMBSR_EL1.MSS` is set as follows:
 - `PMBSR_EL1.FSC` is set to indicate the type of the fault.
- `PMBPTR_EL1` is set to the address that generated the fault.
- If `PMBPTR_EL1` is not the address of the first byte after the last complete sample record written by the SPU, then `PMBSR_EL1.DL` is set to 1. Otherwise, `PMBSR_EL1.DL` is unchanged.
- The other `PMBSR_EL1` fields are unchanged.

———— **Note** —————

Each of these faults gives rise to a Profiling Buffer management interrupt, not an actual MMU fault exception. The ESR and FAR registers are unchanged.

For more information, see [The MMU fault-checking sequence on page D5-2803](#).

Hardware management of dirty state and the Access flag by the Statistical Profiling Extension

It is IMPLEMENTATION DEFINED whether address translations performed by the SPU manage dirty state and the Access flag. This is discoverable by software using `PMBIDR_EL1.F`. See [Hardware management of dirty state on page D5-2768](#) and [Hardware management of the Access flag on page D5-2767](#).

If hardware management of dirty state by the SPU is implemented, and hardware management of dirty state is enabled for the owning translation regime, then the SPU can speculatively update the Translation Table descriptor for any Page or Block in the Statistical Profiling buffer before writing data to it, if the write is otherwise permitted. This includes the case where a buffer management event means the SPU stops writing data before the page or block is written to. For more information, see [The Profiling Buffer on page D9-2968](#).

D9.8.4 External aborts

A write to the Profiling Buffer might generate an External abort, including an External abort on a translation table walk or translation table update. It is an IMPLEMENTATION DEFINED choice whether such an External abort:

- Is reported to the SPU and treated as a Profiling Buffer management event.
- Generates an SError interrupt exception.

If a write to the Profiling Buffer generates an External abort that is reported to the SPU:

- The External abort bit, `PMBSR_EL1.EA`, is set to 1.
- The SPU stops writing sample records to the Profiling Buffer. It is implementation defined whether an External abort on a write to the Profiling Buffer is reported as synchronous or asynchronous:
 - The External abort is reported as *synchronous* if `PMBPTR_EL1` is set to the address that was externally aborted.
 - The External abort is reported as *asynchronous* if `PMBPTR_EL1` is not guaranteed to be set to the address that was externally aborted.
- If the External abort is reported as asynchronous or `PMBPTR_EL1` is not the address of the first byte of the sample record being written by the SPU, then `PMBSR_EL1.DL` is set to 1. Otherwise, `PMBSR_EL1.DL` is unchanged.

———— **Note** —————

Following an External abort reported asynchronously to the SPU, software must not assume that any valid data has been written to the Profiling Buffer.

- The other `PMBSR_EL1` fields are unchanged.
- If `PMBSR_EL1.S == 0`, a buffer management event is generated:
 - `PMBSR_EL1.S` is set to 1.
 - `PMBSR_EL1.EC` is set to one of:
 - 0b100100, stage 1 data abort on write to buffer.
 - 0b100101, stage 2 data abort on write to buffer.
 - `PMBSR_EL1.MSS` is set as follows:
 - `PMBSR_EL1.FSC` is set to indicate a synchronous or asynchronous external abort.

If a write to the Profiling Buffer generates an External abort that is taken as an SError interrupt exception, the PE takes the SError interrupt exception as normal, and `PMBSR_EL1` fields are unchanged.

———— **Note** —————

Treating the External abort as a Profiling Buffer management event:

- Sets `PMBSR_EL1.S` to 1 and so disables the SPU.
- Allows error recovery software to isolate the event to the actions of the SPU.

Taking an SError interrupt:

- Means that the SPU will be disabled only if the SError interrupt is taken to an Exception level where the SPU is disabled.
- Might not allow error recovery software to isolate the event and error containment.

D9.9 Synchronization and Statistical Profiling

The profiling operation of the SPU:

- Makes indirect reads and indirect writes of System registers.
- Writes to memory.
- Makes further indirect writes to `PMBPTR_EL1` as a result of an External abort on a write to memory.

The indirect reads of the `PMSCR_EL1`.{E1SPE, E0SPE} and `PMSCR_EL2`.{E2SPE, E0HSPE} controls when determining whether to select an operation for profiling are treated as indirect reads made by the instruction being executed, and subject to the standard requirements for synchronization.

Otherwise, although the profiling operation is generated by a sampled operation, the profiling operation executes independently of the instructions that are executed on the PE, and acts as a separate memory observer from the PE in the system.

A `DSB` instruction guarantees that all memory transactions that are made by the PE are observable by writes made by a profiling operation relating to a sampled operation in program order after the `DSB` instruction.

A `Context synchronization event` guarantees that a direct write to a System register made by the PE in program order before the context synchronization event are observable by indirect reads and indirect writes of the same System register made by a profiling operation relating to a sampled operation in program order after the context synchronization event.

To synchronize previous profiling operations, software must execute a `PSB CSYNC` Buffer Synchronization instruction.

———— **Note** —————

The `PSB CSYNC` instruction is not defined in the AArch32 instruction set architecture.

Following a context synchronization event, a `PSB CSYNC` instruction is guaranteed to synchronize the profiling operations for all instructions that are executed in program order before the context synchronization event.

Synchronized by the `PSB CSYNC` instruction means:

- A direct read of a System register in program order following a `PSB CSYNC` instruction requires explicit synchronization to observe an indirect write to the same System register made by a profiling operation synchronized by the `PSB CSYNC` instruction.
- An indirect write to a System register made by a profiling operation synchronized by a `PSB CSYNC` instruction does not affect a direct write to the same System register made in program order following the `PSB CSYNC` instruction.
- A direct write to a System register in program order following a `PSB CSYNC` instruction is not allowed to affect an indirect read of the same System register made by a profiling operation synchronized by the `PSB CSYNC` instruction.
- A `DSB` instruction in program order following a `PSB CSYNC` instruction does not complete before the writes to the Profiling Buffer of sample records for profiling operations synchronized by the `PSB CSYNC` instruction have completed. The `DSB` instruction must apply to both loads and stores.

For the indirect write to `PMBSTR_EL1` that is made as a result of an External abort on a write of a sample record to memory, the synchronization rules apply only after the write has completed.

Although the SPU acts as another observer in the system, for determining the Shareability domain of the `DSB` instructions, the writes of sample records are treated as coming from the PE that is being profiled.

———— **Note** —————

If profiling is not disabled when the context synchronization event occurs, further profiling operations might be generated that are not guaranteed to be synchronized by the `PSB CSYNC` instruction.

If the PE takes an exception to an Exception level where profiling is disabled, no new operations are selected for sampling. Profiling is always disabled if the owning Exception level is a lower Exception level than the current Exception level.

In the absence of a context synchronization event, a `PSB CSYNC` instruction is not required to execute in program order with respect to sampled operations.

D9.9.1 UNPREDICTABLE behavior

In the absence of correct context synchronization events, it is UNPREDICTABLE whether an indirect read of a System register made by a profiling operation will return the old or the new values.

If the indirect reads mean that `ProfilingBufferEnabled()` returns FALSE when a sample record or records are about to be written to memory, then it is further UNPREDICTABLE whether the sample record or records:

- Are written to memory.
- Are silently discarded and not written to memory.
- Are discarded and not written to memory, and a Profiling Buffer management event is generated:
 - `PMBSR_EL1.DL` is set to 1.
 - `PMBSR_EL1.EC` is set to `0x00`.
 - `PMBSR_EL1.BSC` is set to `0x00` to indicate that the buffer is not full.

If `SCR_EL3.NS` does not match the Security state of the owning translation regime, it is UNPREDICTABLE whether an address translation made by the PE writing a sample record to memory uses the value of `SCR_EL3.NS` or the identity of the owning translation regime.

This means that software must execute a `PSB CSYNC` instruction to force any sample records to be written to the Profiling Buffer before changing context.

Chapter D10

Statistical Profiling Extension Sample Record Specification

This chapter describes the sample records generated by the Statistical Profiling Extension. It contains the following sections:

- [About the Statistical Profiling Extension Sample Records on page D10-2980.](#)
- [Alphabetical list of Statistical Profiling Extension packets on page D10-2983.](#)

D10.1 About the Statistical Profiling Extension Sample Records

The Statistical Profiling Extension sample record format version is identified by `PMSIDR_EL1.Format`. The architecture currently defines only version 0.

———— **Note** ————

Armv8.7 defines the SPE sample record format version, allowing future architecture updates to extend or change the record format. `PMSIDR_EL1.Format` was previously a RES0 field in a read-only register. Software that reads and checks `PMSIDR_EL1.Format` on any implementation prior to Armv8.7 that includes SPE will read a value indicating format version 0 is supported.

The sample record format version 0 is self-describing and extensible. This format allows software to parse profile data even when that profile data contains extended information.

The Statistical Profiling Extension writes a series of sample records to memory, each record consisting of a sequence of packets, and each packet consisting of:

- One or two header bytes.
- Zero, 1, 2, 4 or 8 payload bytes.

D10.1.1 Headers

The first header byte encodes the number of payload bytes:

0x00-0x1F	Single byte header, no payload.
0x20-0x3F	First byte of extended header. Second byte encodes the payload length.
0x40-0x4F, 0x80-0x8F, 0xC0-0xCF	Header with an 8-bit payload.
0x50-0x5F, 0x90-0x9F, 0xD0-0xDF	Header with a 16-bit payload.
0x60-0x6F, 0xA0-0xAF, 0xE0-0xEF	Header with a 32-bit payload.
0x70-0x7F, 0xB0-0xBF, 0xF0-0xFF	Header with a 64-bit payload.

D10.1.2 Records

A record consists of multiple packets. A record comprises, in ascending address order:

- A sequence of headers, each followed by their payload byte or bytes.
- Either:
 - An End packet header.
 - A Timestamp packet.

Figures in this chapter show each packet as a sequence of bytes. [Figure D10-1 on page D10-2981](#) shows how bytes are stored in memory in increasing addresses from left to right.

First byte	1	2	3	4	Last Byte
Header (16-bit data)	Data		Header (8-bit data)	Data	0x01 End Packet
	LSB	MSB			

First Byte	1	2	3	4	5	6	...	12	Last Byte
Header (16-bit data)	Data		Header (8-bit data)	Data	0x71 Timestamp Packet	TS [7:0]	...	TS [55:48]	TS [63:56]
	LSB	MSB							

Figure D10-1 Convention for packet descriptions

In some sections, the figures are split into separate figures for the header byte and payload bytes. For instance, where the number of payload bytes varies according to a field in the header.

The header bytes and payload bytes are described in ascending memory address order. Within a payload value, values are in little-endian byte order.

The size of the access granule for writes to the Profiling Buffer by the Statistical Profiling Unit is IMPLEMENTATION DEFINED, up to a maximum of 2KB. The size of the access granule can vary from time to time.

D10.1.3 Protocol framing packets and forwards compatibility

The padding header, alignment command, timestamp packet, and end packet are protocol framing packets that frame the records created by the Statistical Profiling Unit. Only padding headers and alignment commands are permitted between records.

———— **Note** ————

[PMBIDR_EL1](#).Align defines a minimum alignment for records. However, implementations must nevertheless create a valid protocol stream that can be parsed without knowledge of the minimum alignment.

The packet types are described in the following sections. Software must ignore unknown packets, using the size field encoded in the header. This includes packets containing reserved values in fields.

The following sections give an overview of the Statistical Profiling Unit packets output to a memory-mapped Profiling Buffer or Device memory:

- [Statistical Profiling Extension protocol packet headers](#) on page D10-2981

D10.1.4 Statistical Profiling Extension protocol packet headers

8-bit headers

For Address packets and Counter packets, the 8-bit header format is described as the *short format*.

Table D10-1 8-bit header encodings

[7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]	Description
0	0	0	0	0	0	0	0	Padding on page D10-3003
0	0	0	0	0	0	0	1	End packet on page D10-2992
0	1	1	1	0	0	0	1	Timestamp packet on page D10-3004
0	1	x	x	0	0	1	0	Events packet on page D10-2993

Table D10-1 8-bit header encodings (continued)

[7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]	Description
0	1	x	x	0	0	1	1	<i>Data Source packet on page D10-2991</i>
0	1	1	0	0	1	x	x	<i>Context packet on page D10-2987</i>
0	1	0	0	1	0	x	x	<i>Operation Type packet on page D10-2998</i>
1	0	1	1	0	x	x	x	<i>Address packet on page D10-2983 (Short format)</i>
1	0	0	1	1	x	x	x	<i>Counter packet on page D10-2988 (Short format)</i>

16-bit headers

For Address packets and Counter packets, the 16-bit header format is described as the *extended format*.

Table D10-2 16-bit header encodings

Byte 0								Byte 1								Description
[7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]	[7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]	
0	0	1	0	0	0	x	x	1	0	1	1	0	x	x	x	<i>Address packet on page D10-2983</i>
0	0	1	0	0	0	x	x	1	0	0	1	1	x	x	x	<i>Counter packet on page D10-2988</i>

D10.2 Alphabetical list of Statistical Profiling Extension packets

D10.2.1 Address packet

The Address packet characteristics are:

- Purpose** Provides an address value for the record. Addresses are always 64 bits.
- Attributes** Multi-part packet comprising:
- 8 or 16-bit header.
 - 64-bit payload.

Address packet header

When Extended format is used, the Address packet header bit assignments are:

7	6	5	4	3	2	1	0	
0	0	1	0	0	0	INDEX[4:3]		Byte 0
1	0	SZ		0	INDEX[2:0]			Byte 1
		1	1					

When Short format is used, the Address packet header bit assignments are:

7	6	5	4	3	2	1	0	
1	0	SZ		0	INDEX			Byte 0
		1	1					

Byte 1 bits [7:6], when Extended format, Byte 0 bits [7:6], when Short format

This field reads as 0b10.

SZ, byte 1 bits [5:4], when Extended format, SZ, byte 0 bits [5:4], when Short format

Payload size. The defined values of this field are:

0b11 Doubleword.

This field reads as 0b11.

Byte 1 bit [3], when Extended format, Byte 0 bit [3], when Short format

This bit reads as 0b0.

Byte 0 bits [7:5], when Extended format

This field reads as 0b001.

Byte 0 bits [4:2], when Extended format

This field reads-as-zero.

INDEX, byte 0 bits [1:0], byte 1 bits [2:0], when Extended format, INDEX, byte 0 bits [2:0], when Short format

The defined values of this field are:

0b00000 Issued instruction virtual address (PC). Included for all operations.

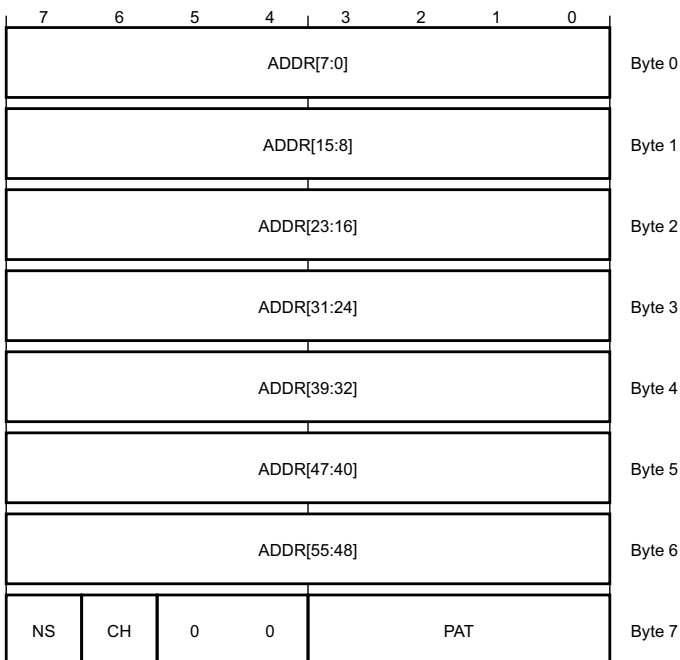

0b00001 Branch target address:

- It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this address is included for an Exception Return to an Exception level where profiling is disabled.
- Included for all other branch and exception return instructions.

- 0b00010 Data access virtual address. Included for all load, store and atomic operations.
 - 0b00011 Data access physical address:
 - It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this address included for accesses that generate Permission or Access Flag faults.
 - Not included for all other accesses that generate an abort, or if disabled by CollectPhysicalAddress.
 - Included for all other load, store and atomic operations.
 - 0b00100 Previous branch target address. The target virtual address of the most recently taken branch operation in program order before the sampled operation. This value is defined when FEAT_SPEv1p2 is implemented and reserved otherwise.
 - 0b0011x IMPLEMENTATION DEFINED address.
 - 0b1xxxx IMPLEMENTATION DEFINED address.
- All other values are reserved.
In the Short format header, bits [4:3] are zero.

Address packet payload

When Data access physical address, the Address packet payload bit assignments are:

When Data access virtual address, the Address packet payload bit assignments are:

When Instruction virtual address, the Address packet payload bit assignments are:

TAG byte <7>, when Data access virtual address

Top-byte tag.

If the value of the applicable TBI bit is one, a data access virtual address includes the top-byte tag. If the applicable TBI bit is zero, it is IMPLEMENTATION DEFINED whether this field reads as zero or holds the address tag of the applicable address.

NS, byte 7 bit [7], when Instruction virtual address

Non-secure state. The Security state associated with the address. For an issued instruction virtual address (PC) this is the Security state the instruction was executed in. For a branch target address, this is the Security state at the target of the branch. The defined values of this bit are:

- 0 Secure state.
- 1 Non-secure state.

NS, byte 7 bit [7], when Data access physical address

Physical address space identifier. The Security attribute for the physical address. The defined values of this bit are:

- 0 Secure physical address space.
- 1 Non-secure physical address space.

CH, byte 7 bit[6], when Data access physical address

When [FEAT_MTE2](#) is implemented, Checked access identifier. Checked or Unchecked access. The defined values of this bit are:

- 0 Tag Unchecked access.
- 1 Tag Checked access.

For more information see [Chapter D6 Memory Tagging Extension](#).

If [FEAT_MTE2](#) is not implemented this bit is RAZ.

When Tag Check Faults are configured to be ignored by [SCTLR_ELx.TCF](#) or [SCTLR_ELx.TCF0](#), it is IMPLEMENTATION DEFINED whether this bit is 1 or 0 on a Tag Checked access.

EL, byte 7 bits [6:5], when Instruction virtual address

Exception level. The Exception level associated with the address. For an issued instruction virtual address (PC) this is the Exception level the instruction was executed in. For a branch target address, this is the Exception level at the target of the branch. The defined values of this field are:

- 0b00 EL0.
- 0b01 EL1.
- 0b10 EL2.
- 0b11 EL3.

Note

For an Exception Return, the Exception level at the target of the branch might be different to the Exception level the instruction was executed in.

Byte 7 bits [5:4], when Data access physical address

This field reads as 0b00.

PAT, Byte 7 bits [3:0], when Data access physical address

When [FEAT_MTE2](#) is implemented, this field provides the Physical Address Tag for a Tag Checked access. If the access is Unchecked this field reads as an IMPLEMENTATION DEFINED choice between 0b0000 and the Physical Address Tag used to perform the access.

For more information see [Chapter D6 Memory Tagging Extension](#).

If [FEAT_MTE2](#) is not implemented this field is RAZ.

Byte 7 bits [4:0], when Instruction virtual address

This field reads as 0b00000.

ADDR, bytes <6:0>

Address. Bits [55:0] of the address.

D10.2.2 Context packet

The Context packet characteristics are:

- Purpose** Provides context information for the record.
- Attributes** Multi-part packet comprising:
- 8-bit header.
 - 32-bit payload.

Context packet header

The Context packet header bit assignments are:

Byte 0 bits [7:6]

This field reads as 0b01.

SZ, byte 0 bits [5:4]

Payload size. The defined values of this field are:

0b10 Word.

This field reads as 0b10.

Byte 0 bits [3:2]

This field reads as 0b01.

INDEX, byte 0 bits [1:0]

Identifies the context value. The defined values of this field are:

0b00 CONTEXTIDR_EL1. Included for all operations if enabled by CollectContextIDR1.

0b01 CONTEXTIDR_EL2. Included for all operations if enabled by CollectContextIDR2.

All other values are reserved.

Context packet payload

The Context packet payload bit assignments are:

CONTEXT, bytes <3:0>

The context value.

D10.2.3 Counter packet

The Counter packet characteristics are:

- Purpose** Count of cycles the operation spent performing all or part of its behavior. The counter value occupies the least significant bits of the payload. The remaining bits are set to zero.
- Attributes** Multi-part packet comprising:
- 8 or 16-bit header.
 - 16-bit payload.

Counter packet header

When Extended format, the Counter packet header bit assignments are:

When Short format, the Counter packet header bit assignments are:

Byte 1 bits [7:6], when Extended format, Byte 0 bits [7:6], when Short format

This field reads as 0b10.

SZ, byte 1 bits [5:4], when Extended format, SZ, byte 0 bits [5:4], when Short format

Payload size. The defined values of this field are:

0b01 Halfword.

This field reads as 0b01.

Byte 1 bit [3], when Extended format, Byte 0 bit [3], when Short format

This bit reads as 0b1.

Byte 0 bits [7:5], when Extended format

This field reads as 0b001.

Byte 0 bits [4:2], when Extended format

This field reads-as-zero.

INDEX, byte 0 bits [1:0], byte 1 bits [2:0], when Extended format, INDEX, byte 0 bits [2:0], when Short format

The defined values of this field are:

- 0b00000 Total latency. Cycle count from the operation being dispatched for issue to the operation being microarchitecturally-finished. Included for all operations.
- 0b00001 Issue latency. Cycle count from the operation being dispatched for issue to the operation being issued for execution. This counts any delay in waiting the operation being ready to issue. Included for all operations.
- 0b00010 Translation latency. Cycle count from a virtual address being passed to the MMU for translation to the result of the translation being available. Included for all load, store and atomic operations.
- 0b0011x IMPLEMENTATION DEFINED counter value.

0b1xxxx IMPLEMENTATION DEFINED counter value.

All other values are reserved.

In the Short format header, bits [4:3] are zero.

For the purposes of defining these counter values:

- Dispatched for issue means:
 - The operation has been decoded.
 - The operation might not be ready to start execution because it is waiting for input values. The operation might be put into a queue.
- Issued for execution means the operation is ready to start executing:
 - For example, for a memory operation, this should be indicative of the cycle count from memory operation being dispatched for issue to access being initiated (virtual address).
- Microarchitecturally-finished means:
 - The operation has completed execution and is no longer capable of stalling any instruction that consumes its output. The results of the operation are not required to be coherent or observable by other PEs.
 - It is IMPLEMENTATION DEFINED whether the operation is speculative, or has committed its results to the architectural state of the PE.
 - For example:
 - For an arithmetic, floating-point, or SIMD operation with variable timing, such as divide, the results of the operation are available.
 - For load and atomic operations that return data, all data have been returned from memory.
 - For store and atomic operations that do not return data, it is not required that the store is complete for other observers.
 - For branch operations, the branch has been resolved as taken or not taken.
 - For barrier operations, the barrier has completed.

For WFE and WFI operations, it is IMPLEMENTATION DEFINED whether:

- The instruction is complete before the PE enters a low-power state or when the PE wakes from the low-power state.
- Counters count in the low power state.
- Sampling an operation is itself a wake-up event.

Counter packet payload

The Counter packet payload bit assignments are:

Byte 1 bits [7:4]

This field reads-as-zero.

COUNT, byte 1 bits [3:0], byte <0>, when a 12-bit counter is implemented

The counter value occupies the least significant bits of the payload. The remaining bits are set to zero. The counters are:

- Unsigned numbers.

- 12 bits.
- Saturating.

The value 0xFFF indicates the count has saturated.

D10.2.4 Data Source packet

The Data Source packet characteristics are:

Purpose If the implementation includes support for indicating the loaded data source, the Data Source packet indicates where the data returned for a load operation was sourced. It might also include other information, such as the state of the data at the source. It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this is included for load and atomic operations that generate an External abort. It is IMPLEMENTATION DEFINED whether this is included for atomic operations that do not return data to a PE register. Included for all other load and atomic operations.

Attributes Multi-part packet comprising:

- 8-bit header.
- 8 or 16-bit payload.

Data Source packet header

The Data Source packet header bit assignments are:

Byte 0 bits [7:6]

This field reads as 0b01.

SZ, byte 0 bits [5:4]

Payload size. The defined values of this field are:

0b00 Byte.
0b01 Halfword.

Byte 0 bits [3:0]

This field reads as 0b0011.

Data Source packet payload

When SZ == 0b00, the Data Source packet payload bit assignments are:

When SZ == 0b01, the Data Source packet payload bit assignments are:

SOURCE, byte <0>, when SZ == 0b00, SOURCE, bytes <1:0>, when SZ == 0b01

Because the list of data sources varies from system to system, the definition of this field is IMPLEMENTATION DEFINED. If a sampled operation generated multiple data accesses, it is IMPLEMENTATION DEFINED how the data source information is combined.

D10.2.5 End packet

The End packet characteristics are:

Purpose Defines the end of a record if a [Timestamp packet](#) is not present.

Attributes 8-bit packet.

Field descriptions

The End packet bit assignments are:

7	6	5	4	3	2	1	0	
0	0	0	0	0	0	0	1	Byte 0

Byte <0>

This field reads as 0b00000001.

D10.2.6 Events packet

The Events packet characteristics are:

Purpose Indicates up to 64 events generated by the sampled operation. If `FEAT_PMUv3p1` is implemented and an event counter is configured to count PMU events, then a sampled operation that causes the event counter to be incremented has the event recorded as one, and conversely a sampled operation that does not cause the counter to be incremented is recorded as zero.

———— **Note** —————

Arm recommends that the Performance Monitors Extension implements the Events.

Attributes Multi-part packet comprising:

- 8-bit header.
- 8, 16, 32, or 64-bit payload.

Events packet header

The Events packet header bit assignments are:

Byte 0 bits [7:6]

This field reads as `0b01`.

SZ, byte 0 bits [5:4]

Payload size. The defined values of this field are:

<code>0b00</code>	Byte.
<code>0b01</code>	Halfword.
<code>0b10</code>	Word.
<code>0b11</code>	Doubleword.

Software must treat bits that are not output as zero.

Byte 0 bits [3:0]

This field reads as `0b0010`.

Events packet payload

When `SZ == 0b00`, the Events packet payload bit assignments are:

When `SZ == 0b01`, the Events packet payload bit assignments are:

When $SZ == 0b10$, the Events packet payload bit assignments are:

7	6	5	4	3	2	1	0	
E[7]	E[6]	E[5]	E[4]	E[3]	E[2]	E[1]	E[0]	Byte 0
E[15:12]				E[11]	E[10]	E[9]	E[8]	Byte 1
0	0	0	0	0	E[18]	E[17]	E[16]	Byte 2
E[31:24]								Byte 3

When $SZ == 0b11$, the Events packet payload bit assignments are:

7	6	5	4	3	2	1	0	
E[7]	E[6]	E[5]	E[4]	E[3]	E[2]	E[1]	E[0]	Byte 0
E[15:12]				E[11]	E[10]	E[9]	E[8]	Byte 1
0	0	0	0	0	E[18]	E[17]	E[16]	Byte 2
E[31:24]								Byte 3
0	0	0	0	0	0	0	0	Byte 4
0	0	0	0	0	0	0	0	Byte 5
E[55:48]								Byte 6
E[63:56]								Byte 7

E[63:48], bytes <7:6>, when $SZ == 0b11$

Events 63 to 48. IMPLEMENTATION DEFINED.

Bytes <5:4,2>, byte 1 bit [3], when $SZ == 0b11$

This field reads-as-zero.

E[31:24], byte <3>, when $SZ == 0b10$, or when $SZ == 0b11$

Events 31 to 24. IMPLEMENTATION DEFINED.

E[18], byte 2 bit [18], when $SZ == 0b10$, or $SZ == 0b11$

Empty predicate.

When [The Scalable Vector Extension \(SVE\)](#) and [FEAT_SPEv1p1](#) are implemented the defined values of this bit are:

0 Operation was not an SVE operation, was unpredicated or executed with all elements Active.

1 SVE operation executed with all elements Inactive.

Otherwise this bit reads-as-zero.

If [FEAT_PMUv3](#) and [FEAT_SVE](#) are implemented this Event is required to be implemented consistently with [SVE_PRED_EMPTY_SPEC](#) in the *Arm Architecture Reference Manual Supplement, the Scalable Vector Extension, for v8-A*.

E[17], byte 2 bit [17], when SZ == 0b10, or SZ == 0b11

Partial predicate.

When [The Scalable Vector Extension \(SVE\)](#) and [FEAT_SPEv1p1](#) are implemented the defined values of this bit are:

- | | |
|---|---|
| 0 | Operation was not an SVE operation, was unpredicated, or executed with all elements Active. |
| 1 | Predicated SVE operation executed with at least one Inactive element. |

Otherwise this bit reads-as-zero.

If [FEAT_PMUv3](#) and [FEAT_SVE](#) are implemented this Event is required to be implemented consistently with [SVE_PRED_EMPTY_SPEC](#) and [SVE_PRED_PARTIAL_SPEC](#) in the *Arm Architecture Reference Manual Supplement, the Scalable Vector Extension, for v8-A*.

E[15:12], byte 1 bits [7:4], when SZ == 0b01, when SZ == 0b10, or when SZ == 0b11

Events 15 to 12. IMPLEMENTATION DEFINED.

E[11], byte 1 bit [3], when SZ == 0b01, when SZ == 0b10, or when SZ == 0b11

Alignment.

When [FEAT_SPEv1p1](#) is implemented the defined values of this bit are:

- | | |
|---|--|
| 0 | Load/store operation that was optimally aligned for the size of data being accessed. |
| 1 | Load/store operation that, due to the alignment of the address and size of data being accessed, incurred additional latency. |

Otherwise this bit reads-as-zero.

If [FEAT_PMUv3](#) is implemented this Event is required to be implemented consistently with [LDST_ALIGN_LAT](#).

E[10], byte 1 bit [2], when SZ == 0b01, when SZ == 0b10, or when SZ == 0b11

Remote access. The defined values of this bit are:

- | | |
|---|---|
| 0 | Did not cause access to another socket. |
| 1 | Load/store operation caused an access to another socket in a multi-socket system. This includes each data memory access that accesses another socket in a multi-socket system, including those that do not return data. |

This event is optional. When this event is implemented, it is further IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether a store can finish execution before this event is generated, meaning this event is never recorded for stores.

If this event and [FEAT_PMUv3](#) are both implemented, this event is required to be implemented consistently with [REMOTE_ACCESS](#) or [REMOTE_ACCESS_RD](#).

E[9], byte 1 bit [1], when SZ == 0b01, when SZ == 0b10, or when SZ == 0b11

Last Level cache miss. The defined values of this bit are:

- | | |
|---|---|
| 0 | Did not miss Last Level cache. |
| 1 | Load/store operation caused an access to at least the Last Level cache but is not completed by the Last Level cache. That is, each: |

- Load operation that does not return data from the Last Level cache.
- Store operation that does not update the Last Level cache.

The event is not set for operations that are completed by a cache above the Last Level cache.

This event is optional. When this event is implemented, it is further IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether a store can finish execution before this event is generated, meaning this event is never recorded for stores.

If this event and [FEAT_PMUv3](#) are both implemented, this event is required to be implemented consistently with [LL_CACHE_MISS](#) or [LL_CACHE_MISS_RD](#).

E[8], byte 1 bit [0], when SZ == 0b01, when SZ == 0b10, or when SZ == 0b11

Last Level cache access. The defined values of this bit are:

- | | |
|---|--|
| 0 | Did not access Last Level data or unified cache. |
| 1 | Load/store operation caused a cache access to at least the Last Level data or unified cache. |

———— **Note** —————

The architecture does not define the Last Level cache. The Last Level cache is typically the largest cache on this device shared by all PEs in the Inner or Outer Shareable domain of this PE. In a multi-socket system, it is IMPLEMENTATION DEFINED whether this includes caches on other sockets.

This event is optional. When this event is implemented, it is further IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether a store can finish execution before this event is generated, meaning this event is never recorded for stores.

If this event and [FEAT_PMUv3](#) are both implemented, this event is required to be implemented consistently with [LL_CACHE](#) or [LL_CACHE_RD](#).

E[7], byte 0 bit [7]

Mispredicted. The defined values of this bit are:

- | | |
|---|--|
| 0 | Did not cause correction to the predicted program flow. |
| 1 | A branch that caused a correction to the predicted program flow. |

If [FEAT_PMUv3](#) is implemented this Event is required to be implemented consistently with either [BR_MIS_PRED](#) or [BR_MIS_PRED_RETIRED](#).

E[6], byte 0 bit [6]

Not taken. The defined values of this bit are:

- | | |
|---|--|
| 0 | Did not fail condition code check. |
| 1 | A conditional instruction that failed its condition code check. This includes conditional branches, compare-and-branch, conditional select, and conditional compares: <ul style="list-style-type: none">• For a conditional branch or compare-and-branch instruction, this means the branch was not taken.• For a conditional select, this means the second operand was written to the result.• For a condition compare, this means the condition flags were set to the immediate value and not the result of the compare. |

———— **Note** —————

This Event includes branches, selects, [CCMP \(register\)](#), and [CCMP \(immediate\)](#).

E[5], byte 0 bit [5]

TLB walk. The defined values of this bit are:

- | | |
|---|--|
| 0 | Did not generate TLB walk. |
| 1 | Load/store operation that causes a refill of a data or unified TLB, involving at least one translation table walk access. This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches. |

If [FEAT_PMUv3](#) is implemented this Event is required to be implemented consistently with [DTLB_WALK](#).

E[4], byte 0 bit [4]

TLB access. The defined values of this bit are:

- 0 Did not access TLB.
- 1 Load/store operation caused an access to at least the first level of data or unified TLB.

If [FEAT_PMUv3](#) is implemented this Event is required to be implemented consistently with [L1D_TLB](#).

E[3], byte 0 bit [3]

Level 1 Data cache refill. The defined values of this bit are:

- 0 Did not cause level 1 data cache refill.
- 1 Load/store operation caused a refill of at least the first level of data or unified cache. This includes each data memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether a store can finish execution before this event is generated, meaning this event is never recorded for stores.

If [FEAT_PMUv3](#) is implemented this event is required to be implemented consistently with [L1D_CACHE_REFILL](#) or [L1D_CACHE_REFILL_RD](#).

E[2], byte 0 bit [2]

Level 1 Data cache access. The defined values of this bit are:

- 0 Did not access level 1 data cache.
- 1 Load/store operation caused a cache access to at least the first level of data or unified cache.

It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether a store can finish execution before this event is generated, meaning this event is never recorded for stores.

If [FEAT_PMUv3](#) is implemented this event is required to be implemented consistently with [L1D_CACHE](#) or [L1D_CACHE_RD](#).

E[1], byte 0 bit [1]

Architecturally executed. The defined values of this bit are:

- 0 Did not retire.
- 1 Committed its results to the architectural state of the PE, or completed with a synchronous architectural exception.

Note

A conditional instruction can retire even if it fails its condition code check.

If [FEAT_PMUv3](#) is implemented this Event is required to be implemented consistently with [INST_RETIRED](#).

E[0], byte 0 bit [0]

Generated exception. The defined values of this bit are:

- 0 Did not generate an exception.
- 1 Completed with a synchronous exception.

If E[1] in the same Events packet is set to 0, then the meaning of this bit is IMPLEMENTATION DEFINED.

If [FEAT_PMUv3](#) is implemented this Event is required to be implemented consistently with [EXC_TAKEN](#).

D10.2.7 Operation Type packet

The Operation Type packet characteristics are:

- Purpose** Defines the type of operation sampled. Included for all operations.
- Attributes** Multi-part packet comprising:
- 8-bit header.
 - 8-bit payload.

Operation Type packet header

The Operation Type packet header bit assignments are:

Byte 0 bits [7:6]

This field reads as 0b01.

SZ, byte 0 bits [5:4]

Payload size. The defined values of this field are:

0b00 Byte.

This field reads as 0b00.

Byte 0 bits [3:2]

This field reads as 0b10.

CLASS, byte 0 bits [1:0]

Top-level instruction class. The defined values of this field are:

0b00 Other.

0b01 Load, store, or atomic.

0b10 Branch or exception return.

All other values are reserved.

Operation Type packet payload (Other)

When Other operation, the Operation Type packet payload (Other) bit assignments are:

When an SVE operation, the Operation Type packet payload (Other) bit assignments are:

SUBCLASS, byte<0>

Second-level instruction class. Defines the type of instruction. The defined values of this field are:

0b0000000x Other operation.

0b0xxx1xx0 SVE operation. If FEAT_SVE is implemented, and if FEAT_SPE is implemented, bits [6:4:2:1] are further defined as the EVL, PRED, and FP fields.

Otherwise this value is reserved.

EVL, byte 0 bits [6:4], when SVE operation

Effective Vector Length. Defines the sampled operation vector length, rounded up to a power of two. That is, the length of vector operated on by the sampled operation. The defined values of this field are:

0b000 32 bits.

0b001 64 bits.

0b010 128 bits.

0b011 256 bits.

0b100 512 bits.

0b101 1024 bits.

0b110 2048 bits.

All other values reserved.

The accessible vector length is always quantized into multiples of 128 bits. However, the effective vector length can be any size down to the smallest element size.

If the effective vector length is not a power of two, or is less than 32 bits, the value is rounded up before it is encoded in this field.

PRED, byte 0 bit[2], when SVE operation

Predicated SVE operation. The defined values of this bit are:

0 Not predicated.

1 Predicated SVE operation. The operation is an SVE operation that writes to a vector destination register under a Governing predicate using either zeroing or merging predication.

FP, byte 0 bits [6:4], when SVE operation

Floating-point operation. The defined values of this bit are:

0 Integer.

1 Floating-point.

COND, byte 0 bit [0], when Other operation

Conditional. The defined values of this bit are:

0 Unconditional operation.

1 Conditional operation or select.

Operation Type packet payload (Branch)

The Operation Type packet payload (Branch) bit assignments are:

SUBCLASS, byte <0>

Second-level instruction class. Describes the branch type. The defined values of this field are:

0b0000000x Direct branch.

0b0000001x Indirect branch.

All other values are reserved.

COND, byte 0 bit [0]

Conditional. The defined values of this bit are:

0 Unconditional branch.

1 Conditional branch.

Operation Type packet payload (load/store)

When the FEAT_NV2 transformed System register access, the Operation Type packet payload (load/store) bit assignments are:

When Extended load/store, the Operation Type packet payload (load/store) bit assignments are:

When General-purpose load/store, the Operation Type packet payload (load/store) bit assignments are:

When SIMD&FP load/store, the Operation Type packet payload (load/store) bit assignments are:

When SVE load/store, the Operation Type packet payload (load/store) bit assignments are:

When Unspecified load/store the Operation type packet payload (load/store) bit assignments are:

SUBCLASS, byte <0>

Second-level instruction class. Indicates the load/store type. The defined values of this field are:

- 0b0000000x A load/store targeting the general-purpose registers, other than an atomic operation, load-acquire, store-release or exclusive.
- 0b000xxx1x An atomic operation, load-acquire, store-release or exclusive. Bits [4:2] are further subdivided as described by the AR, EXCL and AT fields.
- 0b0000010x A load/store targeting the SIMD&FP registers.
- 0bxxxx1x0x A load/store targeting the SVE registers. Bits [7:4,2] are further defined as SG, EVL and PRED fields.
This value is defined only if both [The Scalable Vector Extension \(SVE\)](#) and [FEAT_SPEv1p1](#) are implemented.
This value is reserved otherwise.
- 0b0001000x A load/store targeting unspecified registers.
This value is defined only if [FEAT_SPEv1p1](#) is implemented.
This value is reserved otherwise.
- 0b0011000x An MRS or MSR operation at EL1 transformed to a load/store when [HCR_EL2.NV2](#) is 1.
This value is defined only if [FEAT_NV2](#) is implemented and reserved otherwise.

All other values are reserved.

SG, byte 0 bit [7], when SVE load/store

Gather/scatter load/store. The defined values of this bit are:

- 0 Not gather load or scatter store.
- 1 Gather load or scatter store.

EVL, byte 0 bits [6:4], when SVE load/store

Effective Vector Length. Defines the sampled operation vector length, rounded up to a power of two. That is, the length of vector operated on by the sampled operation. The defined values of this field are:

- 0b000 32 bits.
- 0b001 64 bits.
- 0b010 128 bits.
- 0b011 256 bits.
- 0b100 512 bits.
- 0b101 1024 bits.
- 0b110 2048 bits.

All other values reserved.

The accessible vector length is always quantized into multiples of 128 bits. However, the effective vector length can be any size down to the smallest element size.

If the effective vector length is not a power of two, or is less than 32 bits, the value is rounded up before it is encoded in this field.

AR, byte 0 bit [4], when Extended load/store

Acquire/Release. The defined values of this bit are:

- 0 Load/store/atomic without Acquire or Release semantics.
- 1 Load/store/atomic with Acquire or Release semantics.

EXCL, byte 0 bit [3], when Extended load/store

Exclusive. The defined values of this bit are:

- 0 Load/store/atomic without Exclusive.
- 1 Load/store with Exclusive.

This bit is RES0 if AT == 1.

PRED, byte 0 bit[2], when SVE load/store

Predicated SVE operation. The defined values of this bit are:

- 0 Not predicated.
- 1 Predicated SVE operation. The operation is an SVE operation that writes to a vector destination register under a Governing predicate using either zeroing or merging predication.

AT, byte 0 bit [2], when Extended load/store

Atomic load/store. The defined values of this bit are:

- 0 Not atomic.
- 1 Atomic.

LDST, byte 0 bit [0]

Store not load. The defined values of this bit are:

- 0 Load or swap.
- 1 Store.

D10.2.8 Padding

The Padding characteristics are:

Purpose Allows the PE to create alignment in the protocol buffer.

Attributes 8-bit packet.

Field descriptions

The Padding bit assignments are:

Byte <0>

This field reads as 0b00000000.

D10.2.9 Timestamp packet

The Timestamp packet characteristics are:

Purpose The 64-bit timestamp value when the operation was sampled. The Timestamp packet must come at the end of the record. If the Timestamp packet is not present, an [End packet](#) must come at the end of the record.

Attributes Multi-part packet comprising:

- 8-bit header.
- 64-bit payload.

Timestamp packet header

The Timestamp packet header bit assignments are:

Byte 0 bits [7:6]

This field reads as 0b01.

SZ, byte 0 bits [5:4]

Payload size. The defined values of this field are:

0b11 Doubleword.

This field reads as 0b11.

Byte 0 bits [3:0]

This field reads as 0b0001.

Timestamp packet payload

The Timestamp packet payload bit assignments are:

TS, bytes <7:0>

Timestamp value when the operation was sampled. The value depends on the result of [CollectTimeStamp\(\)](#):

- If `TimeStamp_Virtual`, this is the virtual timestamp, [CNTVCT_EL0](#).
- If `TimeStamp_Physical`, this is the physical timestamp, [CNTPCT_EL0](#).
- If `TimeStamp_OffsetPhysical`, this is the offset physical timestamp, [CNTPCT_EL0 - CNTPOFF_EL2](#).
- If `TimeStamp_None`, the timestamp packet is not included and an [End packet](#) must come at the end of the record.

However, if the Generic Timer System counter is disabled and [CollectTimeStamp\(\)](#) returns a value other than `TimeStamp_None`, then it is IMPLEMENTATION DEFINED whether:

- The Statistical Profiling Unit behaves as if [CollectTimeStamp\(\)](#) returns the value `TimeStamp_None`.
- The value of this field in the record is UNKNOWN.

Note

This relaxation refers to when the actual System counter is disabled, that is, `CNTEN.EN == 0`. It does not apply when the System counter is enabled but not accessible at the current Exception level.

Chapter D11

The Generic Timer in AArch64 state

This chapter describes the implementation of the Arm Generic Timer. It includes an overview of the AArch64 System register interface to an Arm Generic Timer.

It contains the following sections:

- [About the Generic Timer on page D11-3008.](#)
- [The AArch64 view of the Generic Timer on page D11-3012.](#)

[Chapter G6 The Generic Timer in AArch32 state](#) describes the AArch32 view of the Generic Timer, and [Chapter I2 System Level Implementation of the Generic Timer](#) describes the system level implementation of the Generic Timer.

D11.1 About the Generic Timer

Figure D11-1 on page D11-3008 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The *ARM Generic Interrupt Controller Architecture Specification* defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

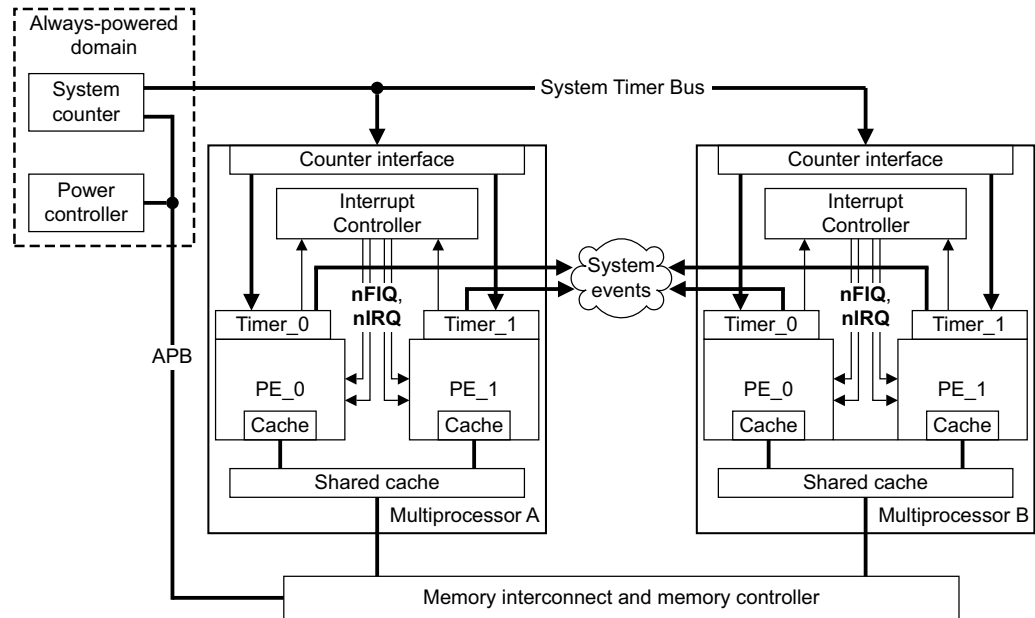

Figure D11-1 Generic Timer example

The Generic Timer:

- Provides a system counter that measures the passing of time in real-time.
 - **Note** —
 - The Generic Timer can also provide other components at a system level, but Figure D11-1 on page D11-3008 does not show any such components.
- Supports *virtual counters* that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.
- Can trigger events after a period of time has passed. The timers:
 - Can be used as count-up or as count-down timers.
 - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure D11-1 on page D11-3008 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch64 state. Chapter G6 *The Generic Timer in AArch32 state* describes access to this component from AArch32 state.

A Generic Timer implementation must also include a memory-mapped system component. This component:

- Must provide the System counter shown in Figure D11-1 on page D11-3008.
- Optionally, can provide timer components for use at a system level.

Chapter I2 *System Level Implementation of the Generic Timer* describes this memory-mapped component.

D11.1.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

The system counter

This provides a uniform view of system time, see *The system counter* on page D11-3010. Because this must be implemented at the system level, it is accessed through *The system level memory-mapped implementation of the Generic Timer* on page D11-3009. However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

PE implementations of the Generic Timer

Each PE implementation of the Generic Timer provides the following components:

- A physical counter, that gives access to the count value of the system counter. When `FEAT_ECV` is implemented, the `CNTPOFF_EL2` register allows offsetting of physical timers and counters.
- A virtual counter, that gives access to virtual time. In AArch64 state, the `CNTVOFF_EL2` register defines the offset between physical time, as defined by the value of the system counter, and virtual time.
- A number of timers. In an implementation where all Exception levels are implemented and can use AArch64 state, the timers that are accessible from AArch64 state are:
 - An EL1 physical timer.
 - A Non-secure EL2 physical timer.
 - An EL3 physical timer.
 - An EL1 virtual timer.
 - A Non-secure EL2 virtual timer.
 - A Secure EL2 virtual timer.
 - A Secure EL2 physical timer.

The Non-secure EL2 virtual timer is available only when `FEAT_VHE` is implemented.

The Secure EL2 timers are available only when `FEAT_SEL2` is implemented.

The AArch64 view of the Generic Timer on page D11-3012 describes these components.

The system level memory-mapped implementation of the Generic Timer

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into *frames*. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, `CNTControlBase`.
- A status frame, `CNTReadBase`.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, `CNTCTLBase`.

Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the CNTBase N frame.
- Optionally, provides an unprivileged view of the timer in the CNTEL0Base N frame.

N is the timer number, and the corresponding frame number, in the range 0-7.

Chapter 12 *System Level Implementation of the Generic Timer* describes these components.

D11.1.2 The system counter

The Generic Timer provides a system counter with the following specification:

Width	From Armv8.0 to Armv8.5 inclusive, at least 56 bits wide. The value returned by any 64-bit read of the counter is zero-extended to 64 bits. From Armv8.6, must be 64 bits wide.
Frequency	From Armv8.0 to Armv8.5 inclusive, increments at a fixed frequency, typically in the range 1-50MHz. It can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving. From Armv8.6, increments at a fixed frequency of 1GHz.
Roll-over	Roll-over time of not less than 40 years.
Accuracy	Arm does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period. Use of lower-frequency modes must not affect the implemented accuracy.
Start-up	Starts operating from zero.

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes in architectures from Armv8.0 to Armv8.5, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

From Armv8.6 the counter operates at a higher fixed frequency of 1GHz.

———— Note —————

Though each unit of the counter is set to 1ns, this does not require that the counter is incremented every 1ns. A step in the counter might be more than a single bit increment. It is recommended that the count is not incremented at a rate that is less than 50MHz in normal running operation.

The CNTFRQ_ELO register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information, see *Initializing and reading the system counter frequency* on page D11-3011.

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

Note

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. [Gray-count scheme for timer distribution scheme on page K5-8470](#) gives more information about this possibility.

Initializing and reading the system counter frequency

The `CNTFRQ_EL0` register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the system counter frequency to the `CNTFRQ_EL0` register. Only software executing at the highest implemented Exception level can write to `CNTFRQ_EL0`.

Note

The `CNTFRQ_EL0` register is UNKNOWN at reset, and therefore the counter frequency must be set as part of the system boot process.

Software can read the `CNTFRQ_EL0` register, to determine the current system counter frequency, in the following states:

- Secure and Non-secure EL2.
- Secure and Non-secure EL1.
- When `CNTKCTL_EL1`.{`ELOPCTEN`, `ELOVCTEN`} is not {0,0} and `CNTHCTL_EL2`.{`ELOPCTEN`, `ELOVCTEN`} is not {0,0}, Secure and Non-secure EL0.

Memory-mapped controls of the system counter

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see [Chapter 12 System Level Implementation of the Generic Timer](#).

D11.2 The AArch64 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch64 state:

- [The physical counter on page D11-3012.](#)
- [The virtual counter on page D11-3013.](#)
- [Event streams on page D11-3015.](#)
- [Timers on page D11-3016.](#)

D11.2.1 The physical counter

The PE includes a physical counter that contains the count value of the system counter. The `CNTPCT_EL0` register holds the current physical counter value. When `FEAT_ECV` is implemented, the `CNTPOFF_EL2` register holds the optional physical offset that can be applied at EL0 and EL1 whether EL0 and EL1 are using AArch64 state or AArch32 state. For more information, see [The physical offset register on page D11-3013.](#)

Reads of `CNTPCT_EL0` can occur speculatively and out of order relative to other instructions executed on the same PE.

The self-synchronized view of the physical counter

When `FEAT_ECV` is implemented, an alternative way to read the physical counter is supported. The `CNTPCTSS_EL0` register is a non-speculative view of the physical counter, as seen from the Exception level that `CNTPCTSS_EL0` is read from.

Accesses to the `CNTPCTSS_EL0` are subject to the same traps as accesses to the `CNTPCT_EL0`.

Reads of `CNTPCT_EL0` occur in program order relative to reads of `CNTPCT_EL0` or `CNTPCTSS_EL0`.

Reads of `CNTPCTSS_EL0` occur in program order relative to reads of `CNTPCT_EL0` or `CNTPCTSS_EL0`.

Example D11-1 Ensuring reads of the physical counter occur after signal read from memory

If a read from memory is used to obtain a signal from another agent that indicates that `CNTPCT_EL0` must be read, an ISB is used to ensure that the read of `CNTPCT_EL0` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
  LDR X1, [X2]
  CMP X1, #1        ; has had the value 1 written to it
  B.NE loop
  ISB               ; without this the CNTPCT_EL0 could be read before the memory location in [X2]
  MRS X1, CNTPCT_EL0
```

When `FEAT_ECV` is implemented, an access to `CNTPCTSS_EL0` can be used in place of the `CNTPCT_EL0` which, because it cannot be accessed speculatively, allows the ISB to be removed. This means that the following code sequence can be used:

```
loop                ; polling for some communication to indicate a requirement to read the timer
  LDR X1, [X2]
  CMP X1, #1        ; has had the value 1 written to it
  B.NE loop
  MRS X1, CNTPCTSS_EL0
```

Similarly where a read of the physical counter is required to take place after the completion of all loads and stores appearing in program order before the read of the counter, then the following code sequences can be used:

```
...                ; earlier loads and stores
DSB                ; completes the earlier loads and stores
ISB                ; without this the CNTPCT_EL0 could be read before the completion of the earlier
                  ; loads and stores
MRS X1, CNTPCT_EL0
```

Or, if `FEAT_ECV` is implemented:

```
...                ; earlier loads and stores
DSB                 ; completes earlier loads and stores
MRS X1, CNTPCTSS_EL0
```

Neither view of the physical counter ensures that:

- Context changes occurring in program order before the read of the counter have been synchronized.
- Accesses to memory appearing in program order after the read of the counter are executed before the counter has been read.

Example D11-2 Ensuring reads of the physical counter occur after previous memory accesses

To ensure that all previous memory accesses have completed and all previous context changes have been synchronized before the read of the counter, the following sequence should be used:

```
DSB
ISB
MRS Xn, CNTPCT{SS}_EL0 ; either view of the physical counter has the same effect in this example
```

To ensure that a memory access only occurs after a read of the counter, the following sequence should be used:

```
MRS Xn, CNTPCT{SS}_EL0 ; either view of the physical counter has the same effect in this example
ISB
LDR Xa, [Xb]           ; this load will be executed after the timer has been read
```

The physical offset register

When `FEAT_ECV` is implemented, the `CNTPOFF_EL2` register allows an offset to be applied to the physical counter, as viewed from EL1 and EL0, and to the EL1 physical timer. The functionality of this 64-bit register is affected by `CNTHCTL_EL2.ECV`.

When `CNTHCTL_EL2.ECV` is 1, an MRS to `CNTPCT_EL0` or `CNTPCTSS_EL0` from either EL0 or EL1 that is not trapped will return the value (PCount<63:0> - CNTPOFF_EL2<63:0>). For information on how the EL1 physical timer interrupt is triggered when `CNTHCTL_EL2.ECV` is 1, see *Operation of the CompareValue views of the timers* on page D11-3017.

When EL2 is not enabled for the current Security state, or when `CNTHCTL_EL2.ECV` is 0, then:

- An MRS to `CNTPCT_EL0` from either EL0 or EL1 that is not trapped will return the value PCount<63:0>.
- The physical offset is treated as zero for all timer and counter calculations involving the physical offset.

When EL2 is not enabled for the current Security state, or when `CNTHCTL_EL2.ECV` is 0, then the behavior of the counters and timers is as described for Armv8.5 and the optional physical offset is not used.

When `SCR_EL3.ECVEn` is 0, all values of `CNTPOFF_EL2` are treated as 0 for all purposes other than direct reads or writes to the register from EL3.

D11.2.2 The virtual counter

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time.

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing at EL1 or EL0, the virtual offset value relates to the current virtual machine.

The `CNTVOFF_EL2` register contains the virtual offset, see *The virtual offset register* on page D11-3015.

The `CNTVCT_EL0` register holds the current virtual counter value.

Reads of `CNTVCT_EL0` can occur speculatively and out of order relative to other instructions executed on the same PE.

The self-synchronized view of the virtual counter

When `FEAT_ECV` is implemented, an alternative way to read the virtual counter is supported. The `CNTVCTSS_EL0` register is a non-speculative view of the virtual counter, as seen from the Exception level that `CNTVCTSS_EL0` is read from.

Accesses to the `CNTVCTSS_EL0` are subject to the same traps as accesses to the `CNTVCT_EL0`.

Reads of `CNTVCT_EL0` occur in program order relative to reads of `CNTVCT_EL0` or `CNTVCTSS_EL0`.

Reads of `CNTVCTSS_EL0` occur in program order relative to reads of `CNTVCT_EL0` or `CNTVCTSS_EL0`.

Example D11-3 Ensuring reads of the virtual counter occur after signal read from memory

If a read from memory is used to obtain a signal from another agent that indicates that `CNTVCT_EL0` must be read, an ISB is used to ensure that the read of `CNTVCT_EL0` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
  LDR X1, [X2]
  CMP X1, #1        ; has had the value 1 written to it
  B.NE loop
  ISB               ; without this the CNTVCT_EL0 could be read before the memory location in [X2]
  MRS X1, CNTVCT_EL0
```

When `FEAT_ECV` is implemented, an access to `CNTVCTSS_EL0` can be used in place of the `CNTVCT_EL0`, which, because it cannot be accessed speculatively, allows the ISB to be removed. This means that the following code sequence can be used:

```
loop                ; polling for some communication to indicate a requirement to read the timer
  LDR X1, [X2]
  CMP X1, #1        ; has had the value 1 written to it
  B.NE loop
  MRS X1, CNTVCTSS_EL0
```

Similarly where a read of the virtual counter is required to take place after the completion of all loads and stores appearing in program order before the read of the counter, then the following two sequences can be used:

```
...                ; earlier loads and stores
DSB                ; completes earlier loads and stores
ISB                ; without this CNTVCT_EL0 could be read before the completion of the earlier
                  ; loads and stores
MRS X1, CNTVCT_EL0
```

Or, if `FEAT_ECV` is implemented:

```
...                ; earlier loads and stores
DSB                ; completes earlier loads and stores
MRS X1, CNTVCTSS_EL0
```

Neither view of the virtual counter ensures that:

- Context changes occurring in program order before the read of the counter have been synchronized.
- Accesses to memory appearing in program order after the read of the counter are executed before the counter has been read.

Example D11-4 Ensuring reads of the virtual counter occur after previous memory accesses

To ensure that all previous memory accesses have completed and all previous context changes have been synchronized before the read of the counter, the following sequence should be used:

```
DSB
ISB
MRS Xn, CNTVCT{SS}_EL0 ; either view of the virtual counter has the same effect in this example
```

To ensure that a memory access only occurs after a read of the counter, the following sequence should be used:

```
MRS Xn, CNTVCT{SS}_EL0 ; either view of the virtual counter has the same effect in this example
ISB
LDR Xa, [Xb] ; this load will be executed after the timer has been read
```

The virtual offset register

The virtual counter is a counter that has a *virtual offset* relative to the physical counter as viewed from EL2 and EL3. This virtual offset is held in the register `CNTVOFF_EL2`. The virtual counter value is the count compared by the EL1 virtual timer.

If EL2 is not implemented and enabled, then the virtual counter uses a fixed offset of zero.

D11.2.3 Event streams

An implementation that includes the Generic Timer can use the system counter to generate one or more *event streams*, to generate periodic wake-up events as part of the mechanism described in [Wait for Event mechanism and Send event on page D1-2536](#).

———— Note ————

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

The `CNTKCTL_EL1`.{EVNTEN, EVNTPDIR, EVNTI, EVNTIS} fields define an event stream that is generated from the virtual counter.

In all implementations, the `CNTHCTL_EL2`.{EVNTEN, EVNTPDIR, EVNTI, EVNTIS} fields define an event stream that is generated from the physical counter.

The event stream is configured as follows:

- EVNTI selects the counter bit that triggers the event.
- If `FEAT_ECV` is not implemented, EVNTI selects between bits[0:15].
- If `FEAT_ECV` is implemented, EVNTIS selects whether EVNTI selects between bits[0:15] or bits[8:23].
- EVNTPDIR selects whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

———— Note ————

If the event stream is configured to produce events from the low order bits of the counter when the counter frequency is very high (for example 1GHz), then the practical update rate of the counter might mean that the event stream is not generated as the low order bit might not change. Software can rely on an event stream rate of at least 1MHz in normal operation.

The operation of an event stream is as follows:

- The pseudocode variables PreviousCNTVCT and PreviousCNTPCT are initialized as:

```
// Variables used for generation of the timer event stream.
bits(64) PreviousCNTVCT = bits(64) UNKNOWN;
bits(64) PreviousCNTPCT = bits(64) UNKNOWN;
```

- The pseudocode functions TestEventCNTV() and TestEventCNTP() are called on each cycle of the PE clock.
- The TestEventCNTx() pseudocode template defines the functions TestEventCNTV() and TestEventCNTP():

```
// TestEventCNTx()
// =====

// Template for the TestEventCNTV() and TestEventCNTP() functions
// Describes operation when all Exception levels are using AArch64:
// CNTxCT_EL0      is CNTVCT_EL0      or CNTPCT_EL0      64-bit count value
// CNTxCTL_ELx     is CNTKCTL_EL1     or CNHCTL_EL2     Control register
// PreviousCNTxCT_EL0 is PreviousCNTVCT_EL0 or PreviousCNTPCT_EL0

TestEventCNTx()
    if CNTxCTL_ELx.EVNTEN == '1' then
        n = UInt(CNTxCTL_ELx.EVNTI);

        if CNTxCTL_ELx.EVNTIS == '1' then
            n = n + 8;

        SampleBit = CNTxCT_EL0<n>;
        PreviousBit = PreviousCNTxCT_ELx<n>;

        if CNTxCTL_ELx.EVNTDIR == '0' then
            if PreviousBit == '0' && SampleBit == '1' then EventRegisterSet();
        else
            if PreviousBit == '1' && SampleBit == '0' then EventRegisterSet();

        PreviousCNTxCT_EL0 = CNTxCT_EL0;

    return;
```

D11.2.4 Timers

In an implementation of the Generic Timer that includes EL3, if EL3 can use AArch64, the following timers are implemented:

- An EL1 physical timer, that:
 - In Secure state, can be accessed from EL1.
 - In Non-secure state, can be accessed from EL1 unless those accesses are trapped to EL2.
When this timer can be accessed from EL1, an EL1 control determines whether it can be accessed from EL0.
- A Non-secure EL2 physical timer.
- A Secure EL3 physical timer. An EL3 control determines whether this register is accessible from Secure EL1.
- An EL1 virtual timer.
- When FEAT_VHE is implemented, a Non-secure EL2 virtual timer.
- When FEAT_SEL2 is implemented, a Secure EL2 physical timer.
- When FEAT_SEL2 is implemented, a Secure EL2 virtual timer.

The output of each implemented timer:

- Provides an output signal to the system.
- If the PE interfaces to a *Generic Interrupt Controller* (GIC), signals a *Private Peripheral Interrupt* (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer:

- Is based around a 64-bit CompareValue that provides a 64-bit unsigned upcounter.
- Provides an alternative view of the CompareValue, called the TimerValue, that appears to operate as a 32-bit downcounter.

- Has, in addition, a 32-bit Control register.

Table D11-1 Physical timer registers summary for the Generic Timer

Timer ^a register	EL1 physical timer	EL2 physical timer	Secure EL2 physical timer ^b	EL3 physical timer
CV	CNTP_CVAL_EL0	CNTHP_CVAL_EL2	CNTHPS_CVAL_EL2	CNTPS_CVAL_EL1
TV	CNTP_TVAL_EL0	CNTHP_TVAL_EL2	CNTHPS_TVAL_EL2	CNTPS_TVAL_EL1
Control	CNTP_CTL_EL0	CNTHP_CTL_EL2	CNTHPS_CTL_EL2	CNTPS_CTL_EL1

- a. In this column, CV indicates the CompareValue register, and TV indicates the TimerValue register.
b. Only present when the implementation includes FEAT_SEL2.

Table D11-2 Virtual timer register summary for the Generic Timer

Timer ^a register	EL1 virtual timer	EL2 virtual timer ^b	Secure EL2 virtual timer ^c
CV	CNTV_CVAL_EL0	CNTHV_CVAL_EL2	CNTHVS_CVAL_EL2
TV	CNTV_TVAL_EL0	CNTHV_TVAL_EL2	CNTHVS_TVAL_EL2
Control	CNTV_CTL_EL0	CNTHV_CTL_EL2	CNTHVS_CTL_EL2

- a. In this column, CV indicates the CompareValue register, and TV indicates the TimerValue register.
b. Only when the implementation includes FEAT_VHE.
c. Only present when the implementation includes FEAT_SEL2.

Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL_EL0, CNTHP_CTL_EL2, CNTHPS_CTL_EL2, CNTPS_CTL_EL1, CNTV_CTL_EL0, CNTHV_CTL_EL2 or CNTHVS_CTL_EL2. For CNTP_CTL_EL0, the asserted interrupt is the same as the interrupt asserted by the Non-secure instance of the AArch32 register CNTP_CTL.

The operation of this view of a timer is:

$$\text{TimerConditionMet} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) \geq 0)$$

Where:

TimerConditionMet	Is TRUE if the timer condition for this counter is met, and FALSE otherwise.
Counter	The physical counter value, that can be read from the CNTPCT_EL0 register.
Offset	For the EL1 physical timer, if ID_AA64MMFR0_EL1.ECV is 0b10 and CNTHCTL_EL2.ECV is 0b1, then the offset value is held in the CNTPOFF_EL2 register. Otherwise the offset value of the EL1 physical timer is zero. For the EL1 virtual timer, the offset value is held in the CNTVOFF_EL2 register. For the EL2 physical and virtual timers, the offset value is zero.
CompareValue	The value of the appropriate CompareValue register, CNTP_CVAL_EL0, CNTHP_CVAL_EL2, CNTPS_CVAL_EL1, CNTHPS_CVAL_EL2, CNTV_CVAL_EL0, CNTHV_CVAL_EL2, or CNTHVS_CVAL_EL2.

In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.

Note

This means that a timer with a CompareValue of, or close to, `0xFFFF_FFFF_FFFF_FFFF` might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.

Software can observe the counter value by the offset in some situations by reading `CNTVCT_EL0`.

Operation of the TimerValue views of the timers

The TimerValue view of a timer appears to operate as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, `CNTP_CTL_EL0`, `CNTHP_CTL_EL2`, `CNTHPS_CTL_EL2`, `CNTPS_CTL_EL1`, `CNTV_CTL_EL0`, `CNTHV_CTL_EL2`, or `CNTHVS_CTL_EL2`.

This view of a timer depends on the following behavior of accesses to TimerValue registers:

Reads `TimerValue = (CompareValue - (Counter - Offset))[31:0]`

Writes `CompareValue = ((Counter - Offset)[63:0] + SignExtend(TimerValue))[63:0]`

Where the arguments other than TimerValue have the definitions used in *Operation of the CompareValue views of the timers on page D11-3017*, and in addition:

TimerValue The value of a TimerValue register, `CNTP_TVAL_EL0`, `CNTHP_TVAL_EL2`, `CNTHPS_TVAL_EL2`, `CNTPS_TVAL_EL1`, `CNTV_TVAL_EL0`, `CNTHV_TVAL_EL2`, or `CNTHVS_TVAL_EL2`.

In this view of a timer, values are signed in standard two's complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.

Note

- *Operation of the CompareValue views of the timers on page D11-3017* gives a strict definition of `TimerConditionMet`. However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from `0x80000000`, the TimerValue view can be used as giving an effect equivalent to:
$$\text{TimerConditionMet} = (\text{TimerValue} \leq 0)$$
 - Programming TimerValue to a negative number with magnitude greater than $(\text{Counter} - \text{Offset})$ can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays meeting the timer condition for an extremely long period of time.
-

Chapter D12

AArch64 System Register Encoding

This chapter describes the AArch64 System register encoding space. It contains the following sections:

- *The System register encoding space on page D12-3020.*
- *op0==0b10, Moves to and from debug and trace System registers on page D12-3021.*
- *op0==0b11, Moves to and from non-debug System registers, Special-purpose registers on page D12-3023.*

D12.1 The System register encoding space

The A64 instruction set includes instructions that access the System register encoding space. These instructions provide:

- Access to *System registers*, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as [SPSR_ELx](#), [ELR_ELx](#), and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the CLREX instruction.
- Architectural hint instructions.

This section describes the parts of the System register encoding space that provides access to the System registers described in [Chapter D13 AArch64 System Register Descriptions](#).

———— **Note** —————

- See [Fixed values in AArch64 instruction and System register descriptions on page C2-211](#) for information about abbreviations used in the System instruction descriptions.
- In AArch32 state much of this functionality is provided through the System register interface described in [The AArch32 System register interface on page G1-6109](#). In AArch64 state, the parameters used to characterize the System register encoding space are {op0, op1, CRn, CRm, op2}. These are based on the parameters that characterize the AArch32 System register encoding space, which reflect the original implementation of these registers, as described in [Background to the System register interface on page G1-6110](#). In Armv8, there is no particular significance to the naming of these parameters, and no functional distinction between the opn parameters and the CRx parameters.

[Principles of the System instruction class encoding on page C5-394](#) describes some general properties of these encodings. [System instruction class encoding overview on page C5-395](#) then describes the top-level encoding of these instructions, identifying that:

- Entries in the encoding space are characterized by the parameter set {op0, op1, CRn, CRm, op2}.
- op0 is the most significant parameter for determining allocations in this space.

Much of this encoding space is used for System instructions, as described in [Chapter C5 The A64 System Instruction Class](#). This chapter describes only the part of the encoding space that is used for System registers, in the following sections:

- [op0==0b10, Moves to and from debug and trace System registers on page D12-3021](#).
- [op0==0b11, Moves to and from non-debug System registers, Special-purpose registers on page D12-3023](#).

D12.2 $op0==0b10$, Moves to and from debug and trace System registers

The instructions that move data to and from the debug, Execution environment, and trace System registers are encoded with $op0==0b10$. This means the encoding of these instructions is:

———— **Note** —————

- The section describes the use of all of the $op0==0b10$ region of the System register encoding space.
- These encodings access the registers that are equivalent to the AArch32 System registers in the ($coproc==0b1110$) encoding space.

The value of $op1$ provides the next level of decode of these instructions, as follows:

$op1 == \{0, 3, 4\}$

Debug. See [Instructions for accessing debug System registers on page D12-3021](#)

———— **Note** —————

The standard encoding of debug registers is $op0==0b10$, $op1 == \{0, 3, 4\}$. The registers in the $op0==0b11$ encoding space that are classified as debug registers are [DLR_EL0](#), [DSPSR_EL0](#), [MDCR_EL2](#), [MDCR_EL3](#), and [SDER32_EL3](#). See [Instructions for accessing non-debug System registers on page D12-3023](#) for the encodings of these registers.

$op1 == 1$ Trace. See the appropriate trace architecture specification.

D12.2.1 Instructions for accessing debug System registers

The instructions for accessing debug System registers are:

MSR <System register>, Xt ; Write to System register
MRS Xt, <System register> ; Read from System register

Where <System_register> is the register name, for example [MDCCSR_EL0](#).

This section includes only the System register access encodings for which both:

- $op0$ is $0b10$.
- The value of $op1$ is one of $\{0, 3, 4\}$.

———— **Note** —————

These encodings access the registers that are equivalent to the AArch32 System registers in the ($coproc==0b1110$) encoding space.

Table D12-1 on page D12-3022 shows the mapping of the System register encodings for debug System register access.

Table D12-1 Instruction encodings for debug System register access

Register	Access instruction encoding					Permitted accesses
	op0	op1	CRn	CRm	op2	
OSDTRRX_EL1	2	0	0	0	2	RW
MDCCINT_EL1				2	0	RW
MDSCR_EL1					2	RW
OSDTRTX_EL1				3	2	RW
OSECCR_EL1				6	2	RW
DBGBVR<n>_EL1				0-15 ^a	4	RW
DBGBCR<n>_EL1				0-15 ^a	5	RW
DBGWVR<n>_EL1				0-15 ^a	6	RW
DBGWCR<n>_EL1				0-15 ^a	7	RW
MDRAR_EL1	2	0	1	0	0	RO
OSLAR_EL1					4	WO
OSLSR_EL1				1	4	RO
OSDLR_EL1				3	4	RW
DBGPRCR_EL1				4	4	RW
DBGCLAIMSET_EL1			7	8	6	RW
DBGCLAIMCLR_EL1				9	6	RW
DBGAUTHSTATUS_EL1				14	6	RO
MDCCSR_EL0		3	0	1	0	RO
DBGDTR_EL0				4	0	RW
DBGDTRRX_EL0				5	0	RO
DBGDTRTX_EL0						WO
DBGVCR32_EL2	4	0	7	7	0	RW

a. Accesses to not implemented breakpoint and watchpoint register access instructions are UNDEFINED. CRm encodes <n>, the breakpoint or watchpoint number.

For more information, see *Mapping of the System registers between the Execution states* on page D1-2548.

D12.3 op0==0b11, Moves to and from non-debug System registers, Special-purpose registers

The instructions that move data to and from non-debug System registers are encoded with op0==0b11, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0
1	1	0	1	0	1	0	1	0	0	L	1	1	op1	CRn	CRm	op2	Rt					

op0

The value of CRn provides the next level of decode of these instructions, as follows:

CRn=={0, 1, 2, 3, 5, 6, 7, 9, 10, 12, 13, 14}

See [Instructions for accessing non-debug System registers on page D12-3023](#).

CRn==4 See [Instructions for accessing Special-purpose registers on page C5-405](#).

CRn=={11, 15} See [Reserved encodings for IMPLEMENTATION DEFINED registers on page D12-3038](#).

D12.3.1 Instructions for accessing non-debug System registers

The A64 instructions for accessing System registers are:

```
MSR <System register>, Xt    ; Write to System register
MRS Xt, <System register>    ; Read from System register
```

Where <System_register> is the register name, for example [MIDR_EL1](#).

This section includes only the System register access encodings for which both:

- op0 is 0b11.
- The value of CRn is one of {0, 1, 2, 3, 4, 5, 6, 7, 9, 10, 12, 13, 14}.

———— **Note** —————

- These encodings access the registers that are equivalent to the AArch32 System registers in the (coproc==0b1111) encoding space.
- While this group is described as accessing the non-debug System registers, its correct characterization is by the {op0, CRn} values given in this subsection, and the group includes the debug registers [DLR_EL0](#), [DSPSR_EL0](#), [MDCR_EL2](#), [MDCR_EL3](#), and [SDER32_EL3](#), that are described in [Debug registers on page D13-3810](#). These registers are exceptions to the standard encoding of debug registers, that has op0==0b10, see [Instructions for accessing debug System registers on page D12-3021](#).

The instruction encoding for these accesses is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0
1	1	0	1	0	1	0	1	0	0	L	1	1	op1	CRn	CRm	op2	Rt					

op0

See text for permitted values of CRn

[Table D12-2 on page D12-3024](#) shows the encodings of the register access instructions. In the [Notes on page D12-3024](#) column of the table:

- Config-RO** Means it is configurable whether read accesses are permitted. Write accesses are UNDEFINED.
- Config-WO** Means it is configurable whether write accesses are permitted. Read accesses are UNDEFINED.
- Config-RW** Means it is configurable whether accesses are permitted. Either read and write accesses are permitted, or read and write accesses are UNDEFINED.

See the register descriptions for information about the control that determines whether these accesses are permitted.

- n. Defined to allow access from AArch64 state to registers that are only used in AArch32 state.

About the GIC System registers

From version 3.0 of the GIC architecture specification, the specification defines three groups of System registers, identified by the prefix of the register name:

- ICC_** GIC physical CPU interface System registers.
- ICH_** GIC virtual interface control System registers.
- ICV_** GIC Virtual CPU interface System registers.

————— **Note** —————

These registers are in addition to the GIC memory-mapped register groups GICC_, GICD_, GICH_, GICR_, GICV_, and GITS_.

When implemented, the GIC System registers form part of an Arm processor implementation, and therefore these registers are included in the register summaries. However, the registers are defined only in the GIC Architecture Specification.

As [Table D12-2 on page D12-3024](#) shows, the ICV_* registers have the same {op0, op1, CRn, CRm, op2} encodings as the corresponding ICC_* registers. For these encodings, GIC register configuration fields determine which register is accessed.

For more information, see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* (ARM IHI 0069).

D12.3.2 Reserved encodings for IMPLEMENTATION DEFINED registers

The System register encoding space with op0==0b11 reserves the following encodings for IMPLEMENTATION DEFINED registers:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0
1	1	0	1	0	1	0	1	0	0	L	1	1	op1	1	x	1	1	CRm	op2			Rt
											op0		CRn									

The value of L defines the access type and the use of Rt as follows:

- 0** Write the value in Rt to the IMPLEMENTATION DEFINED register.
- 1** Read the value of the IMPLEMENTATION DEFINED register to Rt.

For more information about these encodings, see [S3_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED registers on page D13-3606](#). As that section describes, any IMPLEMENTATION DEFINED registers are accessed in a similar way to architecturally-defined System registers, using MRS and MSR instructions, see:

- [MRS on page C6-1236](#).
- [MSR \(immediate\) on page C6-1237](#).
- [MSR \(register\) on page C6-1240](#).

The Arm architecture guarantees not to define any register name prefixed with *IMP_* as part of the standard Arm architecture.

———— **Note** —————

Arm strongly recommends that any register names created in the IMPLEMENTATION DEFINED register spaces be prefixed with *IMP_* and postfixed with *_ELx*, where appropriate.

Chapter D13

AArch64 System Register Descriptions

This chapter defines the AArch64 System registers. It contains the following sections:

- *About the AArch64 System registers* on page D13-3040.
- *General system control registers* on page D13-3049.
- *Debug registers* on page D13-3810.
- *Performance Monitors registers* on page D13-3929.
- *Activity Monitors registers* on page D13-4001.
- *Statistical Profiling Extension registers* on page D13-4042.
- *RAS registers* on page D13-4091.
- *Generic Timer registers* on page D13-4139.

D13.1 About the AArch64 System registers

The following sections describe common features of the AArch64 registers:

- [Fixed values in the System register descriptions on page D13-3040.](#)
- [General behavior of accesses to the AArch64 System registers on page D13-3040.](#)
- [Principles of the ID scheme for fields in ID registers on page D13-3045.](#)

D13.1.1 Fixed values in the System register descriptions

See [Fixed values in AArch64 instruction and System register descriptions on page C2-211](#). This section defines how the glossary terms [RAZ](#), [RES0](#), [RAO](#), and [RES1](#) can be represented in the System register descriptions.

D13.1.2 General behavior of accesses to the AArch64 System registers

The following subsections give general information about the behavior of accesses to the System registers:

- [Reset behavior of AArch64 System registers on page D13-3040.](#)
- [Synchronization requirements for AArch64 System registers on page D13-3041.](#)

Reset behavior of AArch64 System registers

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.
- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.
- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.
- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.
- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch64, see:

- [PE state on reset to AArch64 state on page D1-2472.](#)
- The appropriate Trace architecture specification, for the Trace System registers.

For a PE reset into an Exception level that is using AArch64, the architecture defines which AArch64 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and [PE state on reset to AArch64 state on page D1-2472](#) summarizes these architectural requirements. Otherwise, RW registers that have a meaningful reset value reset to an architecturally UNKNOWN value.

———— Note —————

When the PE resets into an Exception level that is using AArch32, no PE state that relates to execution in AArch64 state is accessible until another reset causes the Execution state to change to AArch64. Therefore, on a reset into AArch32 state, PE state that relates only to execution in AArch64 state cannot have a meaningful reset value.

Pseudocode description of resetting System registers

The `AArch64.ResetSystemRegisters()` pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and [PE state on reset to AArch64 state on page D1-2472](#).

Note

For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

Synchronization requirements for AArch64 System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

- Any data dependencies between the instructions, including read-after-read dependencies, are respected.
- The reads to the register do not occur earlier than the most recent *Context synchronization event* to its architectural position in the instruction stream.

Note

In particular, the values read from System registers that hold self-incrementing counts, such as the Performance Monitors counters or the Generic Timer counter or timers, could be accessed from any time after the previous *Context synchronization event*. For example, where a memory access is used to communicate a read of such a counter, an ISB must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the read having completed, and the read of the counter, if it is necessary that the counter returns a count value after the memory communication.

Direct writes using the instructions in [Table D12-2 on page D12-3024](#) require synchronization before software can rely on the effects of changes to the System registers to affect instructions appearing in program order after the direct write to the System register. Direct writes to these registers are not allowed to affect any instructions appearing in program order before the direct write. The only exceptions are:

- All direct writes to the same register, that use the same encoding for that register, are guaranteed to occur in program order relative to each other
- All direct writes to a register occur in program order with respect to all direct reads to the same register using the same encoding.
- Any System register access that an Arm *Architecture Specification* or equivalent specification defines as not requiring synchronization.

Explicit synchronization occurs as a result of a *Context synchronization event*, which is one of the following events:

- Execution of an ISB instruction.
- Exception entry, if [FEAT_ExS](#) is not implemented, or if [FEAT_ExS](#) is implemented and defines that exception entries to this Exception level are context synchronization events.
- Exception return, if [FEAT_ExS](#) is not implemented, or if [FEAT_ExS](#) is implemented and defines that exception returns from this Exception level are context synchronization events.
- Execution of a DCPS instruction in Debug state.
- Execution of a DRPS instruction in Debug state.
- Exit from Debug state.

Note

The ISB and exception entry events are applicable both in Debug state and in Non-debug state.

Conceptually, explicit synchronization occurs as the first step of each of these events, so that if the event uses state that has previously been changed but was not synchronized by the time of the event, the event is guaranteed to use the state as if it had been synchronized.

Note

This explicit synchronization applies as the first step of the execution of the events, and does not apply to any effect of System registers that apply to the fetch and decode of the instructions that cause these events, such as breakpoints or changes to the translation table.

In addition, any system instructions that cause a write to a System register must be synchronized before the result is guaranteed to be visible to subsequent direct reads of that System register.

Direct reads to any one of the following registers, using the same encoding, occur in program order relative to each other:

- [ISR_EL1](#).
- The Generic Timer registers, that is, [CNTPCT_EL0](#) and [CNTVCT_EL0](#), and the Counter registers [CNTPTVAL_EL0](#), [CNTV_TVAL_EL0](#), [CNTHP_TVAL_EL2](#), and [CNTPTS_TVAL_EL1](#).
- [DBGCLAIMCLR_EL1](#).
- The PMU Counters, that is, [PMCCNTR_EL0](#), [PMEVCNTR<n>_EL0](#), [PMXVCNTR_EL0](#), [PMOVSCLR_EL0](#), and [PMOVSSET_EL0](#).
- The Debug Communications Channel registers, that is, [DBGDTRRX_EL0](#), [DBGDTR_EL0](#), and [MDCCSR_EL0](#).

All other direct reads of System registers can occur in any order if synchronization has not been performed.

[Table D13-1 on page D13-3042](#) describes the synchronization requirements between two successive read or write accesses to the same register, where the ordering of the read or write accesses is:

1. Program order, in the event that both the reads or writes are caused by an instruction executed on this PE, other than one caused by a memory access by this PE.
2. The order of arrival of asynchronous reads and writes at the PE relative to the execution of instructions that cause reads or writes.
3. The order of arrival of asynchronous reads and writes at the PE relative to each other.

Table D13-1 Synchronization requirements

First read-write	Second read-write	Synchronization requirement
Direct read	Direct read	None
	Direct write	None
	Indirect read	None
	Indirect write	None, see Notes on page D13-3043
Direct write	Direct read	None
	Direct write	None
	Indirect read	Required
	Indirect write	None, see Notes on page D13-3043
Indirect read	Direct read	None
	Direct write	None
	Indirect read	None
	Indirect write	None

Table D13-1 Synchronization requirements (continued)

First read-write	Second read-write	Synchronization requirement
Indirect write	Direct read	Required, see Notes on page D13-3043
	Direct write	None, see Notes on page D13-3043
	Indirect read	Required, see Notes on page D13-3043
	Indirect write	None, see Notes on page D13-3043

Notes

The terms Direct read, Direct write, Indirect read, and Indirect write, as used in [Table D13-1 on page D13-3042](#), are defined as follows:

Direct read Where software uses an [MRS](#) system register access instruction to read that register into a general purpose register.

Where a direct read of a register has a side-effect that changes the contents of a register, the effect of a direct read on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to have occurred, and be visible to subsequent direct or indirect reads or writes, if synchronization is performed after the direct read.

Direct write Where software uses an [MSR \(register\)](#) access instruction to write to that register from a general purpose register.

Where a direct write to a register has an effect on the register that means that the value in the register is not always the last value that is written (as is the case with set and clear registers), the effect of a direct write on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Indirect read Where an instruction uses a System register to establish operating conditions for the instruction, for example, the [TTBR_ELx](#) address or whether memory accesses are forced to be Non-cacheable. This includes situations where the contents of one System register selects what value is read or written using a different register. Indirect reads also include reads of the System register by external agents such as debuggers. Where an indirect read of a register has a side-effect that changes the contents of that register, that is defined to be an indirect write.

Indirect write Where a System register is written as the consequence of some other instruction, exception, operation, or by the asynchronous operation of an external agent, including the passage of time as seen in counters, timers, or performance counters, the assertion of interrupts, or writes from an external debugger.

———— **Note** —————

Since an exception is context synchronizing, registers such as the Exception Syndrome registers that are indirectly written as part of exception entry do not require additional synchronization.

Where a direct read or write to a register is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two accesses.

Where an indirect write caused by a direct write is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two indirect accesses.

Where a direct read to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated, the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct read and before the subsequent direct or indirect reads or writes.

Where a direct write to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated as a side-effect of that direct write (as opposed to simply being a direct write to the different encoding), the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Where indirect writes are caused by the actions of external agents such as debuggers, or by memory-mapped reads or writes by the PE, then an indirect write by that agent and mechanism to a register, followed by an indirect read by that agent and mechanism to the same register using the same address, does not require synchronization.

Where an indirect write occurs as a side-effect of an access, this happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

Indirect writes caused by external agents, autonomous asynchronous events, or as a result of memory-mapped writes, to the registers shown in [Table D13-2 on page D13-3044](#), are required to be observable to:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.

Table D13-2 Registers with a guarantee of observability, VMSAv8-64

Registers	Notes
ISR_EL1	Interrupt Status Register
DBGCLAIMCLR_EL1 , DBGCLAIMSET_EL1	Debug CLAIM registers
CNTPCT_EL0 , CNTVCT_EL0 , CNTP_TVAL_EL0 , CNTV_TVAL_EL0 , CNTHP_TVAL_EL2 , CNTPS_TVAL_EL1	Generic Timer registers
PMCCNTR_EL0 , PMEVCNTR<n>_EL0 , PMXEVCNTR_EL0 , PMOVSCLR_EL0 , PMOVSSET_EL0	PMU Counters
DBGDTRTX_EL0 , DBGDTRRX_EL0 , DBGDTR_EL0 , and the DCC flags in MDCCSR_EL0 and EDSCR	Debug Communication Channel registers
EDSCR.PipeAdv	External Debug Status and Control Register PipeAdv field

In addition to the requirements shown in [Table D13-2 on page D13-3044](#):

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
 - [OSLAR_EL1](#). [OSLAR_EL1](#) is indirectly read to determine whether the subsequent access is permitted.
 - [EDLAR](#), if implemented. [EDLAR](#) is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

Note

This requirement is stricter than the general requirement for the observability of indirect writes.

- The requirement that an indirect write to the registers in [Table D13-2 on page D13-3044](#) is observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time. For example, an increment of the system counter is an autonomous asynchronous event that performs an indirect write to the counter. This asynchronous event might generate a timer interrupt request, resulting in a [Context synchronization event](#). When a GIC is used, the timer interrupt might arrive at the GIC after the PE has taken an interrupt request from another source, but before software reads the current interrupt ID from the GIC. This means that the GIC might identify the timer interrupt as the current interrupt. Software must not assume that a subsequent direct read of the counter register is guaranteed to observe the updated value of that register. Although this example uses the counter-timer registers, it applies equally to other registers that might be linked to interrupt requests, including the PMU and Statistical Profiling status registers.
- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See [DCC and ITR access in Debug state on page H4-7417](#).

Note

- The provision of explicit synchronization requirements to System registers is provided to allow the direct access to these registers to be implemented in a small number of cycles, and that updates to multiple registers can be performed quickly with the synchronization penalty being paid only when the updates have occurred.
- Since toolkits might use registers such as the thread-local storage registers within compiled code, it is recommended that access to these registers is implemented to take a small number of cycles.
- While no synchronization is required between a direct write and a direct read, or between a direct read and an indirect write, this does not imply that a direct read causes synchronization of a previous direct write. That is, the sequence direct write → direct read → indirect read, with no intervening context synchronization, does not guarantee that the indirect read observes the result of the direct write.
- If [FEAT_MTE2](#) is implemented, a DSB instruction over the Non-shareable domain or an exception entry to Ely with `SCTLR_Ely.ITFSB = 0b1` is required between an indirect write to [TFSRE0_EL1](#), or any [TFSR_ELx](#) accessible at Ely, and a direct read or direct write of that register.

D13.1.3 Principles of the ID scheme for fields in ID registers

The Arm architecture specifies a number of *ID registers* that are characterized as comprising a set of 4-bit *ID fields*. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. [ID registers to which this scheme applies on page D13-3047](#) identifies the set of ID registers.

A small number of ID fields do not follow the scheme described in this section. In these cases, the field description states that it does not follow this scheme.

Note

- The ID fields described here are distinct from register fields that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors, or the amount of memory.
- ID fields that do not follow this scheme include the [ID_AA64DFR0_EL1.PMUVer](#), [ID_DFR0_EL1.PerfMon](#), [ID_DFR0.PerfMon](#) and [EDDFR.PMUVer](#) fields, see [Alternative ID scheme used for the Performance Monitors Extension version on page D13-3047](#).
- The presence of an ID field for a feature does not imply that the feature is optional.

To provide forward compatibility, software can rely on the features of these fields that are described in this section.

The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, if a value of 0x1 indicates the presence of some instructions, then the value 0x2 will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```
if (value >= number) {  
    // do something that relies on the value of the feature  
}
```

For ID fields where the value 0x0 defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value 0xF indicates that the feature is not implemented.
- The field value 0x0 indicates that the feature is implemented.
- Software that depends on the feature can use the test:

```
if value >= 0 {  
    // Software features that depend on the presence of the hardware feature  
}
```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a *fractional* field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle, a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. [Example D13-1 on page D13-3046](#) shows the use of such a field.

Example D13-1 Example of the use of a fractional field

For a field describing some class of functionality:

- The value 0x1 was defined as indicating that item A is present.
- The value 0x2 was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value 0x1 when A and B only are present. This fractional field is valid only when the original ID field has the value 0x1.

This approach means that:

- Software that depends on the test if (value >= 0x2) can rely on features A, B, and C being present,
- Software that depends on the test if (value >= 0x1) can rely on feature A being present.
- If new software needs to check only that features A and B are present, then it can test:

```
if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {  
    // Software features that depend on A and B only  
}
```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

ID registers to which this scheme applies

This scheme applies to the following registers:

AArch64 System registers

- The AArch64 views of the AArch32 feature ID registers given by:
 - The AArch32 Auxiliary Feature register [ID_AFR0_EL1](#).
 - The AArch32 Processor Feature registers [ID_PFR0_EL1](#) and [ID_PFR1_EL1](#).
 - The AArch32 Debug Feature register [ID_DFR0_EL1](#).
 - The AArch32 Memory Model Feature registers [ID_MMFR0_EL1](#), [ID_MMFR1_EL1](#), [ID_MMFR2_EL1](#), [ID_MMFR3_EL1](#), and [ID_MMFR4_EL1](#).
 - The AArch32 Instruction Set Attribute registers [ID_ISAR0_EL1](#), [ID_ISAR1_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR3_EL1](#), [ID_ISAR4_EL1](#), and [ID_ISAR5_EL1](#).
 - The AArch32 Media and VFP Feature registers [MVFR0_EL1](#), [MVFR1_EL1](#), and [MVFR2_EL1](#).
- The AArch64 Auxiliary Feature registers [ID_AA64AFR0_EL1](#) and [ID_AA64AFR1_EL1](#).
- The AArch64 Processor Feature registers [ID_AA64PFR0_EL1](#) and [ID_AA64PFR1_EL1](#).
- The AArch64 Debug Feature registers [ID_AA64DFR0_EL1](#) and [ID_AA64DFR1_EL1](#).
- The AArch64 Memory Model Feature registers [ID_AA64MMFR0_EL1](#), [ID_AA64MMFR1_EL1](#), and [ID_AA64MMFR2_EL1](#).
- The AArch64 Instruction Set Attribute registers [ID_AA64ISAR0_EL1](#) and [ID_AA64ISAR1_EL1](#).

AArch32 System registers

- The AArch32 Auxiliary Feature register [ID_AFR0](#).
- The AArch32 Processor Feature registers [ID_PFR0](#) and [ID_PFR1](#).
- The AArch32 Debug Feature register [ID_DFR0](#).
- The AArch32 Memory Model Feature registers [ID_MMFR0](#), [ID_MMFR1](#), [ID_MMFR2](#), [ID_MMFR3](#), and [ID_MMFR4](#).
- The AArch32 Instruction Set Attribute registers [ID_ISAR0](#), [ID_ISAR1](#), [ID_ISAR2](#), [ID_ISAR3](#), [ID_ISAR4](#), and [ID_ISAR5](#).
- The AArch32 Media and FP Feature registers [MVFR0](#), [MVFR1](#), and [MVFR2](#).

Memory-mapped registers

- The External Debug Processor Feature register [EDPFR](#).
- The External Debug Feature register [EDDFR](#).

Alternative ID scheme used for the Performance Monitors Extension version

The [ID_AA64DFR0_EL1.PMUVer](#), [ID_DFR0_EL1.PerfMon](#), [ID_DFR0.PerfMon](#) and [EDDFR.PMUVer](#) fields, that identify the version of the Performance Monitors Extension, do not follow the standard ID scheme. Software must treat these fields as follows:

- The value 0xF indicates that the Arm-architected Performance Monitors Extension is not implemented.
- If the field value is not 0xF the field is treated as an unsigned value, as described for the standard ID scheme.

This means that software that depends on the implementation of a particular version of the Arm Performance Monitors Extension must be written in the form:

```
if (value != 0xF and value >= number) {  
    // do something that relies on version 'number' of the feature  
}
```

For these fields, Arm deprecates use of the value 0xF in new implementations.

Alternative ID scheme used for ID_AA64MMFR0_EL1 stage 2 granule sizes

The [ID_AA64MMFR0_EL1.TGran4_2](#), [ID_AA64MMFR0_EL1.TGran16_2](#) and [ID_AA64MMFR0_EL1.TGran64_2](#) fields that identify the memory translation stage 2 granule size, do not follow the standard ID scheme. Software must treat these fields as follows:

- The value 0x0 indicates that support is identified by another field.
- If the field value is not 0x0, the value indicates the level of support provided.

This means that software should use a test of the form:

```
if (field !=0 and field > value) {  
    // do something that relies on the value of the feature  
}
```

D13.2 General system control registers

This section lists the System registers in AArch64 that are not part of one of the other listed groups.

D13.2.1 ACCDATA_EL1, Accelerator Data

The ACCDATA_EL1 characteristics are:

Purpose

Holds the lower 32 bits of the data that is stored by an ST64BV0, Single-copy atomic 64-byte EL0 store instruction.

Configurations

This register is present only when FEAT_LS64_ACCDATA is implemented. Otherwise, direct accesses to ACCDATA_EL1 are UNDEFINED.

Attributes

ACCDATA_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

ACCDATA, bits [31:0]

Accelerator Data field. Holds bits[31:0] of the data that is stored by an ST64BV0 instruction.

Accessing ACCDATA_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ACCDATA_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1101	0b0000	0b101

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then

    end
elsif PSTATE.EL == EL3 then
    ACCDATA_EL1 = X[t];
end

```

D13.2.2 ACTLR_EL1, Auxiliary Control Register (EL1)

The ACTLR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

Note

Arm recommends the contents of this register have no effect on the PE when HCR_EL2.{E2H, TGE} is {1, 1}, and instead the configuration and control fields are provided by the ACTLR_EL2 register. This avoids the need for software to manage the contents of these register when switching between a Guest OS and a Host OS.

Configurations

AArch64 System register ACTLR_EL1 bits [31:0] are architecturally mapped to AArch32 System register ACTLR[31:0].

AArch64 System register ACTLR_EL1 bits [63:32] are architecturally mapped to AArch32 System register ACTLR2[31:0].

Attributes

ACTLR_EL1 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ACTLR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ACTLR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b001

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TACR == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && HCR_EL2.<NV2,NV1,NV> == '1x1' then
        return NVMem[0x118];

```

```

else
    return ACTLR_EL1;
elseif PSTATE.EL == EL2 then
    return ACTLR_EL1;
elseif PSTATE.EL == EL3 then
    return ACTLR_EL1;

```

MSR ACTLR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b001

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TACR == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && HCR_EL2.<NV2,NV1,NV> == '1x1' then
        NVMem[0x118] = X[t];
    else
        ACTLR_EL1 = X[t];
elseif PSTATE.EL == EL2 then
    ACTLR_EL1 = X[t];
elseif PSTATE.EL == EL3 then
    ACTLR_EL1 = X[t];

```

D13.2.3 ACTLR_EL2, Auxiliary Control Register (EL2)

The ACTLR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL2.

———— Note ————

Arm recommends the contents of this register are updated to apply to EL0 when [HCR_EL2](#).{E2H, TGE} is {1, 1}, gaining configuration and control fields from the [ACTLR_EL1](#). This avoids the need for software to manage the contents of these register when switching between a Guest OS and a Host OS.

Configurations

AArch64 System register ACTLR_EL2 bits [31:0] are architecturally mapped to AArch32 System register [HACTLR](#)[31:0].

AArch64 System register ACTLR_EL2 bits [63:32] are architecturally mapped to AArch32 System register [HACTLR2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

ACTLR_EL2 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ACTLR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ACTLR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0000	0b001

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
```

```

else
    UNDEFINED;
elseif PSTATE.EL == EL2 then
    return ACTLR_EL2;
elseif PSTATE.EL == EL3 then
    return ACTLR_EL2;

```

MSR ACTLR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0000	0b001

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    ACTLR_EL2 = X[t];
elseif PSTATE.EL == EL3 then
    ACTLR_EL2 = X[t];

```

D13.2.4 ACTLR_EL3, Auxiliary Control Register (EL3)

The ACTLR_EL3 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL3.

Configurations

This register is present only when EL3 is implemented. Otherwise, direct accesses to ACTLR_EL3 are UNDEFINED.

Attributes

ACTLR_EL3 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ACTLR_EL3

Accesses to this register use the following encodings in the System register encoding space:

D13.2.17 APDBKeyHi_EL1, Pointer Authentication Key B for Data (bits[127:64])

The APDBKeyHi_EL1 characteristics are:

Purpose

Holds bits[127:64] of key B used for authentication of data pointer values.

Note

The term APDBKey_EL1 is used to describe the concatenation of [APDBKeyHi_EL1](#):
[APDBKeyLo_EL1](#).

Configurations

This register is present only when FEAT_PAAuth is implemented. Otherwise, direct accesses to APDBKeyHi_EL1 are UNDEFINED.

Attributes

APDBKeyHi_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

64 bit value, bits[127:64] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APDBKeyHi_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, APDBKeyHi_EL1

D13.2.22 APIAKeyLo_EL1, Pointer Authentication Key A for Instruction (bits[63:0])

The APIAKeyLo_EL1 characteristics are:

Purpose

Holds bits[63:0] of key A used for authentication of instruction pointer values.

Note

The term APIAKey_EL1 is used to describe the concatenation of [APIAKeyHi_EL1](#):
APIAKeyLo_EL1.

Configurations

This register is present only when FEAT_PAAuth is implemented. Otherwise, direct accesses to APIAKeyLo_EL1 are UNDEFINED.

Attributes

APIAKeyLo_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

64 bit value, bits[63:0] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APIAKeyLo_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, APIAKeyLo_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0001	0b000

```

D13.2.25 CCSIDR2_EL1, Current Cache Size ID Register 2

The CCSIDR2_EL1 characteristics are:

Purpose

Provides the information about the architecture of the currently selected cache from bits[63:32] of [CCSIDR_EL1](#).

Configurations

AArch64 System register CCSIDR2_EL1 bits [31:0] are architecturally mapped to AArch32 System register [CCSIDR2](#)[31:0].

This register is present only when FEAT_CCIDX is implemented. Otherwise, direct accesses to CCSIDR2_EL1 are UNDEFINED.

In an implementation which does not support AArch32 at EL1, it is IMPLEMENTATION DEFINED whether reading this register gives an UNKNOWN value or is UNDEFINED.

The implementation includes one CCSIDR2_EL1 for each cache that it can access. [CSSELR_EL1](#) selects which Cache Size ID Register is accessible.

Attributes

CCSIDR2_EL1 is a 64-bit register.

Field descriptions

Bits [63:24]

Reserved, RES0.

NumSets, bits [23:0]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Accessing CCSIDR2_EL1

If [CSSELR_EL1](#).Level is programmed to a cache level that is not implemented, then on a read of the CCSIDR2_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR2_EL1 read is treated as NOP.
- The CCSIDR2_EL1 read is UNDEFINED.
- The CCSIDR2_EL1 read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CCSIDR2_EL1

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b010

```

if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        if EL2Enabled() && HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
        else
            UNDEFINED;
    elsif PSTATE.EL == EL1 then
        if EL2Enabled() && HCR_EL2.TID2 == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        elsif EL2Enabled() && HCR_EL2.TID4 == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            return CCSIDR2_EL1;
    elsif PSTATE.EL == EL2 then
        return CCSIDR2_EL1;
    elsif PSTATE.EL == EL3 then
        return CCSIDR2_EL1;

```

D13.2.26 CCSIDR_EL1, Current Cache Size ID Register

The CCSIDR_EL1 characteristics are:

Purpose

Provides information about the architecture of the currently selected cache.

Configurations

AArch64 System register CCSIDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register [CCSIDR](#)[31:0].

AArch64 System register CCSIDR_EL1 bits [63:32] are architecturally mapped to AArch32 System register [CCSIDR2](#)[31:0].

The implementation includes one CCSIDR_EL1 for each cache that it can access. [CSSELR_EL1](#) selects which Cache Size ID Register is accessible.

Attributes

CCSIDR_EL1 is a 64-bit register.

Field descriptions

When FEAT_CCIDX is implemented:

Note

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Bits [63:56]

Reserved, RES0.

NumSets, bits [55:32]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Bits [31:24]

Reserved, RES0.

Associativity, bits [23:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

($\log_2(\text{Number of bytes in cache line})$) - 4. For example:

- For a line length of 16 bytes: $\log_2(16) = 4$, LineSize entry = 0. This is the minimum line length.
- For a line length of 32 bytes: $\log_2(32) = 5$, LineSize entry = 1.

When [FEAT_MTE](#) is implemented and enabled, where a cache only holds Allocation tags, this field is RES0.

Otherwise:

Note

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Bits [63:32]

Reserved, RES0.

Bits [31:28]

Reserved, UNKNOWN.

NumSets, bits [27:13]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

($\log_2(\text{Number of bytes in cache line})$) - 4. For example:

- For a line length of 16 bytes: $\log_2(16) = 4$, LineSize entry = 0. This is the minimum line length.
- For a line length of 32 bytes: $\log_2(32) = 5$, LineSize entry = 1.

Accessing CCSIDR_EL1

If [CSSELR_EL1](#).Level is programmed to a cache level that is not implemented, then on a read of the CCSIDR_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR_EL1 read is treated as NOP.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CCSIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b000

```

    elseif PSTATE.EL == EL3 then
        return CCSIDR_EL1;

```

D13.2.27 CLIDR_EL1, Cache Level ID Register

The CLIDR_EL1 characteristics are:

Purpose

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

Configurations

AArch64 System register CLIDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register [CLIDR](#)[31:0].

Attributes

CLIDR_EL1 is a 64-bit register.

Field descriptions

Bits [63:47]

Reserved, RES0.

Ttype<n>, bits [2(n-1)+34:2(n-1)+33], for n = 7 to 1

When FEAT_MTE2 is implemented:

Ttype<n>

Tag cache type. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy.

0b00 No Tag Cache.

0b01 Separate Allocation Tag Cache.

0b10 Unified Allocation Tag and Data cache, Allocation Tags and Data in unified lines.

0b11 Unified Allocation Tag and Data cache, Allocation Tags and Data in separate lines.

Otherwise:

Reserved, RES0.

ICB, bits [32:30]

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The possible values are:

0b000 Not disclosed by this mechanism.

0b001 L1 cache is the highest Inner Cacheable level.

0b010 L2 cache is the highest Inner Cacheable level.

0b011 L3 cache is the highest Inner Cacheable level.

0b100 L4 cache is the highest Inner Cacheable level.
 0b101 L5 cache is the highest Inner Cacheable level.
 0b110 L6 cache is the highest Inner Cacheable level.
 0b111 L7 cache is the highest Inner Cacheable level.

LoUU, bits [29:27]

Level of Unification Uniprocessor for the cache hierarchy.

———— **Note** —————

When **FEAT_S2FWB** is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

LoC, bits [26:24]

Level of Coherence for the cache hierarchy.

LoUIS, bits [23:21]

Level of Unification Inner Shareable for the cache hierarchy.

———— **Note** —————

When **FEAT_S2FWB** is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 7 to 1

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

0b000 No cache.
 0b001 Instruction cache only.
 0b010 Data cache only.
 0b011 Separate instruction and data caches.
 0b100 Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no caches that can be managed using the architected cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

Accessing CLIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CLIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b001

    elsif PSTATE.EL == EL3 then
        return CLIDR_EL1;
```

D13.2.28 CONTEXTIDR_EL1, Context ID Register (EL1)

The CONTEXTIDR_EL1 characteristics are:

Purpose

Identifies the current Process Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Configurations

AArch64 System register CONTEXTIDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register [CONTEXTIDR](#)[31:0].

Attributes

CONTEXTIDR_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

Note

In AArch32 state, when [TTBCR.EAE](#) is set to 0, [CONTEXTIDR.ASID](#) holds the ASID.

In AArch64 state, CONTEXTIDR_EL1 is independent of the ASID, and for the EL1&0 translation regime either [TTBR0_EL1](#) or [TTBR1_EL1](#) holds the ASID.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CONTEXTIDR_EL1

When [HCR_EL2.E2H](#) is 1, without explicit synchronization, access from EL3 using the mnemonic [CONTEXTIDR_EL1](#) or [CONTEXTIDR_EL12](#) are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

D13.2.29 CONTEXTIDR_EL2, Context ID Register (EL2)

The CONTEXTIDR_EL2 characteristics are:

Purpose

Identifies the current Process Identifier for EL2.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Configurations

This register is present only when FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented. Otherwise, direct accesses to CONTEXTIDR_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

CONTEXTIDR_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CONTEXTIDR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CONTEXTIDR_EL2 or CONTEXTIDR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

```

D13.2.30 CPACR_EL1, Architectural Feature Access Control Register

The CPACR_EL1 characteristics are:

Purpose

Controls access to trace, SVE, and Advanced SIMD and floating-point functionality.

Configurations

AArch64 System register CPACR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CPACR[31:0].

When EL2 is implemented and enabled in the current Security state and HCR_EL2.{E2H, TGE} == {1, 1}, the fields in this register have no effect on execution at EL0 and EL1. In this case, the controls provided by CPTR_EL2 are used.

Attributes

CPACR_EL1 is a 64-bit register.

Field descriptions

Bits [63:29]

Reserved, RES0.

TTA, bit [28]

Traps EL0 and EL1 System register accesses to all implemented trace registers from both Execution states to EL1, or to EL2 when it is implemented and enabled in the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to trace registers are trapped, reported using ESR_ELx.EC value 0x18.
- In AArch32 state, MRC and MCR accesses to trace registers are trapped, reported using ESR_ELx.EC value 0x05.
- In AArch32 state, MRRC and MCRR accesses to trace registers are trapped, reported using ESR_ELx.EC value 0x0C.

0b0 This control does not cause any instructions to be trapped.

0b1 This control causes EL0 and EL1 System register accesses to all implemented trace registers to be trapped.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the PE trace unit implements FEAT_ETMv4, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPACR_EL1.TTA is 1.
- The Armv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not implemented, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:22]

Reserved, RES0.

FPEN, bits [21:20]

Traps execution at EL1 and EL0 of instructions that access the Advanced SIMD and floating-point registers from both Execution states to EL1, reported using ESR_ELx.EC value 0x07, or to EL2 reported using ESR_ELx.EC value 0x00 when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to **FPCR**, **FPSR**, any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-31 registers.
- In AArch32 state, **FPSCR**, and any of the SIMD and floating-point registers Q0-15, including their views as D0-D31 registers or S0-31 registers.

Traps execution at EL1 and EL0 of SVE instructions to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and HCR_EL2.TGE is 1. The exception is reported using ESR_ELx.EC value 0x07.

A trap taken as a result of CPACR_EL1.ZEN has precedence over a trap taken as a result of CPACR_EL1.FPEN.

0b00 This control causes execution of these instructions at EL1 and EL0 to be trapped.

0b01 This control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL1 to be trapped.

0b10 This control causes execution of these instructions at EL1 and EL0 to be trapped.

0b11 This control does not cause execution of any instructions to be trapped.

Writes to **MVFR0**, **MVFR1**, and **MVFR2** from EL1 or higher are CONstrained UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONstrained UNPREDICTABLE behavior.

Note

- Attempts to write to the FPSID count as use of the registers for accesses from EL1 or higher.
- Accesses from EL0 to **FPSID**, **MVFR0**, **MVFR1**, **MVFR2**, and **FPEXC** are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPACR_EL1.FPEN is not 0b11.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:18]

Reserved, RES0.

ZEN, bits [17:16]

When FEAT_SVE is implemented:

ZEN

Traps execution at EL1 and EL0 of SVE instructions and instructions that directly access the ZCR_EL1 System register to EL1, or to EL2 when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE is 1.

The exception is reported using ESR_ELx.EC value 0x19.

A trap taken as a result of CPACR_EL1.ZEN has precedence over a trap taken as a result of CPACR_EL1.FPEN.

0b00 This control causes execution of these instructions at EL1 and EL0 to be trapped.

- 0b01 This control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL1 to be trapped.
- 0b10 This control causes execution of these instructions at EL1 and EL0 to be trapped.
- 0b11 This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [15:0]

Reserved, RES0.

Accessing CPACR_EL1

When [HCR_EL2.E2H](#) is 1, without explicit synchronization, access from EL3 using the mnemonic [CPACR_EL1](#) or [CPACR_EL12](#) are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

D13.2.31 CPTR_EL2, Architectural Feature Trap Register (EL2)

The CPTR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of accesses to [CPACR](#), [CPACR_EL1](#), trace, Activity Monitor, SVE, and Advanced SIMD and floating-point functionality.

Configurations

AArch64 System register CPTR_EL2 bits [31:0] are architecturally mapped to AArch32 System register [HCPTR](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

CPTR_EL2 is a 64-bit register.

Field descriptions

When FEAT_VHE is implemented and HCR_EL2.E2H == 1:

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

In AArch64 state, traps accesses to [CPACR_EL1](#) from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x18.

In AArch32 state, traps accesses to [CPACR](#) from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x03.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 accesses to [CPACR_EL1](#) and [CPACR](#) are trapped to EL2, when EL2 is enabled in the current Security state.

When [HCR_EL2.TGE](#) is 1, this control does not cause any instructions to be trapped.

Note

[CPACR_EL1](#) and [CPACR](#) are not accessible at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TAM, bit [30]

When FEAT_AMUv1 is implemented:

TAM

Trap Activity Monitor access. Traps EL1 and EL0 accesses to all Activity Monitor registers to EL2, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using ESR_ELx.EC value 0x18:
 - [AMUSERENR_EL0](#), [AMCFGR_EL0](#), [AMCGCR_EL0](#), [AMCNTENCLR0_EL0](#), [AMCNTENCLR1_EL0](#), [AMCNTENSET0_EL0](#), [AMCNTENSET1_EL0](#), [AMCR_EL0](#), [AMEVCNTR0<n>_EL0](#), [AMEVCNTR1<n>_EL0](#), [AMEVTYPER0<n>_EL0](#), and [AMEVTYPER1<n>_EL0](#).
- In AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2 and reported using ESR_ELx.EC value 0x03:
 - [AMUSERENR](#), [AMCFGR](#), [AMCGCR](#), [AMCNTENCLR0](#), [AMCNTENCLR1](#), [AMCNTENSET0](#), [AMCNTENSET1](#), [AMCR](#), [AMEVTYPER0<n>](#), and [AMEVTYPER1<n>](#).
- In AArch32 state, MRRC or MCRR accesses to [AMEVCNTR0<n>](#) and [AMEVCNTR1<n>](#), are trapped to EL2, reported using ESR_ELx.EC value 0x04.

0b0 Accesses from EL1 and EL0 to Activity Monitor registers are not trapped.

0b1 Accesses from EL1 and EL0 to Activity Monitor registers are trapped to EL2, when EL2 is enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [29]

Reserved, RES0.

TTA, bit [28]

Traps System register accesses to all implemented trace registers from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to trace registers with op0=2, op1=1, and CRn<0b1000 are trapped to EL2, reported using EC syndrome value 0x18.
- In AArch32 state, MRC or MCR accesses to trace registers with cpnum=14, opc1=1, and CRn<0b1000 are trapped to EL2, reported using EC syndrome value 0x05.

0b0 This control does not cause any instructions to be trapped.

0b1 Any attempt at EL0, EL1 or EL2, to execute a System register access to an implemented trace register is trapped to EL2, when EL2 is enabled in the current Security state, unless [HCR_EL2.TGE](#) is 0 and it is trapped by [CPACR.NSTRCDIS](#) or [CPACR_EL1.TTA](#). When [HCR_EL2.TGE](#) is 1, any attempt at EL0 or EL2 to execute a System register access to an implemented trace register is trapped to EL2, when EL2 is enabled in the current Security state.

———— **Note** —————

The ETMv4 architecture does not permit EL0 to access the trace registers. If the PE trace unit implements FEAT_ETMv4, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than this trap exception that would be generated because the value of CPTR_EL2.TTA is 1.

EL2 does not provide traps on trace register accesses through the optional Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not supported, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:22]

Reserved, RES0.

FPEN, bits [21:20]

Traps execution at EL2, EL1, and EL0 of instructions that access the Advanced SIMD and floating-point registers from both Execution states to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x07.

Traps execution at EL2, EL1, and EL0 of SVE instructions to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x07.

A trap taken as a result of CPTR_EL2.ZEN has precedence over a trap taken as a result of CPTR_EL2.FPEN.

0b00 This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

0b01 When HCR_EL2.TGE is 0, this control does not cause execution of any instructions to be trapped.

When HCR_EL2.TGE is 1, this control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL2 to be trapped.

0b10 This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

0b11 This control does not cause execution of any instructions to be trapped.

Writes to MVFR0, MVFR1, and MVFR2 from EL1 or higher are CONSTRAINED UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONSTRAINED UNPREDICTABLE behavior.

Note

- Attempts to write to the FPSID count as use of the registers for accesses from EL1 or higher.
- Accesses from EL0 to FPSID, MVFR0, MVFR1, MVFR2, and FPEXC are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.FPEN is not 0b11.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:18]

Reserved, RES0.

ZEN, bits [17:16]

When FEAT_SVE is implemented:

ZEN

Traps execution at EL2, EL1, and EL0 of SVE instructions, and instructions that directly access the ZCR_EL1 or ZCR_EL2 System registers to EL2, when EL2 is enabled in the current Security state.

The exception is reported using ESR_ELx.EC value 0x19.

A trap taken as a result of CPTR_EL2.ZEN has precedence over a trap taken as a result of CPTR_EL2.FPEN.

0b00 This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

0b01 When HCR_EL2.TGE is 0, this control does not cause execution of any instructions to be trapped.

When HCR_EL2.TGE is 1, this control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL2 to be trapped.

0b10 This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

0b11 This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [15:0]

Reserved, RES0.

Otherwise:

This format applies in all Armv8.0 implementations.

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

In AArch64 state, traps accesses to [CPACR_EL1](#) from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x18.

In AArch32 state, traps accesses to [CPACR](#) from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x03.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 accesses to [CPACR_EL1](#) and [CPACR](#) are trapped to EL2, when EL2 is enabled in the current Security state.

When [HCR_EL2.TGE](#) is 1, this control does not cause any instructions to be trapped.

Note

[CPACR_EL1](#) and [CPACR](#) are not accessible at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TAM, bit [30]

When FEAT_AMUv1 is implemented:

TAM

Trap Activity Monitor access. Traps EL1 and EL0 accesses to all Activity Monitor registers to EL2, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using ESR_ELx.EC value 0x18:
 - [AMUSERENR_EL0](#), [AMCFGR_EL0](#), [AMCGCR_EL0](#), [AMCNTENCLR0_EL0](#), [AMCNTENCLR1_EL0](#), [AMCNTENSET0_EL0](#), [AMCNTENSET1_EL0](#), [AMCR_EL0](#), [AMEVCNTR0<n>_EL0](#), [AMEVCNTR1<n>_EL0](#), [AMEVTYPER0<n>_EL0](#), and [AMEVTYPER1<n>_EL0](#).

- In AArch32 state, MCR or MRC accesses to the following registers are trapped to EL2 and reported using ESR_ELx.EC value 0x03:
 - [AMUSERENR](#), [AMCFGR](#), [AMCGCR](#), [AMCNTENCLR0](#), [AMCNTENCLR1](#), [AMCNTENSET0](#), [AMCNTENSET1](#), [AMCR](#), [AMEVTYPER0<n>](#), and [AMEVTYPER1<n>](#).
 - In AArch32 state, MCRR or MRRC accesses to [AMEVCNTR0<n>](#) and [AMEVCNTR1<n>](#), are trapped to EL2, reported using ESR_ELx.EC value 0x04.
- 0b0 Accesses from EL1 and EL0 to Activity Monitor registers are not trapped.
- 0b1 Accesses from EL1 and EL0 to Activity Monitor registers are trapped to EL2, when EL2 is enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:21]

Reserved, RES0.

TTA, bit [20]

Traps System register accesses to all implemented trace registers from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to trace registers with $op0=2$, $op1=1$, and $CRn<0b1000$ are trapped to EL2, reported using EC syndrome value 0x18.
- In AArch32 state, MRC or MCR accesses to trace registers with $cpnum=14$, $opc1=1$, and $CRn<0b1000$ are trapped to EL2, reported using EC syndrome value 0x05.

0b0 This control does not cause any instructions to be trapped.

0b1 Any attempt at EL0, EL1, or EL2, to execute a System register access to an implemented trace register is trapped to EL2, when EL2 is enabled in the current Security state, unless it is trapped by [CPACR.TRCDIS](#) or [CPACR.EL1.TTA](#).

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the PE trace unit implements FEAT_ETMv4, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of [CPTR_EL2.TTA](#) is 1.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not supported, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:14]

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

Bit [11]

Reserved, RES0.

TFP, bit [10]

Traps execution of instructions which access the Advanced SIMD and floating-point functionality, from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using ESR_ELx.EC value 0x07:
 - [FPCR](#), [FPSR](#), [FPEXC32_EL2](#), any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-31 registers.
- In AArch32 state, accesses to the following registers are trapped to EL2, reported using ESR_ELx.EC value 0x07:
 - [MVFR0](#), [MVFR1](#), [MVFR2](#), [FPSCR](#), [FPEXC](#), and any of the SIMD and floating-point registers Q0-15, including their views as D0-D31 registers or S0-31 registers. For the purposes of this trap, the architecture defines a VMSR access to [FPSID](#) from EL1 or higher as an access to a SIMD and floating-point register. Otherwise, permitted VMSR accesses to [FPSID](#) are ignored.

Traps execution at the same Exception levels of SVE instructions to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x07.

A trap taken as a result of CPTR_EL2.TZ has precedence over a trap taken as a result of CPTR_EL2.TFP.

0b0 This control does not cause execution of any instructions to be trapped.

0b1 This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

———— **Note** —————

[FPEXC32_EL2](#) is not accessible from EL0 using AArch64.

[FPSID](#), [MVFR0](#), [MVFR1](#), and [FPEXC](#) are not accessible from EL0 using AArch32.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [9]

Reserved, RES1.

TZ, bit [8]

When FEAT_SVE is implemented:

TZ

Traps execution at EL2, EL1, and EL0 of SVE instructions and instructions that directly access the ZCR_EL2 or ZCR_EL1 System registers to EL2, when EL2 is enabled in the current Security state.

The exception is reported using ESR_ELx.EC value 0x19.

A trap taken as a result of CPTR_EL2.TZ has precedence over a trap taken as a result of CPTR_EL2.TFP.

0b0 This control does not cause execution of any instructions to be trapped.

0b1 This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

Bits [7:0]

Reserved, RES1.

D13.2.32 CPTR_EL3, Architectural Feature Trap Register (EL3)

The CPTR_EL3 characteristics are:

Purpose

Controls trapping to EL3 of accesses to [CPACR](#), [CPACR_EL1](#), [HCPTR](#), [CPTR_EL2](#), trace, Activity Monitor, SVE, and Advanced SIMD and floating-point functionality.

Configurations

This register is present only when EL3 is implemented. Otherwise, direct accesses to CPTR_EL3 are UNDEFINED.

Attributes

CPTR_EL3 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

Traps all of the following to EL3, from both Security states and both Execution states.

- EL2 accesses to [CPTR_EL2](#), reported using ESR_ELx.EC value 0x18, or [HCPTR](#), reported using ESR_ELx.EC value 0x03.
- EL2 and EL1 accesses to [CPACR_EL1](#) reported using ESR_ELx.EC value 0x18, or [CPACR](#) reported using ESR_ELx.EC value 0x03.

When CPTR_EL3.TCPAC is:

- 0b0 This control does not cause any instructions to be trapped.
- 0b1 EL2 accesses to the [CPTR_EL2](#) or [HCPTR](#), and EL2 and EL1 accesses to the [CPACR_EL1](#) or [CPACR](#), are trapped to EL3, unless they are trapped by [CPTR_EL2](#).TCPAC.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TAM, bit [30]

When FEAT_AMUv1 is implemented:

TAM

Trap Activity Monitor access. Traps EL2, EL1, and EL0 accesses to all Activity Monitor registers to EL3.

Accesses to the Activity Monitors registers are trapped as follows:

- In AArch64 state, the following registers are trapped to EL3 and reported with ESR_ELx.EC value 0x18:
 - [AMUSERENR_EL0](#), [AMCFGR_EL0](#), [AMCGCR_EL0](#), [AMCNTENCLR0_EL0](#), [AMCNTENCLR1_EL0](#), [AMCNTENSET0_EL0](#), [AMCNTENSET1_EL0](#), [AMCR_EL0](#), [AMEVCNTR0<n>_EL0](#), [AMEVCNTR1<n>_EL0](#), [AMEVTYPER0<n>_EL0](#), and [AMEVTYPER1<n>_EL0](#).
- In AArch32 state, accesses with MRC or MCR to the following registers reported with ESR_ELx.EC value 0x03:
 - [AMUSERENR](#), [AMCFGR](#), [AMCGCR](#), [AMCNTENCLR0](#), [AMCNTENCLR1](#), [AMCNTENSET0](#), [AMCNTENSET1](#), [AMCR](#), [AMEVTYPER0<n>](#), and [AMEVTYPER1<n>](#).
- In AArch32 state, accesses with MRRC or MCRR to the following registers, reported with ESR_ELx.EC value 0x04:
 - [AMEVCNTR0<n>](#), [AMEVCNTR1<n>](#).

0b0 Accesses from EL2, EL1, and EL0 to Activity Monitor registers are not trapped.

0b1 Accesses from EL2, EL1, and EL0 to Activity Monitor registers are trapped to EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:21]

Reserved, RES0.

TTA, bit [20]

Traps System register accesses. Accesses to the trace registers, from all Exception levels, both Security states, and both Execution states are trapped to EL3 as follows:

- In AArch64 state, Trace registers with op0=2, op1=1, and CRn<0b1000 are trapped to EL3 and reported using EC syndrome value 0x18.
- In AArch32 state, accesses using MCR or MRC to the Trace registers with cpnum=14, opc1=1, and CRn<0b1000 are reported using EC syndrome value 0x05.

0b0 This control does not cause any instructions to be trapped.

0b1 Any System register access to the trace registers is trapped to EL3, unless it is trapped by [CPACR.TRCDIS](#), [CPACR_EL1.TTA](#), or [CPTR_EL2.TTA](#).

If System register access to trace functionality is not supported, this bit is RES0.

———— Note —————

The ETMv4 architecture does not permit EL0 to access the trace registers. If the PE trace unit implements FEAT_ETMv4, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than this trap exception.

EL3 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see [Traps on instructions on page D1-2511](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:11]

Reserved, RES0.

TFP, bit [10]

Traps execution of instructions which access the Advanced SIMD and floating-point functionality, from all Exception levels, both Security states, and both Execution states, to EL3.

This includes the following registers, all reported using ESR_ELx.EC value 0x07:

- [FPCR](#), [FPSR](#), [FPEXC32_EL2](#), and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers.
- [MVFR0](#), [MVFR1](#), [MVFR2](#), [FPSCR](#), [FPEXC](#), and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers.
- VMSR accesses to [FPSID](#).

Permitted VMSR accesses to [FPSID](#) are ignored, but for the purposes of this trap the architecture defines a VMSR access to the [FPSID](#) from EL1 or higher as an access to a SIMD and floating-point register.

Traps execution at all Exception levels of SVE instructions to EL3 from any Security state. The exception is reported using ESR_ELx.EC value 0x07.

A trap taken as a result of CPTR_EL3.EZ has precedence over a trap taken as a result of CPTR_EL3.TFP.

Defined values are:

- 0b0 This control does not cause execution of any instructions to be trapped.
- 0b1 This control causes execution of these instructions at all Exception levels to be trapped.

———— **Note** ————

[FPEXC32_EL2](#) is not accessible from EL0 using AArch64.

[FPSID](#), [MVFR0](#), [MVFR1](#), and [FPEXC](#) are not accessible from EL0 using AArch32.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [9]

Reserved, RES0.

EZ, bit [8]

When FEAT_SVE is implemented:

EZ

Traps execution of SVE instructions and instructions that directly access the ZCR_EL3, ZCR_EL2, or ZCR_EL1 System registers, from all Exception levels and both Security states, to EL3.

The exception is reported using ESR_ELx.EC value 0x19.

A trap taken as a result of CPTR_EL3.EZ has precedence over a trap taken as a result of CPTR_EL3.TFP.

- 0b0 This control causes execution of these instructions at all Exception levels to be trapped.
- 0b1 This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [7:0]

Reserved, RES0.

Accessing CPTR_EL3

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CPTR_EL3

op0	op1	CRn	CRm	op2
0b11	0b110	0b0001	0b0001	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    return CPTR_EL3;
```

MSR CPTR_EL3, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b110	0b0001	0b0001	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    CPTR_EL3 = X[t];
```

D13.2.33 CSSELR_EL1, Cache Size Selection Register

The CSSELR_EL1 characteristics are:

Purpose

Selects the current Cache Size ID Register, [CCSIDR_EL1](#), by specifying the required cache level and the cache type (either instruction or data cache).

Configurations

AArch64 System register CSSELR_EL1 bits [31:0] are architecturally mapped to AArch32 System register [CSSELR](#)[31:0].

Attributes

CSSELR_EL1 is a 64-bit register.

Field descriptions

Bits [63:5]

Reserved, RES0.

TnD, bit [4]

When FEAT_MTE2 is implemented:

TnD

Allocation Tag not Data bit.

0b0 Data, Instruction or Unified cache.

0b1 Separate Allocation Tag cache.

When CSSELR_EL1.InD == 1, this bit is RES0.

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR_EL1 is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache.

0b000 Level 1 cache.

0b001 Level 2 cache.

0b010 Level 3 cache.

0b011 Level 4 cache.

0b100 Level 5 cache.

0b101 Level 6 cache.

0b110 Level 7 cache.

All other values are reserved.

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR_EL1 is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

InD, bit [0]

Instruction not Data bit.

0b0 Data or unified cache.

0b1 Instruction cache.

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 is CONSTRAINED UNPREDICTABLE, and returns UNKNOWN values for CSSELR_EL1.{Level, InD}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CSSELR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CSSELR_EL1

op0	op1	CRn	CRm	op2
0b11	0b010	0b0000	0b0000	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TID2 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && HCR_EL2.TID4 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGTR_EL2.CSSELR_EL1 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        return CSSELR_EL1;
elseif PSTATE.EL == EL2 then
    return CSSELR_EL1;
elseif PSTATE.EL == EL3 then
    return CSSELR_EL1;

```

MSR CSSELR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b010	0b0000	0b0000	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TID2 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);

```

```
elseif EL2Enabled() && HCR_EL2.TID4 == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
elseif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGWTR_EL2.CSSELR_EL1 == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
else
    CSSELR_EL1 = X[t];
elseif PSTATE.EL == EL2 then
    CSSELR_EL1 = X[t];
elseif PSTATE.EL == EL3 then
    CSSELR_EL1 = X[t];
```

D13.2.34 CTR_EL0, Cache Type Register

The CTR_EL0 characteristics are:

Purpose

Provides information about the architecture of the caches.

Configurations

AArch64 System register CTR_EL0 bits [31:0] are architecturally mapped to AArch32 System register CTR[31:0].

Attributes

CTR_EL0 is a 64-bit register.

Field descriptions

Bits [63:38]

Reserved, RES0.

TminLine, bits [37:32]

When FEAT_MTE2 is implemented:

TminLine

Tag minimum Line. \log_2 of the number of words covered by Allocation Tags in the smallest cache line of all caches which can contain Allocation tags that are controlled by the PE.

Note

- For an implementation with cache lines containing 64 bytes of data and 4 Allocation Tags, this will be $\log_2(64/4) = 4$.
- For an implementation with Allocations Tags in separate cache lines of 128 Allocation Tags per line, this will be $\log_2(128*16/4) = 9$.

Otherwise:

Reserved, RES0.

Bit [31]

Reserved, RES1.

Bit [30]

Reserved, RES0.

DIC, bit [29]

Instruction cache invalidation requirements for data to instruction coherence.

0b0 Instruction cache invalidation to the Point of Unification is required for data to instruction coherence.

0b1 Instruction cache invalidation to the Point of Unification is not required for data to instruction coherence.

IDC, bit [28]

Data cache clean requirements for instruction to data coherence. The meaning of this bit is:

0b0 Data cache clean to the Point of Unification is required for instruction to data coherence, unless `CLIDR_EL1.LoC == 0b000` or (`CLIDR_EL1.LoUIS == 0b000` && `CLIDR_EL1.LoUU == 0b000`).

0b1 Data cache clean to the Point of Unification is not required for instruction to data coherence.

CWG, bits [27:24]

Cache writeback granule. \log_2 of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified. A value of `0b0000` indicates that this register does not provide Cache writeback granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than `0b1001` are reserved.

Arm recommends that an implementation that does not support cache write-back implements this field as `0b0001`. This applies, for example, to an implementation that supports only write-through caches.

ERG, bits [23:20]

Exclusives reservation granule. \log_2 of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

The use of the value `0b0000` is deprecated.

The value `0b0001` and values greater than `0b1001` are reserved.

DminLine, bits [19:16]

\log_2 of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

0b00 *When FEAT_VPIPT is implemented:*

VMID aware Physical Index, Physical tag (VPIPT).

0b01 ASID-tagged Virtual Index, Virtual Tag (AIVIVT).

0b10 Virtual Index, Physical Tag (VIPT).

0b11 Physical Index, Physical Tag (PIPT).

The value `0b01` is reserved in Armv8.

The value `0b00` is permitted only in an implementation that includes [FEAT_VPIPT](#), otherwise the value is reserved.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

\log_2 of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

Accessing CTR_ELO

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CTR_ELO

op0	op1	CRn	CRm	op2
0b11	0b011	0b0000	0b0000	0b001

```

if PSTATE.EL == EL0 then
    if !(EL2Enabled() && HCR_EL2.<E2H,TGE> == '11') && SCTLRL1.UCT == '0' then
        if EL2Enabled() && HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
        elsif EL2Enabled() && HCR_EL2.<E2H,TGE> != '11' && HCR_EL2.TID2 == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        elsif EL2Enabled() && HCR_EL2.<E2H,TGE> != '11' && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') &&
HFGTR_EL2.CTR_ELO == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        elsif EL2Enabled() && HCR_EL2.<E2H,TGE> == '11' && SCTLRL2.UCT == '0' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            return CTR_ELO;
    elsif PSTATE.EL == EL1 then
        if EL2Enabled() && HCR_EL2.TID2 == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        elsif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGTR_EL2.CTR_ELO == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            return CTR_ELO;
    elsif PSTATE.EL == EL2 then
        return CTR_ELO;
    elsif PSTATE.EL == EL3 then
        return CTR_ELO;

```

D13.2.35 DACR32_EL2, Domain Access Control Register

The DACR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 [DACR](#) register from AArch64 state only. Its value has no effect on execution in AArch64 state.

Configurations

AArch64 System register DACR32_EL2 bits [31:0] are architecturally mapped to AArch32 System register [DACR](#)[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DACR32_EL2 are UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

Attributes

DACR32_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

D<n>, bits [2n+1:2n], for n = 15 to 0

Domain n access permission, where n = 0 to 15. Permitted values are:

- 0b00 No access. Any access to the domain generates a Domain fault.
- 0b01 Client. Accesses are checked against the permission bits in the translation tables.
- 0b11 Manager. Accesses are not checked against the permission bits in the translation tables.

The value 0b10 is reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing DACR32_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DACR32_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0011	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
```

```

if EL2Enabled() && HCR_EL2.NV == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
else
    UNDEFINED;
elseif PSTATE.EL == EL2 then
    return DACR32_EL2;
elseif PSTATE.EL == EL3 then
    return DACR32_EL2;

```

0b11	0b100	0b0011	0b0000	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    DACR32_EL2 = X[t];
elseif PSTATE.EL == EL3 then
    DACR32_EL2 = X[t];

```

D13.2.36 DCZID_EL0, Data Cache Zero ID register

The DCZID_EL0 characteristics are:

Purpose

Indicates the block size that is written with byte values of 0 by the [DC ZVA](#) (Data Cache Zero by Address) System instruction.

If [FEAT_MTE](#) is implemented, this register also indicates the granularity at which the [DC GVA](#) and [DC GZVA](#) instructions write.

Configurations

There are no configuration notes.

Attributes

DCZID_EL0 is a 64-bit register.

Field descriptions

Bits [63:5]

Reserved, RES0.

DZP, bit [4]

Data Zero Prohibited. This field indicates whether use of [DC ZVA](#) instructions is permitted or prohibited.

If [FEAT_MTE](#) is implemented, this field also indicates whether use of the [DC GVA](#) and [DC GZVA](#) instructions are permitted or prohibited.

0b0 Instructions are permitted.

0b1 Instructions are prohibited.

The value read from this field is governed by the access state and the values of the [HCR_EL2.TDZ](#) and [SCTLR_EL1.DZE](#) bits.

BS, bits [3:0]

Log₂ of the block size in words. The maximum size supported is 2KB (value == 9).

Accessing DCZID_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DCZID_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b0000	0b0000	0b111

```
if PSTATE.EL == EL0 then
    if EL2Enabled() && HCR_EL2.<E2H,TGE> != '11' && (!HaveEL(EL3) || SCR_EL3.FGTEN == '1') &&
```

```
HFGTR_EL2.DCZID_EL0 == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
else
    return DCZID_EL0;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGTR_EL2.DCZID_EL0 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        return DCZID_EL0;
elsif PSTATE.EL == EL2 then
    return DCZID_EL0;
elsif PSTATE.EL == EL3 then
    return DCZID_EL0;
```

D13.2.37 ESR_EL1, Exception Syndrome Register (EL1)

The ESR_EL1 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL1.

Configurations

AArch64 System register ESR_EL1 bits [31:0] are architecturally mapped to AArch32 System register [DFSR](#)[31:0].

Attributes

ESR_EL1 is a 64-bit register.

Field descriptions

ESR_EL1 is made UNKNOWN as a result of an exception return from EL1.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL1, the value of ESR_EL1 is UNKNOWN. The value written to ESR_EL1 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

Bits [63:37]

Reserved, RES0.

ISS2, bits [36:32]**When FEAT_LS64 is implemented:**

ISS2

If a memory access generated by an ST64BV or ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field holds register specifier, Xs.

For any other Data Abort, this field is RES0.

Otherwise:

Reserved, RES0.

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

EC == 0b000000

Unknown reason.

See [ISS encoding for exceptions with an unknown reason](#).

EC == 0b000001

Trapped WF* instruction execution.

Conditional WF* instructions that fail their condition code check do not cause an exception.

See [ISS encoding for an exception from a WF* instruction](#).

EC == 0b000011

When AArch32 is supported at EL0:

Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC 0b000000.

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 0b000100

When AArch32 is supported at EL0:

Trapped MCRR or MRRC access with (coproc==0b1111) that is not reported using EC 0b000000.

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 0b000101

When AArch32 is supported at EL0:

Trapped MCR or MRC access with (coproc==0b1110).

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 0b000110

When AArch32 is supported at EL0:

Trapped LDC or STC access.

The only architected uses of these instruction are:

- An STC to write data to memory from [DBGDTRRXint](#).
- An LDC to read data from memory to [DBGDTRTXint](#).

See [ISS encoding for an exception from an LDC or STC instruction](#).

EC == 0b000111

Access to SVE, Advanced SIMD or floating-point functionality trapped by [CPACR_EL1.FPEN](#), [CPTR_EL2.FPEN](#), [CPTR_EL2.TFP](#), or [CPTR_EL3.TFP](#) control. Excludes exceptions resulting from [CPACR_EL1](#) when the value of [HCR_EL2.TGE](#) is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000 as described in [The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1](#) on page D1-2483.

See [ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from the FPEN and TFP traps](#).

EC == 0b001010

When FEAT_LS64 is implemented:

Trapped execution of an LD64B, ST64B, ST64BV, or ST64BV0 instruction.

See [ISS encoding for an exception from an LD64B or ST64B* instruction](#).

EC == 0b001100

When AArch32 is supported at EL0:

Trapped MRRC access with (coproc==0b1110).

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 0b001101

When FEAT_BTI is implemented:

Branch Target Exception.

See [ISS encoding for an exception from Branch Target Identification instruction](#).

EC == 0b001110

Illegal Execution state.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault.](#)

EC == 0b010001

When AArch32 is supported at EL0:

SVC instruction execution in AArch32 state.

See [ISS encoding for an exception from HVC or SVC instruction execution.](#)

EC == 0b010101

When AArch64 is supported at the highest implemented Exception level:

SVC instruction execution in AArch64 state.

See [ISS encoding for an exception from HVC or SVC instruction execution.](#)

EC == 0b011000

When AArch64 is supported at the highest implemented Exception level:

Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC 0b000000, 0b000001, or 0b000111.

This includes all instructions that cause exceptions that are part of the encoding space defined in [System instruction class encoding overview on page C5-395](#), except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.

See [ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state.](#)

EC == 0b011001

When FEAT_SVE is implemented:

Access to SVE functionality trapped as a result of CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ, that is not reported using EC 0b000000.

See [ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ.](#)

EC == 0b011100

When FEAT_FPAC is implemented:

Exception from a Pointer Authentication instruction authentication failure

See [ISS encoding for an exception from a Pointer Authentication instruction authentication failure.](#)

EC == 0b100000

Instruction Abort from a lower Exception level.

Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from an Instruction Abort.](#)

EC == 0b100001

Instruction Abort taken without a change in Exception level.

Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from an Instruction Abort.](#)

EC == 0b100010

PC alignment fault exception.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault.](#)

EC == 0b100100

Data Abort from a lower Exception level.

Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from a Data Abort](#).

EC == 0b100101

Data Abort taken without a change in Exception level.

Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from a Data Abort](#).

EC == 0b100110

SP alignment fault exception.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

EC == 0b101000

When AArch32 is supported at EL0:

Trapped floating-point exception taken from AArch32 state.

This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.

See [ISS encoding for an exception from a trapped floating-point exception](#).

EC == 0b101100

When AArch64 is supported at the highest implemented Exception level:

Trapped floating-point exception taken from AArch64 state.

This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.

See [ISS encoding for an exception from a trapped floating-point exception](#).

EC == 0b101111

SError interrupt.

See [ISS encoding for an SError interrupt](#).

EC == 0b110000

Breakpoint exception from a lower Exception level.

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#).

EC == 0b110001

Breakpoint exception taken without a change in Exception level.

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#).

EC == 0b110010

Software Step exception from a lower Exception level.

See [ISS encoding for an exception from a Software Step exception](#).

EC == 0b110011

Software Step exception taken without a change in Exception level.

See [ISS encoding for an exception from a Software Step exception](#).

EC == 0b110100

Watchpoint exception from a lower Exception level.

See [ISS encoding for an exception from a Watchpoint exception](#).

EC == 0b110101

Watchpoint exception taken without a change in Exception level.

See [ISS encoding for an exception from a Watchpoint exception](#).

EC == 0b111000

When AArch32 is supported at EL0:

BKPT instruction execution in AArch32 state.

See [ISS encoding for an exception from execution of a Breakpoint instruction](#).

EC == 0b111100

When AArch64 is supported at the highest implemented Exception level:

BRK instruction execution in AArch64 state.

See [ISS encoding for an exception from execution of a Breakpoint instruction](#).

All other EC values are reserved by Arm, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

- | | |
|-----|---|
| 0b0 | 16-bit instruction trapped. |
| 0b1 | 32-bit instruction trapped. This value is also used when the exception is one of the following: |
- An SError interrupt.
 - An Instruction Abort exception.
 - A PC alignment fault exception.
 - An SP alignment fault exception.
 - A Data Abort exception for which the value of the ISV bit is 0.
 - An Illegal Execution state exception.
 - Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
 - 0b0: 16-bit T32 BKPT instruction.
 - 0b1: 32-bit A32 BKPT instruction or A64 BRK instruction.
 - An exception reported using EC value 0b000000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

For an exception taken from AArch32 state, see [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

If the AArch32 register descriptor is 0b1111, then:

- If the instruction that generated the exception was not **UNPREDICTABLE**, the field takes the value 0b11111.

- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
 - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
 - The value 0b11111.

ISS encoding for exceptions with an unknown reason

Bits [24:0]

Reserved, RES0.

When an exception is reported using this EC code the IL field is set to 1.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
 - A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
 - A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
 - Instruction encodings that are unallocated.
 - Instruction encodings for instructions or System registers that are not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the [SCTLR_EL1](#).{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
 - An HVC instruction when disabled by [HCR_EL2](#).HCD or [SCR_EL3](#).HCE.
 - An SMC instruction when disabled by [SCR_EL3](#).SMD.
 - An HLT instruction when disabled by [EDSCR](#).HDE.
- Attempted execution of an MSR or MRS instruction to access [SP_EL0](#) when the value of [SPSel](#).SP is 0.
- Attempted execution of an MSR or MRS instruction using a [_EL12](#) register name when [HCR_EL2](#).E2H == 0.
- Attempted execution, in Debug state, of:
 - A DCPS1 instruction when the value of [HCR_EL2](#).TGE is 1 and EL2 is disabled or not implemented in the current Security state.

- A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
- A DCPS3 instruction when the value of `EDSCR.SDD` is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using `R13_mon`. See *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-2530.
- In Debug state when the value of `EDSCR.SDD` is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to `SPSR_mon`, `SP_mon`, or `LR_mon`.
- An exception that is taken to EL2 because the value of `HCR_EL2.TGE` is 1 that, if the value of `HCR_EL2.TGE` was 0 would have been reported with an `ESR_ELx.EC` value of `0b000111`.

ISS encoding for an exception from a WF* instruction

CV, bit [24]

Condition code valid.

`0b0` The COND field is not valid.

`0b1` The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to `0b1110`, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the `SPSR.IT` field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:10]

Reserved, RES0.

RN, bits [9:5]

When FEAT_WFxT2 is implemented:

RN

Indicates the Register Number supplied for a WFET or WFIT instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [4:3]

Reserved, RES0.

RV, bit [2]

When FEAT_WFxT2 is implemented:

RV

Register field Valid.

If TI[1] == 1, then this field indicates whether RN holds a valid register number for the register argument to the trapped WFET or WFIT instruction.

0b0 Register field invalid.

0b1 Register field valid.

If TI[1] == 0, then this field is RES0.

When FEAT_WFxT2 is implemented, RV is set to 1 on a trap on WFET or WFIT.

When FEAT_WFxT2 is not implemented, RV is set to 0 on a trap on WFET or WFIT.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

0b00 WFI trapped.

0b01 WFE trapped.

0b10 *When FEAT_WFxT is implemented:*
WFIT trapped.

0b11 *When FEAT_WFxT is implemented:*
WFET trapped.

When FEAT_WFxT is implemented, this is a two bit field as shown. Otherwise, bit[1] is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating this exception:

- [SCTLR_EL1](#).{nTWE, nTWI}.
- [HCR_EL2](#).{TWE, TWI}.
- [SCR_EL3](#).{TWE, TWI}.

ISS encoding for an exception from an MCR or MRC access

CV, bit [24]

Condition code valid.

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value 0b000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value 0b111.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

If the Rt value is not 0b1111, then the reported value gives the AArch64 view of the register.

Otherwise, if the Rt value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value 0b0000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write to System register space. MCR instruction.

0b1 Read from System register space. MRC or VMRS instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000011:

- [CNTKCTL_EL1](#).{ELOPTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [PMUSERENR_EL0](#).{ER, CR, SW, EN}, for accesses to Performance Monitor registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [AMUSERENR_EL0](#).EN, for accesses to Activity Monitors registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [HCR_EL2](#).{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).TTLB, for execution of TLB maintenance instructions at EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).{TSW, TPC, TPU} for execution of cache maintenance instructions at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).TACR, for accesses to the Auxiliary Control Register at EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).TIDCP, for accesses to lockdown, DMA, and TCM operations at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).{TID1, TID2, TID3}, for accesses to ID registers at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL2](#).TCPAC, for accesses to [CPACR_EL1](#) or [CPACR](#) using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HSTR_EL2](#).T<n>, for accesses to System registers using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CNTHCTL_EL2](#).EL1PCEN, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [MDCR_EL2](#).{TPM, TPMCR}, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL2](#).TAM, for accesses to Activity Monitors registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL3](#).TCPAC, for accesses to [CPACR](#) from EL1 and EL2, and accesses to [HCPTR](#) from EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.
- [MDCR_EL3](#).TPM, for accesses to Performance Monitor registers from EL0, EL1 and EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.
- [CPTR_EL3](#).TAM, for accesses to Activity Monitors registers from EL0, EL1 and EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.
- For information on other traps using EC value 0b000011, see [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2530](#).
- If [FEAT_FGT](#) is implemented, MCR or MRC access to some registers at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000101:

- **CPACR_EL1**.TTA for accesses to trace registers, MCR or MRC access (coproc == 0b1110) trapped to EL1 or EL2.
- **MDSCR_EL1**.TDCC, for accesses to the Debug Communications Channel (DCC) registers at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL1 or EL2.
- If **FEAT_FGT** is implemented, **MDCR_EL2**.TDCC for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and **MDCR_EL3**.TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.
- **HCR_EL2**.TID0, for accesses to the **JIDR** register in the ID group 0 at EL0 and EL1 using AArch32, MRC access (coproc == 0b1110) trapped to EL2.
- **CPTR_EL2**.TTA, for accesses to trace registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **MDCR_EL2**.TDRA, for accesses to Debug ROM registers **DBGDRAR** and **DBGDSAR** using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **MDCR_EL2**.TDOSA, for accesses to powerdown debug registers, using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **MDCR_EL2**.TDA, for accesses to other debug registers, using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **CPTR_EL3**.TTA, for accesses to trace registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.
- **MDCR_EL3**.TDOSA, for accesses to powerdown debug registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.
- **MDCR_EL3**.TDA, for accesses to other debug registers, using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b001000:

- **HCR_EL2**.TID0, for accesses to the **FPSID** register in ID group 0 at EL1 using AArch32 state, VMRS access trapped to EL2.
- **HCR_EL2**.TID3, for accesses to registers in ID group 3 including **MVFR0**, **MVFR1** and **MVFR2**, VMRS access trapped to EL2.

ISS encoding for an exception from an LD64B or ST64B* instruction

ISS, bits [24:0]

- 0b00000000000000000000000000000000 ST64BV instruction trapped.
- 0b00000000000000000000000000000001 ST64BV0 instruction trapped.
- 0b00000000000000000000000000000010 LD64B or ST64B instruction trapped.
- All other values are reserved.

ISS encoding for an exception from an MCRR or MRRC access

CV, bit [24]

Condition code valid.

0b0 The COND field is not valid.

0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

Rt2, bits [14:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer. If the Rt2 value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt2 value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer. If the Rt value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write to System register space. MCRR instruction.

0b1 Read from System register space. MRRC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000100:

- **CNTKCTL_EL1**. {EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.

- [PMUSERENR_EL0](#).{CR, EN}, for accesses to Performance Monitor registers from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [AMUSERENR_EL0](#).{EN}, for accesses to Activity Monitors registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [HCR_EL2](#).{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- [HSTR_EL2](#).T<n>, for accesses to System registers using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- [CNTHCTL_EL2](#).{ELIPCEN, EL1PCTEN}, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- [MDCR_EL2](#).{TPM, TPMCR}, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL2](#).TAM, for accesses to Activity Monitors registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- [MDCR_EL3](#).TPM, for accesses to Performance Monitor registers from EL0, EL1 and EL2 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL3.
- [CPTR_EL3](#).TAM, for accesses to Activity Monitors registers from EL0, EL1 and EL2 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL3.
- If [FEAT_FGT](#) is implemented, [HDFGRTR_EL2](#).PMCCNTR_EL0 for MRRC access and [HDFGWTR_EL2](#).PMCCNTR_EL0 for MCRR access to [PMCCNTR](#) at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- [MDCR_EL1](#).TDCC, for accesses to the Debug ROM registers [DBGDSAR](#) and [DBGDRAR](#) at EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1110) trapped to EL1 or EL2.
- [MDCR_EL2](#).TDRA, for accesses to Debug ROM registers [DBGDRAR](#) and [DBGDSAR](#) using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL2.
- [MDCR_EL3](#).TDA, for accesses to debug registers, using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL3.
- [CPACR_EL1](#).TTA for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL1 or EL2.
- [CPTR_EL2](#).TTA, for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL2.
- [CPTR_EL3](#).TTA, for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL3.

———— **Note** —————

If the Armv8-A architecture is implemented with an ETMv4 implementation, MCRR and MRRC accesses to trace registers are UNDEFINED and the resulting exception is higher priority than an exception due to these traps.

ISS encoding for an exception from an LDC or STC instruction

CV, bit [24]

Condition code valid.

0b0 The COND field is not valid.

0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

imm8, bits [19:12]

The immediate value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:10]

Reserved, RES0.

Rn, bits [9:5]

The Rn value from the issued instruction, the general-purpose register used for the transfer.

If the Rn value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rn value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

0b0 Subtract offset.
0b1 Add offset.

This bit corresponds to the U bit in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

0b000 Immediate unindexed.
0b001 Immediate post-indexed.
0b010 Immediate offset.
0b011 Immediate pre-indexed.
0b100 For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
0b110 For a trapped STC instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-8423](#).

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write to memory. STC instruction.
0b1 Read from memory. LDC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe the configuration settings for the traps that are reported using EC value 0b000110:

- **MDCR_EL1**.TDCC, for accesses using AArch32 state, LDC access to **DBGDTRXint** or STC access to **DBGDTRRXint** trapped to EL1 or EL2.
- **MDCR_EL2**.TDA, for accesses using AArch32 state, LDC access to **DBGDTRXint** or STC access to **DBGDTRRXint** MCR or MRC access trapped to EL2.
- **MDCR_EL3**.TDA, for accesses using AArch32 state, LDC access to **DBGDTRXint** or STC access to **DBGDTRRXint** MCR or MRC access trapped to EL3.
- If **FEAT_FGT** is implemented, **MDCR_EL2**.TDCC for LDC and STC accesses to the DCC registers at EL0 and EL1 trapped to EL2, and **MDCR_EL3**.TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.

ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from the FPEN and TFP traps

The accesses covered by this trap include:

- Execution of SVE or Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.

For an implementation that does not include either SVE or support for Advanced SIMD and floating-point, the exception is reported using the EC value 0b000000.

CV, bit [24]

Condition code valid.

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.

- With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

The following fields describe the configuration settings for the traps that are reported using EC value 0b000111:

- CPACR_EL1.FPEN, for accesses to SIMD and floating-point registers trapped to EL1.
- CPTR_EL2.FPEN and CPTR_EL2.TFP, for accesses to SIMD and floating-point registers trapped to EL2.
- CPTR_EL3.TFP, for accesses to SIMD and floating-point registers trapped to EL3.

ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ

The accesses covered by this trap include:

- Execution of SVE instructions.
- Accesses to the SVE System registers, ZCR_ELx.

For an implementation that does not include SVE, the exception is reported using the EC value 0b000000.

Bits [24:0]

Reserved, RES0.

The following fields describe the configuration settings for the traps that are reported using EC value 0b011001:

- CPACR_EL1.ZEN, for execution of SVE instructions and accesses to SVE registers at EL0 or EL1, trapped to EL1.
- CPTR_EL2.ZEN and CPTR_EL2.TZ, for execution of SVE instructions and accesses to SVE registers at EL0, EL1, or EL2, trapped to EL2.
- CPTR_EL3.EZ, for execution of SVE instructions and accesses to SVE registers from all Exception levels, trapped to EL3.

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

Bits [24:0]

Reserved, RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about these exceptions, see [The Illegal Execution state exception on page D1-2488](#) and [PC alignment checking on page D1-2469](#).

[SP alignment checking on page D1-2469](#) describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from HVC or SVC instruction execution

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
 - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
 - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see [SVC](#) and [HVC](#).

For A64 instructions, see [SVC](#) and [HVC](#).

If [FEAT_FGT](#) is implemented, [HFGITR_EL2](#).{SVC_EL1, SVC_EL0} control fine-grained traps on SVC execution.

ISS encoding for an exception from SMC instruction execution in AArch32 state

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from EL1 because `HCR_EL2.TSC` is 1, the ISS encoding is as shown in the diagram.

CV, bit [24]

Condition code valid.

0b0 The COND field is not valid.

0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

0b0 The instruction was unconditional, or was conditional and passed its condition code check.

0b1 The instruction was conditional, and might have failed its condition code check.

———— **Note** ————

In an implementation in which an SMC instruction that fails its code check is not trapped, this field can always return the value 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [18:0]

Reserved, RES0.

[HCR_EL2.TSC](#) describes the configuration settings for trapping SMC instructions to EL2.

[System calls on page D1-2535](#) describes the case where these exceptions are trapped to EL3.

ISS encoding for an exception from SMC instruction execution in AArch64 state

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the issued SMC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

[HCR_EL2.TSC](#) describes the configuration settings for trapping SMC from EL1 modes.

[System calls on page D1-2535](#) describes the case where these exceptions are trapped to EL3.

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write access, including MSR instructions.

0b1 Read access, including MRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For exceptions caused by System instructions, see [System instructions on page C4-294](#) for the encoding values returned by an instruction.

The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:

- [SCTLR_EL1](#).UCI, for execution of cache maintenance instructions using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).UCT, for accesses to [CTR_EL0](#) using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).DZE, for execution of DC ZVA instructions using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [CPACR_EL1](#).TTA, for accesses to the trace registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [MDSCR_EL1](#).TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- If [FEAT_FGT](#) is implemented, [MDCR_EL2](#).TDCC for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and [MDCR_EL3](#).TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.

- [CNTKCTL_EL1](#).{ELOPTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [PMUSERENR_EL0](#).{ER, CR, SW, EN}, for accesses to the Performance Monitor registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [AMUSERENR_EL0](#).EN, for accesses to Activity Monitors registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [HCR_EL2](#).{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TDZ, for execution of DC ZVA instructions using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TTLB, for execution of TLB maintenance instructions using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{TSW, TPC, TPU}, for execution of cache maintenance instructions using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TACR, for accesses to the Auxiliary Control Register, [ACTLR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{TID1, TID2, TID3}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TCPAC, for accesses to [CPACR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TTA, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TTRF, for accesses to the trace filter control register, [TRFCR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDOSA, for accesses to powerdown debug registers using AArch64 state, MSR or MRS access trapped to EL2.
- [CNTHCTL_EL2](#).{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDA, for accesses to debug registers using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).{TPM, TPMCR}, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).APK, for accesses to Pointer authentication key registers. using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{NV, NV1}, for Nested virtualization register access, using AArch64 state, MSR or MRS access, trapped to EL2.
- [HCR_EL2](#).AT, for execution of AT S1E* instructions, using AArch64 state, MSR or MRS access, trapped to EL2.

- [HCR_EL2](#).{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.
- [SCR_EL3](#).APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [SCR_EL3](#).ST, for accesses to the Counter-timer Physical Secure timer registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [SCR_EL3](#).{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [CPTR_EL3](#).TCPAC, for accesses to [CPTR_EL2](#) and [CPACR_EL1](#) using AArch64 state, MSR or MRS access trapped to EL3.
- [CPTR_EL3](#).TTA, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [MDCR_EL3](#).TTRF, for accesses to the trace filter control registers, [TRFCR_EL1](#) and [TRFCR_EL2](#), using AArch64 state, MSR or MRS access trapped to EL3.
- [MDCR_EL3](#).TDA, for accesses to debug registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [MDCR_EL3](#).TDOSA, for accesses to powerdown debug registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [MDCR_EL3](#).TPM, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [CPTR_EL3](#).TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access, trapped to EL3.
- If [FEAT_EVT](#) is implemented, the following registers control traps for EL1 and EL0 Cache controls that use this EC value:
 - [HCR_EL2](#).{TTLBOS, TTLBIS, TICAB, TOCU, TID4}.
 - [HCR2](#).{TTLBIS, TICAB, TOCU, TID4}.
- If [FEAT_FGT](#) is implemented:
 - [SCR_EL3](#).FGTE_n, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
 - [HFGRTR_EL2](#) for reads and [HFGWTR_EL2](#) for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 trapped to EL2.
 - [HFGITR_EL2](#) for execution of system instructions, MSR or MRS access trapped to EL2
 - [HDFGRTR_EL2](#) for reads and [HDFGWTR_EL2](#) for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 state trapped to EL2.
 - [HAFGRTR_EL2](#) for reads of Activity Monitor counters, using AArch64 state, MRS access at EL0 and EL1 trapped to EL2.

ISS encoding for an IMPLEMENTATION DEFINED exception to EL3

IMPLEMENTATION DEFINED, bits [24:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from an Instruction Abort

Bits [24:13]

Reserved, RES0.

SET, bits [12:11]

When FEAT_RAS is implemented:

SET

Synchronous Error Type. When IFSC is 0b010000, describes the PE error state after taking the Instruction Abort exception.

0b00 Recoverable state (UER).

0b10 Uncontainable (UC).

0b11 Restartable state (UEO).

All other values are reserved.

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in a PE state that is not recoverable.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 FAR is valid.

0b1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.

0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

0b000000 Address size fault, level 0 of translation or translation table base register.

0b000001 Address size fault, level 1.

0b000010 Address size fault, level 2.

0b000011 Address size fault, level 3.

0b000100 Translation fault, level 0.

0b000101 Translation fault, level 1.

0b000110 Translation fault, level 2.

0b000111 Translation fault, level 3.

0b001001 Access flag fault, level 1.

0b001010 Access flag fault, level 2.

0b001011 Access flag fault, level 3.

0b001000 *When FEAT_LPA2 is implemented:*

Access flag fault, level 0.

0b001100 *When FEAT_LPA2 is implemented:*

Permission fault, level 0.

0b001101 Permission fault, level 1.

0b001110 Permission fault, level 2.

0b001111 Permission fault, level 3.

0b010000 Synchronous External abort, not on translation table walk or hardware update of translation table.

0b010011 *When FEAT_LPA2 is implemented:*

Synchronous External abort on translation table walk or hardware update of translation table, level -1.

0b010100 Synchronous External abort on translation table walk or hardware update of translation table, level 0.

0b010101 Synchronous External abort on translation table walk or hardware update of translation table, level 1.

0b010110 Synchronous External abort on translation table walk or hardware update of translation table, level 2.

0b010111 Synchronous External abort on translation table walk or hardware update of translation table, level 3.

- 0b011000 *When FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access, not on translation table walk.
- 0b011011 *When FEAT_LPA2 is implemented and FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.
- 0b011100 *When FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.
- 0b011101 *When FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.
- 0b011110 *When FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.
- 0b011111 *When FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.
- 0b101001 *When FEAT_LPA2 is implemented:*
Address size fault, level -1.
- 0b101011 *When FEAT_LPA2 is implemented:*
Translation fault, level -1.
- 0b110000 TLB conflict abort.
- 0b110001 *When FEAT_HAFDBS is implemented:*
Unsupported atomic hardware update fault.

All other values are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on page D5-2806](#).

Note

Because Access flag faults and Permission faults can result only from a Block or Page translation table descriptor, they cannot occur at level 0.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a Data Abort

When FEAT_LS64 is implemented, if a memory access generated by an ST64BV or ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this ISS encoding includes ISS2, bits[36:32].

ISV, bit [24]

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] is valid.

- 0b0 No valid instruction syndrome. ISS[23:14] are RES0.

0b1 ISS[23:14] hold a valid instruction syndrome.

In ESR_EL2, ISV is 1 when FEAT_LS64 is implemented and a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

For other faults reported in ESR_EL2, ISV is 0 except for the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).
- AArch32 instructions where the instruction:
 - Is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
 - Is not performing register writeback.
 - Is not using R15 as a source or destination register.

For these stage 2 aborts, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

For faults reported in ESR_EL1 or ESR_EL3, ISV is 1 when FEAT_LS64 is implemented and a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault. ISV is 0 for all other faults reported in ESR_EL1 or ESR_EL3.

When FEAT_RAS is implemented, ISV is 0 for any synchronous External abort.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

When FEAT_MTE is implemented, for a synchronous Tag Check Fault abort taken to ELx, ESR_ELx.FNV is 0 and FAR_ELx is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == 1:

SAS

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

0b00	Byte
0b01	Halfword
0b10	Word
0b11	Doubleword

When FEAT_LS64 is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0b11.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSE, bit [21]

When ISV == 1:

SSE

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

0b0 Sign-extension not required.

0b1 Data item must be sign-extended.

When [FEAT_LS64](#) is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SRT, bits [20:16]

When ISV == 1:

SRT

Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

If the exception was taken from an Exception level that is using AArch32, then this is the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SF, bit [15]

When ISV == 1:

SF

Width of the register accessed by the instruction is Sixty-Four.

0b0 Instruction loads/stores a 32-bit wide register.

0b1 Instruction loads/stores a 64-bit wide register.

———— **Note** ————

This field specifies the register width identified by the instruction, not the Execution state.

When [FEAT_LS64](#) is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AR, bit [14]

When ISV == 1:

AR

Acquire/Release.

0b0 Instruction did not have acquire/release semantics.

0b1 Instruction did have acquire/release semantics.

When [FEAT_LS64](#) is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VNCR, bit [13]

When FEAT_NV2 is implemented:

VNCR

Indicates that the fault came from use of [VNCR_EL2](#) register by EL1 code.

0b0 The fault was not generated by the use of [VNCR_EL2](#), by an MRS or MSR instruction executed at EL1.

0b1 The fault was generated by the use of [VNCR_EL2](#), by an MRS or MSR instruction executed at EL1.

This field is 0 in ESR_EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits[12:11]

When FEAT_RAS is implemented and FEAT_LS64 is not implemented:

SET

Synchronous Error Type. When DFSC is 0b010000, describes the PE error state after taking the Data Abort exception.

0b00 Recoverable state (UER).

0b10 Uncontainable (UC).

0b11 Restartable state (UEO).

All other values are reserved.

———— **Note** ————

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in a PE state that is not recoverable.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_LS64 is implemented:

LST

Load/Store Type. Used when an LD64B, ST64B, ST64BV, or ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

0b01 An ST64BV instruction generated the Data Abort.

0b10 An LD64B or ST64B instruction generated the Data Abort.

0b11 An ST64BV0 instruction generated the Data Abort.

All other values are reserved.

This field is valid only if the DFSC code is 0b110101. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 FAR is valid.

0b1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

0b0 The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.

0b1 The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.

0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

0b0 Abort caused by an instruction reading from a memory location.

0b1 Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101 or 0b110001, indicating an unsupported Exclusive or atomic access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

0b000000 Address size fault, level 0 of translation or translation table base register.

0b000001 Address size fault, level 1.

0b000010 Address size fault, level 2.

0b000011 Address size fault, level 3.

0b000100 Translation fault, level 0.

0b000101 Translation fault, level 1.

0b000110 Translation fault, level 2.

0b000111 Translation fault, level 3.

0b001001 Access flag fault, level 1.

0b001010 Access flag fault, level 2.

0b001011 Access flag fault, level 3.

0b001000 *When FEAT_LPA2 is implemented:*
Access flag fault, level 0.

0b001100 *When FEAT_LPA2 is implemented:*
Permission fault, level 0.

0b001101	Permission fault, level 1.
0b001110	Permission fault, level 2.
0b001111	Permission fault, level 3.
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.
0b010001	<i>When FEAT_MTE2 is implemented:</i> Synchronous Tag Check Fault.
0b010011	<i>When FEAT_LPA2 is implemented:</i> Synchronous External abort on translation table walk or hardware update of translation table, level -1.
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.
0b011000	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access, not on translation table walk.
0b011011	<i>When FEAT_LPA2 is implemented and FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.
0b011100	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.
0b011101	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.
0b011110	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.
0b011111	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.
0b100001	Alignment fault.
0b101001	<i>When FEAT_LPA2 is implemented:</i> Address size fault, level -1.
0b101011	<i>When FEAT_LPA2 is implemented:</i> Translation fault, level -1.
0b110000	TLB conflict abort.
0b110001	<i>When FEAT_HAFDBS is implemented:</i> Unsupported atomic hardware update fault.
0b110100	IMPLEMENTATION DEFINED fault (Lockdown).
0b110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).

All other values are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on page D5-2806](#).

———— **Note** —————

Because Access flag faults and Permission faults can result only from a Block or Page translation table descriptor, they cannot occur at level 0.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception

Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

- 0b0 The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
- 0b1 One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see [Floating-point exceptions and exception traps on page D1-2495](#).

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

———— **Note** —————

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Input denormal floating-point exception has not occurred.
- 0b1 Input denormal floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Inexact floating-point exception has not occurred.
- 0b1 Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Underflow floating-point exception has not occurred.
- 0b1 Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Overflow floating-point exception has not occurred.
- 0b1 Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Divide by Zero floating-point exception has not occurred.
- 0b1 Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Invalid Operation floating-point exception has not occurred.

0b1 Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the **FPCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the **FPSCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for an SError interrupt

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

0b0 Bits [23:0] of the ISS field holds the fields described in this encoding.

Note

If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.

0b1 Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError interrupt.

Note

This field was previously called ISV.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:14]

Reserved, RES0.

IESB, bit [13]

When FEAT_IESB is implemented:

IESB

Implicit error synchronization event.

0b0 The SError interrupt was either not synchronized by the implicit error synchronization event or not taken immediately.

0b1 The SError interrupt was synchronized by the implicit error synchronization event and taken immediately.

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other errors.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AET, bits [12:10]

When FEAT_RAS is implemented:

AET

Asynchronous Error Type.

When DFSC is 0b010001, describes the PE error state after taking the SError interrupt exception.

0b000 Uncontainable (UC).

0b001 Unrecoverable state (UEU).

0b010 Restartable state (UEO).

0b011 Recoverable state (UER).

0b110 Corrected (CE).

All other values are reserved.

If multiple errors are taken as a single SError interrupt exception, the overall PE error state is reported.

———— **Note** —————

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other errors.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented:

EA

External abort type. When DFSC is 0b010001, provides an IMPLEMENTATION DEFINED classification of External aborts.

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other errors.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:

DFSC

Data Fault Status Code.

0b000000 Uncategorized error.

0b010001 Asynchronous SError interrupt.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

0b100010 Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions:

- For exceptions from AArch64, see [Breakpoint exceptions on page D2-2579](#).
- For exceptions from AArch32, see [Breakpoint exceptions on page G2-6170](#) and [Vector Catch exceptions on page G2-6209](#).

ISS encoding for an exception from a Software Step exception

ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

0b0 EX bit is RES0.

0b1 EX bit is valid.

See the EX bit description for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

0b0 An instruction other than a Load-Exclusive instruction was stepped.

0b1 A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]

Instruction Fault Status Code.

0b100010 Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Software Step exceptions* on page D2-2613.

ISS encoding for an exception from a Watchpoint exception

Bits [24:15]

Reserved, RES0.

Bit [14]

Reserved, RES0.

VNCR, bit [13]

When FEAT_NV2 is implemented:

VNCR

Indicates that the watchpoint came from use of [VNCR_EL2](#) register by EL1 code.

0b0 The watchpoint was not generated by the use of [VNCR_EL2](#) by EL1 code.

0b1 The watchpoint was generated by the use of [VNCR_EL2](#) by EL1 code.

This field is 0 in [ESR_EL1](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [12:9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance or address translation instruction:

0b0 The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.

0b1 The Watchpoint exception was generated by either the execution of a cache maintenance instruction or by a synchronous Watchpoint exception on the execution of an address translation instruction. The [DC ZVA](#), [DC GVA](#), and [DC GZVA](#) instructions are not classified as a cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

0b0 Watchpoint exception caused by an instruction reading from a memory location.

0b1 Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance and address translation instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

0b100010 Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see [Watchpoint exceptions on page D2-2598](#).

ISS encoding for an exception from execution of a Breakpoint instruction

Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

For the AArch32 BKPT instructions, the comment field is described as the immediate field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see [Breakpoint Instruction exceptions on page D2-2577](#).

ISS encoding for an exception from an ERET, ERETA, or ERETAB instruction

This EC value applies when [FEAT_FGT](#) is implemented, or when [HCR_EL2.NV](#) is 1.

Bits [24:2]

Reserved, RES0.

ERET, bit [1]

Indicates whether an ERET or ERETA* instruction was trapped to EL2.

0b0 ERET instruction trapped to EL2.

0b1 ERETAA or ERETAB instruction trapped to EL2.

If this bit is 0, the ERETA field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ERETA, bit [0]

Indicates whether an ERETAA or ERETAB instruction was trapped to EL2.

0b0 ERETAA instruction trapped to EL2.

0b1 ERETAB instruction trapped to EL2.

When the ERET field is 0, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see [HCR_EL2.NV](#).

If [FEAT_FGT](#) is implemented, [HFGITR_EL2.ERET](#) controls fine-grained trap exceptions from ERET, ERETAA and ERETAB execution.

ISS encoding for an exception from Branch Target Identification instruction

Bits [24:2]

Reserved, RES0.

BTYPE, bits [1:0]

This field is set to the PSTATE.BTYPE value that generated the Branch Target Exception.

For more information about generating these exceptions, see [Chapter B1 The AArch64 Application Level Programmers' Model](#).

ISS encoding for an exception from a Pointer Authentication instruction when $HCR_EL2.API == 0$ || $SCR_EL3.API == 0$

Bits [24:0]

Reserved, RES0.

For more information about generating these exceptions, see:

- [HCR_EL2.API](#), for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL2.
- [SCR_EL3.API](#), for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL3.

ISS encoding for an exception from a Pointer Authentication instruction authentication failure

Bits [24:2]

Reserved, RES0.

Bit [1]

This field indicates whether the exception is as a result of an Instruction key or a Data key.

0b0 Instruction Key.

0b1 Data Key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

This field indicates whether the exception is as a result of an A key or a B key.

0b0 A key.

0b1 B key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following instructions generate an exception when the Pointer Authentication Code (PAC) is incorrect:

- AUTIASP, AUTIAZ, AUTIA1716.
- AUTIBSP, AUTIBZ, AUTIB1716.
- AUTIA, AUTDA, AUTIB, AUTDB.
- AUTIZA, AUTIZB, AUTDZA, AUTDZB.

It is IMPLEMENTATION DEFINED whether the following instructions generate an exception directly from the authorization failure, rather than changing the address in a way that will generate a Translation fault when the address is accessed:

- RETAA, RETAB.
- BRAA, BRAB, BLRAA, BLRAB.
- BRAAZ, BRABZ, BLRAAZ, BLRABZ.
- ERETA, ERETA.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.

Accessing ESR_EL1

When `HCR_EL2.E2H` is 1, without explicit synchronization, access from EL3 using the mnemonic `ESR_EL1` or `ESR_EL12` are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ESR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0010	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;

```

D13.2.38 ESR_EL2, Exception Syndrome Register (EL2)

The ESR_EL2 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL2.

Configurations

AArch64 System register ESR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HSR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

ESR_EL2 is a 64-bit register.

Field descriptions

ESR_EL2 is made UNKNOWN as a result of an exception return from EL2.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of ESR_EL2 is UNKNOWN. The value written to ESR_EL2 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

Bits [63:37]

Reserved, RES0.

ISS2, bits [36:32]

When FEAT_LS64 is implemented:

ISS2

If a memory access generated by an ST64BV or ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field holds register specifier, Xs.

For any other Data Abort, this field is RES0.

Otherwise:

Reserved, RES0.

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

EC == 0b000000

Unknown reason.

See [ISS encoding for exceptions with an unknown reason](#).

EC == 0b000001

Trapped WF* instruction execution.

Conditional WF* instructions that fail their condition code check do not cause an exception.

See [ISS encoding for an exception from a WF* instruction](#).

EC == 0b000011

When AArch32 is supported at EL0:

Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC 0b000000.

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 0b000100

When AArch32 is supported at EL0:

Trapped MCRR or MRRC access with (coproc==0b1111) that is not reported using EC 0b000000.

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 0b000101

When AArch32 is supported at EL0:

Trapped MCR or MRC access with (coproc==0b1110).

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 0b000110

When AArch32 is supported at EL0:

Trapped LDC or STC access.

The only architected uses of these instruction are:

- An STC to write data to memory from [DBGDTRRXint](#).
- An LDC to read data from memory to [DBGDTRTXint](#).

See [ISS encoding for an exception from an LDC or STC instruction](#).

EC == 0b000111

Access to SVE, Advanced SIMD or floating-point functionality trapped by [CPACR_EL1.FPEN](#), [CPTR_EL2.FPEN](#), [CPTR_EL2.TFP](#), or [CPTR_EL3.TFP](#) control. Excludes exceptions resulting from [CPACR_EL1](#) when the value of [HCR_EL2.TGE](#) is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000 as described in [The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1](#) on page D1-2483.

See [ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from the FPEN and TFP traps](#).

EC == 0b001000

When AArch32 is supported at EL0:

Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 0b001001

When FEAT_PAuth is implemented:

Trapped use of a Pointer authentication instruction because [HCR_EL2.API == 0](#) || [SCR_EL3.API == 0](#).

See [ISS encoding for an exception from a Pointer Authentication instruction when HCR_EL2.API == 0 || SCR_EL3.API == 0](#).

EC == 0b001010

When FEAT_LS64 is implemented:

Trapped execution of an LD64B, ST64B, ST64BV, or ST64BV0 instruction.

See [ISS encoding for an exception from an LD64B or ST64B* instruction](#).

EC == 0b001100

When AArch32 is supported at EL0:

Trapped MRRC access with (coproc==0b1110).

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 0b001101

When FEAT_BTI is implemented:

Branch Target Exception.

See [ISS encoding for an exception from Branch Target Identification instruction](#).

EC == 0b001110

Illegal Execution state.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

EC == 0b010001

When AArch32 is supported at EL0:

SVC instruction execution in AArch32 state.

This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TGE is 1.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 0b010010

When AArch32 is supported at EL0:

HVC instruction execution in AArch32 state, when HVC is not disabled.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 0b010011

When AArch32 is supported at EL0:

SMC instruction execution in AArch32 state, when SMC is not disabled.

This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.

See [ISS encoding for an exception from SMC instruction execution in AArch32 state](#).

EC == 0b010101

When AArch64 is supported at the highest implemented Exception level:

SVC instruction execution in AArch64 state.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 0b010110

When AArch64 is supported at the highest implemented Exception level:

HVC instruction execution in AArch64 state, when HVC is not disabled.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 0b010111

When AArch64 is supported at the highest implemented Exception level:

SMC instruction execution in AArch64 state, when SMC is not disabled.

This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.

See [ISS encoding for an exception from SMC instruction execution in AArch64 state](#).

EC == 0b011000

When AArch64 is supported at the highest implemented Exception level:

Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC 0b000000, 0b000001 or 0b000111.

This includes all instructions that cause exceptions that are part of the encoding space defined in [System instruction class encoding overview on page C5-395](#), except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.

See [ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state.](#)

EC == 0b011001

When FEAT_SVE is implemented:

Access to SVE functionality trapped as a result of [CPACR_EL1.ZEN](#), [CPTR_EL2.ZEN](#), [CPTR_EL2.TZ](#), or [CPTR_EL3.EZ](#), that is not reported using EC 0b000000.

See [ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ.](#)

EC == 0b011010

When FEAT_PAuth is implemented and FEAT_NV is implemented:

Trapped ERET, ERETAA, or ERETAB instruction execution.

See [ISS encoding for an exception from an ERET, ERETAA, or ERETAB instruction.](#)

EC == 0b011100

When FEAT_FPAC is implemented:

Exception from a Pointer Authentication instruction authentication failure

See [ISS encoding for an exception from a Pointer Authentication instruction authentication failure.](#)

EC == 0b100000

Instruction Abort from a lower Exception level.

Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from an Instruction Abort.](#)

EC == 0b100001

Instruction Abort taken without a change in Exception level.

Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from an Instruction Abort.](#)

EC == 0b100010

PC alignment fault exception.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault.](#)

EC == 0b100100

Data Abort from a lower Exception level, excluding Data Aborts taken to EL2 as a result of accesses generated associated with [VNCR_EL2](#) as part of nested virtualization support.

These Data Aborts might be generated from Exception levels in any Execution state.

Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from a Data Abort.](#)

EC == 0b100101

Data Abort without a change in Exception level, or Data Aborts taken to EL2 as a result of accesses generated associated with [VNCR_EL2](#) as part of nested virtualization support.

Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from a Data Abort.](#)

EC == 0b100110

SP alignment fault exception.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault.](#)

EC == 0b101000

When AArch32 is supported at EL0:

Trapped floating-point exception taken from AArch32 state.

This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.

See [ISS encoding for an exception from a trapped floating-point exception.](#)

EC == 0b101100

When AArch64 is supported at the highest implemented Exception level:

Trapped floating-point exception taken from AArch64 state.

This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.

See [ISS encoding for an exception from a trapped floating-point exception.](#)

EC == 0b101111

SError interrupt.

See [ISS encoding for an SError interrupt.](#)

EC == 0b110000

Breakpoint exception from a lower Exception level.

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception.](#)

EC == 0b110001

Breakpoint exception taken without a change in Exception level.

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception.](#)

EC == 0b110010

Software Step exception from a lower Exception level.

See [ISS encoding for an exception from a Software Step exception.](#)

EC == 0b110011

Software Step exception taken without a change in Exception level.

See [ISS encoding for an exception from a Software Step exception.](#)

EC == 0b110100

Watchpoint from a lower Exception level, excluding Watchpoint Exceptions taken to EL2 as a result of accesses generated associated with [VNCR_EL2](#) as part of nested virtualization support.

These Watchpoint Exceptions might be generated from Exception levels using any Execution state.

See [ISS encoding for an exception from a Watchpoint exception.](#)

EC == 0b110101

Watchpoint exceptions without a change in Exception level, or Watchpoint exceptions taken to EL2 as a result of accesses generated associated with [VNCR_EL2](#) as part of nested virtualization support.

See [ISS encoding for an exception from a Watchpoint exception.](#)

EC == 0b111000

When AArch32 is supported at EL0:

BKPT instruction execution in AArch32 state.

See [ISS encoding for an exception from execution of a Breakpoint instruction.](#)

EC == 0b111010

When AArch32 is supported at EL0:

Vector Catch exception from AArch32 state.

The only case where a Vector Catch exception is taken to an Exception level that is using AArch64 is when the exception is routed to EL2 and EL2 is using AArch64.

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#).

EC == 0b111100

When AArch64 is supported at the highest implemented Exception level:

BRK instruction execution in AArch64 state.

See [ISS encoding for an exception from execution of a Breakpoint instruction](#).

All other EC values are reserved by Arm, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONstrained UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

- | | |
|-----|---|
| 0b0 | 16-bit instruction trapped. |
| 0b1 | 32-bit instruction trapped. This value is also used when the exception is one of the following: |
- An SError interrupt.
 - An Instruction Abort exception.
 - A PC alignment fault exception.
 - An SP alignment fault exception.
 - A Data Abort exception for which the value of the ISV bit is 0.
 - An Illegal Execution state exception.
 - Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
 - 0b0: 16-bit T32 BKPT instruction.
 - 0b1: 32-bit A32 BKPT instruction or A64 BRK instruction.
 - An exception reported using EC value 0b000000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

For an exception taken from AArch32 state, see [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

If the AArch32 register descriptor is 0b1111, then:

- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
 - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
 - The value 0b11111.

ISS encoding for exceptions with an unknown reason

Bits [24:0]

Reserved, RES0.

When an exception is reported using this EC code the IL field is set to 1.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
 - A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
 - A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
 - Instruction encodings that are unallocated.
 - Instruction encodings for instructions or System registers that are not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the [SCTLR_EL1](#).{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
 - An HVC instruction when disabled by [HCR_EL2.HCD](#) or [SCR_EL3.HCE](#).
 - An SMC instruction when disabled by [SCR_EL3.SMD](#).
 - An HLT instruction when disabled by [EDSCR.HDE](#).
- Attempted execution of an MSR or MRS instruction to access [SP_EL0](#) when the value of [SPSel.SP](#) is 0.
- Attempted execution of an MSR or MRS instruction using a [_EL12](#) register name when [HCR_EL2.E2H](#) == 0.

- Attempted execution, in Debug state, of:
 - A DCPS1 instruction when the value of `HCR_EL2.TGE` is 1 and EL2 is disabled or not implemented in the current Security state.
 - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
 - A DCPS3 instruction when the value of `EDSCR.SDD` is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using `R13_mon`. See *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-2530.
- In Debug state when the value of `EDSCR.SDD` is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to `SPSR_mon`, `SP_mon`, or `LR_mon`.
- An exception that is taken to EL2 because the value of `HCR_EL2.TGE` is 1 that, if the value of `HCR_EL2.TGE` was 0 would have been reported with an `ESR_ELx.EC` value of `0b000111`.

ISS encoding for an exception from a WF* instruction

CV, bit [24]

Condition code valid.

`0b0` The COND field is not valid.

`0b1` The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to `0b1110`, the value for unconditional.
 - With the COND value held in the instruction.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:10]

Reserved, RES0.

RN, bits [9:5]

When FEAT_WFxT2 is implemented:

RN

Indicates the Register Number supplied for a WFET or WFIT instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [4:3]

Reserved, RES0.

RV, bit [2]

When FEAT_WFxT2 is implemented:

RV

Register field Valid.

If TI[1] == 1, then this field indicates whether RN holds a valid register number for the register argument to the trapped WFET or WFIT instruction.

0b0 Register field invalid.

0b1 Register field valid.

If TI[1] == 0, then this field is RES0.

When FEAT_WFxT2 is implemented, RV is set to 1 on a trap on WFET or WFIT.

When FEAT_WFxT2 is not implemented, RV is set to 0 on a trap on WFET or WFIT.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

0b00 WFI trapped.

0b01 WFE trapped.

- 0b10 *When FEAT_WFxFt is implemented:*
WFIT trapped.
- 0b11 *When FEAT_WFxFt is implemented:*
WFET trapped.

When **FEAT_WFxFt** is implemented, this is a two bit field as shown. Otherwise, bit[1] is RES0.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating this exception:

- **SCTLR_EL1**.{nTWE, nTWI}.
- **HCR_EL2**.{TWE, TWI}.
- **SCR_EL3**.{TWE, TWI}.

ISS encoding for an exception from an MCR or MRC access

CV, bit [24]

Condition code valid.

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.

— CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value 0b000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value 0b111.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

If the Rt value is not 0b1111, then the reported value gives the AArch64 view of the register.

Otherwise, if the Rt value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value 0b0000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write to System register space. MCR instruction.

0b1 Read from System register space. MRC or VMRS instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000011:

- [CNTKCTL_EL1](#).{ELOPTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [PMUSERENR_EL0](#).{ER, CR, SW, EN}, for accesses to Performance Monitor registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [AMUSERENR_EL0](#).EN, for accesses to Activity Monitors registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [HCR_EL2](#).{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).TTLB, for execution of TLB maintenance instructions at EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).{TSW, TPC, TPU} for execution of cache maintenance instructions at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).TACR, for accesses to the Auxiliary Control Register at EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).TIDCP, for accesses to lockdown, DMA, and TCM operations at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).{TID1, TID2, TID3}, for accesses to ID registers at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL2](#).TCPAC, for accesses to [CPACR_EL1](#) or [CPACR](#) using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HSTR_EL2](#).T<n>, for accesses to System registers using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CNTHCTL_EL2](#).EL1PCEN, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [MDCR_EL2](#).{TPM, TPMCR}, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL2](#).TAM, for accesses to Activity Monitors registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL3](#).TCPAC, for accesses to [CPACR](#) from EL1 and EL2, and accesses to [HCPTR](#) from EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.
- [MDCR_EL3](#).TPM, for accesses to Performance Monitor registers from EL0, EL1 and EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.
- [CPTR_EL3](#).TAM, for accesses to Activity Monitors registers from EL0, EL1 and EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.
- For information on other traps using EC value 0b000011, see [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2530](#).

- If **FEAT_FGT** is implemented, MCR or MRC access to some registers at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000101:

- **CPACR_EL1.TTA** for accesses to trace registers, MCR or MRC access (coproc == 0b1110) trapped to EL1 or EL2.
- **MDSCR_EL1.TDCC**, for accesses to the Debug Communications Channel (DCC) registers at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL1 or EL2.
- If **FEAT_FGT** is implemented, **MDSCR_EL2.TDCC** for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and **MDSCR_EL3.TDCC** for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.
- **HCR_EL2.TID0**, for accesses to the **JIDR** register in the ID group 0 at EL0 and EL1 using AArch32, MRC access (coproc == 0b1110) trapped to EL2.
- **CPTR_EL2.TTA**, for accesses to trace registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **MDCR_EL2.TDRA**, for accesses to Debug ROM registers **DBGDRAR** and **DBGDSAR** using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **MDCR_EL2.TDOSA**, for accesses to powerdown debug registers, using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **MDCR_EL2.TDA**, for accesses to other debug registers, using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **CPTR_EL3.TTA**, for accesses to trace registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.
- **MDCR_EL3.TDOSA**, for accesses to powerdown debug registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.
- **MDCR_EL3.TDA**, for accesses to other debug registers, using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b001000:

- **HCR_EL2.TID0**, for accesses to the **FPSID** register in ID group 0 at EL1 using AArch32 state, VMRS access trapped to EL2.
- **HCR_EL2.TID3**, for accesses to registers in ID group 3 including **MVFR0**, **MVFR1** and **MVFR2**, VMRS access trapped to EL2.

ISS encoding for an exception from an LD64B or ST64B* instruction

ISS, bits [24:0]

- 0b00000000000000000000000000000000 ST64BV instruction trapped.
 - 0b00000000000000000000000000000001 ST64BV0 instruction trapped.
 - 0b00000000000000000000000000000010 LD64B or ST64B instruction trapped.
- All other values are reserved.

ISS encoding for an exception from an MCRR or MRRC access

CV, bit [24]

Condition code valid.

0b0 The COND field is not valid.

0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

Rt2, bits [14:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer. If the Rt2 value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt2 value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer. If the Rt value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write to System register space. MCRR instruction.

0b1 Read from System register space. MRRC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000100:

- **CNTKCTL_EL1**. {EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.

- [PMUSERENR_EL0](#).{CR, EN}, for accesses to Performance Monitor registers from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [AMUSERENR_EL0](#).{EN}, for accesses to Activity Monitors registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [HCR_EL2](#).{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- [HSTR_EL2](#).T<n>, for accesses to System registers using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- [CNTHCTL_EL2](#).{ELIPCEN, EL1PCTEN}, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- [MDCR_EL2](#).{TPM, TPMCR}, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL2](#).TAM, for accesses to Activity Monitors registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- [MDCR_EL3](#).TPM, for accesses to Performance Monitor registers from EL0, EL1 and EL2 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL3.
- [CPTR_EL3](#).TAM, for accesses to Activity Monitors registers from EL0, EL1 and EL2 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL3.
- If [FEAT_FGT](#) is implemented, [HDFGRTR_EL2](#).PMCCNTR_EL0 for MRRC access and [HDFGWTR_EL2](#).PMCCNTR_EL0 for MCRR access to [PMCCNTR](#) at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- [MDCR_EL1](#).TDCC, for accesses to the Debug ROM registers [DBGDSAR](#) and [DBGDRAR](#) at EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1110) trapped to EL1 or EL2.
- [MDCR_EL2](#).TDRA, for accesses to Debug ROM registers [DBGDRAR](#) and [DBGDSAR](#) using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL2.
- [MDCR_EL3](#).TDA, for accesses to debug registers, using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL3.
- [CPACR_EL1](#).TTA for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL1 or EL2.
- [CPTR_EL2](#).TTA, for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL2.
- [CPTR_EL3](#).TTA, for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL3.

———— **Note** —————

If the Armv8-A architecture is implemented with an ETMv4 implementation, MCRR and MRRC accesses to trace registers are UNDEFINED and the resulting exception is higher priority than an exception due to these traps.

ISS encoding for an exception from an LDC or STC instruction

CV, bit [24]

Condition code valid.

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

imm8, bits [19:12]

The immediate value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:10]

Reserved, RES0.

Rn, bits [9:5]

The Rn value from the issued instruction, the general-purpose register used for the transfer.

If the Rn value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rn value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

0b0 Subtract offset.
0b1 Add offset.

This bit corresponds to the U bit in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

0b000 Immediate unindexed.
0b001 Immediate post-indexed.
0b010 Immediate offset.
0b011 Immediate pre-indexed.
0b100 For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
0b110 For a trapped STC instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-8423](#).

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write to memory. STC instruction.
0b1 Read from memory. LDC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe the configuration settings for the traps that are reported using EC value 0b000110:

- **MDCR_EL1.TDCC**, for accesses using AArch32 state, LDC access to **DBGDTRXint** or STC access to **DBGDTRRXint** trapped to EL1 or EL2.
- **MDCR_EL2.TDA**, for accesses using AArch32 state, LDC access to **DBGDTRXint** or STC access to **DBGDTRRXint** MCR or MRC access trapped to EL2.
- **MDCR_EL3.TDA**, for accesses using AArch32 state, LDC access to **DBGDTRXint** or STC access to **DBGDTRRXint** MCR or MRC access trapped to EL3.
- If **FEAT_FGT** is implemented, **MDCR_EL2.TDCC** for LDC and STC accesses to the DCC registers at EL0 and EL1 trapped to EL2, and **MDCR_EL3.TDCC** for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.

ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from the FPEN and TFP traps

The accesses covered by this trap include:

- Execution of SVE or Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.

For an implementation that does not include either SVE or support for Advanced SIMD and floating-point, the exception is reported using the EC value 0b000000.

CV, bit [24]

Condition code valid.

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.

- With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

The following fields describe the configuration settings for the traps that are reported using EC value 0b000111:

- CPACR_EL1.FPEN, for accesses to SIMD and floating-point registers trapped to EL1.
- CPTR_EL2.FPEN and CPTR_EL2.TFP, for accesses to SIMD and floating-point registers trapped to EL2.
- CPTR_EL3.TFP, for accesses to SIMD and floating-point registers trapped to EL3.

ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ

The accesses covered by this trap include:

- Execution of SVE instructions.
- Accesses to the SVE System registers, ZCR_ELx.

For an implementation that does not include SVE, the exception is reported using the EC value 0b000000.

Bits [24:0]

Reserved, RES0.

The following fields describe the configuration settings for the traps that are reported using EC value 0b011001:

- CPACR_EL1.ZEN, for execution of SVE instructions and accesses to SVE registers at EL0 or EL1, trapped to EL1.
- CPTR_EL2.ZEN and CPTR_EL2.TZ, for execution of SVE instructions and accesses to SVE registers at EL0, EL1, or EL2, trapped to EL2.
- CPTR_EL3.EZ, for execution of SVE instructions and accesses to SVE registers from all Exception levels, trapped to EL3.

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

Bits [24:0]

Reserved, RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about these exceptions, see [The Illegal Execution state exception on page D1-2488](#) and [PC alignment checking on page D1-2469](#).

[SP alignment checking on page D1-2469](#) describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from HVC or SVC instruction execution

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
 - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
 - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see [SVC](#) and [HVC](#).

For A64 instructions, see [SVC](#) and [HVC](#).

If [FEAT_FGT](#) is implemented, [HFGITR_EL2](#).{SVC_EL1, SVC_EL0} control fine-grained traps on SVC execution.

ISS encoding for an exception from SMC instruction execution in AArch32 state

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from EL1 because `HCR_EL2.TSC` is 1, the ISS encoding is as shown in the diagram.

CV, bit [24]

Condition code valid.

0b0 The COND field is not valid.

0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

0b0 The instruction was unconditional, or was conditional and passed its condition code check.

0b1 The instruction was conditional, and might have failed its condition code check.

———— **Note** ————

In an implementation in which an SMC instruction that fails its code check is not trapped, this field can always return the value 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [18:0]

Reserved, RES0.

[HCR_EL2.TSC](#) describes the configuration settings for trapping SMC instructions to EL2.

[System calls on page D1-2535](#) describes the case where these exceptions are trapped to EL3.

ISS encoding for an exception from SMC instruction execution in AArch64 state

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the issued SMC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

[HCR_EL2.TSC](#) describes the configuration settings for trapping SMC from EL1 modes.

[System calls on page D1-2535](#) describes the case where these exceptions are trapped to EL3.

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write access, including MSR instructions.

0b1 Read access, including MRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For exceptions caused by System instructions, see [System instructions on page C4-294](#) for the encoding values returned by an instruction.

The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:

- [SCTLR_EL1](#).UCI, for execution of cache maintenance instructions using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).UCT, for accesses to [CTR_EL0](#) using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).DZE, for execution of DC ZVA instructions using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [CPACR_EL1](#).TTA, for accesses to the trace registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [MDSCR_EL1](#).TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- If [FEAT_FGT](#) is implemented, [MDCR_EL2](#).TDCC for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and [MDCR_EL3](#).TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.

- [CNTKCTL_EL1](#).{ELOPTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [PMUSERENR_EL0](#).{ER, CR, SW, EN}, for accesses to the Performance Monitor registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [AMUSERENR_EL0](#).EN, for accesses to Activity Monitors registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [HCR_EL2](#).{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TDZ, for execution of DC ZVA instructions using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TTLB, for execution of TLB maintenance instructions using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{TSW, TPC, TPU}, for execution of cache maintenance instructions using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TACR, for accesses to the Auxiliary Control Register, [ACTLR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{TID1, TID2, TID3}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TCPAC, for accesses to [CPACR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TTA, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TTRF, for accesses to the trace filter control register, [TRFCR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDOSA, for accesses to powerdown debug registers using AArch64 state, MSR or MRS access trapped to EL2.
- [CNTHCTL_EL2](#).{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDA, for accesses to debug registers using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).{TPM, TPMCR}, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).APK, for accesses to Pointer authentication key registers. using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{NV, NV1}, for Nested virtualization register access, using AArch64 state, MSR or MRS access, trapped to EL2.
- [HCR_EL2](#).AT, for execution of AT S1E* instructions, using AArch64 state, MSR or MRS access, trapped to EL2.

- [HCR_EL2](#).{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.
- [SCR_EL3](#).APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [SCR_EL3](#).ST, for accesses to the Counter-timer Physical Secure timer registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [SCR_EL3](#).{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [CPTR_EL3](#).TCPAC, for accesses to [CPTR_EL2](#) and [CPACR_EL1](#) using AArch64 state, MSR or MRS access trapped to EL3.
- [CPTR_EL3](#).TTA, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [MDCR_EL3](#).TTRF, for accesses to the trace filter control registers, [TRFCR_EL1](#) and [TRFCR_EL2](#), using AArch64 state, MSR or MRS access trapped to EL3.
- [MDCR_EL3](#).TDA, for accesses to debug registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [MDCR_EL3](#).TDOSA, for accesses to powerdown debug registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [MDCR_EL3](#).TPM, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [CPTR_EL3](#).TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access, trapped to EL3.
- If [FEAT_EVT](#) is implemented, the following registers control traps for EL1 and EL0 Cache controls that use this EC value:
 - [HCR_EL2](#).{TTLBOS, TTLBIS, TICAB, TOCU, TID4}.
 - [HCR2](#).{TTLBIS, TICAB, TOCU, TID4}.
- If [FEAT_FGT](#) is implemented:
 - [SCR_EL3](#).FGTE_n, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
 - [HFGRTR_EL2](#) for reads and [HFGWTR_EL2](#) for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 trapped to EL2.
 - [HFGITR_EL2](#) for execution of system instructions, MSR or MRS access trapped to EL2
 - [HDFGRTR_EL2](#) for reads and [HDFGWTR_EL2](#) for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 state trapped to EL2.
 - [HAFGRTR_EL2](#) for reads of Activity Monitor counters, using AArch64 state, MRS access at EL0 and EL1 trapped to EL2.

ISS encoding for an IMPLEMENTATION DEFINED exception to EL3

IMPLEMENTATION DEFINED, bits [24:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from an Instruction Abort

Bits [24:13]

Reserved, RES0.

SET, bits [12:11]

When FEAT_RAS is implemented:

SET

Synchronous Error Type. When IFSC is 0b010000, describes the PE error state after taking the Instruction Abort exception.

0b00 Recoverable state (UER).

0b10 Uncontainable (UC).

0b11 Restartable state (UEO).

All other values are reserved.

———— Note ————

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in a PE state that is not recoverable.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 FAR is valid.

0b1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.

0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

0b000000 Address size fault, level 0 of translation or translation table base register.

0b000001 Address size fault, level 1.

0b000010 Address size fault, level 2.

0b000011 Address size fault, level 3.

0b000100 Translation fault, level 0.

0b000101 Translation fault, level 1.

0b000110 Translation fault, level 2.

0b000111 Translation fault, level 3.

0b001001 Access flag fault, level 1.

0b001010 Access flag fault, level 2.

0b001011 Access flag fault, level 3.

0b001000 *When FEAT_LPA2 is implemented:*

Access flag fault, level 0.

0b001100 *When FEAT_LPA2 is implemented:*

Permission fault, level 0.

0b001101 Permission fault, level 1.

0b001110 Permission fault, level 2.

0b001111 Permission fault, level 3.

0b010000 Synchronous External abort, not on translation table walk or hardware update of translation table.

0b010011 *When FEAT_LPA2 is implemented:*

Synchronous External abort on translation table walk or hardware update of translation table, level -1.

0b010100 Synchronous External abort on translation table walk or hardware update of translation table, level 0.

0b010101 Synchronous External abort on translation table walk or hardware update of translation table, level 1.

0b010110 Synchronous External abort on translation table walk or hardware update of translation table, level 2.

0b010111 Synchronous External abort on translation table walk or hardware update of translation table, level 3.

- 0b011000 *When FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access, not on translation table walk.
- 0b011011 *When FEAT_LPA2 is implemented and FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.
- 0b011100 *When FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.
- 0b011101 *When FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.
- 0b011110 *When FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.
- 0b011111 *When FEAT_RAS is not implemented:*
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.
- 0b101001 *When FEAT_LPA2 is implemented:*
Address size fault, level -1.
- 0b101011 *When FEAT_LPA2 is implemented:*
Translation fault, level -1.
- 0b110000 TLB conflict abort.
- 0b110001 *When FEAT_HAFDBS is implemented:*
Unsupported atomic hardware update fault.

All other values are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on page D5-2806](#).

————— Note —————

Because Access flag faults and Permission faults can result only from a Block or Page translation table descriptor, they cannot occur at level 0.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a Data Abort

When FEAT_LS64 is implemented, if a memory access generated by an ST64BV or ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this ISS encoding includes ISS2, bits[36:32].

ISV, bit [24]

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] is valid.

- 0b0 No valid instruction syndrome. ISS[23:14] are RES0.

0b1 ISS[23:14] hold a valid instruction syndrome.

In ESR_EL2, ISV is 1 when FEAT_LS64 is implemented and a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

For other faults reported in ESR_EL2, ISV is 0 except for the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).
- AArch32 instructions where the instruction:
 - Is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
 - Is not performing register writeback.
 - Is not using R15 as a source or destination register.

For these stage 2 aborts, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

For faults reported in ESR_EL1 or ESR_EL3, ISV is 1 when FEAT_LS64 is implemented and a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault. ISV is 0 for all other faults reported in ESR_EL1 or ESR_EL3.

When FEAT_RAS is implemented, ISV is 0 for any synchronous External abort.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

When FEAT_MTE is implemented, for a synchronous Tag Check Fault abort taken to ELx, ESR_ELx.FNV is 0 and FAR_ELx is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == 1:

SAS

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

0b00 Byte
0b01 Halfword
0b10 Word
0b11 Doubleword

When FEAT_LS64 is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0b11.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSE, bit [21]

When ISV == 1:

SSE

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

0b0 Sign-extension not required.

0b1 Data item must be sign-extended.

When [FEAT_LS64](#) is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SRT, bits [20:16]

When ISV == 1:

SRT

Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

If the exception was taken from an Exception level that is using AArch32, then this is the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SF, bit [15]

When ISV == 1:

SF

Width of the register accessed by the instruction is Sixty-Four.

0b0 Instruction loads/stores a 32-bit wide register.

0b1 Instruction loads/stores a 64-bit wide register.

———— **Note** ————

This field specifies the register width identified by the instruction, not the Execution state.

When [FEAT_LS64](#) is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AR, bit [14]

When ISV == 1:

AR

Acquire/Release.

0b0 Instruction did not have acquire/release semantics.

0b1 Instruction did have acquire/release semantics.

When [FEAT_LS64](#) is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VNCR, bit [13]

When FEAT_NV2 is implemented:

VNCR

Indicates that the fault came from use of [VNCR_EL2](#) register by EL1 code.

0b0 The fault was not generated by the use of [VNCR_EL2](#), by an MRS or MSR instruction executed at EL1.

0b1 The fault was generated by the use of [VNCR_EL2](#), by an MRS or MSR instruction executed at EL1.

This field is 0 in ESR_EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits[12:11]

When FEAT_RAS is implemented and FEAT_LS64 is not implemented:

SET

Synchronous Error Type. When DFSC is 0b010000, describes the PE error state after taking the Data Abort exception.

0b00 Recoverable state (UER).

0b10 Uncontainable (UC).

0b11 Restartable state (UEO).

All other values are reserved.

———— **Note** ————

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in a PE state that is not recoverable.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_LS64 is implemented:

LST

Load/Store Type. Used when an LD64B, ST64B, ST64BV, or ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

0b01 An ST64BV instruction generated the Data Abort.

0b10 An LD64B or ST64B instruction generated the Data Abort.

0b11 An ST64BV0 instruction generated the Data Abort.

All other values are reserved.

This field is valid only if the DFSC code is 0b110101. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 FAR is valid.

0b1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

0b0 The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.

0b1 The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The **DC ZVA**, **DC GVA**, and **DC GZVA** instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SIPTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.

0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

0b0 Abort caused by an instruction reading from a memory location.

0b1 Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101 or 0b110001, indicating an unsupported Exclusive or atomic access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

0b000000 Address size fault, level 0 of translation or translation table base register.

0b000001 Address size fault, level 1.

0b000010 Address size fault, level 2.

0b000011 Address size fault, level 3.

0b000100 Translation fault, level 0.

0b000101 Translation fault, level 1.

0b000110 Translation fault, level 2.

0b000111 Translation fault, level 3.

0b001001 Access flag fault, level 1.

0b001010 Access flag fault, level 2.

0b001011 Access flag fault, level 3.

0b001000 *When FEAT_LPA2 is implemented:*
Access flag fault, level 0.

0b001100 *When FEAT_LPA2 is implemented:*
Permission fault, level 0.

0b001101	Permission fault, level 1.
0b001110	Permission fault, level 2.
0b001111	Permission fault, level 3.
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.
0b010001	<i>When FEAT_MTE2 is implemented:</i> Synchronous Tag Check Fault.
0b010011	<i>When FEAT_LPA2 is implemented:</i> Synchronous External abort on translation table walk or hardware update of translation table, level -1.
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.
0b011000	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access, not on translation table walk.
0b011011	<i>When FEAT_LPA2 is implemented and FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.
0b011100	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.
0b011101	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.
0b011110	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.
0b011111	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.
0b100001	Alignment fault.
0b101001	<i>When FEAT_LPA2 is implemented:</i> Address size fault, level -1.
0b101011	<i>When FEAT_LPA2 is implemented:</i> Translation fault, level -1.
0b110000	TLB conflict abort.
0b110001	<i>When FEAT_HAFDBS is implemented:</i> Unsupported atomic hardware update fault.
0b110100	IMPLEMENTATION DEFINED fault (Lockdown).
0b110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).

All other values are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on page D5-2806](#).

———— **Note** ————

Because Access flag faults and Permission faults can result only from a Block or Page translation table descriptor, they cannot occur at level 0.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception

Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

- 0b0 The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
- 0b1 One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see [Floating-point exceptions and exception traps on page D1-2495](#).

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

———— **Note** ————

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Input denormal floating-point exception has not occurred.
- 0b1 Input denormal floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Inexact floating-point exception has not occurred.
- 0b1 Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Underflow floating-point exception has not occurred.
- 0b1 Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Overflow floating-point exception has not occurred.
- 0b1 Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Divide by Zero floating-point exception has not occurred.
- 0b1 Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0 Invalid Operation floating-point exception has not occurred.

0b1 Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the **FPCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the **FPSCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for an SError interrupt

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

0b0 Bits [23:0] of the ISS field holds the fields described in this encoding.

Note

If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.

0b1 Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError interrupt.

Note

This field was previously called ISV.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:14]

Reserved, RES0.

IESB, bit [13]

When FEAT_IESB is implemented:

IESB

Implicit error synchronization event.

0b0 The SError interrupt was either not synchronized by the implicit error synchronization event or not taken immediately.

0b1 The SError interrupt was synchronized by the implicit error synchronization event and taken immediately.

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other errors.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AET, bits [12:10]

When FEAT_RAS is implemented:

AET

Asynchronous Error Type.

When DFSC is 0b010001, describes the PE error state after taking the SError interrupt exception.

0b000 Uncontainable (UC).

0b001 Unrecoverable state (UEU).

0b010 Restartable state (UEO).

0b011 Recoverable state (UER).

0b110 Corrected (CE).

All other values are reserved.

If multiple errors are taken as a single SError interrupt exception, the overall PE error state is reported.

———— **Note** —————

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other errors.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented:

EA

External abort type. When DFSC is 0b010001, provides an IMPLEMENTATION DEFINED classification of External aborts.

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other errors.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:

DFSC

Data Fault Status Code.

0b000000 Uncategorized error.

0b010001 Asynchronous SError interrupt.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

0b100010 Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions:

- For exceptions from AArch64, see [Breakpoint exceptions on page D2-2579](#).
- For exceptions from AArch32, see [Breakpoint exceptions on page G2-6170](#) and [Vector Catch exceptions on page G2-6209](#).

ISS encoding for an exception from a Software Step exception

ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

0b0 EX bit is RES0.

0b1 EX bit is valid.

See the EX bit description for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

0b0 An instruction other than a Load-Exclusive instruction was stepped.

0b1 A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]

Instruction Fault Status Code.

0b100010 Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Software Step exceptions* on page D2-2613.

ISS encoding for an exception from a Watchpoint exception

Bits [24:15]

Reserved, RES0.

Bit [14]

Reserved, RES0.

VNCR, bit [13]

When FEAT_NV2 is implemented:

VNCR

Indicates that the watchpoint came from use of [VNCR_EL2](#) register by EL1 code.

0b0 The watchpoint was not generated by the use of [VNCR_EL2](#) by EL1 code.

0b1 The watchpoint was generated by the use of [VNCR_EL2](#) by EL1 code.

This field is 0 in [ESR_EL1](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [12:9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance or address translation instruction:

0b0 The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.

0b1 The Watchpoint exception was generated by either the execution of a cache maintenance instruction or by a synchronous Watchpoint exception on the execution of an address translation instruction. The [DC ZVA](#), [DC GVA](#), and [DC GZVA](#) instructions are not classified as a cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

0b0 Watchpoint exception caused by an instruction reading from a memory location.

0b1 Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance and address translation instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

0b100010 Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see [Watchpoint exceptions on page D2-2598](#).

ISS encoding for an exception from execution of a Breakpoint instruction

Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

For the AArch32 BKPT instructions, the comment field is described as the immediate field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see [Breakpoint Instruction exceptions on page D2-2577](#).

ISS encoding for an exception from an ERET, ERETA, or ERETA instruction

This EC value applies when [FEAT_FGT](#) is implemented, or when [HCR_EL2.NV](#) is 1.

Bits [24:2]

Reserved, RES0.

ERET, bit [1]

Indicates whether an ERET or ERETA* instruction was trapped to EL2.

0b0 ERET instruction trapped to EL2.

0b1 ERETAA or ERETAB instruction trapped to EL2.

If this bit is 0, the ERETA field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ERETA, bit [0]

Indicates whether an ERETAA or ERETAB instruction was trapped to EL2.

0b0 ERETAA instruction trapped to EL2.

0b1 ERETAB instruction trapped to EL2.

When the ERET field is 0, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see [HCR_EL2.NV](#).

If [FEAT_FGT](#) is implemented, [HFGITR_EL2.ERET](#) controls fine-grained trap exceptions from ERET, ERETAA and ERETAB execution.

ISS encoding for an exception from Branch Target Identification instruction

Bits [24:2]

Reserved, RES0.

BTYPE, bits [1:0]

This field is set to the PSTATE.BTYPE value that generated the Branch Target Exception.

For more information about generating these exceptions, see [Chapter B1 The AArch64 Application Level Programmers' Model](#).

ISS encoding for an exception from a Pointer Authentication instruction when [HCR_EL2.API](#) == 0 || [SCR_EL3.API](#) == 0

Bits [24:0]

Reserved, RES0.

For more information about generating these exceptions, see:

- [HCR_EL2.API](#), for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL2.
- [SCR_EL3.API](#), for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL3.

ISS encoding for an exception from a Pointer Authentication instruction authentication failure

Bits [24:2]

Reserved, RES0.

Bit [1]

This field indicates whether the exception is as a result of an Instruction key or a Data key.

0b0 Instruction Key.

0b1 Data Key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

This field indicates whether the exception is as a result of an A key or a B key.

0b0 A key.

0b1 B key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following instructions generate an exception when the Pointer Authentication Code (PAC) is incorrect:

- AUTIASP, AUTIAZ, AUTIA1716.
- AUTIBSP, AUTIBZ, AUTIB1716.
- AUTIA, AUTDA, AUTIB, AUTDB.
- AUTIZA, AUTIZB, AUTDZA, AUTDZB.

It is IMPLEMENTATION DEFINED whether the following instructions generate an exception directly from the authorization failure, rather than changing the address in a way that will generate a Translation fault when the address is accessed:

- RETAA, RETAB.
- BRAA, BRAB, BLRAA, BLRAB.
- BRAAZ, BRABZ, BLRAAZ, BLRABZ.
- ERETA, ERETA.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.

Accessing ESR_EL2

When `HCR_EL2.E2H` is 1, without explicit synchronization, access from EL2 using the mnemonic `ESR_EL2` or `ESR_EL1` are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ESR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
        return ESR_EL1;
    elseif EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    return ESR_EL2;
elseif PSTATE.EL == EL3 then
    return ESR_EL2;

```

MSR ESR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
        ESR_EL1 = X[t];
    elseif EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    ESR_EL2 = X[t];
elseif PSTATE.EL == EL3 then
    ESR_EL2 = X[t];

```

MRS <Xt>, ESR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0010	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then

```

```

if EL2Enabled() && HCR_EL2.TRVM == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
elseif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGTR_EL2.ESR_EL1 == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
elseif EL2Enabled() && HCR_EL2.<NV2,NV1,NV> == '111' then
    return NVMem[0x138];
else
    return ESR_EL1;
elseif PSTATE.EL == EL2 then
    if HCR_EL2.E2H == '1' then
        return ESR_EL2;
    else
        return ESR_EL1;
elseif PSTATE.EL == EL3 then
    return ESR_EL1;

```

MSR ESR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0010	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGWTR_EL2.ESR_EL1 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && HCR_EL2.<NV2,NV1,NV> == '111' then
        NVMem[0x138] = X[t];
    else
        ESR_EL1 = X[t];
elseif PSTATE.EL == EL2 then
    if HCR_EL2.E2H == '1' then
        ESR_EL2 = X[t];
    else
        ESR_EL1 = X[t];
elseif PSTATE.EL == EL3 then
    ESR_EL1 = X[t];

```

D13.2.39 ESR_EL3, Exception Syndrome Register (EL3)

The ESR_EL3 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL3.

Configurations

This register is present only when EL3 is implemented. Otherwise, direct accesses to ESR_EL3 are UNDEFINED.

Attributes

ESR_EL3 is a 64-bit register.

Field descriptions

ESR_EL3 is made UNKNOWN as a result of an exception return from EL3.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL3, the value of ESR_EL3 is UNKNOWN. The value written to ESR_EL3 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

Bits [63:37]

Reserved, RES0.

ISS2, bits [36:32]**When FEAT_LS64 is implemented:**

ISS2

If a memory access generated by an ST64BV or ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field holds register specifier, Xs.

For any other Data Abort, this field is RES0.

Otherwise:

Reserved, RES0.

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

EC == 0b000000

Unknown reason.

See [ISS encoding for exceptions with an unknown reason](#).

EC == 0b000001

Trapped WF* instruction execution.

Conditional WF* instructions that fail their condition code check do not cause an exception.

See [ISS encoding for an exception from a WF* instruction](#).

EC == 0b000011

When AArch32 is supported at EL0:

Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC 0b000000.

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 0b000100

When AArch32 is supported at EL0:

Trapped MCRR or MRRC access with (coproc==0b1111) that is not reported using EC 0b000000.

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 0b000101

When AArch32 is supported at EL0:

Trapped MCR or MRC access with (coproc==0b1110).

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 0b000110

When AArch32 is supported at EL0:

Trapped LDC or STC access.

The only architected uses of these instruction are:

- An STC to write data to memory from [DBGDTRRXint](#).
- An LDC to read data from memory to [DBGDTRTXint](#).

See [ISS encoding for an exception from an LDC or STC instruction](#).

EC == 0b000111

Access to SVE, Advanced SIMD or floating-point functionality trapped by [CPACR_EL1.FPEN](#), [CPTR_EL2.FPEN](#), [CPTR_EL2.TFP](#), or [CPTR_EL3.TFP](#) control. Excludes exceptions resulting from [CPACR_EL1](#) when the value of [HCR_EL2.TGE](#) is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000 as described in [The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1](#) on page D1-2483.

See [ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from the FPEN and TFP traps](#).

EC == 0b001001

When FEAT_PAuth is implemented:

Trapped use of a Pointer authentication instruction because [HCR_EL2.API](#) == 0 || [SCR_EL3.API](#) == 0.

See [ISS encoding for an exception from a Pointer Authentication instruction when HCR_EL2.API == 0 || SCR_EL3.API == 0](#).

EC == 0b001010

When FEAT_LS64 is implemented:

Trapped execution of an LD64B, ST64B, ST64BV, or ST64BV0 instruction.

See [ISS encoding for an exception from an LD64B or ST64B* instruction](#).

EC == 0b001100

When AArch32 is supported at EL0:

Trapped MRRC access with (coproc==0b1110).

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 0b001101

When FEAT_BTI is implemented:

Branch Target Exception.

See [ISS encoding for an exception from Branch Target Identification instruction](#).

EC == 0b001110

Illegal Execution state.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

EC == 0b010011

When AArch32 is supported at EL0:

SMC instruction execution in AArch32 state, when SMC is not disabled.

See [ISS encoding for an exception from SMC instruction execution in AArch32 state](#).

EC == 0b010101

When AArch64 is supported at the highest implemented Exception level:

SVC instruction execution in AArch64 state.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 0b010110

When AArch64 is supported at the highest implemented Exception level:

HVC instruction execution in AArch64 state, when HVC is not disabled.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 0b010111

When AArch64 is supported at the highest implemented Exception level:

SMC instruction execution in AArch64 state, when SMC is not disabled.

See [ISS encoding for an exception from SMC instruction execution in AArch64 state](#).

EC == 0b011000

When AArch64 is supported at the highest implemented Exception level:

Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC 0b000000, 0b000001 or 0b000111.

This includes all instructions that cause exceptions that are part of the encoding space defined in [System instruction class encoding overview](#) on page C5-395, except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.

See [ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state](#).

EC == 0b011001

When FEAT_SVE is implemented:

Access to SVE functionality trapped as a result of CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ, that is not reported using EC 0b000000.

See [ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ](#).

EC == 0b011100

When FEAT_FPAC is implemented:

Exception from a Pointer Authentication instruction authentication failure

See [ISS encoding for an exception from a Pointer Authentication instruction authentication failure](#).

EC == 0b011111

IMPLEMENTATION DEFINED exception to EL3.

See [ISS encoding for an IMPLEMENTATION DEFINED exception to EL3](#).

EC == 0b100000

Instruction Abort from a lower Exception level.

Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from an Instruction Abort](#).

EC == 0b100001

Instruction Abort taken without a change in Exception level.

Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from an Instruction Abort](#).

EC == 0b100010

PC alignment fault exception.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

EC == 0b100100

Data Abort from a lower Exception level.

Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from a Data Abort](#).

EC == 0b100101

Data Abort taken without a change in Exception level.

Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See [ISS encoding for an exception from a Data Abort](#).

EC == 0b100110

SP alignment fault exception.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

EC == 0b101100

When AArch64 is supported at the highest implemented Exception level:

Trapped floating-point exception taken from AArch64 state.

This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.

See [ISS encoding for an exception from a trapped floating-point exception](#).

EC == 0b101111

SError interrupt.

See [ISS encoding for an SError interrupt](#).

EC == 0b111100

When AArch64 is supported at the highest implemented Exception level:

BRK instruction execution in AArch64 state.

This is reported in [ESR_EL3](#) only if a BRK instruction is executed in EL3. This is the only debug exception that can be taken to EL3 when EL3 is using AArch64.

See [ISS encoding for an exception from execution of a Breakpoint instruction](#).

All other EC values are reserved by Arm, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

0b0 16-bit instruction trapped.
0b1 32-bit instruction trapped. This value is also used when the exception is one of the following:

- An SError interrupt.
- An Instruction Abort exception.
- A PC alignment fault exception.
- An SP alignment fault exception.
- A Data Abort exception for which the value of the ISV bit is 0.
- An Illegal Execution state exception.
- Any debug exception except for Breakpoint instruction exceptions.
- An exception reported using EC value 0b000000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

For an exception taken from AArch32 state, see [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

If the AArch32 register descriptor is 0b1111, then:

- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
 - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
 - The value 0b11111.

ISS encoding for exceptions with an unknown reason

Bits [24:0]

Reserved, RES0.

When an exception is reported using this EC code the IL field is set to 1.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
 - A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
 - A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
 - Instruction encodings that are unallocated.
 - Instruction encodings for instructions or System registers that are not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the [SCTLR_EL1](#). {ITD, SED, CP15BEN} control bits.
- Attempted execution of:
 - An HVC instruction when disabled by [HCR_EL2.HCD](#) or [SCR_EL3.HCE](#).
 - An SMC instruction when disabled by [SCR_EL3.SMD](#).
 - An HLT instruction when disabled by [EDSCR.HDE](#).
- Attempted execution of an MSR or MRS instruction to access [SP_EL0](#) when the value of [SPSel.SP](#) is 0.
- Attempted execution of an MSR or MRS instruction using a [_EL12](#) register name when [HCR_EL2.E2H](#) == 0.
- Attempted execution, in Debug state, of:
 - A DCPS1 instruction when the value of [HCR_EL2.TGE](#) is 1 and EL2 is disabled or not implemented in the current Security state.
 - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
 - A DCPS3 instruction when the value of [EDSCR.SDD](#) is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using [R13_mon](#). See [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2530](#).
- In Debug state when the value of [EDSCR.SDD](#) is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to [SPSR_mon](#), [SP_mon](#), or [LR_mon](#).
- An exception that is taken to EL2 because the value of [HCR_EL2.TGE](#) is 1 that, if the value of [HCR_EL2.TGE](#) was 0 would have been reported with an [ESR_ELx.EC](#) value of `0b000111`.

ISS encoding for an exception from a WF* instruction

CV, bit [24]

Condition code valid.

0b0 The COND field is not valid.

0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:10]

Reserved, RES0.

RN, bits [9:5]

When FEAT_WFxT2 is implemented:

RN

Indicates the Register Number supplied for a WFET or WFIT instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [4:3]

Reserved, RES0.

RV, bit [2]

When FEAT_WFxT2 is implemented:

RV

Register field Valid.

If $TI[1] = 1$, then this field indicates whether RN holds a valid register number for the register argument to the trapped WFET or WFIT instruction.

0b0 Register field invalid.

0b1 Register field valid.

If $TI[1] = 0$, then this field is RES0.

When FEAT_WFxT2 is implemented, RV is set to 1 on a trap on WFET or WFIT.

When FEAT_WFxT2 is not implemented, RV is set to 0 on a trap on WFET or WFIT.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

0b00 WFI trapped.

0b01 WFE trapped.

0b10 *When FEAT_WFxT is implemented:*
WFIT trapped.

0b11 *When FEAT_WFxT is implemented:*
WFET trapped.

When FEAT_WFxT is implemented, this is a two bit field as shown. Otherwise, bit[1] is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating this exception:

- [SCTLR_EL1](#).{nTWE, nTWI}.
- [HCR_EL2](#).{TWE, TWI}.
- [SCR_EL3](#).{TWE, TWI}.

ISS encoding for an exception from an MCR or MRC access

CV, bit [24]

Condition code valid.

0b0 The COND field is not valid.

0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value 0b000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value 0b111.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

If the Rt value is not 0b1111, then the reported value gives the AArch64 view of the register.

Otherwise, if the Rt value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states](#) on page D1-2546.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value 0b0000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write to System register space. MCR instruction.

0b1 Read from System register space. MRC or VMRS instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000011:

- [CNTKCTL_EL1](#). {ELOPTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [PMUSERENR_EL0](#). {ER, CR, SW, EN}, for accesses to Performance Monitor registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- [AMUSERENR_EL0](#). EN, for accesses to Activity Monitors registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.

- [HCR_EL2](#).{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).TTLB, for execution of TLB maintenance instructions at EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).{TSW, TPC, TPU} for execution of cache maintenance instructions at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).TACR, for accesses to the Auxiliary Control Register at EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).TIDCP, for accesses to lockdown, DMA, and TCM operations at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HCR_EL2](#).{TID1, TID2, TID3}, for accesses to ID registers at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL2](#).TCPAC, for accesses to [CPACR_EL1](#) or [CPACR](#) using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [HSTR_EL2](#).T<n>, for accesses to System registers using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CNTHCTL_EL2](#).EL1PCEN, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [MDCR_EL2](#).{TPM, TPMCR}, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL2](#).TAM, for accesses to Activity Monitors registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- [CPTR_EL3](#).TCPAC, for accesses to [CPACR](#) from EL1 and EL2, and accesses to [HCPTR](#) from EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.
- [MDCR_EL3](#).TPM, for accesses to Performance Monitor registers from EL0, EL1 and EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.
- [CPTR_EL3](#).TAM, for accesses to Activity Monitors registers from EL0, EL1 and EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.
- For information on other traps using EC value 0b000011, see [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32](#) on page D1-2530.
- If [FEAT_FGT](#) is implemented, MCR or MRC access to some registers at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000101:

- [CPACR_EL1](#).TTA for accesses to trace registers, MCR or MRC access (coproc == 0b1110) trapped to EL1 or EL2.
- [MDCR_EL1](#).TDCC, for accesses to the Debug Communications Channel (DCC) registers at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL1 or EL2.
- If [FEAT_FGT](#) is implemented, [MDCR_EL2](#).TDCC for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and [MDCR_EL3](#).TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.
- [HCR_EL2](#).TID0, for accesses to the [JIDR](#) register in the ID group 0 at EL0 and EL1 using AArch32, MRC access (coproc == 0b1110) trapped to EL2.
- [CPTR_EL2](#).TTA, for accesses to trace registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL2.

- **MDCR_EL2.TDRA**, for accesses to Debug ROM registers **DBGDRAR** and **DBGDSAR** using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **MDCR_EL2.TDOSA**, for accesses to powerdown debug registers, using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **MDCR_EL2.TDA**, for accesses to other debug registers, using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL2.
- **CPTR_EL3.TTA**, for accesses to trace registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.
- **MDCR_EL3.TDOSA**, for accesses to powerdown debug registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.
- **MDCR_EL3.TDA**, for accesses to other debug registers, using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b001000:

- **HCR_EL2.TID0**, for accesses to the **FPSID** register in ID group 0 at EL1 using AArch32 state, VMRS access trapped to EL2.
- **HCR_EL2.TID3**, for accesses to registers in ID group 3 including **MVFR0**, **MVFR1** and **MVFR2**, VMRS access trapped to EL2.

ISS encoding for an exception from an LD64B or ST64B* instruction

ISS, bits [24:0]

- 0b000000000000000000000000 ST64BV instruction trapped.
 - 0b0000000000000000000000001 ST64BV0 instruction trapped.
 - 0b0000000000000000000000010 LD64B or ST64B instruction trapped.
- All other values are reserved.

ISS encoding for an exception from an MCRR or MRRC access

CV, bit [24]

- Condition code valid.
- 0b0 The COND field is not valid.
 - 0b1 The COND field is valid.
- For exceptions taken from AArch64, CV is set to 1.
- For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1.
 - When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

Rt2, bits [14:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

If the Rt2 value is not 0b1111, then the reported value gives the AArch64 view of the register.

Otherwise, if the Rt2 value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer. If the Rt value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b11111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write to System register space. MCRR instruction.

0b1 Read from System register space. MRRC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000100:

- **CNTKCTL_EL1**. {ELOPTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.
- **PMUSERENR_EL0**. {CR, EN}, for accesses to Performance Monitor registers from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.
- **AMUSERENR_EL0**. {EN}, for accesses to Activity Monitors registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.
- **HCR_EL2**. {TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- **HSTR_EL2**. T<n>, for accesses to System registers using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- **CNTHCTL_EL2**. {ELIPCEN, EL1PCTEN}, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- **MDCR_EL2**. {TPM, TPMCR}, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
- **CPTR_EL2**. TAM, for accesses to Activity Monitors registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.

- **MDCR_EL3.TPM**, for accesses to Performance Monitor registers from EL0, EL1 and EL2 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL3.
- **CPTR_EL3.TAM**, for accesses to Activity Monitors registers from EL0, EL1 and EL2 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL3.
- If **FEAT_FGT** is implemented, **HDFGRTR_EL2.PMCCNTR_EL0** for MRRC access and **HDFGWTR_EL2.PMCCNTR_EL0** for MCRR access to **PMCCNTR** at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- **MDCR_EL1.TDCC**, for accesses to the Debug ROM registers **DBGDSAR** and **DBGDRAR** at EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1110) trapped to EL1 or EL2.
- **MDCR_EL2.TDRA**, for accesses to Debug ROM registers **DBGDRAR** and **DBGDSAR** using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL2.
- **MDCR_EL3.TDA**, for accesses to debug registers, using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL3.
- **CPACR_EL1.TTA** for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL1 or EL2.
- **CPTR_EL2.TTA**, for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL2.
- **CPTR_EL3.TTA**, for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL3.

———— **Note** —————

If the Armv8-A architecture is implemented with an ETMv4 implementation, MCRR and MRRC accesses to trace registers are UNDEFINED and the resulting exception is higher priority than an exception due to these traps.

ISS encoding for an exception from an LDC or STC instruction

CV, bit [24]

Condition code valid.

0b0 The COND field is not valid.

0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

imm8, bits [19:12]

The immediate value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:10]

Reserved, RES0.

Rn, bits [9:5]

The Rn value from the issued instruction, the general-purpose register used for the transfer.

If the Rn value is not 0b1111, then the reported value gives the AArch64 view of the register.

Otherwise, if the Rn value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b1111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
 - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
 - The value 0b1111.

See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

- 0b0 Subtract offset.
- 0b1 Add offset.

This bit corresponds to the U bit in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

- 0b000 Immediate unindexed.
- 0b001 Immediate post-indexed.
- 0b010 Immediate offset.
- 0b011 Immediate pre-indexed.
- 0b100 For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
- 0b110 For a trapped STC instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONstrained UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-8423](#).

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

- 0b0 Write to memory. STC instruction.
- 0b1 Read from memory. LDC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe the configuration settings for the traps that are reported using EC value 0b000110:

- [MDSCR_EL1](#).TDCC, for accesses using AArch32 state, LDC access to [DBGDTRTXint](#) or STC access to [DBGDTRRXint](#) trapped to EL1 or EL2.
- [MDCR_EL2](#).TDA, for accesses using AArch32 state, LDC access to [DBGDTRTXint](#) or STC access to [DBGDTRRXint](#) MCR or MRC access trapped to EL2.
- [MDCR_EL3](#).TDA, for accesses using AArch32 state, LDC access to [DBGDTRTXint](#) or STC access to [DBGDTRRXint](#) MCR or MRC access trapped to EL3.
- If [FEAT_FGT](#) is implemented, [MDCR_EL2](#).TDCC for LDC and STC accesses to the DCC registers at EL0 and EL1 trapped to EL2, and [MDCR_EL3](#).TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.

ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from the FPEN and TFP traps

The accesses covered by this trap include:

- Execution of SVE or Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.

For an implementation that does not include either SVE or support for Advanced SIMD and floating-point, the exception is reported using the EC value `0b000000`.

CV, bit [24]

Condition code valid.

`0b0` The COND field is not valid.

`0b1` The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to `0b1110`, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

The following fields describe the configuration settings for the traps that are reported using EC value 0b000111:

- [CPACR_EL1.FPEN](#), for accesses to SIMD and floating-point registers trapped to EL1.
- [CPTR_EL2.FPEN](#) and [CPTR_EL2.TFP](#), for accesses to SIMD and floating-point registers trapped to EL2.
- [CPTR_EL3.TFP](#), for accesses to SIMD and floating-point registers trapped to EL3.

ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ

The accesses covered by this trap include:

- Execution of SVE instructions.
- Accesses to the SVE System registers, ZCR_ELx.

For an implementation that does not include SVE, the exception is reported using the EC value 0b000000.

Bits [24:0]

Reserved, RES0.

The following fields describe the configuration settings for the traps that are reported using EC value 0b011001:

- [CPACR_EL1.ZEN](#), for execution of SVE instructions and accesses to SVE registers at EL0 or EL1, trapped to EL1.
- [CPTR_EL2.ZEN](#) and [CPTR_EL2.TZ](#), for execution of SVE instructions and accesses to SVE registers at EL0, EL1, or EL2, trapped to EL2.
- [CPTR_EL3.EZ](#), for execution of SVE instructions and accesses to SVE registers from all Exception levels, trapped to EL3.

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

Bits [24:0]

Reserved, RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about these exceptions, see [The Illegal Execution state exception on page D1-2488](#) and [PC alignment checking on page D1-2469](#).

[SP alignment checking on page D1-2469](#) describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from HVC or SVC instruction execution

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
 - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
 - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see [SVC](#) and [HVC](#).

For A64 instructions, see [SVC](#) and [HVC](#).

If [FEAT_FGT](#) is implemented, [HFGITR_EL2](#).{SVC_EL1, SVC_EL0} control fine-grained traps on SVC execution.

ISS encoding for an exception from SMC instruction execution in AArch32 state

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from EL1 because [HCR_EL2](#).TSC is 1, the ISS encoding is as shown in the diagram.

CV, bit [24]

Condition code valid.

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

0b0 The instruction was unconditional, or was conditional and passed its condition code check.

0b1 The instruction was conditional, and might have failed its condition code check.

————— Note —————

In an implementation in which an SMC instruction that fails its code check is not trapped, this field can always return the value 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [18:0]

Reserved, RES0.

[HCR_EL2.TSC](#) describes the configuration settings for trapping SMC instructions to EL2.

[System calls on page D1-2535](#) describes the case where these exceptions are trapped to EL3.

ISS encoding for an exception from SMC instruction execution in AArch64 state

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the issued SMC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

[HCR_EL2.TSC](#) describes the configuration settings for trapping SMC from EL1 modes.

[System calls on page D1-2535](#) describes the case where these exceptions are trapped to EL3.

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

0b0 Write access, including MSR instructions.

0b1 Read access, including MRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For exceptions caused by System instructions, see *System instructions* on page C4-294 for the encoding values returned by an instruction.

The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:

- [SCTLR_EL1](#).UCI, for execution of cache maintenance instructions using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).UCT, for accesses to [CTR_EL0](#) using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).DZE, for execution of DC ZVA instructions using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [CPACR_EL1](#).TTA, for accesses to the trace registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [MDSCR_EL1](#).TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- If [FEAT_FGT](#) is implemented, [MDCR_EL2](#).TDCC for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and [MDCR_EL3](#).TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.
- [CNTKCTL_EL1](#).{ELOPTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [PMUSERENR_EL0](#).{ER, CR, SW, EN}, for accesses to the Performance Monitor registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [AMUSERENR_EL0](#).EN, for accesses to Activity Monitors registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [HCR_EL2](#).{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TDZ, for execution of DC ZVA instructions using AArch64 state, MSR or MRS access trapped to EL2.

- [HCR_EL2](#).TTLB, for execution of TLB maintenance instructions using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{TSW, TPC, TPU}, for execution of cache maintenance instructions using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TACR, for accesses to the Auxiliary Control Register, [ACTLR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{TID1, TID2, TID3}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TCPAC, for accesses to [CPACR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TTA, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TTRF, for accesses to the trace filter control register, [TRFCR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDOSA, for accesses to powerdown debug registers using AArch64 state, MSR or MRS access trapped to EL2.
- [CNTHCTL_EL2](#).{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDA, for accesses to debug registers using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).{TPM, TPMCR}, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).APK, for accesses to Pointer authentication key registers. using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{NV, NV1}, for Nested virtualization register access, using AArch64 state, MSR or MRS access, trapped to EL2.
- [HCR_EL2](#).AT, for execution of AT S1E* instructions, using AArch64 state, MSR or MRS access, trapped to EL2.
- [HCR_EL2](#).{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.
- [SCR_EL3](#).APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [SCR_EL3](#).ST, for accesses to the Counter-timer Physical Secure timer registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [SCR_EL3](#).{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access trapped to EL3.
- [CPTR_EL3](#).TCPAC, for accesses to [CPTR_EL2](#) and [CPACR_EL1](#) using AArch64 state, MSR or MRS access trapped to EL3.

- **CPTR_EL3.TTA**, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL3.
- **MDCR_EL3.TTRF**, for accesses to the trace filter control registers, **TRFCR_EL1** and **TRFCR_EL2**, using AArch64 state, MSR or MRS access trapped to EL3.
- **MDCR_EL3.TDA**, for accesses to debug registers, using AArch64 state, MSR or MRS access trapped to EL3.
- **MDCR_EL3.TDOSA**, for accesses to powerdown debug registers, using AArch64 state, MSR or MRS access trapped to EL3.
- **MDCR_EL3.TPM**, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL3.
- **CPTR_EL3.TAM**, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access, trapped to EL3.
- If **FEAT_EVT** is implemented, the following registers control traps for EL1 and EL0 Cache controls that use this EC value:
 - **HCR_EL2**. {TTLBOS, TTLBIS, TICAB, TOCU, TID4}.
 - **HCR2**. {TTLBIS, TICAB, TOCU, TID4}.
- If **FEAT_FGT** is implemented:
 - **SCR_EL3.FGTEn**, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
 - **HFGRTR_EL2** for reads and **HFGWTR_EL2** for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 trapped to EL2.
 - **HFGITR_EL2** for execution of system instructions, MSR or MRS access trapped to EL2
 - **HDFGRTR_EL2** for reads and **HDFGWTR_EL2** for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 state trapped to EL2.
 - **HAFGRTR_EL2** for reads of Activity Monitor counters, using AArch64 state, MRS access at EL0 and EL1 trapped to EL2.

ISS encoding for an IMPLEMENTATION DEFINED exception to EL3

IMPLEMENTATION DEFINED, bits [24:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from an Instruction Abort

Bits [24:13]

Reserved, RES0.

SET, bits [12:11]

When FEAT_RAS is implemented:

SET

Synchronous Error Type. When IFSC is 0b010000, describes the PE error state after taking the Instruction Abort exception.

0b00 Recoverable state (UER).

0b10 Uncontainable (UC).

0b11 Restartable state (UEO).

All other values are reserved.

———— **Note** ————

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in a PE state that is not recoverable.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 FAR is valid.

0b1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [8]

Reserved, RES0.

SIPTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.

0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

0b000000	Address size fault, level 0 of translation or translation table base register.
0b000001	Address size fault, level 1.
0b000010	Address size fault, level 2.
0b000011	Address size fault, level 3.
0b000100	Translation fault, level 0.
0b000101	Translation fault, level 1.
0b000110	Translation fault, level 2.
0b000111	Translation fault, level 3.
0b001001	Access flag fault, level 1.
0b001010	Access flag fault, level 2.
0b001011	Access flag fault, level 3.
0b001000	<i>When FEAT_LPA2 is implemented:</i> Access flag fault, level 0.
0b001100	<i>When FEAT_LPA2 is implemented:</i> Permission fault, level 0.
0b001101	Permission fault, level 1.
0b001110	Permission fault, level 2.
0b001111	Permission fault, level 3.
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.
0b010011	<i>When FEAT_LPA2 is implemented:</i> Synchronous External abort on translation table walk or hardware update of translation table, level -1.
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.
0b011000	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access, not on translation table walk.
0b011011	<i>When FEAT_LPA2 is implemented and FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.
0b011100	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.
0b011101	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.
0b011110	<i>When FEAT_RAS is not implemented:</i>

Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.

0b011111 *When FEAT_RAS is not implemented:*

Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.

0b101001 *When FEAT_LPA2 is implemented:*

Address size fault, level -1.

0b101011 *When FEAT_LPA2 is implemented:*

Translation fault, level -1.

0b110000 TLB conflict abort.

0b110001 *When FEAT_HAFDBS is implemented:*

Unsupported atomic hardware update fault.

All other values are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on page D5-2806](#).

———— **Note** ————

Because Access flag faults and Permission faults can result only from a Block or Page translation table descriptor, they cannot occur at level 0.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a Data Abort

When [FEAT_LS64](#) is implemented, if a memory access generated by an ST64BV or ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this ISS encoding includes ISS2, bits[36:32].

ISV, bit [24]

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] is valid.

- 0b0 No valid instruction syndrome. ISS[23:14] are RES0.
- 0b1 ISS[23:14] hold a valid instruction syndrome.

In ESR_EL2, ISV is 1 when [FEAT_LS64](#) is implemented and a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

For other faults reported in ESR_EL2, ISV is 0 except for the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).
- AArch32 instructions where the instruction:
 - Is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.

- Is not performing register writeback.
- Is not using R15 as a source or destination register.

For these stage 2 aborts, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

For faults reported in ESR_EL1 or ESR_EL3, ISV is 1 when FEAT_LS64 is implemented and a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault. ISV is 0 for all other faults reported in ESR_EL1 or ESR_EL3.

When FEAT_RAS is implemented, ISV is 0 for any synchronous External abort.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

When FEAT_MTE is implemented, for a synchronous Tag Check Fault abort taken to ELx, ESR_ELx.FNV is 0 and FAR_ELx is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == 1:

SAS

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

0b00	Byte
0b01	Halfword
0b10	Word
0b11	Doubleword

When FEAT_LS64 is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0b11.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSE, bit [21]

When ISV == 1:

SSE

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

0b0	Sign-extension not required.
0b1	Data item must be sign-extended.

When FEAT_LS64 is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SRT, bits [20:16]

When ISV == 1:

SRT

Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

If the exception was taken from an Exception level that is using AArch32, then this is the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states on page D1-2546](#).

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SF, bit [15]

When ISV == 1:

SF

Width of the register accessed by the instruction is Sixty-Four.

0b0 Instruction loads/stores a 32-bit wide register.

0b1 Instruction loads/stores a 64-bit wide register.

———— **Note** —————

This field specifies the register width identified by the instruction, not the Execution state.

When [FEAT_LS64](#) is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AR, bit [14]

When ISV == 1:

AR

Acquire/Release.

0b0 Instruction did not have acquire/release semantics.

0b1 Instruction did have acquire/release semantics.

When **FEAT_LS64** is implemented, if a memory access generated by an ST64BV, ST64BV0, ST64B, or LD64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VNCR, bit [13]

When FEAT_NV2 is implemented:

VNCR

Indicates that the fault came from use of **VNCR_EL2** register by EL1 code.

0b0 The fault was not generated by the use of **VNCR_EL2**, by an MRS or MSR instruction executed at EL1.

0b1 The fault was generated by the use of **VNCR_EL2**, by an MRS or MSR instruction executed at EL1.

This field is 0 in ESR_EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits[12:11]

When FEAT_RAS is implemented and FEAT_LS64 is not implemented:

SET

Synchronous Error Type. When DFSC is 0b010000, describes the PE error state after taking the Data Abort exception.

0b00 Recoverable state (UER).

0b10 Uncontainable (UC).

0b11 Restartable state (UEO).

All other values are reserved.

———— **Note** —————

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in a PE state that is not recoverable.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_LS64 is implemented:

LST

Load/Store Type. Used when an LD64B, ST64B, ST64BV, or ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

0b01 An ST64BV instruction generated the Data Abort.

0b10 An LD64B or ST64B instruction generated the Data Abort.

0b11 An ST64BV0 instruction generated the Data Abort.
All other values are reserved.
This field is valid only if the DFSC code is 0b110101. It is RES0 for all other aborts.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 FAR is valid.
0b1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

0b0 The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1 The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The **DC ZVA**, **DC GVA**, and **DC GZVA** instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SIPTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

0b0 Abort caused by an instruction reading from a memory location.

0b1 Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101 or 0b110001, indicating an unsupported Exclusive or atomic access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

0b000000 Address size fault, level 0 of translation or translation table base register.

0b000001 Address size fault, level 1.

0b000010 Address size fault, level 2.

0b000011 Address size fault, level 3.

0b000100 Translation fault, level 0.

0b000101 Translation fault, level 1.

0b000110 Translation fault, level 2.

0b000111 Translation fault, level 3.

0b001001 Access flag fault, level 1.

0b001010 Access flag fault, level 2.

0b001011 Access flag fault, level 3.

0b001000 *When FEAT_LPA2 is implemented:*
Access flag fault, level 0.

0b001100 *When FEAT_LPA2 is implemented:*
Permission fault, level 0.

0b001101 Permission fault, level 1.

0b001110 Permission fault, level 2.

0b001111 Permission fault, level 3.

0b010000 Synchronous External abort, not on translation table walk or hardware update of translation table.

0b010001 *When FEAT_MTE2 is implemented:*
Synchronous Tag Check Fault.

0b010011 *When FEAT_LPA2 is implemented:*
Synchronous External abort on translation table walk or hardware update of translation table, level -1.

0b010100 Synchronous External abort on translation table walk or hardware update of translation table, level 0.

0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.
0b011000	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access, not on translation table walk.
0b011011	<i>When FEAT_LPA2 is implemented and FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.
0b011100	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.
0b011101	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.
0b011110	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.
0b011111	<i>When FEAT_RAS is not implemented:</i> Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.
0b100001	Alignment fault.
0b101001	<i>When FEAT_LPA2 is implemented:</i> Address size fault, level -1.
0b101011	<i>When FEAT_LPA2 is implemented:</i> Translation fault, level -1.
0b110000	TLB conflict abort.
0b110001	<i>When FEAT_HAFDBS is implemented:</i> Unsupported atomic hardware update fault.
0b110100	IMPLEMENTATION DEFINED fault (Lockdown).
0b110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).

All other values are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on page D5-2806](#).

———— **Note** —————

Because Access flag faults and Permission faults can result only from a Block or Page translation table descriptor, they cannot occur at level 0.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception

Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

0b0 The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.

0b1 One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see [Floating-point exceptions and exception traps on page D1-2495](#).

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

Note

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Input denormal floating-point exception has not occurred.

0b1 Input denormal floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Inexact floating-point exception has not occurred.

0b1 Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Underflow floating-point exception has not occurred.

0b1 Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Overflow floating-point exception has not occurred.

0b1 Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZE, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Divide by Zero floating-point exception has not occurred.

0b1 Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Invalid Operation floating-point exception has not occurred.

0b1 Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the [FPCR](#).{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

- From an Exception level using AArch32, the **FPSCR**. {IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for an SError interrupt

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

0b0 Bits [23:0] of the ISS field holds the fields described in this encoding.

Note

If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.

0b1 Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError interrupt.

Note

This field was previously called ISV.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:14]

Reserved, RES0.

IESB, bit [13]

When FEAT_IESB is implemented:

IESB

Implicit error synchronization event.

0b0 The SError interrupt was either not synchronized by the implicit error synchronization event or not taken immediately.

0b1 The SError interrupt was synchronized by the implicit error synchronization event and taken immediately.

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other errors.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AET, bits [12:10]

When FEAT_RAS is implemented:

AET

Asynchronous Error Type.

When DFSC is 0b010001, describes the PE error state after taking the SError interrupt exception.

0b000 Uncontainable (UC).

0b001 Unrecoverable state (UEU).

0b010 Restartable state (UEO).
0b011 Recoverable state (UER).
0b110 Corrected (CE).

All other values are reserved.

If multiple errors are taken as a single SError interrupt exception, the overall PE error state is reported.

———— **Note** ————

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

—————

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other errors.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented:

EA

External abort type. When DFSC is 0b010001, provides an IMPLEMENTATION DEFINED classification of External aborts.

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other errors.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:

DFSC

Data Fault Status Code.

0b000000 Uncategorized error.

0b010001 Asynchronous SError interrupt.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

0b100010 Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions:

- For exceptions from AArch64, see [Breakpoint exceptions on page D2-2579](#).
- For exceptions from AArch32, see [Breakpoint exceptions on page G2-6170](#) and [Vector Catch exceptions on page G2-6209](#).

ISS encoding for an exception from a Software Step exception

ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

0b0 EX bit is RES0.

0b1 EX bit is valid.

See the EX bit description for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

0b0 An instruction other than a Load-Exclusive instruction was stepped.

0b1 A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]

Instruction Fault Status Code.

0b100010 Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see [Software Step exceptions](#) on page D2-2613.

ISS encoding for an exception from a Watchpoint exception

Bits [24:15]

Reserved, RES0.

Bit [14]

Reserved, RES0.

VNCR, bit [13]

When FEAT_NV2 is implemented:

VNCR

Indicates that the watchpoint came from use of [VNCR_EL2](#) register by EL1 code.

0b0 The watchpoint was not generated by the use of [VNCR_EL2](#) by EL1 code.

0b1 The watchpoint was generated by the use of [VNCR_EL2](#) by EL1 code.

This field is 0 in ESR_EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [12:9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance or address translation instruction:

0b0 The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.

0b1 The Watchpoint exception was generated by either the execution of a cache maintenance instruction or by a synchronous Watchpoint exception on the execution of an address translation instruction. The [DC ZVA](#), [DC GVA](#), and [DC GZVA](#) instructions are not classified as a cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

0b0 Watchpoint exception caused by an instruction reading from a memory location.

0b1 Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance and address translation instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

0b100010 Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see [Watchpoint exceptions on page D2-2598](#).

ISS encoding for an exception from execution of a Breakpoint instruction

Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

For the AArch32 BKPT instructions, the comment field is described as the immediate field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see [Breakpoint Instruction exceptions on page D2-2577](#).

ISS encoding for an exception from an ERET, ERETA, or ERETAB instruction

This EC value applies when [FEAT_FGT](#) is implemented, or when [HCR_EL2.NV](#) is 1.

Bits [24:2]

Reserved, RES0.

ERET, bit [1]

Indicates whether an ERET or ERETA* instruction was trapped to EL2.

0b0 ERET instruction trapped to EL2.

0b1 ERETAA or ERETAB instruction trapped to EL2.

If this bit is 0, the ERETA field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ERETA, bit [0]

Indicates whether an ERETAA or ERETAB instruction was trapped to EL2.

0b0 ERETAA instruction trapped to EL2.

0b1 ERETAB instruction trapped to EL2.

When the ERET field is 0, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see [HCR_EL2.NV](#).

If [FEAT_FGT](#) is implemented, [HFGITR_EL2.ERET](#) controls fine-grained trap exceptions from ERET, ERETAA and ERETAB execution.

ISS encoding for an exception from Branch Target Identification instruction

Bits [24:2]

Reserved, RES0.

BTYPED, bits [1:0]

This field is set to the PSTATE.BTYPE value that generated the Branch Target Exception.

For more information about generating these exceptions, see [Chapter B1 The AArch64 Application Level Programmers' Model](#).

ISS encoding for an exception from a Pointer Authentication instruction when $HCR_EL2.API == 0$ || $SCR_EL3.API == 0$

Bits [24:0]

Reserved, RES0.

For more information about generating these exceptions, see:

- [HCR_EL2.API](#), for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL2.
- [SCR_EL3.API](#), for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL3.

ISS encoding for an exception from a Pointer Authentication instruction authentication failure

Bits [24:2]

Reserved, RES0.

Bit [1]

This field indicates whether the exception is as a result of an Instruction key or a Data key.

0b0 Instruction Key.

0b1 Data Key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

This field indicates whether the exception is as a result of an A key or a B key.

0b0 A key.

0b1 B key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following instructions generate an exception when the Pointer Authentication Code (PAC) is incorrect:

- AUTIASP, AUTIAZ, AUTIA1716.
- AUTIBSP, AUTIBZ, AUTIB1716.
- AUTIA, AUTDA, AUTIB, AUTDB.
- AUTIZA, AUTIZB, AUTDZA, AUTDZB.

It is IMPLEMENTATION DEFINED whether the following instructions generate an exception directly from the authorization failure, rather than changing the address in a way that will generate a Translation fault when the address is accessed:

- RETAA, RETAB.
- BRAA, BRAB, BLRAA, BLRAB.
- BRAAZ, BRABZ, BLRAAZ, BLRABZ.
- ERETAA, ERETAB.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.

Accessing ESR_EL3

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ESR_EL3

op0	op1	CRn	CRm	op2
0b11	0b110	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    return ESR_EL3;
```

MSR ESR_EL3, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b110	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    ESR_EL3 = X[t];
```

D13.2.40 FAR_EL1, Fault Address Register (EL1)

The FAR_EL1 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort, PC alignment fault and Watchpoint exceptions that are taken to EL1.

Configurations

AArch64 System register FAR_EL1 bits [31:0] are architecturally mapped to AArch32 System register [DFAR](#)[31:0] (NS).

AArch64 System register FAR_EL1 bits [63:32] are architecturally mapped to AArch32 System register [IFAR](#)[31:0] (NS).

Attributes

FAR_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL1. Exceptions that set the FAR_EL1 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), PC alignment faults (EC 0x22), and Watchpoints (EC 0x34 or 0x35). [ESR_EL1](#).EC holds the EC value for the exception.

For a synchronous External abort, if the VA that generated the abort was from an address range for which [TCR_ELx](#).TBI{<0>1} = 1 for the translation regime in use when the abort was generated, then the top eight bits of FAR_EL1 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if [ESR_EL1](#).FnV is 0, and the FAR_EL1 is UNKNOWN if [ESR_EL1](#).FnV is 1.

For all other exceptions taken to EL1, the FAR_EL1 is UNKNOWN.

If a memory fault that sets FAR_EL1, other than a Tag Check Fault, is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

On an exception due to a Tag Check Fault caused by a data cache maintenance or other DC instruction, the address held in FAR_EL1 is IMPLEMENTATION DEFINED as one of the following:

- The lowest address that gave rise to the fault.
- The address specified in the register argument of the instruction as generated by MMU faults caused by [DC ZVA](#).

If the exception that updates FAR_EL1 is taken from an Exception level that is using AArch32, the top 32 bits are all zero, unless both of the following apply, in which case the top 32 bits of FAR_EL1 are 0x00000001:

- The faulting address was generated by a load or store instruction that sequentially incremented from address 0xFFFFFFFF. Such a load or store is CONSTRAINED UNPREDICTABLE.
- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see [Address tagging in AArch64 state on page D5-2676](#).

For a synchronous Tag Check Fault abort, bits[63:60] are UNKNOWN.

Execution at EL0 makes FAR_EL1 become UNKNOWN.

———— **Note** ————

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lower address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR_EL1 is made UNKNOWN on an exception return from EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FAR_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic FAR_EL1 or FAR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, FAR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b0000	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TRVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTen == '1') && HFGTR_EL2.FAR_EL1 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && HCR_EL2.<NV2,NV1,NV> == '111' then
        return NVMem[0x220];
    else
        return FAR_EL1;
elseif PSTATE.EL == EL2 then
    if HCR_EL2.E2H == '1' then
        return FAR_EL2;
    else
        return FAR_EL1;
elseif PSTATE.EL == EL3 then
    return FAR_EL1;

```

D13.2.41 FAR_EL2, Fault Address Register (EL2)

The FAR_EL2 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort, PC alignment fault and Watchpoint exceptions that are taken to EL2.

Configurations

AArch64 System register FAR_EL2 bits [31:0] are architecturally mapped to AArch32 System register [HDFAR](#)[31:0].

AArch64 System register FAR_EL2 bits [63:32] are architecturally mapped to AArch32 System register [HIFAR](#)[31:0].

AArch64 System register FAR_EL2 bits [31:0] are architecturally mapped to AArch32 System register [DFAR](#)[31:0] (S) when EL2 is implemented.

AArch64 System register FAR_EL2 bits [63:32] are architecturally mapped to AArch32 System register [IFAR](#)[31:0] (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

FAR_EL2 is a 64-bit register.

Field descriptions

Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL2. Exceptions that set the FAR_EL2 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), PC alignment faults (EC 0x22), and Watchpoints (EC 0x34 or 0x35). [ESR_EL2](#).EC holds the EC value for the exception.

For a synchronous External abort, if the VA that generated the abort was from an address range for which [TCR_ELx](#).TBI{<0|1>} = 1 for the translation regime in use when the abort was generated, then the top eight bits of FAR_EL2 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if [ESR_EL2](#).FnV is 0, and the FAR_EL2 is UNKNOWN if [ESR_EL2](#).FnV is 1.

For all other exceptions taken to EL2, the FAR_EL2 is UNKNOWN.

If a memory fault that sets FAR_EL2, other than a Tag Check Fault, is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

On an exception due to a Tag Check Fault caused by a data cache maintenance or other DC instruction, the address held in FAR_EL2 is IMPLEMENTATION DEFINED as one of the following:

- The lowest address that gave rise to the fault.
- The address specified in the register argument of the instruction as generated by MMU faults caused by [DC ZVA](#).

If the exception that updates FAR_EL2 is taken from an Exception level that is using AArch32, the top 32 bits are all zero, unless both of the following apply, in which case the top 32 bits of FAR_ELx are 0x00000001:

- The faulting address was generated by a load or store instruction that sequentially incremented from address 0xFFFFFFFF. Such a load or store instruction is CONstrained UNPREDICTABLE.
- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see [Address tagging in AArch64 state on page D5-2676](#).

For a synchronous Tag Check Fault abort, bits[63:60] are UNKNOWN.

Execution at EL1 or EL0 makes FAR_EL2 become UNKNOWN.

———— **Note** —————

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lower address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR_EL2 is made UNKNOWN on an exception return from EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FAR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic FAR_EL2 or FAR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, FAR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b0000	0b000

    elsif PSTATE.EL == EL3 then  
        FAR_EL1 = X[t];
```

D13.2.42 FAR_EL3, Fault Address Register (EL3)

The FAR_EL3 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort and PC alignment fault exceptions that are taken to EL3.

Configurations

This register is present only when EL3 is implemented. Otherwise, direct accesses to FAR_EL3 are UNDEFINED.

Attributes

FAR_EL3 is a 64-bit register.

Field descriptions

Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL3. Exceptions that set the FAR_EL3 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), and PC alignment faults (EC 0x22). [ESR_EL3.EC](#) holds the EC value for the exception.

For a synchronous External abort, if the VA that generated the abort was from an address range for which [TCR_ELx.TBI](#){<0|1>} = 1 for the translation regime in use when the abort was generated, then the top eight bits of FAR_EL3 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if [ESR_EL3.FnV](#) is 0, and the FAR_EL3 is UNKNOWN if [ESR_EL3.FnV](#) is 1.

For all other exceptions taken to EL3, the FAR_EL3 is UNKNOWN.

If a memory fault that sets FAR_EL3, other than a Tag Check Fault, is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

On an exception due to a Tag Check Fault caused by a data cache maintenance or other DC instruction, the address held in FAR_EL3 is IMPLEMENTATION DEFINED as one of the following:

- The lowest address that gave rise to the fault.
- The address specified in the register argument of the instruction as generated by MMU faults caused by [DC ZVA](#).

If the exception that updates FAR_EL3 is taken from an Exception level using AArch32, the top 32 bits are all zero, unless both of the following apply, in which case the top 32 bits of FAR_ELx are 0x00000001:

- The faulting address was generated by a load or store instruction that sequentially incremented from address 0xFFFFFFFF. Such a load or store instruction is CONSTRAINED UNPREDICTABLE.
- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see [Address tagging in AArch64 state on page D5-2676](#).

For a synchronous Tag Check Fault abort, bits[63:60] are UNKNOWN.

Execution at EL2, EL1 or EL0 makes FAR_EL3 become UNKNOWN.

———— **Note** —————

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or data abort. It is the lowest address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR_EL3 is made UNKNOWN on an exception return from EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FAR_EL3

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, FAR_EL3

op0	op1	CRn	CRm	op2
0b11	0b110	0b0110	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    return FAR_EL3;
```

MSR FAR_EL3, <Xt>

0b11	0b110	0b0110	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    FAR_EL3 = X[t];
```

D13.2.43 FPEXC32_EL2, Floating-Point Exception Control register

The FPEXC32_EL2 characteristics are:

Purpose

Allows access to the AArch32 register [FPEXC](#) from AArch64 state only. Its value has no effect on execution in AArch64 state.

Configurations

AArch64 System register FPEXC32_EL2 bits [31:0] are architecturally mapped to AArch32 System register [FPEXC](#)[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to FPEXC32_EL2 are UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

Attributes

FPEXC32_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

EX, bit [31]

Exception bit. From Armv8, this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EN, bit [30]

Enables access to the Advanced SIMD and floating-point functionality from all Exception levels, except that setting this field to 0 does not disable the following:

- VMSR accesses to the [FPEXC](#) or [FPSID](#).
- VMRS accesses from the [FPEXC](#), [FPSID](#), [MVFR0](#), [MVFR1](#), or [MVFR2](#).

0b0 Accesses to the [FPSCR](#), and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are UNDEFINED at all Exception levels.

0b1 This control permits access to the Advanced SIMD and floating-point functionality at all Exception levels.

Execution of Advanced SIMD and floating-point instructions in AArch32 state can be disabled or trapped by the following controls:

- [CPACR](#).cp10, or, if executing at EL0, [CPACR_EL1](#).FPEN.

- FPEXC.EN.
- If executing in Non-secure state:
 - [HCPTR.TCP10](#), or if EL2 is using AArch64, [CPTR_EL2.TFP](#).
 - [NSACR.cp10](#), or if EL3 is using AArch64, [CPTR_EL3.TFP](#).
- For Advanced SIMD instructions only:
 - [CPACR.ASEDIS](#).
 - If executing in Non-secure state, [HCPTR.TASE](#) and [NSACR.NSTRCDIS](#).

See the descriptions of the controls for more information.

———— **Note** —————

When executing at EL0 using AArch32:

- If EL1 is using AArch64, then the Effective value of [FPEXC.EN](#) is 1.
- If EL2 is using AArch64 and is enabled in the current Security state, [HCR_EL2.TGE](#) is 1, and the Effective value of [HCR_EL2.RW](#) is 1, then the Effective value of [FPEXC.EN](#) is 1. However, Arm deprecates using the value of [FPEXC32_EL2.EN](#) to determine behavior.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DEX, bit [29]

Defined synchronous exception on floating-point execution.

This field identifies whether a synchronous exception generated by the attempted execution of an instruction was generated by an unallocated encoding. The instruction must be in the encoding space that is identified by the pseudocode function `ExecutingCP10or11Instr()` returning TRUE. This field also indicates whether the [FPEXC32_EL2.TFV](#) field is valid.

The meaning of this bit is:

- 0b0 The exception was generated by the attempted execution of an unallocated instruction in the encoding space that is identified by the pseudocode function `ExecutingCP10or11Instr()`. If [FPEXC32_EL2.TFV](#) is RW then it is invalid and UNKNOWN. If [FPEXC32_EL2.{IDF, IXF, UFF, OFF, DZF, IOF}](#) are RW then they are invalid and UNKNOWN.
- 0b1 The exception was generated during the execution of an allocated encoding. [FPEXC32_EL2.TFV](#) is valid and indicates the cause of the exception.

On an exception that sets this bit to 1 the exception-handling routine must clear this bit to 0.

On an implementation that both does not support trapping of floating-point exceptions and implements the AArch32 [FPSCR](#).{Stride, Len} fields as RAZ, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FP2V, bit [28]

FPINST2 instruction valid bit. From Armv8, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VV, bit [27]

VECITR valid bit. From Armv8, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TFV, bit [26]

Trapped Fault Valid bit. Valid only when the value of FPEXC.DEX is 1. When valid, it indicates the cause of the exception and therefore whether the FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} bits are valid.

0b0 The exception was caused by the execution of a floating-point VABS, VADD, VDIV, VFMA, VFMS, VFNMA, VFNMS, VMLA, VMLS, VMOV, VMUL, VNEG, VNMLA, VNMLS, VNMUL, VSQRT, or VSUB instruction when one or both of FPSCR.{Stride, Len} was non-zero. If the FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} bits are RW then they are invalid and UNKNOWN.

0b1 FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} indicate the presence of trapped floating-point exceptions that had occurred at the time of the exception. Bits are set for all trapped exceptions that had occurred at the time of the exception.

This bit returns a status value and ignores writes.

When the value of FPEXC.DEX is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

On an implementation that supports the trapping of floating-point exceptions and implements FPSCR.{Stride, Len} as RAZ, this bit is RAO/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [25:11]

Reserved, RES0.

VECITR, bits [10:8]

Vector iteration count. From Armv8, this field is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

0b0 Input Denormal exception has not occurred.

0b1 Input Denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.

————— Note —————

A half-precision floating-point value that is flushed to zero because the value of FPSCR.FZ16 is 1 does not generate an Input Denormal exception.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC32_EL2.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

0b0 Inexact exception has not occurred.

0b1 Inexact exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

0b0 Underflow exception has not occurred.

0b1 Underflow exception has occurred.

Underflow trapped exceptions can occur:

- On half-precision data-processing instructions only when FPSCR.FZ16 is 0.
- Otherwise only when FPSCR.FZ is 0.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC32_EL2.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

0b0 Overflow exception has not occurred.

0b1 Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZE, bit [1]

Divide by Zero trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether a Divide by Zero exception occurred while FPSCR.DZE was 1:

0b0 Divide by Zero exception has not occurred.

0b1 Divide by Zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOF, bit [0]

Invalid Operation trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

0b0 Invalid Operation exception has not occurred.

0b1 Invalid Operation exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FPEXC32_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, FPEXC32_EL2

D13.2.44 GCR_EL1, Tag Control Register.

The GCR_EL1 characteristics are:

Purpose

Tag Control Register.

Configurations

This register is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to GCR_EL1 are UNDEFINED.

Attributes

GCR_EL1 is a 64-bit register.

Field descriptions

Bits [63:17]

Reserved, RES0.

RRND, bit [16]

Controls generation of tag values by the IRG instruction.

0b0 IRG generates a tag value as defined by RandomTag().

0b1 IRG generates an implementation-specific tag value with a distribution of tag values no worse than generated with GCR_EL1.RRND == 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Exclude, bits [15:0]

Allocation Tag values excluded from selection by ChooseNonExcludedTag().

If all bits of GCR_EL1.Exclude are 1, then the Allocation Tag value 0 will be used.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing GCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, GCR_EL1

op0	op1	CRn	CRm	op2

D13.2.45 GMID_EL1, Multiple tag transfer ID register

The GMID_EL1 characteristics are:

Purpose

Indicates the block size that is accessed by the LDGM and STGM System instructions.

Configurations

This register is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to GMID_EL1 are UNDEFINED.

Attributes

GMID_EL1 is a 64-bit register.

Field descriptions

Bits [63:4]

Reserved, RES0.

BS, bits [3:0]

Log₂ of the block size in words. The minimum supported size is 16B (value == 2) and the maximum is 256B (value == 6).

Accessing GMID_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, GMID_EL1

CRn	op0	op1	op2	CRm
0b0000	0b11	0b001	0b100	0b0000

```

D13.2.46 HACR_EL2, Hypervisor Auxiliary Control Register

The HACR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of IMPLEMENTATION DEFINED aspects of EL1 or EL0 operation.

Note

Arm recommends that the values in this register do not cause unnecessary traps to EL2 when `HCR_EL2.{E2H, TGE} == {1, 1}`.

Configurations

AArch64 System register HACR_EL2 bits [31:0] are architecturally mapped to AArch32 System register `HACR`[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

HACR_EL2 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing HACR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HACR_EL2

```

D13.2.47 HAFGRTR_EL2, Hypervisor Activity Monitors Fine-Grained Read Trap Register

The HAFGRTR_EL2 characteristics are:

Purpose

Provides controls for traps of MRS reads of Activity Monitors System registers.

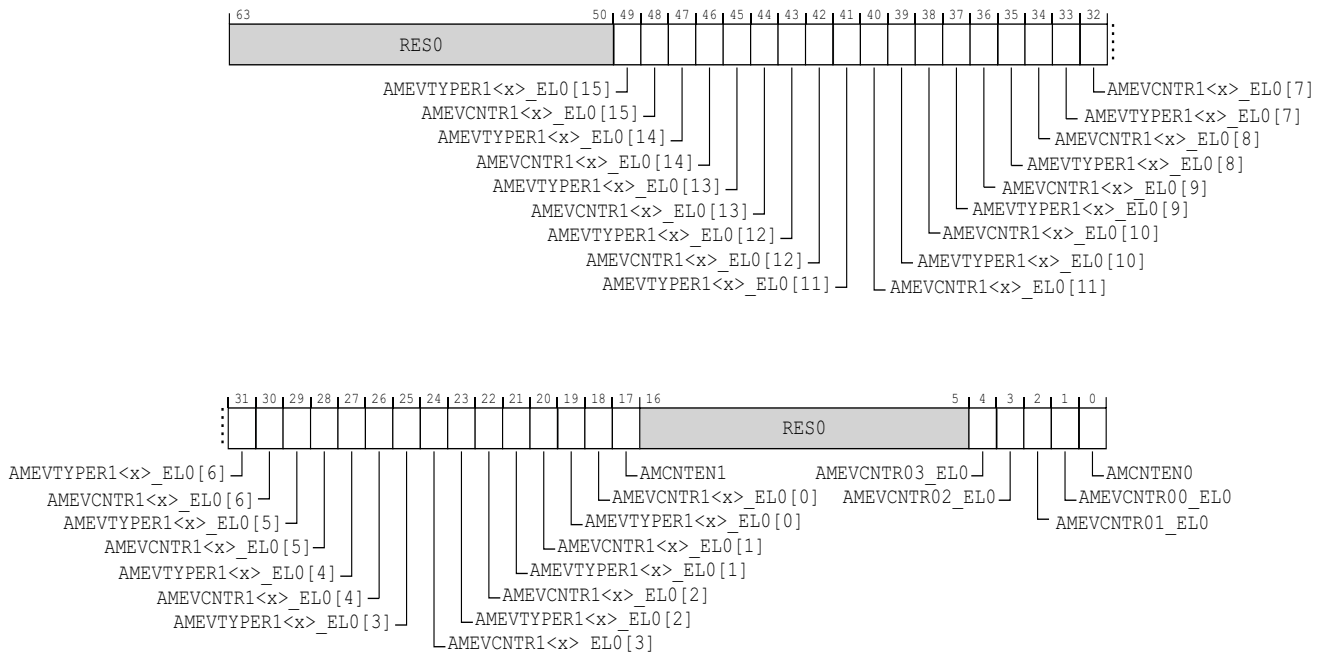

Configurations

This register is present only when FEAT_AMUv1 is implemented and FEAT_FGT is implemented. Otherwise, direct accesses to HAFGRTR_EL2 are UNDEFINED.

Attributes

HAFGRTR_EL2 is a 64-bit register.

Field descriptions

Bits [63:50]

Reserved, RES0.

AMEVTYPERR1<x>_EL0, bit [19+2x], for x = 15 to 0

When AMEVTYPERR1<x> is implemented:

AMEVTYPERR1<x>_EL0

Trap MRS reads of AMEVTYPERR1<n>_EL0 at EL1 and EL0 using AArch64 and MRC reads of AMEVTYPERR1<n> at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MRS reads of AMEVTYPERR1<n>_EL0 at EL1 and EL0 using AArch64 and MRC reads of AMEVTYPERR1<n> at EL0 using AArch32 are not trapped by this mechanism.

- 0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#). {E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the read generates a higher priority exception:
- MRS reads of [AMEVTYPER1<n>_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
 - MRC reads of [AMEVTYPER1<n>](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

AMEVCNTR1<x>_EL0, bit [18+2x], for x = 15 to 0

When AMEVCNTR1<x> is implemented:

AMEVCNTR1<x>_EL0

Trap MRS reads of [AMEVCNTR1<n>_EL0](#) at EL1 and EL0 using AArch64 and MRC reads of [AMEVCNTR1<n>](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

- 0b0 MRS reads of [AMEVCNTR1<n>_EL0](#) at EL1 and EL0 using AArch64 and MRC reads of [AMEVCNTR1<n>](#) at EL0 using AArch32 are not trapped by this mechanism.

- 0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#). {E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the read generates a higher priority exception:
- MRS reads of [AMEVCNTR1<n>_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
 - MRC reads of [AMEVCNTR1<n>](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

AMCNTEN<x>, bit [17x], for x = 1 to 0

Trap MRS reads and MRC reads of multiple System registers.

Enables a trap to EL2 the following operations:

- At EL1 and EL0 using AArch64: MRS reads of [AMCNTENCLR<x>_EL0](#) and [AMCNTENSET<x>_EL0](#).
- At EL0 using AArch32 when EL1 is using AArch64: MRC reads of [AMCNTENCLR<x>](#) and [AMCNTENSET<x>](#).

0b0 The operations listed above are not trapped by this mechanism.

- 0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#). {E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the read generates a higher priority exception:
- MRS reads at EL1 and EL0 using AArch64 of [AMCNTENCLR<x>_EL0](#) and [AMCNTENSET<x>_EL0](#) are trapped to EL2 and reported with EC syndrome value 0x18.
 - MRC reads at EL0 using AArch32 of [AMCNTENCLR<x>](#) and [AMCNTENSET<x>](#) are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Bits [16:5]

Reserved, RES0.

AMEVCNTR0<x>_EL0, bit [x+1], for x = 3 to 0

Trap MRS reads of AMEVCNTR0<n>_EL0 at EL1 and EL0 using AArch64 and MRC reads of AMEVCNTR0<n> at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MRS reads of AMEVCNTR0<n>_EL0 at EL1 and EL0 using AArch64 and MRC reads of AMEVCNTR0<n> at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, HCR_EL2.{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then, unless the read generates a higher priority exception:

- MRS reads of AMEVCNTR0<n>_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
- MRC reads of AMEVCNTR0<n> at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Accessing HAFGRTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```

D13.2.48 HCR_EL2, Hypervisor Configuration Register

The HCR_EL2 characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various operations are trapped to EL2.

Configurations

AArch64 System register HCR_EL2 bits [31:0] are architecturally mapped to AArch32 System register [HCR](#)[31:0].

AArch64 System register HCR_EL2 bits [63:32] are architecturally mapped to AArch32 System register [HCR2](#)[31:0].

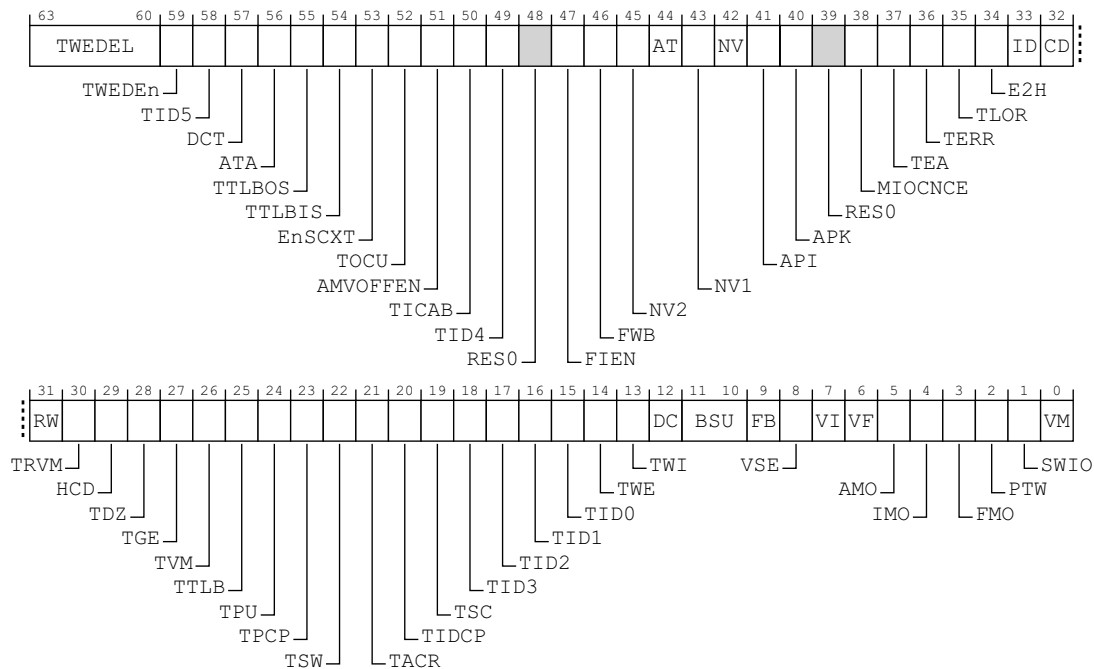

If EL2 is not implemented, this register is RES0 from EL3.

The bits in this register behave as if they are 0 for all purposes other than direct reads of the register if EL2 is not enabled in the current Security state.

Attributes

HCR_EL2 is a 64-bit register.

Field descriptions

TWEDEL, bits [63:60]

When FEAT_TWED is implemented:

TWEDEL

TWE Delay. A 4-bit unsigned number that, when HCR_EL2.TWEDEn is 1, encodes the minimum delay in taking a trap of WFE* caused by HCR_EL2.TWE as $2^{(TWEDEL + 8)}$ cycles.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TWEDEn, bit [59]

When FEAT_TWED is implemented:

TWEDEn

TWE Delay Enable. Enables a configurable delayed trap of the WFE* instruction caused by HCR_EL2.TWE.

0b0 The delay for taking the trap is IMPLEMENTATION DEFINED.

0b1 The delay for taking the trap is at least the number of cycles defined in HCR_EL2.TWEDEL.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TID5, bit [58]

When FEAT_MTE2 is implemented:

TID5

Trap ID group 5. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state:

AArch64:

- [GMID_EL1](#).

0b0 This control does not cause any instructions to be trapped.

0b1 The specified EL1 and EL0 accesses to ID group 5 registers are trapped to EL2.

When the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field has an Effective value of 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DCT, bit [57]

When FEAT_MTE2 is implemented:

DCT

Default Cacheability Tagging. When HCR_EL2.DC is in effect, controls whether stage 1 translations are treated as Tagged or Untagged.

0b0 Stage 1 translations are treated as Untagged.

0b1 Stage 1 translations are treated as Tagged.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ATA, bit [56]

When FEAT_MTE2 is implemented:

ATA

Allocation Tag Access. When HCR_EL2.{E2H,TGE} != {1,1}, controls EL1 and EL0 access to Allocation Tags.

0b0 Access to Allocation Tags is prevented. Accesses at EL1 to [GCR_EL1](#), [RGSRR_EL1](#), [TFSR_EL1](#), [TFSR_EL2](#), or [TFSRE0_EL1](#) that are not UNDEFINED are trapped to EL2.

0b1 This control does not prevent access to Allocation Tags.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TTLBOS, bit [55]

When FEAT_EVT is implemented:

TTLBOS

Trap TLB maintenance instructions that operate on the Outer Shareable domain. Traps execution of those TLB maintenance instructions at EL1 to EL2, when EL2 is enabled in the current Security state. This applies to the following instructions:

[TLBI VMALLE1IOS](#), [TLBI VMALLE1OSNXS](#), [TLBI VAE1IOS](#), [TLBI VAE1OSNXS](#), [TLBI ASIDE1IOS](#), [TLBI ASIDE1OSNXS](#), [TLBI VAAE1IOS](#), [TLBI VAAE1OSNXS](#), [TLBI VALE1IOS](#), [TLBI VALE1OSNXS](#), [TLBI VAALE1IOS](#), [TLBI VAALE1OSNXS](#), [TLBI RVAE1IOS](#), [TLBI RVAE1OSNXS](#), [TLBI RVAE1IOS](#), [TLBI RVAE1OSNXS](#), [TLBI RVALE1IOS](#), [TLBI RVALE1OSNXS](#), [TLBI RVAALE1IOS](#), [TLBI RVAALE1OSNXS](#).

0b0 This control does not cause any instructions to be trapped.

0b1 Execution of the specified instructions are trapped to EL2.

When [FEAT_VHE](#) is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TTLBIS, bit [54]

When FEAT_EVT is implemented:

TTLBIS

Trap TLB maintenance instructions that operate on the Inner Shareable domain. Traps execution of those TLB maintenance instructions at EL1 to EL2, when EL2 is enabled in the current Security state. This applies to the following instructions:

- When EL1 is using AArch64, [TLBI VMALLE1IS](#), [TLBI VMALLE1ISNXS](#), [TLBI VAE1IS](#), [TLBI VAE1ISNXS](#), [TLBI ASIDE1IS](#), [TLBI ASIDE1ISNXS](#), [TLBI VAAE1IS](#), [TLBI VAAE1ISNXS](#), [TLBI VALE1IS](#), [TLBI VALE1ISNXS](#), [TLBI VAALE1IS](#), [TLBI VAALE1ISNXS](#), [TLBI RVAE1IS](#), [TLBI RVAE1ISNXS](#), [TLBI RVAAE1IS](#), [TLBI RVAAE1ISNXS](#), [TLBI RVALE1IS](#), [TLBI RVALE1ISNXS](#), [TLBI RVAALE1IS](#), [TLBI RVAALE1ISNXS](#).
- When EL1 is using AArch32, [TLBIALLIS](#), [TLBIMVAIS](#), [TLBIASIDIS](#), [TLBIMVAAIS](#), [TLBIMVALIS](#), and [TLBIMVAALIS](#).

0b0 This control does not cause any instructions to be trapped.

0b1 Execution of the specified instructions are trapped to EL2.

When [FEAT_VHE](#) is implemented, and the value of [HCR_EL2](#).{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnSCXT, bit [53]

When [FEAT_CSV2_2](#) is implemented or [FEAT_CSV2_1p2](#) is implemented:

EnSCXT

Enable Access to the [SCXTNUM_EL1](#) and [SCXTNUM_EL0](#) registers. The defined values are:

0b0 When [HCR_EL2](#).E2H is 0 or [HCR_EL2](#).TGE is 0, and EL2 is enabled in the current Security state, EL1 and EL0 access to [SCXTNUM_EL0](#) and EL1 access to [SCXTNUM_EL1](#) is disabled by this mechanism, causing an exception to EL2, and the values of these registers to be treated as 0.

When [HCR_EL2](#).{E2H, TGE} is {1, 1} and EL2 is enabled in the current Security state, EL0 access to [SCXTNUM_EL0](#) is disabled by this mechanism, causing an exception to EL2, and the value of this register to be treated as 0.

0b1 This control does not cause accesses to [SCXTNUM_EL0](#) or [SCXTNUM_EL1](#) to be trapped.

When [FEAT_VHE](#) is implemented, and the value of [HCR_EL2](#).{E2H, TGE} is {1,1}, this bit has no effect on execution at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TOCU, bit [52]

When [FEAT_EVT](#) is implemented:

TOCU

Trap cache maintenance instructions that operate to the Point of Unification. Traps execution of those cache maintenance instructions to EL2, when EL2 is enabled in the current Security state. This applies to the following instructions:

- When [SCTLR_EL1](#).UCI is 1, [HCR_EL2](#).{TGE, E2H} is not {1, 1}, and EL0 is using AArch64, [IC IVAU](#), [DC CVAU](#).
- When EL1 is using AArch64, [IC IVAU](#), [IC IALLU](#), [DC CVAU](#).
- When EL1 is using AArch32, [ICIMVAU](#), [IC IALLU](#), [DCCMVAU](#).

———— **Note** ————

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- [IC IALLUIS](#) and [IC IALLU](#) are always UNDEFINED at EL0 using AArch64.
- [ICIMVAU](#), [IC IALLU](#), [IC IALLUIS](#), and [DCCMVAU](#) are always UNDEFINED at EL0 using AArch32.

0b0 This control does not cause any instructions to be trapped.

0b1 Execution of the specified instructions are trapped to EL2.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate to the Point of Unification instruction can be trapped when the value of this control is 1.

When [FEAT_VHE](#) is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AMVOFFEN, bit [51]

When FEAT_AMUv1p1 is implemented:

AMVOFFEN

Activity Monitors Virtual Offsets Enable.

0b0 Virtualization of the Activity Monitors is disabled. Indirect reads of the virtual offset registers are zero.

0b1 Virtualization of the Activity Monitors is enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TICAB, bit [50]

When FEAT_EVT is implemented:

TICAB

Trap ICIALLUIS/IC IALLUIS cache maintenance instructions. Traps execution of those cache maintenance instructions at EL1 to EL2, when EL2 is enabled in the current Security state. This applies to the following instructions:

- When EL1 is using AArch64, [IC IALLUIS](#).
- When EL1 is using AArch32, [ICIALLUIS](#).

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 execution of the specified instructions is trapped to EL2.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate to the Point of Unification instruction can be trapped when the value of this control is 1.

When [FEAT_VHE](#) is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TID4, bit [49]

When FEAT_EVT is implemented:

TID4

Trap ID group 4. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state:

AArch64:

- EL1 reads of [CCSIDR_EL1](#), [CCSIDR2_EL1](#), [CLIDR_EL1](#), and [CSSELR_EL1](#).
- EL1 writes to [CSSELR_EL1](#).

AArch32:

- EL1 reads of [CCSIDR](#), [CCSIDR2](#), [CLIDR](#), and [CSSELR](#).
- EL1 writes to [CSSELR](#).

0b0 This control does not cause any instructions to be trapped.

0b1 The specified EL1 and EL0 accesses to ID group 4 registers are trapped to EL2.

When [FEAT_VHE](#) is implemented, and the value of [HCR_EL2](#).{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [48]

Reserved, RES0.

FIEN, bit [47]

When FEAT_RASv1p1 is implemented:

FIEN

Fault Injection Enable. Unless this bit is set to 1, accesses to the [ERXPFPCDN_EL1](#), [ERXPFPCCTL_EL1](#), and [ERXPFPGF_EL1](#) registers from EL1 generate a Trap exception to EL2, when EL2 is enabled in the current Security state, reported using EC syndrome value 0x18.

0b0 Accesses to the specified registers from EL1 are trapped to EL2, when EL2 is enabled in the current Security state.

0b1 This control does not cause any instructions to be trapped.

If EL2 is disabled in the current Security state, the Effective value of [HCR_EL2](#).FIEN is 0b1.

If [ERRIDR_EL1](#).NUM is zero, meaning no error records are implemented, or no error record accessible using System registers is owned by a node that implements the RAS Common Fault Injection Model Extension, then this bit might be RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FWB, bit [46]

When FEAT_S2FWB is implemented:

FWB

Forced Write-Back. Defines the combined cacheability attributes in a 2 stage translation regime.

Note

When [FEAT_MTE](#) is implemented, if the stage 1 page or block descriptor specifies the Tagged attribute, the final memory type is Tagged only if the final cacheable memory type is Inner and Outer Write-back cacheable and the final allocation hints are Read-Allocate, Write-Allocate.

- 0b0 When this bit is 0, then:
- The combination of stage 1 and stage 2 translations on memory type and cacheability attributes are as described in the Armv8.0 architecture. For more information, see [Combining the stage 1 and stage 2 attributes, EL1&0 translation regime on page D5-2783](#).
 - The encoding of the stage 2 memory type and cacheability attributes in bits[5:2] of the stage 2 page or block descriptors are as described in the Armv8.0 architecture.
- 0b1 When this bit is 1, then:
- Bit[5] of stage 2 page or block descriptor is RES0.
 - When bit[4] of stage 2 page or block descriptor is 1 and when:
 - Bits[3:2] of stage 2 page or block descriptor are 0b11, the resultant memory type and inner or outer cacheability attribute is the same as the stage 1 memory type and inner or outer cacheability attribute.
 - Bits[3:2] of stage 2 page or block descriptor are 0b10, the resultant memory type and attribute is Normal Write-Back.
 - Bits[3:2] of stage 2 page or block descriptor are 0b0x, the resultant memory type will be Normal Non-cacheable except where the stage 1 memory type was Device-<attr> the resultant memory type will be Device-<attr>
 - When bit[4] of stage 2 page or block descriptor is 0 the memory type is Device, and when:
 - Bits[3:2] of stage 2 page or block descriptor are 0b00, the stage 2 memory type is Device-nGnRnE.
 - Bits[3:2] of stage 2 page or block descriptor are 0b01, the stage 2 memory type is Device-nGnRE.
 - Bits[3:2] of stage 2 page or block descriptor are 0b10, the stage 2 memory type is Device-nGRE.
 - Bits[3:2] of stage 2 page or block descriptor are 0b11, the stage 2 memory type is Device-GRE.
 - If the stage 1 translation specifies a cacheable memory type, then the stage 1 cache allocation hint is applied to the final cache allocation hint where the final memory type is cacheable.
 - If the stage 1 translation does not specify a cacheable memory type, then if the final memory type is cacheable, it is treated as read allocate, write allocate.
- The stage 1 and stage 2 memory types are combined in the manner described in [Combining the stage 1 and stage 2 attributes, EL1&0 translation regime on page D5-2783](#).

In Secure state, this bit applies to both the Secure stage 2 translation and the Non-secure stage 2 translation.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NV2, bit [45]

When FEAT_NV2 is implemented:

NV2

Nested Virtualization. Changes the behaviors of HCR_EL2.{NV1, NV} to provide a mechanism for hardware to transform reads and writes from System registers into reads and writes from memory.

0b0 This bit has no effect on the behavior of HCR_EL2.{NV1, NV}. The behavior of HCR_EL2.{NV1, NV} is as defined for [FEAT_NV](#).

0b1 Redefines behavior of HCR_EL2.{NV1, NV} to enable:

- Transformation of read/writes to registers into read/writes to memory.
- Redirection of EL2 registers to EL1 registers.

Any exception taken from EL1 and taken to EL1 causes [SPSR_EL1.M\[3:2\]](#) to be set to 0b10 and not 0b01.

When HCR_EL2.NV is 0, the Effective value of this field is 0 and this field is treated as 0 for all purposes other than direct reads and writes of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AT, bit [44]

When FEAT_NV is implemented:

AT

Address Translation. EL1 execution of the following address translation instructions is trapped to EL2, when EL2 is enabled in the current Security state, reported using EC syndrome value 0x18:

- [AT S1E0R](#), [AT S1E0W](#), [AT S1E1R](#), [AT S1E1W](#), [AT S1E1RP](#), [AT S1E1WP](#).

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 execution of the specified instructions is trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NV1, bit [43]

When FEAT_NV2 is implemented:

NV1

Nested Virtualization.

0b0 If HCR_EL2.{NV2, NV} are both 1, accesses executed from EL1 to implemented EL12, EL02, or EL2 registers are transformed to loads and stores.

If HCR_EL2.NV2 is 0 or HCR_EL2.{NV2, NV} == {1, 0}, this control does not cause any instructions to be trapped.

0b1 If HCR_EL2.NV2 is 1, accesses executed from EL1 to implemented EL2 registers are transformed to loads and stores.

If HCR_EL2.NV2 is 0, EL1 accesses to [VBAR_EL1](#), [ELR_EL1](#), [SPSR_EL1](#), and, when [FEAT_CSV2_2](#) or [FEAT_CSV2_1p2](#) is implemented, [SCXTNUM_EL1](#), are trapped to EL2, when EL2 is enabled in the current Security state, and are reported using EC syndrome value 0x18.

If HCR_EL2.NV2 is 1, the value of HCR_EL2.NV1 defines which EL1 register accesses are transformed to loads and stores. These transformed accesses have priority over the trapping of registers.

The trapping of EL1 registers caused by other control bits has priority over the transformation of these accesses.

If a register is specified that is not implemented by an implementation, then access to that register are UNDEFINED.

For the list of registers affected, see [Enhanced support for nested virtualization on page D5-2795](#).

If HCR_EL2.{NV1, NV} is {0, 1}, any exception taken from EL1, and taken to EL1, causes the [SPSR_EL1.M\[3:2\]](#) to be set to 0b10, and not 0b01.

If HCR_EL2.{NV1, NV} is {1, 1}, then:

- The EL1 translation table Block and Page descriptors:
 - Bit[54] holds the PXN instead of the UXN.
 - Bit[53] is RES0.
 - Bit[6] is treated as 0 regardless of the actual value.
- If Hierarchical Permissions are enabled, the EL1 translation table Table descriptors are as follows:
 - Bit[61] is treated as 0 regardless of the actual value.
 - Bit[60] holds the PXNTable instead of the UXNTable.
 - Bit[59] is RES0.
- When executing at EL1, the PSTATE.PAN bit is treated as zero for all purposes except reading the value of the bit.
- When executing at EL1, the LDTR* instructions are treated as the equivalent LDR* instructions, and the STTR* instructions are treated as the equivalent STR* instructions.

If HCR_EL2.{NV1, NV} are {1, 0}, then the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- Behaving as if HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1 for all purposes other than reading back the value of the HCR_EL2.NV bit.
- Behaving as if HCR_EL2.NV is 0 and HCR_EL2.NV1 is 0 for all purposes other than reading back the value of the HCR_EL2.NV1 bit.
- Behaving with regard to the HCR_EL2.NV and HCR_EL2.NV1 bits behavior as defined in the rest of this description.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_NV is implemented:

NV1

Nested Virtualization. EL1 accesses to certain registers are trapped to EL2, when EL2 is enabled in the current Security state.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 accesses to [VBAR_EL1](#), [ELR_EL1](#), [SPSR_EL1](#), and, when [FEAT_CSV2_2](#) or [FEAT_CSV2_1p2](#) is implemented, [SCXTNUM_EL1](#), are trapped to EL2, when EL2 is enabled in the current Security state, and are reported using EC syndrome value 0x18.

If HCR_EL2.NV is 1 and HCR_EL2.NV1 is 0, then the following effects also apply:

- Any exception taken from EL1, and taken to EL1, causes the [SPSR_EL1.M\[3:2\]](#) to be set to 0b10, and not 0b01.

If HCR_EL2.NV and HCR_EL2.NV1 are both set to 1, then the following effects also apply:

- The EL1 translation table Block and Page descriptors:
 - Bit[54] holds the PXN instead of the UXN.
 - Bit[53] is RES0.
 - Bit[6] is treated as 0 regardless of the actual value.
- If Hierarchical Permissions are enabled, the EL1 translation table Table descriptors are as follows:
 - Bit[61] is treated as 0 regardless of the actual value.
 - Bit[60] holds the PXNTable instead of the UXNTable.
 - Bit[59] is RES0.
- When executing at EL1, the PSTATE.PAN bit is treated as zero for all purposes except reading the value of the bit.
- When executing at EL1, the LDTR* instructions are treated as the equivalent LDR* instructions, and the STTR* instructions are treated as the equivalent STR* instructions.

If HCR_EL2.NV is 0 and HCR_EL2.NV1 is 1, then the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- Behaving as if HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1 for all purposes other than reading back the value of the HCR_EL2.NV bit.
- Behaving as if HCR_EL2.NV is 0 and HCR_EL2.NV1 is 0 for all purposes other than reading back the value of the HCR_EL2.NV1 bit.
- Behaving with regard to the HCR_EL2.NV and HCR_EL2.NV1 bits behavior as defined in the rest of this description.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NV, bit [42]

When FEAT_NV2 is implemented:

NV

Nested Virtualization.

When HCR_EL2.NV2 is 1, redefines register accesses so that:

- Instructions accessing the Special purpose registers [SPSR_EL2](#) and [ELR_EL2](#) instead access [SPSR_EL1](#) and [ELR_EL1](#) respectively.
- Instructions accessing the System registers [ESR_EL2](#) and [FAR_EL2](#) instead access [ESR_EL1](#) and [FAR_EL1](#).

When HCR_EL2.NV2 is 0, or if [FEAT_NV2](#) is not implemented, traps functionality that is permitted at EL2 and would be UNDEFINED at EL1 if this field was 0, when EL2 is enabled in the current Security state. This applies to the following operations:

- EL1 accesses to Special-purpose registers that are not UNDEFINED at EL2.
- EL1 accesses to System registers that are not UNDEFINED at EL2.
- Execution of EL1 or EL2 translation regime address translation and TLB maintenance instructions for EL2 and above.

0b0 When this bit is set to 0, then the PE behaves as if HCR_EL2.NV2 is 0 for all purposes other than reading this register. This control does not cause any instructions to be trapped.

When HCR_EL2.NV2 is 1, no FEAT_NV2 functionality is implemented.

0b1 When HCR_EL2.NV2 is 0, or if FEAT_NV2 is not implemented, EL1 accesses to the specified registers or the execution of the specified instructions are trapped to EL2, when EL2 is enabled in the current Security state. EL1 read accesses to the CurrentEL register return a value of 0x2.

When HCR_EL2.NV2 is 1, this control redefines EL1 register accesses so that instructions accessing SPSR_EL2, ELR_EL2, ESR_EL2, and FAR_EL2 instead access SPSR_EL1, ELR_EL1, ESR_EL1, and FAR_EL1 respectively.

When HCR_EL2.NV2 is 0, or if FEAT_NV2 is not implemented, then:

- The System or Special-purpose registers for which accesses are trapped and reported using EC syndrome value 0x18 are as follows:
 - Registers accessed using MRS or MSR with a name ending in _EL2, except SP_EL2.
 - Registers accessed using MRS or MSR with a name ending in _EL12.
 - Registers accessed using MRS or MSR with a name ending in _EL02.
 - Special-purpose registers SPSR_irq, SPSR_abt, SPSR_und and SPSR_fiq, accessed using MRS or MSR.
 - Special-purpose register SP_EL1 accessed using the dedicated MRS or MSR instruction.
- The instructions for which the execution is trapped and reported using EC syndrome value 0x18 are as follows:
 - EL2 translation regime Address Translation instructions and TLB maintenance instructions.
 - EL1 translation regime Address Translation instructions and TLB maintenance instructions that are accessible only from EL2 and EL3.
- The instructions for which the execution is trapped as follows:
 - SMC in an implementation that does not include EL3 and when HCR_EL2.TSC is 1. HCR_EL2.TSC bit is not RES0 in this case. This is reported using EC syndrome value 0x17.
 - The ERET, ERETAA, and ERETAB instructions, reported using EC syndrome value 0x1A.

Note

The priority of this trap is higher than the priority of the HCR_EL2.API trap. If both of these bits are set so that EL1 execution of an ERETAA or ERETAB instruction is trapped to EL2, then the syndrome reported is 0x1A.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_NV is implemented:

NV

Nested Virtualization. Traps functionality that is permitted at EL2 and would be UNDEFINED at EL1 if this field was 0, when EL2 is enabled in the current Security state. This applies to the following operations:

- EL1 accesses to Special-purpose registers that are not UNDEFINED at EL2.
- EL1 accesses to System registers that are not UNDEFINED at EL2.
- Execution of EL1 or EL2 translation regime address translation and TLB maintenance instructions for EL2 and above.

The possible values are:

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 accesses to the specified registers or the execution of the specified instructions are trapped to EL2, when EL2 is enabled in the current Security state. EL1 read accesses to the [CurrentEL](#) register return a value of 0x2.

The System or Special-purpose registers for which accesses are trapped and reported using EC syndrome value 0x18 are as follows:

- Registers accessed using MRS or MSR with a name ending in `_EL2`, except [SP_EL2](#).
- Registers accessed using MRS or MSR with a name ending in `_EL12`.
- Registers accessed using MRS or MSR with a name ending in `_EL02`.
- Special-purpose registers [SPSR_irq](#), [SPSR_abt](#), [SPSR_und](#) and [SPSR_fiq](#), accessed using MRS or MSR.
- Special-purpose register [SP_EL1](#) accessed using the dedicated MRS or MSR instruction.

The instructions for which the execution is trapped and reported using EC syndrome value 0x18 are as follows:

- EL2 translation regime Address Translation instructions and TLB maintenance instructions.
- EL1 translation regime Address Translation instructions and TLB maintenance instructions that are accessible only from EL2 and EL3.

The execution of the ERET, ERETAA, and ERETAB instructions are trapped and reported using EC syndrome value 0x1A.

————— **Note** —————

The priority of this trap is higher than the priority of the HCR_EL2.API trap. If both of these bits are set so that EL1 execution of an ERETAA or ERETAB instruction is trapped to EL2, then the syndrome reported is 0x1A.

The execution of the SMC instructions in an implementation that does not include EL3 and when HCR_EL2.TSC is 1 are trapped and reported using EC syndrome value 0x17. HCR_EL2.TSC bit is not RES0 in this case.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

API, bit [41]

When FEAT_PAuth is implemented:

API

Controls the use of instructions related to Pointer Authentication:

- In EL0, when HCR_EL2.TGE==0 or HCR_EL2.E2H==0, and the associated [SCTLR_EL1.En<N><M>==1](#).
- In EL1, the associated [SCTLR_EL1.En<N><M>==1](#).

Traps are reported using EC syndrome value 0x09. The Pointer Authentication instructions trapped are:

- AUTDA, AUTDB, AUTDZA, AUTDZB, AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZA, AUTIZB.
- PACGA, PACDA, PACDB, PACDZA, PACDZB, PACIA, PACIA1716, PACIASP, PACIAZ, PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZA, PACIZB.
- RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ.

- ERETAA, ERETAB, LDRAA, and LDRAB.

0b0 The instructions related to Pointer Authentication are trapped to EL2, when EL2 is enabled in the current Security state and the instructions are enabled for the EL1&0 translation regime, from:

- EL0 when $HCR_EL2.TGE=0$ or $HCR_EL2.E2H=0$.
- EL1.

If $HCR_EL2.NV$ is 1, the $HCR_EL2.NV$ trap takes precedence over the $HCR_EL2.API$ trap for the ERETAA and ERETAB instructions.

If EL2 is implemented and enabled in the current Security state and $HFGITR_EL2.ERET=1$, execution at EL1 using AArch64 of ERETAA or ERETAB instructions is reported with EC syndrome value 0x1A with its associated ISS field, as the fine-grained trap has higher priority than the $HCR_EL2.API=0$.

0b1 This control does not cause any instructions to be trapped.

If **FEAT_PAuth** is implemented but EL2 is not implemented or disabled in the current Security state, the system behaves as if this bit is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APK, bit [40]

When FEAT_PAuth is implemented:

APK

Trap registers holding "key" values for Pointer Authentication. Traps accesses to the following registers from EL1 to EL2, when EL2 is enabled in the current Security state, reported using EC syndrome value 0x18:

- [APIAKeyLo_EL1](#), [APIAKeyHi_EL1](#), [APIBKeyLo_EL1](#), [APIBKeyHi_EL1](#), [APDAKeyLo_EL1](#), [APDAKeyHi_EL1](#), [APDBKeyLo_EL1](#), [APDBKeyHi_EL1](#), [APGAKeyLo_EL1](#), and [APGAKeyHi_EL1](#).

0b0 Access to the registers holding "key" values for pointer authentication from EL1 are trapped to EL2, when EL2 is enabled in the current Security state.

0b1 This control does not cause any instructions to be trapped.

———— **Note** —————

If **FEAT_PAuth** is implemented but EL2 is not implemented or is disabled in the current Security state, the system behaves as if this bit is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [39]

Reserved, RES0.

MIOCNCNCE, bit [38]

Mismatched Inner/Outer Cacheable Non-Coherency Enable, for the EL1&0 translation regimes.

0b0 For the EL1&0 translation regimes, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there must be no loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

0b1 For the EL1&0 translation regimes, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there might be a loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

For more information, see *Mismatched memory attributes* on page B2-176.

This field can be implemented as RAZ/WI.

When *FEAT_VHE* is implemented, and the value of *HCR_EL2*.{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TEA, bit [37]

When FEAT_RAS is implemented:

TEA

Route synchronous External abort exceptions to EL2.

0b0 This control does not cause exceptions to be routed from EL0 and EL1 to EL2.

0b1 Route synchronous External abort exceptions from EL0 and EL1 to EL2, when EL2 is enabled in the current Security state, if not routed to EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TERR, bit [36]

When FEAT_RAS is implemented:

TERR

Trap Error record accesses. Trap accesses to the RAS error registers from EL1 to EL2 as follows:

- If EL1 is using AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x18:
 - *ERRIDR_EL1*, *ERRSELR_EL1*, *ERXADDR_EL1*, *ERXCTLR_EL1*, *ERXFR_EL1*, *ERXMISC0_EL1*, *ERXMISC1_EL1*, and *ERXSTATUS_EL1*.
 - When *FEAT_RASv1p1* is implemented, *ERXMISC2_EL1*, and *ERXMISC3_EL1*.
 - If EL1 is using AArch32 state, MCR or MRC accesses are trapped to EL2, reported using EC syndrome value 0x03, MCRR or MRRC accesses are trapped to EL2, reported using EC syndrome value 0x04:
 - *ERRIDR*, *ERRSELR*, *ERXADDR*, *ERXADDR2*, *ERXCTLR*, *ERXCTLR2*, *ERXFR*, *ERXFR2*, *ERXMISC0*, *ERXMISC1*, *ERXMISC2*, *ERXMISC3*, and *ERXSTATUS*.
 - When *FEAT_RASv1p1* is implemented, *ERXMISC4*, *ERXMISC5*, *ERXMISC6*, and *ERXMISC7*.
- 0b0 This control does not cause any instructions to be trapped.
- 0b1 Accesses to the specified registers from EL1 generate a Trap exception to EL2, when EL2 is enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLOR, bit [35]

When FEAT_LOR is implemented:

TLOR

Trap LOR registers. Traps Non-secure EL1 accesses to [LORSA_EL1](#), [LOREA_EL1](#), [LORN_EL1](#), [LORC_EL1](#), and [LORID_EL1](#) registers to EL2.

0b0 This control does not cause any instructions to be trapped.

0b1 Non-secure EL1 accesses to the LOR registers are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

E2H, bit [34]

When FEAT_VHE is implemented:

E2H

EL2 Host. Enables a configuration where a Host Operating System is running in EL2, and the Host Operating System's applications are running in EL0.

0b0 The facilities to support a Host Operating System at EL2 are disabled.

0b1 The facilities to support a Host Operating System at EL2 are enabled.

For information on the behavior of this bit see [Behavior of HCR_EL2.E2H on page D5-2787](#).

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ID, bit [33]

Stage 2 Instruction access cacheability disable. For the EL1&0 translation regime, when EL2 is enabled in the current Security state and HCR_EL2.VM==1, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

0b0 This control has no effect on stage 2 of the EL1&0 translation regime.

0b1 Forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

This bit has no effect on the EL2, EL2&0, or EL3 translation regimes.

When [FEAT_VHE](#) is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CD, bit [32]

Stage 2 Data access cacheability disable. For the EL1&0 translation regime, when EL2 is enabled in the current Security state and HCR_EL2.VM==1, this control forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

0b0 This control has no effect on stage 2 of the EL1&0 translation regime for data accesses and translation table walks.

0b1 Forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

This bit has no effect on the EL2, EL2&0, or EL3 translation regimes.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

RW, bit [31]

When EL1 is capable of using AArch32:

RW

Execution state control for lower Exception levels:

0b0 Lower levels are all AArch32.

0b1 The Execution state for EL1 is AArch64. The Execution state for EL0 is determined by the current value of PSTATE.nRW when executing at EL0.

In an implementation that includes EL3, when EL2 is not enabled in Secure state, the PE behaves as if this bit has the same value as the SCR_EL3.RW bit for all purposes other than a direct read or write access of HCR_EL2.

The RW bit is permitted to be cached in a TLB.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 1 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RAO/WI.

TRVM, bit [30]

Trap Reads of Virtual Memory controls. Traps EL1 reads of the virtual memory control registers to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64 state, the following registers are trapped to EL2 and reported using EC syndrome value 0x18.

— SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, CONTEXTIDR_EL1.

- If EL1 is using AArch32 state, accesses using MRC to the following registers are trapped to EL2 and reported using EC syndrome value 0x03, accesses using MRRC are trapped to EL2 and reported using EC syndrome value 0x04:

— SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADFSAR, AIFSAR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 read accesses to the specified Virtual Memory controls are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

———— **Note** ————

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the memory system. A hypervisor might use this trap as part of its virtualization of memory management.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

HCD, bit [29]

When EL3 is not implemented:

HCD

HVC instruction disable. Disables EL1 execution of HVC instructions, from both Execution states, when EL2 is enabled in the current Security state, reported using EC syndrome value 0x00.

0b0 HVC instruction execution is enabled at EL2 and EL1.

0b1 HVC instructions are UNDEFINED at EL2 and EL1. Any resulting exception is taken to the Exception level at which the HVC instruction is executed.

———— **Note** ————

HVC instructions are always UNDEFINED at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TDZ, bit [28]

Trap DC ZVA instructions. Traps EL0 and EL1 execution of DC ZVA instructions to EL2, when EL2 is enabled in the current Security state, from AArch64 state only, reported using EC syndrome value 0x18.

If FEAT_MTE is implemented, this trap also applies to DC GVA and DC GZVA.

0b0 This control does not cause any instructions to be trapped.

0b1 In AArch64 state, any attempt to execute an instruction this trap applies to at EL1, or at EL0 when the instruction is not UNDEFINED at EL0, is trapped to EL2 when EL2 is enabled in the current Security state.

Reading the DCZID_EL0 returns a value that indicates that the instructions this trap applies to are not supported.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TGE, bit [27]

Trap General Exceptions, from EL0.

0b0 This control has no effect on execution at EL0.

0b1 When EL2 is not enabled in the current Security state, this control has no effect on execution at EL0.

When EL2 is enabled in the current Security state, in all cases:

- All exceptions that would be routed to EL1 are routed to EL2.
- If EL1 is using AArch64, the `SCTLR_EL1.M` field is treated as being 0 for all purposes other than returning the result of a direct read of `SCTLR_EL1`.
- If EL1 is using AArch32, the `SCTLR.M` field is treated as being 0 for all purposes other than returning the result of a direct read of `SCTLR`.
- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.
- The `MDCR_EL2`.{TDRA, TDOSA, TDA, TDE} fields are treated as being 1 for all purposes other than returning the result of a direct read of `MDCR_EL2`.

In addition, when EL2 is enabled in the current Security state, if:

- `HCR_EL2.E2H` is 0, the Effective values of the `HCR_EL2`.{FMO, IMO, AMO} fields are 1.
- `HCR_EL2.E2H` is 1, the Effective values of the `HCR_EL2`.{FMO, IMO, AMO} fields are 0.

For further information on the behavior of this bit when E2H is 1, see [Behavior of HCR_EL2.E2H on page D5-2787](#).

`HCR_EL2.TGE` must not be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TVM, bit [26]

Trap Virtual Memory controls. Traps EL1 writes to the virtual memory control registers to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64 state, the following registers are trapped to EL2 and reported using EC syndrome value 0x18:
 - `SCTLR_EL1`, `TTBR0_EL1`, `TTBR1_EL1`, `TCR_EL1`, `ESR_EL1`, `FAR_EL1`, `AFSR0_EL1`, `AFSR1_EL1`, `MAIR_EL1`, `AMAIR_EL1`, `CONTEXTIDR_EL1`.
- If EL1 is using AArch32 state, accesses using MCR to the following registers are trapped to EL2 and reported using EC syndrome value 0x03, accesses using MCRR are trapped to EL2 and reported using EC syndrome value 0x04:
 - `SCTLR`, `TTBR0`, `TTBR1`, `TTBCR`, `TTBCR2`, `DACR`, `DFSR`, `IFSR`, `DFAR`, `IFAR`, `ADFSR`, `AIFSR`, `PRRR`, `NMRR`, `MAIR0`, `MAIR1`, `AMAIR0`, `AMAIR1`, `CONTEXTIDR`.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 write accesses to the specified EL1 virtual memory control registers are trapped to EL2, when EL2 is enabled in the current Security state.

When `HCR_EL2.TGE` is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TTLB, bit [25]

Trap TLB maintenance instructions. Traps EL1 execution of TLB maintenance instructions to EL2, when EL2 is enabled in the current Security state, as follows:

- When EL1 is using AArch64 state, the following instructions are trapped to EL2 and reported using EC syndrome value 0x18:
 - TLBI VMALLE1, TLBI VMALLE1NXS, TLBI VAE1, TLBI VAE1NXS, TLBI ASIDE1, TLBI ASIDE1NXS, TLBI VAAE1, TLBI VAAE1NXS, TLBI VALE1, TLBI VALE1NXS, TLBI VAALE1, TLBI VAALE1NXS.
 - TLBI VMALLE1IS, TLBI VMALLE1ISNXS, TLBI VAE1IS, TLBI VAE1ISNXS, TLBI ASIDE1IS, TLBI ASIDE1ISNXS, TLBI VAAE1IS, TLBI VAAE1ISNXS, TLBI VALE1IS, TLBI VALE1ISNXS, TLBI VAALE1IS, TLBI VAALE1ISNXS.
 - If FEAT_TLBIOS is implemented, this trap applies to TLBI VMALLE1IOS, TLBI VMALLE1IOSNXS, TLBI VAE1IOS, TLBI VAE1IOSNXS, TLBI ASIDE1IOS, TLBI ASIDE1IOSNXS, TLBI VAAE1IOS, TLBI VAAE1IOSNXS, TLBI VALE1IOS, TLBI VALE1IOSNXS, TLBI VAALE1IOS, TLBI VAALE1IOSNXS.
 - If FEAT_TLBIRANGE is implemented, this trap applies to TLBI RVAE1, TLBI RVAE1NXS, TLBI RVAE1IS, TLBI RVAE1ISNXS, TLBI RVAE1IOS, TLBI RVAE1IOSNXS, TLBI RVALE1, TLBI RVALE1NXS, TLBI RVALE1IS, TLBI RVALE1ISNXS, TLBI RVALE1IOS, TLBI RVALE1IOSNXS, TLBI RVALE1IS, TLBI RVALE1ISNXS.
 - If FEAT_TLBIOS and FEAT_TLBIRANGE are implemented, this trap applies to TLBI RVAE1IOS, TLBI RVAE1IOSNXS, TLBI RVAE1IOS, TLBI RVAE1IOSNXS, TLBI RVALE1IOS, TLBI RVALE1IOSNXS, TLBI RVALE1IOS, TLBI RVALE1IOSNXS.
 - When EL1 is using AArch32 state, the following instructions are trapped to EL2 and reported using EC syndrome value 0x03:
 - TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAAIS, TLBIMVALIS, TLBIMVAALIS.
 - TLBIALL, TLBIMVA, TLBIASID, TLBIMVAA, TLBIMVAL, TLBIMVAAL
 - ITLBIALL, ITLBIMVA, ITLBIASID.
 - DTLBIALL, DTLBIMVA, DTLBIASID.
- 0b0 This control does not cause any instructions to be trapped.
- 0b1 EL1 execution of the specified TLB maintenance instructions are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

———— **Note** —————

The TLB maintenance instructions are UNDEFINED at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps execution of those cache maintenance instructions to EL2, when EL2 is enabled in the current Security state as follows:

- If EL0 is using AArch64 state and the value of SCTLR_EL1.UCI is not 0, the following instructions are trapped to EL2 and reported with EC syndrome value 0x18:
 - IC IVAU, DC CVAU. If the value of SCTLR_EL1.UCI is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.

- If EL1 is using AArch64 state, the following instructions are trapped to EL2 and reported with EC syndrome value 0x18:
 - [IC IVAU](#), [IC IALLU](#), [IC IALLUIS](#), [DC CVAU](#).
- If EL1 is using AArch32 state, the following instructions are trapped to EL2 and reported with EC syndrome value 0x18:
 - [ICIMVAU](#), [IC IALLU](#), [IC IALLUIS](#), [DCCMVAU](#).

———— **Note** —————

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- [IC IALLUIS](#) and [IC IALLU](#) are always UNDEFINED at EL0 using AArch64.
- [ICIMVAU](#), [IC IALLU](#), [IC IALLUIS](#), and [DCCMVAU](#) are always UNDEFINED at EL0 using AArch32.

-
- | | |
|-----|---|
| 0b0 | This control does not cause any instructions to be trapped. |
| 0b1 | Execution of the specified instructions is trapped to EL2, when EL2 is enabled in the current Security state. |

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate to the Point of Unification instruction can be trapped when the value of this control is 1.

When [FEAT_VHE](#) is implemented, and the value of [HCR_EL2](#).{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TPCP, bit [23]

When [FEAT_DPB](#) is implemented:

TPCP

Trap data or unified cache maintenance instructions that operate to the Point of Coherency or Persistence. Traps execution of those cache maintenance instructions to EL2, when EL2 is enabled in the current Security state as follows:

- If EL0 is using AArch64 state and the value of [SCTLR_EL1](#).UCI is not 0, the following instructions are trapped to EL2 and reported using EC syndrome value 0x18:
 - [DC CIVAC](#), [DC CVAC](#), [DC CVAP](#). If the value of [SCTLR_EL1](#).UCI is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.
- If EL1 is using AArch64 state, the following instructions are trapped to EL2 and reported using EC syndrome value 0x18:
 - [DC IVAC](#), [DC CIVAC](#), [DC CVAC](#), [DC CVAP](#).
- If EL1 is using AArch32 state, the following instructions are trapped to EL2 and reported using EC syndrome value 0x03:
 - [DCIMVAC](#), [DCCIMVAC](#), [DCCMVAC](#).

If [FEAT_DPB2](#) is implemented, this trap also applies to [DC CVADP](#).

If [FEAT_MTE](#) is implemented, this trap also applies to [DC CIGVAC](#), [DC CIGDVAC](#), [DC IGVAC](#), [DC IGDVAC](#), [DC CGVAC](#), [DC CGDVAC](#), [DC CGVAP](#) and [DC CGDVAP](#).

If [FEAT_DPB2](#) and [FEAT_MTE](#) are implemented, this trap also applies to [DC CGVADP](#) and [DC CGDVADP](#).

Note

- An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:
 - AArch64 instructions which invalidate by VA to the Point of Coherency are always UNDEFINED at EL0 using AArch64.
 - [DCIMVAC](#), [DCCIMVAC](#), and [DCCMVAC](#) are always UNDEFINED at EL0 using AArch32.
- In Armv8.0 and Armv8.1, this field is named TPC. From Armv8.2, it is named TPCP.

0b0	This control does not cause any instructions to be trapped.
0b1	Execution of the specified instructions is trapped to EL2, when EL2 is enabled in the current Security state.

If the Point of Coherency is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean, invalidate, or clean and invalidate instruction that operates by VA to the point of coherency can be trapped when the value of this control is 1.

If HCR_EL2.{E2H, TGE} is set to {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

TPC

Trap data or unified cache maintenance instructions that operate to the Point of Coherency. Traps execution of those cache maintenance instructions to EL2, when EL2 is enabled in the current Security state as follows:

- If EL0 is using AArch64 state and the value of [SCTLR_EL1.UCI](#) is not 0, accesses to the following registers are trapped and reported using EC syndrome value 0x18:
 - [DC CIVAC](#), [DC CVAC](#). However, if the value of [SCTLR_EL1.UCI](#) is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.
- If EL1 is using AArch64 state, accesses to [DC IVAC](#), [DC CIVAC](#), [DC CVAC](#) are trapped and reported using EC syndrome value 0x18.
- When EL1 is using AArch32, accesses to [DCIMVAC](#), [DCCIMVAC](#), and [DCCMVAC](#) are trapped and reported using EC syndrome value 0x03.

Note

- An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:
 - AArch64 instructions which invalidate by VA to the Point of Coherency are always UNDEFINED at EL0 using AArch64.
 - [DCIMVAC](#), [DCCIMVAC](#), and [DCCMVAC](#) are always UNDEFINED at EL0 using AArch32.
- In Armv8.0 and Armv8.1, this field is named TPC. From Armv8.2, it is named TPCP.

0b0	This control does not cause any instructions to be trapped.
0b1	Execution of the specified instructions is trapped to EL2, when EL2 is enabled in the current Security state.

If the Point of Coherency is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean, invalidate, or clean and invalidate instruction that operates by VA to the point of coherency can be trapped when the value of this control is 1.

When [FEAT_VHE](#) is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TSW, bit [22]

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps execution of those cache maintenance instructions at EL1 to EL2, when EL2 is enabled in the current Security state as follows:

- If EL1 is using AArch64 state, accesses to [DC ISW](#), [DC CSW](#), [DC CISW](#) are trapped to EL2, reported using EC syndrome value 0x18.
- If EL1 is using AArch32 state, accesses to [DCISW](#), [DCCSW](#), [DCCISW](#) are trapped to EL2, reported using EC syndrome value 0x03.

If [FEAT_MTE](#) is implemented, this trap also applies to [DC IGSW](#), [DC IGDSW](#), [DC CGSW](#), [DC CGDSW](#), [DC CIGSW](#), and [DC CIGDSW](#).

Note

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0b0 This control does not cause any instructions to be trapped.

0b1 Execution of the specified instructions is trapped to EL2, when EL2 is enabled in the current Security state.

When [HCR_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TACR, bit [21]

Trap Auxiliary Control Registers. Traps EL1 accesses to the Auxiliary Control Registers to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64 state, accesses to [ACTLR_EL1](#) to EL2, are trapped to EL2 and reported using EC syndrome value 0x18.
- If EL1 is using AArch32 state, accesses to [ACTLR](#) and, if implemented, [ACTLR2](#) are trapped to EL2 and reported using EC syndrome value 0x03.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 accesses to the specified registers are trapped to EL2, when EL2 is enabled in the current Security state.

When [HCR_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

Note

[ACTLR_EL1](#) is not accessible at EL0.

[ACTLR](#) and [ACTLR2](#) are not accessible at EL0.

The Auxiliary Control Registers are IMPLEMENTATION DEFINED registers that might implement global control bits for the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps EL1 accesses to the encodings reserved for IMPLEMENTATION DEFINED functionality to EL2, when EL2 is enabled in the current Security state as follows:

- In AArch64 state, access to any of the encodings in the following reserved encoding spaces are trapped and reported using EC syndrome 0x18:
 - IMPLEMENTATION DEFINED System instructions, which are accessed using SYS and SYSL, with CRn == {11, 15}.
 - IMPLEMENTATION DEFINED System registers, which are accessed using MRS and MSR with the S3_<op1>_<Cn>_<Cm>_<op2> register name.
- In AArch32 state, MCR and MRC access to instructions with the following encodings are trapped and reported using EC syndrome 0x03:
 - All coproc==p15, CRn==c9, opc1 == {0-7}, CRm == {c0-c2, c5-c8}, opc2 == {0-7}.
 - All coproc==p15, CRn==c10, opc1 == {0-7}, CRm == {c0, c1, c4, c8}, opc2 == {0-7}.
 - All coproc==p15, CRn==c11, opc1=={0-7}, CRm == {c0-c8, c15}, opc2 == {0-7}.

When the value of HCR_EL2.TIDCP is 1, it is IMPLEMENTATION DEFINED whether any of this functionality accessed from EL0 is trapped to EL2. If it is not, then it is UNDEFINED, and any attempt to access it from EL0 generates an exception that is taken to EL1.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 accesses to or execution of the specified encodings reserved for IMPLEMENTATION DEFINED functionality are trapped to EL2, when EL2 is enabled in the current Security state.

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

Note

Arm expects the trapping of EL0 accesses to these functions to EL2 to be unusual, and used only when the hypervisor is virtualizing EL0 operation. Arm strongly recommends that unless the hypervisor must virtualize EL0 operation, an EL0 access to any of these functions is UNDEFINED, as it would be if the implementation did not include EL2. The PE then takes any resulting exception to EL1.

The trapping of accesses to these registers from EL1 is higher priority than an exception resulting from the register access being UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TSC, bit [19]

Trap SMC instructions. Traps EL1 execution of SMC instructions to EL2, when EL2 is enabled in the current Security state.

If execution is in AArch64 state, the trap is reported using EC syndrome value 0x17.

If execution is in AArch32 state, the trap is reported using EC syndrome value 0x13.

Note

HCR_EL2.TSC traps execution of the SMC instruction. It is not a routing control for the SMC exception. Trap exceptions and SMC exceptions have different preferred return addresses.

0b0 This control does not cause any instructions to be trapped.

0b1 If EL3 is implemented, then any attempt to execute an SMC instruction at EL1 is trapped to EL2, when EL2 is enabled in the current Security state, regardless of the value of [SCR_EL3.SMD](#).

If EL3 is not implemented, [FEAT_NV](#) is implemented, and HCR_EL2.NV is 1, then any attempt to execute an SMC instruction at EL1 using AArch64 is trapped to EL2, when EL2 is enabled in the current Security state.

If EL3 is not implemented, and either [FEAT_NV](#) is not implemented or HCR_EL2.NV is 0, then it is IMPLEMENTATION DEFINED whether:

- Any attempt to execute an SMC instruction at EL1 is trapped to EL2, when EL2 is enabled in the current Security state.
- Any attempt to execute an SMC instruction is UNDEFINED.

In AArch32 state, the Armv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

SMC instructions are UNDEFINED at EL0.

If EL3 is not implemented, and either [FEAT_NV](#) is not implemented or HCR_EL2.NV is 0, then it is IMPLEMENTATION DEFINED whether this bit is:

- RES0.
- Implemented with the functionality as described in HCR_EL2.TSC.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID3, bit [18]

Trap ID group 3. Traps EL1 reads of group 3 ID registers to EL2, when EL2 is enabled in the current Security state, as follows:

In AArch64 state:

- Reads of the following registers are trapped to EL2, reported using EC syndrome value 0x18:
 - [ID_PFR0_EL1](#), [ID_PFR1_EL1](#), [ID_PFR2_EL1](#), [ID_DFR0_EL1](#), [ID_AFR0_EL1](#), [ID_MMFR0_EL1](#), [ID_MMFR1_EL1](#), [ID_MMFR2_EL1](#), [ID_MMFR3_EL1](#), [ID_ISAR0_EL1](#), [ID_ISAR1_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR3_EL1](#), [ID_ISAR4_EL1](#), [ID_ISAR5_EL1](#), [MVFR0_EL1](#), [MVFR1_EL1](#), [MVFR2_EL1](#).
 - [ID_AA64PFR0_EL1](#), [ID_AA64PFR1_EL1](#), [ID_AA64DFR0_EL1](#), [ID_AA64DFR1_EL1](#), [ID_AA64ISAR0_EL1](#), [ID_AA64ISAR1_EL1](#), [ID_AA64MMFR0_EL1](#), [ID_AA64MMFR1_EL1](#), [ID_AA64AFR0_EL1](#), [ID_AA64AFR1_EL1](#).
 - If [FEAT_FGT](#) is implemented:
 - [ID_MMFR4_EL1](#) and [ID_MMFR5_EL1](#) are trapped to EL2.
 - [ID_AA64MMFR2_EL1](#) and [ID_ISAR6_EL1](#) are trapped to EL2.
 - [ID_DFR1_EL1](#) is trapped to EL2.
 - [ID_AA64ZFR0_EL1](#) is trapped to EL2.
 - [ID_AA64ISAR2_EL1](#) is trapped to EL2.
 - This field traps all MRS accesses to registers in the following range that are not already mentioned in this field description: Op0 == 3, op1 == 0, CRn == c0, CRm == {c1-c7}, op2 == {0-7}.
 - If [FEAT_FGT](#) is not implemented:
 - [ID_MMFR4_EL1](#) and [ID_MMFR5_EL1](#) are trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to [ID_MMFR4_EL1](#) or [ID_MMFR5_EL1](#) are trapped to EL2.
 - [ID_AA64MMFR2_EL1](#) and [ID_ISAR6_EL1](#) are trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to [ID_AA64MMFR2_EL1](#) or [ID_ISAR6_EL1](#) are trapped to EL2.

- `ID_DFR1_EL1` is trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to `ID_DFR1_EL1` are trapped to EL2.
- `ID_AA64ZFR0_EL1` is trapped to EL2, unless implemented as RAZ then it is IMPLEMENTATION DEFINED whether accesses to `ID_AA64ZFR0_EL1` are trapped to EL2.
- `ID_AA64ISAR2_EL1` is trapped to EL2, unless implemented as RAZ then it is IMPLEMENTATION DEFINED whether accesses to `ID_AA64ISAR2_EL1` are trapped to EL2.
- Otherwise, it is IMPLEMENTATION DEFINED whether this bit traps MRS accesses to registers in the following range that are not already mentioned in this field description: `Op0 == 3, op1 == 0, CRn == c0, CRm == {c1-c7}, op2 == {0-7}`.

In AArch32 state:

- VMRS access to `MVFR0`, `MVFR1`, and `MVFR2`, are trapped to EL2, reported using EC syndrome value `0x08`, unless access is also trapped by `HCPTR` which takes priority.
- MRC access to the following registers are trapped to EL2, reported using EC syndrome value `0x03`:
 - `ID_PFR0`, `ID_PFR1`, `ID_PFR2`, `ID_DFR0`, `ID_AFR0`, `ID_MMFR0`, `ID_MMFR1`, `ID_MMFR2`, `ID_MMFR3`, `ID_ISAR0`, `ID_ISAR1`, `ID_ISAR2`, `ID_ISAR3`, `ID_ISAR4`, `ID_ISAR5`.
 - If `FEAT_FGT` is implemented:
 - `ID_MMFR4` and `ID_MMFR5` are trapped to EL2.
 - `ID_ISAR6` is trapped to EL2.
 - `ID_DFR1` is trapped to EL2.
 - This field traps all MRC accesses to encodings in the following range that are not already mentioned in this field description: `coproc == p15, opc1 == 0, CRn == c0, CRm == {c2-c7}, opc2 == {0-7}`.
 - If `FEAT_FGT` is not implemented:
 - `ID_MMFR4` and `ID_MMFR5` are trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to `ID_MMFR4` or `ID_MMFR5` are trapped.
 - `ID_ISAR6` is trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to `ID_ISAR6` are trapped to EL2.
 - `ID_DFR1` is trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to `ID_DFR1` are trapped to EL2.
 - Otherwise, it is IMPLEMENTATION DEFINED whether this bit traps all MRC accesses to registers in the following range not already mentioned in this field description with `coproc == p15, opc1 == 0, CRn == c0, CRm == {c2-c7}, opc2 == {0-7}`.
- `0b0` This control does not cause any instructions to be trapped.
- `0b1` The specified EL1 read accesses to ID group 3 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When `HCR_EL2.TGE` is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID2, bit [17]

Trap ID group 2. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64, reads of [CTR_EL0](#), [CCSIDR_EL1](#), [CCSIDR2_EL1](#), [CLIDR_EL1](#), and [CSSELR_EL1](#) are trapped to EL2, reported using EC syndrome value 0x18.
- If EL0 is using AArch64 and the value of [SCTLR_EL1.UCT](#) is not 0, reads of [CTR_EL0](#) are trapped to EL2, reported using EC syndrome value 0x18. If the value of [SCTLR_EL1.UCT](#) is 0, then EL0 reads of [CTR_EL0](#) are trapped to EL1 and the resulting exception takes precedence over this trap.
- If EL1 is using AArch64, writes to [CSSELR_EL1](#) are trapped to EL2, reported using EC syndrome value 0x18.
- If EL1 is using AArch32, reads of [CTR](#), [CCSIDR](#), [CCSIDR2](#), [CLIDR](#), and [CSSELR](#) are trapped to EL2, reported using EC syndrome value 0x03.
- If EL1 is using AArch32, writes to [CSSELR](#) are trapped to EL2, reported using EC syndrome value 0x03.

0b0 This control does not cause any instructions to be trapped.

0b1 The specified EL1 and EL0 accesses to ID group 2 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When [FEAT_VHE](#) is implemented, and the value of [HCR_EL2.{E2H, TGE}](#) is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID1, bit [16]

Trap ID group 1. Traps EL1 reads of the following registers to EL2, when EL2 is enabled in the current Security state as follows:

- In AArch64 state, accesses of [REVIDR_EL1](#), [AIDR_EL1](#), reported using EC syndrome value 0x18.
- In AArch32 state, accesses of [TCMTR](#), [TLBTR](#), [REVIDR](#), [AIDR](#), reported using EC syndrome value 0x03.

0b0 This control does not cause any instructions to be trapped.

0b1 The specified EL1 read accesses to ID group 1 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When [HCR_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID0, bit [15]

When AArch32 is supported at EL0:

TID0

Trap ID group 0. Traps the following register accesses to EL2:

- EL1 reads of the [JIDR](#), reported using EC syndrome value 0x05.
- If the [JIDR](#) is RAZ from EL0, EL0 reads of the [JIDR](#), reported using EC syndrome value 0x05.
- EL1 accesses using VMRS of the [FPSID](#), reported using EC syndrome value 0x08.

————— **Note** —————

- It is IMPLEMENTATION DEFINED whether the [JIDR](#) is RAZ or UNDEFINED at EL0. If it is UNDEFINED at EL0, then any resulting exception takes precedence over this trap.
- The [FPSID](#) is not accessible at EL0 using AArch32.

- Writes to the [FPSID](#) are ignored, and not trapped by this control.

0b0 This control does not cause any instructions to be trapped.

0b1 The specified EL1 read accesses to ID group 0 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When [FEAT_VHE](#) is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TWE, bit [14]

Traps EL0 and EL1 execution of WFE instructions to EL2, when EL2 is enabled in the current Security state, from both Execution states, reported using EC syndrome value 0x01.

When [FEAT_WFxT](#) or [FEAT_WFxT2](#) is implemented, this trap also applies to the WFET instruction.

0b0 This control does not cause any instructions to be trapped.

0b1 Any attempt to execute a WFE instruction at EL0 or EL1 is trapped to EL2, when EL2 is enabled in the current Security state, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by [SCTLR.nTWE](#) or [SCTLR_EL1.nTWE](#).

In AArch32 state, the attempted execution of a conditional WFE instruction is trapped only if the instruction passes its condition code check.

————— Note —————

Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When [FEAT_VHE](#) is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information about when WFE instructions can cause the PE to enter a low-power state, see [Wait for Event mechanism and Send event on page D1-2536](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TWI, bit [13]

Traps EL0 and EL1 execution of WFI instructions to EL2, when EL2 is enabled in the current Security state, from both Execution states, reported using EC syndrome value 0x01.

When [FEAT_WFxT](#) or [FEAT_WFxT2](#) is implemented, this trap also applies to the WFIT instruction.

0b0 This control does not cause any instructions to be trapped.

0b1 Any attempt to execute a WFI instruction at EL0 or EL1 is trapped to EL2, when EL2 is enabled in the current Security state, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by [SCTLR.nTWI](#) or [SCTLR_EL1.nTWI](#).

In AArch32 state, the attempted execution of a conditional WFI instruction is trapped only if the instruction passes its condition code check.

———— **Note** ————

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When [FEAT_VHE](#) is implemented, and the value of `HCR_EL2.{E2H, TGE}` is `{1, 1}`, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information about when WFI instructions can cause the PE to enter a low-power state, see [Wait For Interrupt](#) on page D1-2540.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DC, bit [12]

Default Cacheability.

0b0 This control has no effect on the EL1&0 translation regime.

0b1 In both Security states:

- When EL1 is using AArch64, the PE behaves as if the value of the [SCTLR_EL1.M](#) field is 0 for all purposes other than returning the value of a direct read of [SCTLR_EL1](#).
- When EL1 is using AArch32, the PE behaves as if the value of the [SCTLR.M](#) field is 0 for all purposes other than returning the value of a direct read of [SCTLR](#).
- The PE behaves as if the value of the `HCR_EL2.VM` field is 1 for all purposes other than returning the value of a direct read of `HCR_EL2`.
- The memory type produced by stage 1 of the EL1&0 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate.

This field has no effect on the EL2, EL2&0, and EL3 translation regimes.

This field is permitted to be cached in a TLB.

When [FEAT_VHE](#) is implemented, and the value of `HCR_EL2.{E2H, TGE}` is `{1, 1}`, this field behaves as 0 for all purposes other than a direct read of the value of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from EL1 or EL0:

0b00 No effect.

0b01 Inner Shareable.

0b10 Outer Shareable.

0b11 Full system.

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

When [FEAT_VHE](#) is implemented, and the value of `HCR_EL2.{E2H, TGE}` is `{1, 1}`, this field behaves as 0b00 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FB, bit [9]

Force broadcast. Causes the following instructions to be broadcast within the Inner Shareable domain when executed from EL1:

AArch32: [BPIALL](#), [TLBIALL](#), [TLBIMVA](#), [TLBIASID](#), [DTLBIALL](#), [DTLBIMVA](#), [DTLBIASID](#), [ITLBIALL](#), [ITLBIMVA](#), [ITLBIASID](#), [TLBIMVAA](#), [ICIALLU](#), [TLBIMVAL](#), [TLBIMVAAL](#).

AArch64: [TLBI VMALLE1](#), [TLBI VMALLE1NXS](#), [TLBI VAE1](#), [TLBI VAE1NXS](#), [TLBI ASIDE1](#), [TLBI ASIDE1NXS](#), [TLBI VAAE1](#), [TLBI VAAE1NXS](#), [TLBI VALE1](#), [TLBI VALE1NXS](#), [TLBI VAALE1](#), [TLBI VAALE1NXS](#), [IC IALLU](#), [TLBI RVAE1](#), [TLBI RVAE1NXS](#), [TLBI RVAAE1](#), [TLBI RVAAE1NXS](#), [TLBI RVALE1](#), [TLBI RVALE1NXS](#), [TLBI RVAALE1](#), [TLBI RVAALE1NXS](#).

0b0 This field has no effect on the operation of the specified instructions.

0b1 When one of the specified instruction is executed at EL1, the instruction is broadcast within the Inner Shareable shareability domain.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VSE, bit [8]

Virtual SError interrupt.

0b0 This mechanism is not making a virtual SError interrupt pending.

0b1 A virtual SError interrupt is pending because of this mechanism.

The virtual SError interrupt is enabled only when the value of HCR_EL2.{TGE, AMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VI, bit [7]

Virtual IRQ Interrupt.

0b0 This mechanism is not making a virtual IRQ pending.

0b1 A virtual IRQ is pending because of this mechanism.

The virtual IRQ is enabled only when the value of HCR_EL2.{TGE, IMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VF, bit [6]

Virtual FIQ Interrupt.

0b0 This mechanism is not making a virtual FIQ pending.

0b1 A virtual FIQ is pending because of this mechanism.

The virtual FIQ is enabled only when the value of HCR_EL2.{TGE, FMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AMO, bit [5]

Physical SError interrupt routing.

0b0 When executing at Exception levels below EL2, and EL2 is enabled in the current Security state:

- When the value of HCR_EL2.TGE is 0, Physical SError interrupts are not taken to EL2.
- When the value of HCR_EL2.TGE is 1, Physical SError interrupts are taken to EL2 unless they are routed to EL3.

- Virtual SError interrupts are disabled.
- 0b1 When executing at any Exception level, and EL2 is enabled in the current Security state:
- Physical SError interrupts are taken to EL2, unless they are routed to EL3.
 - When the value of HCR_EL2.TGE is 0, then virtual SError interrupts are enabled.

If EL2 is enabled in the current Security state and the value of HCR_EL2.TGE is 1:

- Regardless of the value of the AMO bit physical asynchronous External aborts and SError interrupts target EL2 unless they are routed to EL3.
- When FEAT_VHE is not implemented, or if HCR_EL2.E2H is 0, this field behaves as 1 for all purposes other than a direct read of the value of this bit.
- When FEAT_VHE is implemented and HCR_EL2.E2H is 1, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information, see [Asynchronous exception routing on page D1-2501](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IMO, bit [4]

Physical IRQ Routing.

- 0b0 When executing at Exception levels below EL2, and EL2 is enabled in the current Security state:
- When the value of HCR_EL2.TGE is 0, Physical IRQ interrupts are not taken to EL2.
 - When the value of HCR_EL2.TGE is 1, Physical IRQ interrupts are taken to EL2 unless they are routed to EL3.
 - Virtual IRQ interrupts are disabled.
- 0b1 When executing at any Exception level, and EL2 is enabled in the current Security state:
- Physical IRQ interrupts are taken to EL2, unless they are routed to EL3.
 - When the value of HCR_EL2.TGE is 0, then Virtual IRQ interrupts are enabled.

If EL2 is enabled in the current Security state, and the value of HCR_EL2.TGE is 1:

- Regardless of the value of the IMO bit, physical IRQ Interrupts target EL2 unless they are routed to EL3.
- When FEAT_VHE is not implemented, or if HCR_EL2.E2H is 0, this field behaves as 1 for all purposes other than a direct read of the value of this bit.
- When FEAT_VHE is implemented and HCR_EL2.E2H is 1, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information, see [Asynchronous exception routing on page D1-2501](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FMO, bit [3]

Physical FIQ Routing.

- 0b0 When executing at Exception levels below EL2, and EL2 is enabled in the current Security state:
- When the value of HCR_EL2.TGE is 0, Physical FIQ interrupts are not taken to EL2.
 - When the value of HCR_EL2.TGE is 1, Physical FIQ interrupts are taken to EL2 unless they are routed to EL3.
 - Virtual FIQ interrupts are disabled.

- 0b1 When executing at any Exception level, and EL2 is enabled in the current Security state:
- Physical FIQ interrupts are taken to EL2, unless they are routed to EL3.
 - When HCR_EL2.TGE is 0, then Virtual FIQ interrupts are enabled.

If EL2 is enabled in the current Security state and the value of HCR_EL2.TGE is 1:

- Regardless of the value of the FMO bit, physical FIQ Interrupts target EL2 unless they are routed to EL3.
- When FEAT_VHE is not implemented, or if HCR_EL2.E2H is 0, this field behaves as 1 for all purposes other than a direct read of the value of this bit.
- When FEAT_VHE is implemented and HCR_EL2.E2H is 1, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information, see *Asynchronous exception routing* on page D1-2501.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

PTW, bit [2]

Protected Table Walk. In the EL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs, then the value of this bit determines the behavior:

- 0b0 The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.
- 0b1 The memory access generates a stage 2 Permission fault.

This field is permitted to be cached in a TLB.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SWIO, bit [1]

Set/Way Invalidation Override. Causes EL1 execution of the data cache invalidate by set/way instructions to perform a data cache clean and invalidate by set/way:

- 0b0 This control has no effect on the operation of data cache invalidate by set/way instructions.
- 0b1 Data cache invalidate by set/way instructions perform a data cache clean and invalidate by set/way.

When the value of this bit is 1:

AArch32: DCISW performs the same invalidation as a DCCISW instruction.

AArch64: DCISW performs the same invalidation as a DCISW instruction.

This bit can be implemented as RES1.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VM, bit [0]

Virtualization enable. Enables stage 2 address translation for the EL1&0 translation regime, when EL2 is enabled in the current Security state.

- 0b0 EL1&0 stage 2 address translation disabled.
- 0b1 EL1&0 stage 2 address translation enabled.

When the value of this bit is 1, data cache invalidate instructions executed at EL1 perform a data cache clean and invalidate. For the invalidate by set/way instruction this behavior applies regardless of the value of the HCR_EL2.SWIO bit.

This bit is permitted to be cached in a TLB.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing HCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
        return NVMem[0x078];
    elsif EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elsif PSTATE.EL == EL2 then
    return HCR_EL2;
elsif PSTATE.EL == EL3 then
    return HCR_EL2;

```

MSR HCR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
        NVMem[0x078] = X[t];
    elsif EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elsif PSTATE.EL == EL2 then
    HCR_EL2 = X[t];
elsif PSTATE.EL == EL3 then
    HCR_EL2 = X[t];

```

D13.2.49 HCRX_EL2, Extended Hypervisor Configuration Register

The HCRX_EL2 characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various operations are trapped to EL2.

Configurations

This register is present only when FEAT_HCX is implemented. Otherwise, direct accesses to HCRX_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

The bits in this register behave as if they are 0 for all purposes other than direct reads of the register if:

- EL2 is not enabled in the current Security state.
- [SCR_EL3.HXEn](#) is 0.

Attributes

HCRX_EL2 is a 64-bit register.

Field descriptions

Bits [63:5]

Reserved, RES0.

FGTnXS, bit [4]

When FEAT_XS is implemented:

FGTnXS

Determines if the fine-grained traps in HFGITR_EL2 that apply to each of the TLBI maintenance instructions that are accessible at EL1 also apply to the corresponding TLBI maintenance instructions with the nXS qualifier.

- 0b0 The fine-grained trap in the HFGITR_EL2 that applies to a TLBI maintenance instruction at EL1 also applies to the corresponding TLBI instruction with the nXS qualifier at EL1.
- 0b1 The fine-grained trap in the HFGITR_EL2 that applies to a TLBI maintenance instruction at EL1 does not apply to the corresponding TLBI instruction with the nXS qualifier at EL1.

The reset behavior of this field is:

- On a Warm reset, when EL3 is not implemented and EL2 is implemented, this field resets to 0.

Otherwise:

Reserved, RES0.

FnXS, bit [3]

When FEAT_XS is implemented:

FnXS

Determines the behavior of TLBI instructions affected by the XS attribute.

This control bit also determines whether an AArch64 DSB instruction behaves as a DSB instruction with an nXS qualifier when executed at EL0 and EL1.

0b0 This control does not have any effect on the behavior of the TLBI maintenance instructions.

0b1 A TLBI maintenance instruction without the nXS qualifier executed at EL1 behaves in the same way as the corresponding TLBI maintenance instruction with the nXS qualifier.

An AArch64 DSB instruction executed at EL1 or EL0 behaves in the same way as the corresponding DSB instruction with the nXS qualifier executed at EL1 or EL0.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, when EL3 is not implemented and EL2 is implemented, this field resets to 0.

Otherwise:

Reserved, RES0.

EnASR, bit [2]

When FEAT_LS64 is implemented:

EnASR

When [HCR_EL2](#).{E2H, TGE} != {1, 1}, traps execution of an ST64BV instruction at EL0 or EL1 to EL2.

0b0 Execution of an ST64BV instruction at EL0 is trapped to EL2 if the execution is not trapped by [SCTLR_EL1](#).EnASR.

Execution of an ST64BV instruction at EL1 is trapped to EL2.

0b1 This control does not cause any instructions to be trapped.

A trap of an ST64BV instruction is reported using an ESR_ELx.EC value of 0x0A, with an ISS code of 0x0000000.

The reset behavior of this field is:

- On a Warm reset, when EL3 is not implemented and EL2 is implemented, this field resets to 0.

Otherwise:

Reserved, RES0.

EnALS, bit [1]

When FEAT_LS64 is implemented:

EnALS

When [HCR_EL2](#).{E2H, TGE} != {1, 1}, traps execution of an LD64B or ST64B instruction at EL0 or EL1 to EL2.

0b0 Execution of an LD64B or ST64B instruction at EL0 is trapped to EL2 if the execution is not trapped by [SCTLR_EL1](#).EnALS.

Execution of an LD64B or ST64B instruction at EL1 is trapped to EL2.

0b1 This control does not cause any instructions to be trapped.

A trap of an LD64B or ST64B instruction is reported using an ESR_ELx.EC value of 0x0A, with an ISS code of 0x0000002.

The reset behavior of this field is:

- On a Warm reset, when EL3 is not implemented and EL2 is implemented, this field resets to 0.

Otherwise:

Reserved, RES0.

EnAS0, bit [0]

When FEAT_LS64 is implemented:

EnAS0

When HCR_EL2.{E2H, TGE} != {1, 1}, traps execution of an ST64BV0 instruction at EL0 or EL1 to EL2.

0b0 Execution of an ST64BV0 instruction at EL0 is trapped to EL2 if the execution is not trapped by SCTLR_EL1.EnAS0.

Execution of an ST64BV0 instruction at EL1 is trapped to EL2.

0b1 This control does not cause any instructions to be trapped.

A trap of an ST64BV0 instruction is reported using an ESR_ELx.EC value of 0x0A, with an ISS code of 0x0000001.

The reset behavior of this field is:

- On a Warm reset, when EL3 is not implemented and EL2 is implemented, this field resets to 0.

Otherwise:

Reserved, RES0.

Accessing HCRX_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HCRX_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0010	0b010

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
        return NVMem[0xA0];
    elsif EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else

    HCRX_EL2 = X[t];

```

D13.2.50 HDFGRTR_EL2, Hypervisor Debug Fine-Grained Read Trap Register

The HDFGRTR_EL2 characteristics are:

Purpose

Provides controls for traps of MRS and MRC reads of debug, trace, PMU, and Statistical Profiling System registers.

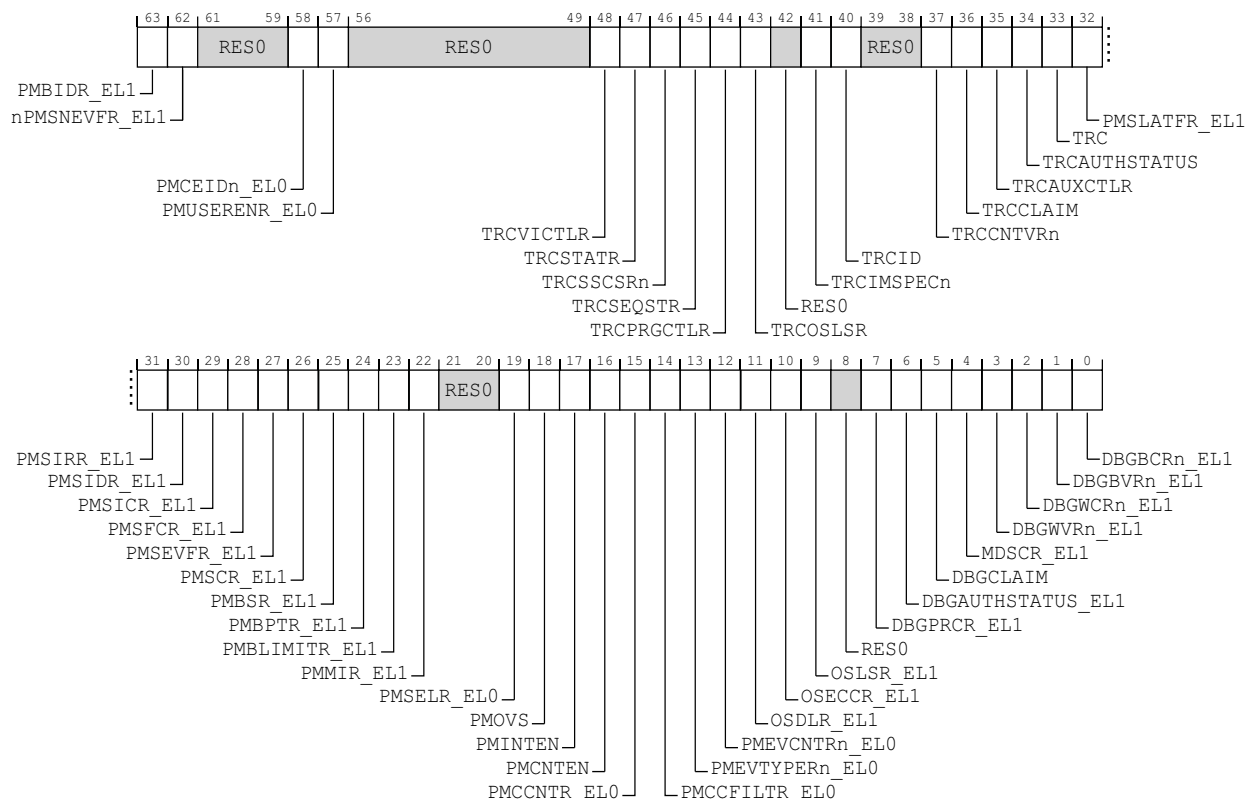

Configurations

This register is present only when FEAT_FGT is implemented. Otherwise, direct accesses to HDFGRTR_EL2 are UNDEFINED.

Attributes

HDFGRTR_EL2 is a 64-bit register.

Field descriptions

PMBIDR_EL1, bit [63]

When FEAT_SPE is implemented:

PMBIDR_EL1

Trap MRS reads of [PMBIDR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [PMBIDR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [PMBIDR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

nPMSNEVFR_EL1, bit [62]

When FEAT_SPEv1p2 is implemented:

nPMSNEVFR_EL1

Trap MRS reads of PMSNEVFR_EL1 at EL1 using AArch64 to EL2.

0b0 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSNEVFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

0b1 MRS reads of PMSNEVFR_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bits [61:59]

Reserved, RES0.

PMCEIDn_EL0, bit [58]

When FEAT_PMUv3 is implemented:

PMCEIDn_EL0

Trap MRS reads of PMCEID<n>_EL0 at EL1 and EL0 using AArch64 and MRC reads of PMCEID<n> at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MRS reads of PMCEID<n>_EL0 at EL1 and EL0 using AArch64 and MRC reads of PMCEID<n> at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, HCR_EL2.{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then, unless the read generates a higher priority exception:

- MRS reads of PMCEID<n>_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
- MRC reads of PMCEID<n> at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMUSERENR_EL0, bit [57]

When FEAT_PMUv3 is implemented:

PMUSERENR_EL0

Trap MRS reads of [PMUSERENR_EL0](#) at EL1 and EL0 using AArch64 and MRC reads of [PMUSERENR](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

- 0b0 MRS reads of [PMUSERENR_EL0](#) at EL1 and EL0 using AArch64 and MRC reads of [PMUSERENR](#) at EL0 using AArch32 are not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTE_n == 1, then, unless the read generates a higher priority exception:
- MRS reads of [PMUSERENR_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
 - MRC reads of [PMUSERENR](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bits [56:49]

Reserved, RES0.

TRCVICTLR, bit [48]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCVICTLR

Trap MRS reads of TRCVICTLR at EL1 using AArch64 to EL2.

- 0b0 MRS reads of TRCVICTLR are not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3](#).FGTE_n == 1, then MRS reads of TRCVICTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCSTATR, bit [47]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCSTATR

Trap MRS reads of TRCSTATR at EL1 using AArch64 to EL2.

- 0b0 MRS reads of TRCSTATR are not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3](#).FGTE_n == 1, then MRS reads of TRCSTATR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCSSCSRn, bit [46]

When FEAT_ETMv4 is implemented, TRCSSCSR<n> are implemented and System register access to the PE Trace Unit registers is implemented:

TRCSSCSRn

Trap MRS reads of TRCSSCSR<n> at EL1 using AArch64 to EL2.

0b0 MRS reads of TRCSSCSR<n> are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of TRCSSCSR<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If Single-shot Comparator n is not implemented, a read of TRCSSCSR<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCSEQSTR, bit [45]

When FEAT_ETMv4 is implemented, TRCSEQSTR is implemented and System register access to the PE Trace Unit registers is implemented:

TRCSEQSTR

Trap MRS reads of TRCSEQSTR at EL1 using AArch64 to EL2.

0b0 MRS reads of TRCSEQSTR are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of TRCSEQSTR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCPRGCTLR, bit [44]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCPRGCTLR

Trap MRS reads of TRCPRGCTLR at EL1 using AArch64 to EL2.

0b0 MRS reads of TRCPRGCTLR are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of TRCPRGCTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCOSLSR, bit [43]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCOSLSR

Trap MRS reads of TRCOSLSR at EL1 using AArch64 to EL2.

0b0 MRS reads of TRCOSLSR are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of TRCOSLSR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [42]

Reserved, RES0.

TRCIMSPECn, bit [41]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCIMSPECn

Trap MRS reads of TRCIMSPEC<n> at EL1 using AArch64 to EL2.

0b0 MRS reads of TRCIMSPEC<n> are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of TRCIMSPEC<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

TRCIMSPEC<1-7> are optional. If TRCIMSPEC<n> is not implemented, a read of TRCIMSPEC<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCID, bit [40]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCID

Trap MRS reads of multiple System registers. Enables a trap on MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- TRCDEVARCH.
- TRCDEVID.
- TRCIDR<n>.

0b0 MRS reads of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bits [39:38]

Reserved, RES0.

TRCCNTVRn, bit [37]

When FEAT_ETMv4 is implemented, TRCCNTVR<n> are implemented and System register access to the PE Trace Unit registers is implemented:

TRCCNTVRn

Trap MRS reads of TRCCNTVR<n> at EL1 using AArch64 to EL2.

0b0 MRS reads of TRCCNTVR<n> are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of TRCCNTVR<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If Counter n is not implemented, a read of TRCCNTVR<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCCLAIM, bit [36]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCCLAIM

Trap MRS reads of multiple System registers. Enables a trap on MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- TRCCLAIMCLR.
- TRCCLAIMSET.

0b0 MRS reads of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCAUXCTLR, bit [35]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCAUXCTLR

Trap MRS reads of TRCAUXCTLR at EL1 using AArch64 to EL2.

0b0 MRS reads of TRCAUXCTLR are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of TRCAUXCTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCAUTHSTATUS, bit [34]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCAUTHSTATUS

Trap MRS reads of TRCAUTHSTATUS at EL1 using AArch64 to EL2.

0b0 MRS reads of TRCAUTHSTATUS are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of TRCAUTHSTATUS at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRC, bit [33]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRC

Trap MRS reads of multiple System registers. Enables a trap on MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- TRCACATR<n>.
- TRCACVR<n>.
- TRCBBCTLR.
- TRCCCCTLR.
- TRCCIDCCTLR0.
- TRCCIDCCTLR1.
- TRCCIDCVR<n>.
- TRCCNTCTLR<n>.
- TRCCNTRLDVR<n>.
- TRCCONFIGR.

- TRCEVENTCTLOR.
- TRCEVENTCTLIR.
- TRCEXTINSELR.
- TRCQCTLR.
- TRCRSCTLR<n>.
- TRCSEQEVR<n>.
- TRCSEQRSTEV.
- TRCSSCCR<n>.
- TRCSSPCICR<n>.
- TRCSTALLCTLR.
- TRCSYNCP.
- TRCTRACEIDR.
- TRCTSCTLR.
- TRCVIIECTLR.
- TRCVIPCSSCTLR.
- TRCVISSCTLR.
- TRCVMIDCCTLR0.
- TRCVMIDCCTLR1.
- TRCVMIDCVR<n>.

0b0 MRS reads of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

A read of an unimplemented register is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSLATFR_EL1, bit [32]

When FEAT_SPE is implemented:

PMSLATFR_EL1

Trap MRS reads of `PMSLATFR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `PMSLATFR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `PMSLATFR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSIRR_EL1, bit [31]

When FEAT_SPE is implemented:

PMSIRR_EL1

Trap MRS reads of PMSIRR_EL1 at EL1 using AArch64 to EL2.

0b0 MRS reads of PMSIRR_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSIRR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSIDR_EL1, bit [30]

When FEAT_SPE is implemented:

PMSIDR_EL1

Trap MRS reads of PMSIDR_EL1 at EL1 using AArch64 to EL2.

0b0 MRS reads of PMSIDR_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSICR_EL1, bit [29]

When FEAT_SPE is implemented:

PMSICR_EL1

Trap MRS reads of PMSICR_EL1 at EL1 using AArch64 to EL2.

0b0 MRS reads of PMSICR_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSICR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSFCR_EL1, bit [28]

When FEAT_SPE is implemented:

PMSFCR_EL1

Trap MRS reads of [PMSFCR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [PMSFCR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [PMSFCR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSEVFR_EL1, bit [27]

When FEAT_SPE is implemented:

PMSEVFR_EL1

Trap MRS reads of [PMSEVFR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [PMSEVFR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [PMSEVFR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSCR_EL1, bit [26]

When FEAT_SPE is implemented:

PMSCR_EL1

Trap MRS reads of [PMSCR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [PMSCR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [PMSCR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMBSR_EL1, bit [25]

When FEAT_SPE is implemented:

PMBSR_EL1

Trap MRS reads of [PMBSR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [PMBSR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `PMBSR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMBPTR_EL1, bit [24]

When FEAT_SPE is implemented:

PMBPTR_EL1

Trap MRS reads of `PMBPTR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `PMBPTR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `PMBPTR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMBLIMITR_EL1, bit [23]

When FEAT_SPE is implemented:

PMBLIMITR_EL1

Trap MRS reads of `PMBLIMITR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `PMBLIMITR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `PMBLIMITR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMMIR_EL1, bit [22]

When FEAT_PMUv3 is implemented:

PMMIR_EL1

Trap MRS reads of `PMMIR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `PMMIR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `PMMIR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bits [21:20]

Reserved, RES0.

PMSELR_EL0, bit [19]

When FEAT_PMUv3 is implemented:

PMSELR_EL0

Trap MRS reads of [PMSELR_EL0](#) at EL1 and EL0 using AArch64 and MRC reads of [PMSELR](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MRS reads of [PMSELR_EL0](#) at EL1 and EL0 using AArch64 and MRC reads of [PMSELR](#) at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTE == 1, then, unless the read generates a higher priority exception:

- MRS reads of [PMSELR_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
- MRC reads of [PMSELR](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMOVS, bit [18]

When FEAT_PMUv3 is implemented:

PMOVS

Trap MRS reads and MRC reads of multiple System registers.

Enables a trap to EL2 the following operations:

- At EL1 and EL0 using AArch64: MRS reads of [PMOVSLR_EL0](#) and [PMOVSSET_EL0](#).
- At EL0 using AArch32 when EL1 is using AArch64: MRC reads of [PMOVS](#) and [PMOVSSET](#).

0b0 The operations listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTE == 1, then, unless the read generates a higher priority exception:

- MRS reads at EL1 and EL0 using AArch64 of [PMOVSLR_EL0](#) and [PMOVSSET_EL0](#) are trapped to EL2 and reported with EC syndrome value 0x18.
- MRC reads at EL0 using AArch32 of [PMOVS](#) and [PMOVSSET](#) are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMINTEN, bit [17]

When FEAT_PMUv3 is implemented:

PMINTEN

Trap MRS reads of multiple System registers. Enables a trap on MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- [PMINTENCLR_EL1](#).
- [PMINTENSET_EL1](#).

0b0 MRS reads of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMCNTEN, bit [16]

When FEAT_PMUv3 is implemented:

PMCNTEN

Trap MRS reads and MRC reads of multiple System registers.

Enables a trap to EL2 the following operations:

- At EL1 and EL0 using AArch64: MRS reads of [PMCNTENCLR_EL0](#) and [PMCNTENSET_EL0](#).
- At EL0 using AArch32 when EL1 is using AArch64: MRC reads of [PMCNTENCLR](#) and [PMCNTENSET](#).

0b0 The operations listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then, unless the read generates a higher priority exception:

- MRS reads at EL1 and EL0 using AArch64 of [PMCNTENCLR_EL0](#) and [PMCNTENSET_EL0](#) are trapped to EL2 and reported with EC syndrome value 0x18.
- MRC reads at EL0 using AArch32 of [PMCNTENCLR](#) and [PMCNTENSET](#) are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMCCNTR_EL0, bit [15]

When FEAT_PMUv3 is implemented:

PMCCNTR_EL0

Trap MRS reads of [PMCCNTR_EL0](#) at EL1 and EL0 using AArch64 and MRC and MRRC reads of [PMCCNTR](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MRS reads of [PMCCNTR_EL0](#) at EL1 and EL0 using AArch64 and MRC and MRRC reads of [PMCCNTR](#) at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTE_n == 1, then, unless the read generates a higher priority exception:

- MRS reads of [PMCCNTR_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
- MRC and MRRC reads of [PMCCNTR](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03 (for MRC) or 0x04 (for MRRC).

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMCCFILTR_EL0, bit [14]

When FEAT_PMUv3 is implemented:

PMCCFILTR_EL0

Trap MRS reads of [PMCCFILTR_EL0](#) at EL1 and EL0 using AArch64 and MRC reads of [PMCCFILTR](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MRS reads of [PMCCFILTR_EL0](#) at EL1 and EL0 using AArch64 and MRC reads of [PMCCFILTR](#) at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTE_n == 1, then, unless the read generates a higher priority exception:

- MRS reads of [PMCCFILTR_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
- MRC reads of [PMCCFILTR](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

[PMCCFILTR_EL0](#) can also be accessed in AArch64 state using [PMXEVTYPEN_EL0](#) when [PMSELR_EL0](#).SEL == 31, and [PMCCFILTR](#) can also be accessed in AArch32 state using [PMXEVTYPEN](#) when [PMSELR](#).SEL == 31.

Setting this field to 1 has no effect on accesses to [PMXEVTYPEN_EL0](#) and [PMXEVTYPEN](#), regardless of the value of [PMSELR_EL0](#).SEL or [PMSELR](#).SEL.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMEVTYPEN_n_EL0, bit [13]

When FEAT_PMUv3 is implemented:

PMEVTYPEN_n_EL0

Trap MRS reads and MRC reads of multiple System registers.

Enables a trap to EL2 the following operations:

- At EL1 and EL0 using AArch64: MRS reads of [PMEVTYPEN<n>_EL0](#) and [PMXEVTYPEN_EL0](#).

- At EL0 using AArch32 when EL1 is using AArch64: MRC reads of [PMEVTYPER<n>](#) and [PMXEVTYPER](#).
- 0b0 The operations listed above are not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the read generates a higher priority exception:
- MRS reads at EL1 and EL0 using AArch64 of [PMEVTYPER<n>_EL0](#) and [PMXEVTYPER_EL0](#) are trapped to EL2 and reported with EC syndrome value 0x18.
 - MRC reads at EL0 using AArch32 of [PMEVTYPER<n>](#) and [PMXEVTYPER](#) are trapped to EL2 and reported with EC syndrome value 0x03.

Regardless of the value of this field, for each value n:

- If event counter n is not implemented, the following accesses are UNDEFINED:
 - In AArch64 state, a read of [PMEVTYPER<n>_EL0](#), or, if n is not 31, a read of [PMXEVTYPER_EL0](#) when [PMSELR_EL0](#).SEL == n.
 - In AArch32 state, a read of [PMEVTYPER<n>](#), or, if n is not 31, a read of [PMXEVTYPER](#) when [PMSELR](#).SEL == n.
- If event counter n is implemented, n is greater-than-or-equal-to [MDCR_EL2](#).HPMN, and EL2 is implemented and enabled in the current Security state, the following generate a Trap exception to EL2 from EL0 or EL1:
 - In AArch64 state, a read of [PMEVTYPER<n>_EL0](#), or a read of [PMXEVTYPER_EL0](#) when [PMSELR_EL0](#).SEL == n, reported with EC syndrome value 0x18.
 - In AArch32 state, a read of [PMEVTYPER<n>](#), or a read of [PMXEVTYPER](#) when [PMSELR](#).SEL == n, reported with EC syndrome value 0x03.

See also [HDFGRTR_EL2](#).PMCCFILTR_EL0.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMEVCNTRn_EL0, bit [12]

When FEAT_PMUv3 is implemented:

[PMEVCNTRn_EL0](#)

Trap MRS reads and MRC reads of multiple System registers.

Enables a trap to EL2 the following operations:

- At EL1 and EL0 using AArch64: MRS reads of [PMEVCNTR<n>_EL0](#) and [PMXEVCNTR_EL0](#).
 - At EL0 using AArch32 when EL1 is using AArch64: MRC reads of [PMEVCNTR<n>](#) and [PMXEVCNTR](#).
- 0b0 The operations listed above are not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the read generates a higher priority exception:
- MRS reads at EL1 and EL0 using AArch64 of [PMEVCNTR<n>_EL0](#) and [PMXEVCNTR_EL0](#) are trapped to EL2 and reported with EC syndrome value 0x18.
 - MRC reads at EL0 using AArch32 of [PMEVCNTR<n>](#) and [PMXEVCNTR](#) are trapped to EL2 and reported with EC syndrome value 0x03.

Regardless of the value of this field, for each value n:

- If event counter n is not implemented, the following accesses are UNDEFINED:
 - In AArch64 state, a read of `PMEVCNTR<n>_EL0`, or a read of `PMXVCNTR_EL0` when `PMSELR_EL0.SEL == n`.
 - In AArch32 state, a read of `PMEVCNTR<n>`, or a read of `PMXVCNTR` when `PMSELR.SEL == n`.
- If event counter n is implemented, n is greater-than-or-equal-to `MDCR_EL2.HPMN`, and EL2 is implemented and enabled in the current Security state, the following generate a Trap exception to EL2 from EL0 or EL1:
 - In AArch64 state, a read of `PMEVCNTR<n>_EL0`, or a read of `PMXVCNTR_EL0` when `PMSELR_EL0.SEL == n`, reported with EC syndrome value `0x18`.
 - In AArch32 state, a read of `PMEVCNTR<n>`, or a read of `PMXVCNTR` when `PMSELR.SEL == n`, reported with EC syndrome value `0x03`.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

Otherwise:

Reserved, RES0.

OSDLR_EL1, bit [11]

When FEAT_DoubleLock is implemented:

OSDLR_EL1

Trap MRS reads of `OSDLR_EL1` at EL1 using AArch64 to EL2.

`0b0` MRS reads of `OSDLR_EL1` are not trapped by this mechanism.

`0b1` If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `OSDLR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

Otherwise:

Reserved, RES0.

OSECCR_EL1, bit [10]

Trap MRS reads of `OSECCR_EL1` at EL1 using AArch64 to EL2.

`0b0` MRS reads of `OSECCR_EL1` are not trapped by this mechanism.

`0b1` If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `OSECCR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

OSLSR_EL1, bit [9]

Trap MRS reads of `OSLSR_EL1` at EL1 using AArch64 to EL2.

`0b0` MRS reads of `OSLSR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `OSLSR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Bit [8]

Reserved, RES0.

DBGPRCR_EL1, bit [7]

Trap MRS reads of `DBGPRCR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `DBGPRCR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `DBGPRCR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGAUTHSTATUS_EL1, bit [6]

Trap MRS reads of `DBGAUTHSTATUS_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `DBGAUTHSTATUS_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `DBGAUTHSTATUS_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGCLAIM, bit [5]

Trap MRS reads of multiple System registers. Enables a trap on MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- `DBGCLAIMCLR_EL1`.
- `DBGCLAIMSET_EL1`.

0b0 MRS reads of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

MDSCR_EL1, bit [4]

Trap MRS reads of `MDSCR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `MDSCR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `MDSCR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGWVRn_EL1, bit [3]

Trap MRS reads of [DBGWVR<n>_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [DBGWVR<n>_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [DBGWVR<n>_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If watchpoint n is not implemented, a read of [DBGWVR<n>_EL1](#) is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGWCRn_EL1, bit [2]

Trap MRS reads of [DBGWCR<n>_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [DBGWCR<n>_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [DBGWCR<n>_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If watchpoint n is not implemented, a read of [DBGWCR<n>_EL1](#) is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGBVRn_EL1, bit [1]

Trap MRS reads of [DBGBVR<n>_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [DBGBVR<n>_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [DBGBVR<n>_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If breakpoint n is not implemented, a read of [DBGBVR<n>_EL1](#) is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGBCRn_EL1, bit [0]

Trap MRS reads of [DBGBCR<n>_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [DBGBCR<n>_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [DBGBCR<n>_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If breakpoint n is not implemented, a read of [DBGBCR<n>_EL1](#) is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Accessing HDFGRTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HDFGRTR_EL2

```

D13.2.51 HDFGWTR_EL2, Hypervisor Debug Fine-Grained Write Trap Register

The HDFGWTR_EL2 characteristics are:

Purpose

Provides controls for traps of MSR and MCR writes of debug, trace, PMU, and Statistical Profiling System registers.

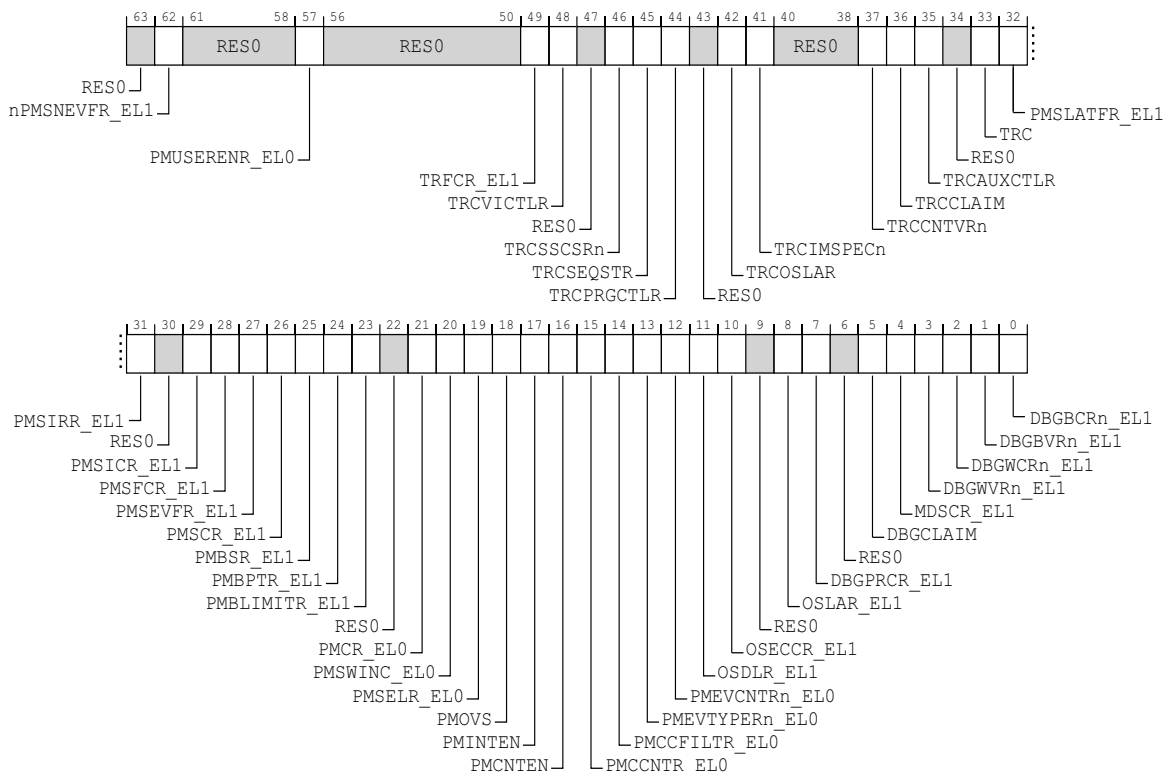

Configurations

This register is present only when FEAT_FGT is implemented. Otherwise, direct accesses to HDFGWTR_EL2 are UNDEFINED.

Attributes

HDFGWTR_EL2 is a 64-bit register.

Field descriptions

Bit [63]

Reserved, RES0.

nPMSNEVFR_EL1, bit [62]

When FEAT_SPEv1p2 is implemented:

nPMSNEVFR_EL1

Trap MSR writes of [PMSNEVFR_EL1](#) at EL1 using AArch64 to EL2.

0b0 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [PMSNEVFR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

0b1 MSR writes of [PMSNEVFR_EL1](#) are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bits [61:58]

Reserved, RES0.

PMUSERENR_EL0, bit [57]

When FEAT_PMUv3 is implemented:

PMUSERENR_EL0

Trap MSR writes of [PMUSERENR_EL0](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [PMUSERENR_EL0](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [PMUSERENR_EL0](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bits [56:50]

Reserved, RES0.

TRFCR_EL1, bit [49]

When FEAT_TRF is implemented:

TRFCR_EL1

Trap MSR writes of [TRFCR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [TRFCR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [TRFCR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCVICTLR, bit [48]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCVICTLR

Trap MSR writes of TRCVICTLR at EL1 using AArch64 to EL2.

0b0 MSR writes of TRCVICTLR are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of TRCVICTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [47]

Reserved, RES0.

TRCSSCSRn, bit [46]

When FEAT_ETMv4 is implemented, TRCSSCSR<n> are implemented and System register access to the PE Trace Unit registers is implemented:

TRCSSCSRn

Trap MSR writes of TRCSSCSR<n> at EL1 using AArch64 to EL2.

0b0 MSR writes of TRCSSCSR<n> are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of TRCSSCSR<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If Single-shot Comparator n is not implemented, a write of TRCSSCSR<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCSEQSTR, bit [45]

When FEAT_ETMv4 is implemented, TRCSEQSTR is implemented and System register access to the PE Trace Unit registers is implemented:

TRCSEQSTR

Trap MSR writes of TRCSEQSTR at EL1 using AArch64 to EL2.

0b0 MSR writes of TRCSEQSTR are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of TRCSEQSTR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCPRGCTLR, bit [44]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCPRGCTLR

Trap MSR writes of TRCPRGCTLR at EL1 using AArch64 to EL2.

0b0 MSR writes of TRCPRGCTLR are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of TRCPRGCTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [43]

Reserved, RES0.

TRCOSLAR, bit [42]

When System register access to the PE Trace Unit registers is implemented and FEAT_ETMv4 is implemented:

TRCOSLAR

Trap MSR writes of TRCOSLAR at EL1 using AArch64 to EL2.

0b0 MSR writes of TRCOSLAR are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of TRCOSLAR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCIMSPECn, bit [41]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCIMSPECn

Trap MSR writes of TRCIMSPEC<n> at EL1 using AArch64 to EL2.

0b0 MSR writes of TRCIMSPEC<n> are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of TRCIMSPEC<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

TRCIMSPEC<1-7> are optional. If TRCIMSPEC<n> is not implemented, a write of TRCIMSPEC<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bits [40:38]

Reserved, RES0.

TRCCNTVRn, bit [37]

When FEAT_ETMv4 is implemented, TRCCNTVR<n> are implemented and System register access to the PE Trace Unit registers is implemented:

TRCCNTVRn

Trap MSR writes of TRCCNTVR<n> at EL1 using AArch64 to EL2.

0b0 MSR writes of TRCCNTVR<n> are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRCCNTVR<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If Counter n is not implemented, a write of TRCCNTVR<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCCCLAIM, bit [36]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCCCLAIM

Trap MSR writes of multiple System registers. Enables a trap on MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- TRCCCLAIMCLR.
- TRCCCLAIMSET.

0b0 MSR writes of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TRCAUXCTLR, bit [35]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRCAUXCTLR

Trap MSR writes of TRCAUXCTLR at EL1 using AArch64 to EL2.

- 0b0 MSR writes of TRCAUXCTLR are not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of TRCAUXCTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [34]

Reserved, RES0.

TRC, bit [33]

When FEAT_ETMv4 is implemented and System register access to the PE Trace Unit registers is implemented:

TRC

Trap MSR writes of multiple System registers. Enables a trap on MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- TRCACATR<n>.
- TRCACVVR<n>.
- TRCBBCTLR.
- TRCCCCTLR.
- TRCCIDCCTLR0.
- TRCCIDCCTLR1.
- TRCCIDCVR<n>.
- TRCCNTCTLR<n>.
- TRCCNTRLDVR<n>.
- TRCCONFIGR.
- TRCEVENTCTL0R.
- TRCEVENTCTL1R.
- TRCEXTINSELR.
- TRCQCTLR.
- TRCRSCTLR<n>.
- TRCSEQEVR<n>.
- TRCSEQRSTEVR.
- TRCSSCCR<n>.
- TRCSSPCICR<n>.
- TRCSTALLCTLR.
- TRCSYNCPR.
- TRCTRACEIDR.

- TRCTSCTLR
- TRCVIIECTLR.
- TRCVIPCSSCTLR.
- TRCVISSCTLR.
- TRCVMIDCCTLR0.
- TRCVMIDCCTLR1.
- TRCVMIDCVR<n>.

0b0 MSR writes of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

A write of an unimplemented register is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSLATFR_EL1, bit [32]

When FEAT_SPE is implemented:

PMSLATFR_EL1

Trap MSR writes of [PMSLATFR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [PMSLATFR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [PMSLATFR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSIRR_EL1, bit [31]

When FEAT_SPE is implemented:

PMSIRR_EL1

Trap MSR writes of [PMSIRR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [PMSIRR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [PMSIRR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [30]

Reserved, RES0.

PMSICR_EL1, bit [29]

When FEAT_SPE is implemented:

PMSICR_EL1

Trap MSR writes of PMSICR_EL1 at EL1 using AArch64 to EL2.

0b0 MSR writes of PMSICR_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMSICR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSFCR_EL1, bit [28]

When FEAT_SPE is implemented:

PMSFCR_EL1

Trap MSR writes of PMSFCR_EL1 at EL1 using AArch64 to EL2.

0b0 MSR writes of PMSFCR_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMSFCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSEVFR_EL1, bit [27]

When FEAT_SPE is implemented:

PMSEVFR_EL1

Trap MSR writes of PMSEVFR_EL1 at EL1 using AArch64 to EL2.

0b0 MSR writes of PMSEVFR_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMSEVFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSCR_EL1, bit [26]

When FEAT_SPE is implemented:

PMSCR_EL1

Trap MSR writes of [PMSCR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [PMSCR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then MSR writes of [PMSCR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMBSR_EL1, bit [25]

When FEAT_SPE is implemented:

PMBSR_EL1

Trap MSR writes of [PMBSR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [PMBSR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then MSR writes of [PMBSR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMBPTR_EL1, bit [24]

When FEAT_SPE is implemented:

PMBPTR_EL1

Trap MSR writes of [PMBPTR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [PMBPTR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then MSR writes of [PMBPTR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMBLIMITR_EL1, bit [23]

When FEAT_SPE is implemented:

PMBLIMITR_EL1

Trap MSR writes of [PMBLIMITR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [PMBLIMITR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [PMBLIMITR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [22]

Reserved, RES0.

PMCR_EL0, bit [21]

When FEAT_PMUv3 is implemented:

PMCR_EL0

Trap MSR writes of [PMCR_EL0](#) at EL1 and EL0 using AArch64 and MCR writes of [PMCR](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MSR writes of [PMCR_EL0](#) at EL1 and EL0 using AArch64 and MCR writes of [PMCR](#) at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then, unless the write generates a higher priority exception:

- MSR writes of [PMCR_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
- MCR writes of [PMCR](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSWINC_EL0, bit [20]

When FEAT_PMUv3 is implemented:

PMSWINC_EL0

Trap MSR writes of [PMSWINC_EL0](#) at EL1 and EL0 using AArch64 and MCR writes of [PMSWINC](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MSR writes of [PMSWINC_EL0](#) at EL1 and EL0 using AArch64 and MCR writes of [PMSWINC](#) at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then, unless the write generates a higher priority exception:

- MSR writes of [PMSWINC_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
- MCR writes of [PMSWINC](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMSELR_EL0, bit [19]

When FEAT_PMUv3 is implemented:

PMSELR_EL0

Trap MSR writes of [PMSELR_EL0](#) at EL1 and EL0 using AArch64 and MCR writes of [PMSELR](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MSR writes of [PMSELR_EL0](#) at EL1 and EL0 using AArch64 and MCR writes of [PMSELR](#) at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the write generates a higher priority exception:

- MSR writes of [PMSELR_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
- MCR writes of [PMSELR](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMOVS, bit [18]

When FEAT_PMUv3 is implemented:

PMOVS

Trap MSR writes and MCR writes of multiple System registers.

Enables a trap to EL2 the following operations:

- At EL1 and EL0 using AArch64: MSR writes of [PMOVSLR_EL0](#) and [PMOVSSET_EL0](#).
- At EL0 using AArch32 when EL1 is using AArch64: MCR writes of [PMOVS](#) and [PMOVSSET](#).

0b0 The operations listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the write generates a higher priority exception:

- MSR writes at EL1 and EL0 using AArch64 of [PMOVSLR_EL0](#) and [PMOVSSET_EL0](#) are trapped to EL2 and reported with EC syndrome value 0x18.
- MCR writes at EL0 using AArch32 of [PMOVS](#) and [PMOVSSET](#) are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMINTEN, bit [17]

When FEAT_PMUv3 is implemented:

PMINTEN

Trap MSR writes of multiple System registers. Enables a trap on MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- [PMINTENCLR_EL1](#).
- [PMINTENSET_EL1](#).

0b0 MSR writes of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMCNTEN, bit [16]

When FEAT_PMUv3 is implemented:

PMCNTEN

Trap MSR writes and MCR writes of multiple System registers.

Enables a trap to EL2 the following operations:

- At EL1 and EL0 using AArch64: MSR writes of [PMCNTENCLR_EL0](#) and [PMCNTENSET_EL0](#).
- At EL0 using AArch32 when EL1 is using AArch64: MCR writes of [PMCNTENCLR](#) and [PMCNTENSET](#).

0b0 The operations listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then, unless the write generates a higher priority exception:

- MSR writes at EL1 and EL0 using AArch64 of [PMCNTENCLR_EL0](#) and [PMCNTENSET_EL0](#) are trapped to EL2 and reported with EC syndrome value 0x18.
- MCR writes at EL0 using AArch32 of [PMCNTENCLR](#) and [PMCNTENSET](#) are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMCCNTR_EL0, bit [15]

When FEAT_PMUv3 is implemented:

PMCCNTR_EL0

Trap MSR writes of [PMCCNTR_EL0](#) at EL1 and EL0 using AArch64 and MCR and MCRR writes of [PMCCNTR](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MSR writes of [PMCCNTR_EL0](#) at EL1 and EL0 using AArch64 and MCR and MCRR writes of [PMCCNTR](#) at EL0 using AArch32 are not trapped by this mechanism.

- 0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#). {E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTE == 1, then, unless the write generates a higher priority exception:
- MSR writes of [PMCCNTR_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
 - MCR and MCRR writes of [PMCCNTR](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03 (for MCR) or 0x04 (for MCRR).

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMCCFILTR_EL0, bit [14]

When FEAT_PMUv3 is implemented:

PMCCFILTR_EL0

Trap MSR writes of [PMCCFILTR_EL0](#) at EL1 and EL0 using AArch64 and MCR writes of [PMCCFILTR](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

- 0b0 MSR writes of [PMCCFILTR_EL0](#) at EL1 and EL0 using AArch64 and MCR writes of [PMCCFILTR](#) at EL0 using AArch32 are not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#). {E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTE == 1, then, unless the write generates a higher priority exception:
- MSR writes of [PMCCFILTR_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
 - MCR writes of [PMCCFILTR](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

[PMCCFILTR_EL0](#) can also be accessed in AArch64 state using [PMXEVTYPEN_EL0](#) when [PMSELR_EL0](#).SEL == 31, and [PMCCFILTR](#) can also be accessed in AArch32 state using [PMXEVTYPEN](#) when [PMSELR](#).SEL == 31.

Setting this field to 1 has no effect on accesses to [PMXEVTYPEN_EL0](#) and [PMXEVTYPEN](#), regardless of the value of [PMSELR_EL0](#).SEL or [PMSELR](#).SEL.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMEVTYPENn_EL0, bit [13]

When FEAT_PMUv3 is implemented:

PMEVTYPENn_EL0

Trap MSR writes and MCR writes of multiple System registers.

Enables a trap to EL2 the following operations:

- At EL1 and EL0 using AArch64: MSR writes of [PMEVTYPEN<n>_EL0](#) and [PMXEVTYPEN_EL0](#).
- At EL0 using AArch32 when EL1 is using AArch64: MCR writes of [PMEVTYPEN<n>](#) and [PMXEVTYPEN](#).

0b0 The operations listed above are not trapped by this mechanism.

- 0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the write generates a higher priority exception:
- MSR writes at EL1 and EL0 using AArch64 of [PMEVTYPER<n>_EL0](#) and [PMXEVTYPER_EL0](#) are trapped to EL2 and reported with EC syndrome value 0x18.
 - MCR writes at EL0 using AArch32 of [PMEVTYPER<n>](#) and [PMXEVTYPER](#) are trapped to EL2 and reported with EC syndrome value 0x03.

Regardless of the value of this field, for each value n:

- If event counter n is not implemented, the following accesses are UNDEFINED:
 - In AArch64 state, a write of [PMEVTYPER<n>_EL0](#), or, if n is not 31, a write of [PMXEVTYPER_EL0](#) when [PMSELR_EL0](#).SEL == n.
 - In AArch32 state, a write of [PMEVTYPER<n>](#), or, if n is not 31, a write of [PMXEVTYPER](#) when [PMSELR](#).SEL == n.
- If event counter n is implemented, n is greater-than-or-equal-to [MDCR_EL2](#).HPMN, and EL2 is implemented and enabled in the current Security state, the following generate a Trap exception to EL2 from EL0 or EL1:
 - In AArch64 state, a write of [PMEVTYPER<n>_EL0](#), or a write of [PMXEVTYPER_EL0](#) when [PMSELR_EL0](#).SEL == n, reported with EC syndrome value 0x18.
 - In AArch32 state, a write of [PMEVTYPER<n>](#), or a write of [PMXEVTYPER](#) when [PMSELR](#).SEL == n, reported with EC syndrome value 0x03.

See also [HDFGWTR_EL2](#).PMCCFILTR_EL0.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

PMEVCNTRn_EL0, bit [12]

When FEAT_PMUv3 is implemented:

[PMEVCNTRn_EL0](#)

Trap MSR writes and MCR writes of multiple System registers.

Enables a trap to EL2 the following operations:

- At EL1 and EL0 using AArch64: MSR writes of [PMEVCNTR<n>_EL0](#) and [PMXEVCNTR_EL0](#).
- At EL0 using AArch32 when EL1 is using AArch64: MCR writes of [PMEVCNTR<n>](#) and [PMXEVCNTR](#).

0b0 The operations listed above are not trapped by this mechanism.

- 0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the write generates a higher priority exception:
- MSR writes at EL1 and EL0 using AArch64 of [PMEVCNTR<n>_EL0](#) and [PMXEVCNTR_EL0](#) are trapped to EL2 and reported with EC syndrome value 0x18.
 - MCR writes at EL0 using AArch32 of [PMEVCNTR<n>](#) and [PMXEVCNTR](#) are trapped to EL2 and reported with EC syndrome value 0x03.

Regardless of the value of this field, for each value n :

- If event counter n is not implemented, the following accesses are UNDEFINED:
 - In AArch64 state, a write of `PMEVCNTR<n>_EL0`, or a write of `PMXEVCNTR_EL0` when `PMSELR_EL0.SEL == n`.
 - In AArch32 state, a write of `PMEVCNTR<n>`, or a write of `PMXEVCNTR` when `PMSELR.SEL == n`.
- If event counter n is implemented, n is greater-than-or-equal-to `MDCR_EL2.HPMN`, and EL2 is implemented and enabled in the current Security state, the following generate a Trap exception to EL2 from EL0 or EL1:
 - In AArch64 state, a write of `PMEVCNTR<n>_EL0`, or a write of `PMXEVCNTR_EL0` when `PMSELR_EL0.SEL == n`, reported with EC syndrome value `0x18`.
 - In AArch32 state, a write of `PMEVCNTR<n>`, or a write of `PMXEVCNTR` when `PMSELR.SEL == n`, reported with EC syndrome value `0x03`.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

Otherwise:

Reserved, RES0.

OSDLR_EL1, bit [11]

When FEAT_DoubleLock is implemented:

OSDLR_EL1

Trap MSR writes of `OSDLR_EL1` at EL1 using AArch64 to EL2.

`0b0` MSR writes of `OSDLR_EL1` are not trapped by this mechanism.

`0b1` If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `OSDLR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

Otherwise:

Reserved, RES0.

OSECCR_EL1, bit [10]

Trap MSR writes of `OSECCR_EL1` at EL1 using AArch64 to EL2.

`0b0` MSR writes of `OSECCR_EL1` are not trapped by this mechanism.

`0b1` If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `OSECCR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

Bit [9]

Reserved, RES0.

OSLAR_EL1, bit [8]

Trap MSR writes of [OSLAR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [OSLAR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [OSLAR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGPRCR_EL1, bit [7]

Trap MSR writes of [DBGPRCR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [DBGPRCR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [DBGPRCR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Bit [6]

Reserved, RES0.

DBGCLAIM, bit [5]

Trap MSR writes of multiple System registers. Enables a trap on MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- [DBGCLAIMCLR_EL1](#).
- [DBGCLAIMSET_EL1](#).

0b0 MSR writes of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

MDSCR_EL1, bit [4]

Trap MSR writes of [MDSCR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [MDSCR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [MDSCR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGWVRn_EL1, bit [3]

Trap MSR writes of [DBGWVR<n>_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [DBGWVR<n>_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `DBGWVR<n>_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If watchpoint n is not implemented, a write of `DBGWVR<n>_EL1` is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGWCRn_EL1, bit [2]

Trap MSR writes of `DBGWCR<n>_EL1` at EL1 using AArch64 to EL2.

0b0 MSR writes of `DBGWCR<n>_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `DBGWCR<n>_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If watchpoint n is not implemented, a write of `DBGWCR<n>_EL1` is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGBVRn_EL1, bit [1]

Trap MSR writes of `DBGBVR<n>_EL1` at EL1 using AArch64 to EL2.

0b0 MSR writes of `DBGBVR<n>_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `DBGBVR<n>_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If breakpoint n is not implemented, a write of `DBGBVR<n>_EL1` is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DBGBCRn_EL1, bit [0]

Trap MSR writes of `DBGBCR<n>_EL1` at EL1 using AArch64 to EL2.

0b0 MSR writes of `DBGBCR<n>_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `DBGBCR<n>_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If breakpoint n is not implemented, a write of `DBGBCR<n>_EL1` is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Accessing HDFGWTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HDFGWTR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0011	0b0001	0b101

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then

```

D13.2.52 HFGITR_EL2, Hypervisor Fine-Grained Instruction Trap Register

The HFGITR_EL2 characteristics are:

Purpose

Provides instruction trap controls.

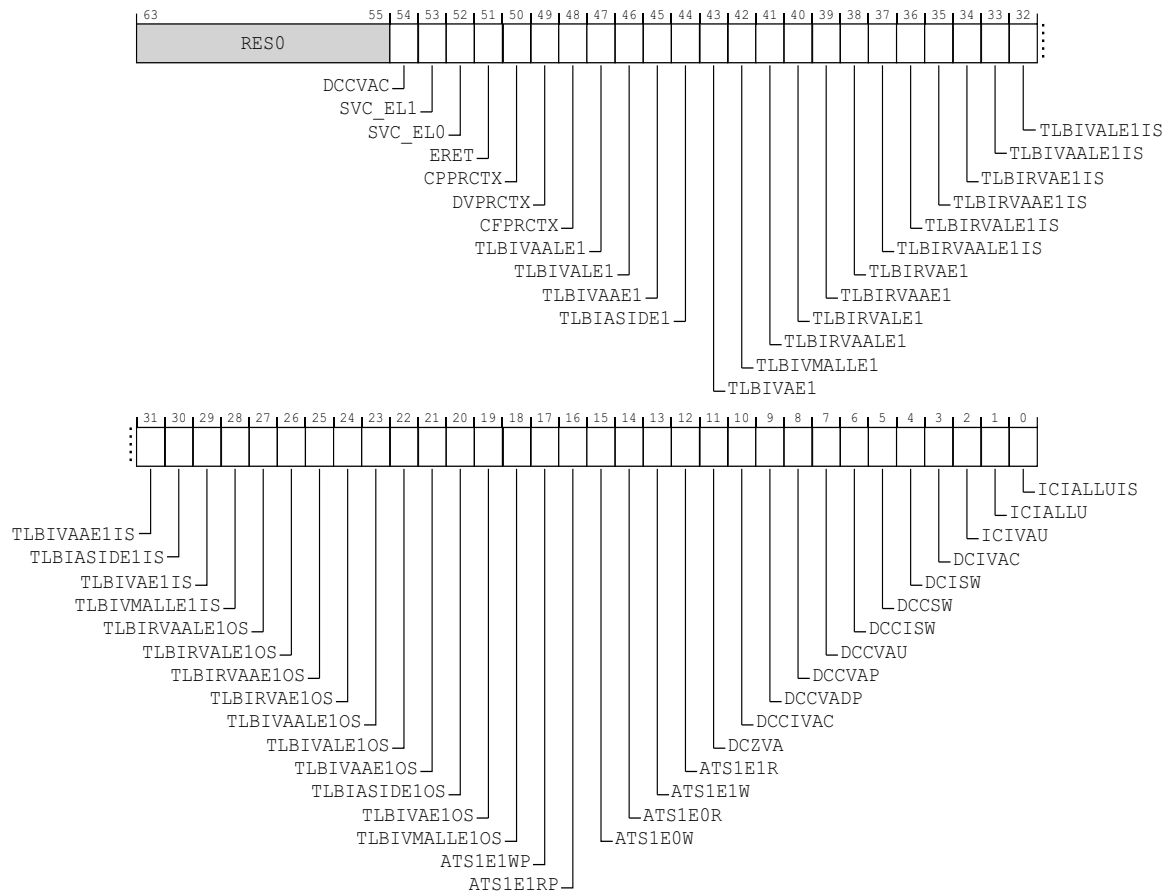

Configurations

This register is present only when FEAT_FGT is implemented. Otherwise, direct accesses to HFGITR_EL2 are UNDEFINED.

Attributes

HFGITR_EL2 is a 64-bit register.

Field descriptions

Bits [63:55]

Reserved, RES0.

DCCVAC, bit [54]

Trap execution of multiple instructions. Enables a trap on execution at EL1 and EL0 using AArch64 of any of the following AArch64 instructions to EL2:

- [DC CVAC](#).

- [DC CGVAC](#), if [FEAT_MTE](#) is implemented.
- [DC CGDVAC](#), if [FEAT_MTE](#) is implemented.

0b0 Execution of the instructions listed above is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, and either EL3 is not implemented or [SCR_EL3](#).FGTE == 1, then execution at EL1 and EL0 using AArch64 of any of the instructions listed above is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

SVC_EL1, bit [53]

Trap execution of SVC at EL1 using AArch64 to EL2.

0b0 Execution of SVC is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3](#).FGTE == 1, then execution of SVC at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x15, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

SVC_EL0, bit [52]

Trap execution of SVC at EL0 using AArch64 and execution of SVC at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 Execution of SVC at EL0 using AArch64 and execution of SVC at EL0 using AArch32 is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTE == 1, then, unless the instruction generates a higher priority exception:

- Execution of SVC at EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x15.
- Execution of SVC at EL0 using AArch32 is trapped to EL2 and reported with EC syndrome value 0x11.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

ERET, bit [51]

Trap execution of multiple instructions. Enables a trap on execution at EL1 using AArch64 of any of the following AArch64 instructions to EL2:

- ERET.
- ERETAA, if [FEAT_PAuth](#) is implemented.
- ERETAB, if [FEAT_PAuth](#) is implemented.

0b0 Execution of the instructions listed above is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3](#).FGTE == 1, then execution at EL1 using AArch64 of any of the instructions listed above is trapped to EL2 and reported with EC syndrome value 0x1A, unless the instruction generates a higher priority exception.

If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).API == 0, and this field enables a fine-grained trap on the instruction, then execution at EL1 using AArch64 of ERETAA or ERETAB instructions is trapped to EL2 and reported with EC syndrome value 0x1A with its associated ISS field, as the fine-grained trap has higher priority than the trap enabled by [HCR_EL2](#).API == 0.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

CPPRCTX, bit [50]

When FEAT_SPECRES is implemented:

CPPRCTX

Trap execution of [CPP RCTX](#) at EL1 and EL0 using AArch64 and execution of [CPPRCTX](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 Execution of [CPP RCTX](#) at EL1 and EL0 using AArch64 and execution of [CPPRCTX](#) at EL0 using AArch32 is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the instruction generates a higher priority exception:

- Execution of [CPP RCTX](#) at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18.
- Execution of [CPPRCTX](#) at EL0 using AArch32 is trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

DVPRCTX, bit [49]

When FEAT_SPECRES is implemented:

DVPRCTX

Trap execution of [DVP RCTX](#) at EL1 and EL0 using AArch64 and execution of [DVPRCTX](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 Execution of [DVP RCTX](#) at EL1 and EL0 using AArch64 and execution of [DVPRCTX](#) at EL0 using AArch32 is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then, unless the instruction generates a higher priority exception:

- Execution of [DVP RCTX](#) at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18.
- Execution of [DVPRCTX](#) at EL0 using AArch32 is trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

CFPRCTX, bit [48]

When FEAT_SPECRES is implemented:

CFPRCTX

Trap execution of `CFP RCTX` at EL1 and EL0 using AArch64 and execution of `CFPRCTX` at EL0 using AArch32 when EL1 is using AArch64 to EL2.

- 0b0 Execution of `CFP RCTX` at EL1 and EL0 using AArch64 and execution of `CFPRCTX` at EL0 using AArch32 is not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, `HCR_EL2`.{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or `SCR_EL3`.FGTE_n == 1, then, unless the instruction generates a higher priority exception:
- Execution of `CFP RCTX` at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18.
 - Execution of `CFPRCTX` at EL0 using AArch32 is trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIVAALE1, bit [47]

Trap execution of `TLBI VAALE1`, `TLBI VAALE1NXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2`.FGT_nX_S == 0, this field also traps execution of `TLBI VAALE1NXS`.

- 0b0 Execution of `TLBI VAALE1`, `TLBI VAALE1NXS` is not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3`.FGTE_n == 1, then execution of `TLBI VAALE1`, `TLBI VAALE1NXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIVALE1, bit [46]

Trap execution of `TLBI VALE1`, `TLBI VALE1NXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2`.FGT_nX_S == 0, this field also traps execution of `TLBI VALE1NXS`.

- 0b0 Execution of `TLBI VALE1`, `TLBI VALE1NXS` is not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3`.FGTE_n == 1, then execution of `TLBI VALE1`, `TLBI VALE1NXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIVAAE1, bit [45]

Trap execution of `TLBI VAAE1`, `TLBI VAAE1NXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2`.FGT_nX_S == 0, this field also traps execution of `TLBI VAAE1NXS`.

- 0b0 Execution of `TLBI VAAE1`, `TLBI VAAE1NXS` is not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3`.FGTE_n == 1, then execution of `TLBI VAAE1`, `TLBI VAAE1NXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIASIDE1, bit [44]

Trap execution of [TLBI ASIDE1](#), [TLBI ASIDE1NXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI ASIDE1NXS](#).

- 0b0 Execution of [TLBI ASIDE1](#), [TLBI ASIDE1NXS](#) is not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI ASIDE1](#), [TLBI ASIDE1NXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIVAE1, bit [43]

Trap execution of [TLBI VAE1](#), [TLBI VAE1NXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI VAE1NXS](#).

- 0b0 Execution of [TLBI VAE1](#), [TLBI VAE1NXS](#) is not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI VAE1](#), [TLBI VAE1NXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIVMALE1, bit [42]

Trap execution of [TLBI VMALLE1](#), [TLBI VMALLE1NXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI VMALLE1NXS](#).

- 0b0 Execution of [TLBI VMALLE1](#), [TLBI VMALLE1NXS](#) is not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI VMALLE1](#), [TLBI VMALLE1NXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIRVALE1, bit [41]

When FEAT_TLBIRANGE is implemented:

TLBIRVALE1

Trap execution of [TLBI RVALE1](#), [TLBI RVALE1NXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI RVALE1NXS](#).

- 0b0 Execution of [TLBI RVALE1](#), [TLBI RVALE1NXS](#) is not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI RVALE1](#), [TLBI RVALE1NXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIRVALE1, bit [40]

When FEAT_TLBIRANGE is implemented:

TLBIRVALE1

Trap execution of [TLBI RVALE1](#), [TLBI RVALE1NXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI RVALE1NXS](#).

- 0b0 Execution of [TLBI RVALE1](#), [TLBI RVALE1NXS](#) is not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI RVALE1](#), [TLBI RVALE1NXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIRVAAE1, bit [39]

When FEAT_TLBIRANGE is implemented:

TLBIRVAAE1

Trap execution of [TLBI RVAAE1](#), [TLBI RVAAE1NXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI RVAAE1NXS](#).

- 0b0 Execution of [TLBI RVAAE1](#), [TLBI RVAAE1NXS](#) is not trapped by this mechanism.
- 0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI RVAAE1](#), [TLBI RVAAE1NXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIRVAE1, bit [38]

When FEAT_TLBIRANGE is implemented:

TLBIRVAE1

Trap execution of [TLBI RVAE1](#), [TLBI RVAE1NXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI RVAE1NXS](#).

- 0b0 Execution of [TLBI RVAE1](#), [TLBI RVAE1NXS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI RVAE1`, `TLBI RVAE1NXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

Otherwise:

Reserved, RES0.

TLBIRVAALE1IS, bit [37]

When FEAT_TLBIRANGE is implemented:

TLBIRVAALE1IS

Trap execution of `TLBI RVAALE1IS`, `TLBI RVAALE1ISNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI RVAALE1ISNXS`.

0b0 Execution of `TLBI RVAALE1IS`, `TLBI RVAALE1ISNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI RVAALE1IS`, `TLBI RVAALE1ISNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

Otherwise:

Reserved, RES0.

TLBIRVALE1IS, bit [36]

When FEAT_TLBIRANGE is implemented:

TLBIRVALE1IS

Trap execution of `TLBI RVALE1IS`, `TLBI RVALE1ISNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI RVALE1ISNXS`.

0b0 Execution of `TLBI RVALE1IS`, `TLBI RVALE1ISNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI RVALE1IS`, `TLBI RVALE1ISNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

Otherwise:

Reserved, RES0.

TLBIRVAAE1IS, bit [35]

When FEAT_TLBIRANGE is implemented:

TLBIRVAAE1IS

Trap execution of [TLBI RVAAE1IS](#), [TLBI RVAAE1ISNXXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI RVAAE1ISNXXS](#).

0b0 Execution of [TLBI RVAAE1IS](#), [TLBI RVAAE1ISNXXS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI RVAAE1IS](#), [TLBI RVAAE1ISNXXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIRVAE1IS, bit [34]

When FEAT_TLBIRANGE is implemented:

TLBIRVAE1IS

Trap execution of [TLBI RVAE1IS](#), [TLBI RVAE1ISNXXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI RVAE1ISNXXS](#).

0b0 Execution of [TLBI RVAE1IS](#), [TLBI RVAE1ISNXXS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI RVAE1IS](#), [TLBI RVAE1ISNXXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIVAALE1IS, bit [33]

Trap execution of [TLBI VAALE1IS](#), [TLBI VAALE1ISNXXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI VAALE1ISNXXS](#).

0b0 Execution of [TLBI VAALE1IS](#), [TLBI VAALE1ISNXXS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI VAALE1IS](#), [TLBI VAALE1ISNXXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIVALE1IS, bit [32]

Trap execution of [TLBI VALE1IS](#), [TLBI VALE1ISNXXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI VALE1ISNXXS](#).

0b0 Execution of [TLBI VALE1IS](#), [TLBI VALE1ISNXXS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI VALE1IS`, `TLBI VALE1ISNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIVAAE1IS, bit [31]

Trap execution of `TLBI VAAE1IS`, `TLBI VAAE1ISNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI VAAE1ISNXS`.

0b0 Execution of `TLBI VAAE1IS`, `TLBI VAAE1ISNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI VAAE1IS`, `TLBI VAAE1ISNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIASIDE1IS, bit [30]

Trap execution of `TLBI ASIDE1IS`, `TLBI ASIDE1ISNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI ASIDE1ISNXS`.

0b0 Execution of `TLBI ASIDE1IS`, `TLBI ASIDE1ISNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI ASIDE1IS`, `TLBI ASIDE1ISNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIVAE1IS, bit [29]

Trap execution of `TLBI VAE1IS`, `TLBI VAE1ISNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI VAE1ISNXS`.

0b0 Execution of `TLBI VAE1IS`, `TLBI VAE1ISNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI VAE1IS`, `TLBI VAE1ISNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIVMALLE1IS, bit [28]

Trap execution of `TLBI VMALLE1IS`, `TLBI VMALLE1ISNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI VMALLE1ISNXS`.

0b0 Execution of `TLBI VMALLE1IS`, `TLBI VMALLE1ISNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI VMALLE1IS`, `TLBI VMALLE1ISNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TLBIRVAALE1OS, bit [27]

When FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented:

TLBIRVAALE1OS

Trap execution of `TLBI RVAALE1OS`, `TLBI RVAALE1OSNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI RVAALE1OSNXS`.

0b0 Execution of `TLBI RVAALE1OS`, `TLBI RVAALE1OSNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI RVAALE1OS`, `TLBI RVAALE1OSNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIRVALE1OS, bit [26]

When FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented:

TLBIRVALE1OS

Trap execution of `TLBI RVALE1OS`, `TLBI RVALE1OSNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI RVALE1OSNXS`.

0b0 Execution of `TLBI RVALE1OS`, `TLBI RVALE1OSNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI RVALE1OS`, `TLBI RVALE1OSNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIRVAAE1OS, bit [25]

When FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented:

TLBIRVAAE1OS

Trap execution of `TLBI RVAAE1OS`, `TLBI RVAAE1OSNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI RVAAE1OSNXS`.

0b0 Execution of `TLBI RVAAE1OS`, `TLBI RVAAE1OSNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI RVAAE1OS`, `TLBI RVAAE1OSNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIRVAE1OS, bit [24]

When `FEAT_TLBIRANGE` is implemented and `FEAT_TLBIOS` is implemented:

TLBIRVAE1OS

Trap execution of `TLBI RVAE1OS`, `TLBI RVAE1OSNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI RVAE1OSNXS`.

0b0 Execution of `TLBI RVAE1OS`, `TLBI RVAE1OSNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI RVAE1OS`, `TLBI RVAE1OSNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIVAALE1OS, bit [23]

When `FEAT_TLBIOS` is implemented:

TLBIVAALE1OS

Trap execution of `TLBI VAALE1OS`, `TLBI VAALE1OSNXS` at EL1 using AArch64 to EL2.

If `FEAT_XS` is implemented and `HCRX_EL2.FGTnXS == 0`, this field also traps execution of `TLBI VAALE1OSNXS`.

0b0 Execution of `TLBI VAALE1OS`, `TLBI VAALE1OSNXS` is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then execution of `TLBI VAALE1OS`, `TLBI VAALE1OSNXS` at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIVALE1OS, bit [22]

When FEAT_TLBIOS is implemented:

TLBIVALE1OS

Trap execution of [TLBI VALE1OS](#), [TLBI VALE1OSNXXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI VALE1OSNXXS](#).

0b0 Execution of [TLBI VALE1OS](#), [TLBI VALE1OSNXXS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI VALE1OS](#), [TLBI VALE1OSNXXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIVAAE1OS, bit [21]

When FEAT_TLBIOS is implemented:

TLBIVAAE1OS

Trap execution of [TLBI VAAE1OS](#), [TLBI VAAE1OSNXXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI VAAE1OSNXXS](#).

0b0 Execution of [TLBI VAAE1OS](#), [TLBI VAAE1OSNXXS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI VAAE1OS](#), [TLBI VAAE1OSNXXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIASIDE1OS, bit [20]

When FEAT_TLBIOS is implemented:

TLBIASIDE1OS

Trap execution of [TLBI ASIDE1OS](#), [TLBI ASIDE1OSNXXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI ASIDE1OSNXXS](#).

0b0 Execution of [TLBI ASIDE1OS](#), [TLBI ASIDE1OSNXXS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI ASIDE1OS](#), [TLBI ASIDE1OSNXXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIVAE1OS, bit [19]

When FEAT_TLBIOS is implemented:

TLBIVAE1OS

Trap execution of [TLBI VAE1OS](#), [TLBI VAE1OSNXXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI VAE1OSNXXS](#).

0b0 Execution of [TLBI VAE1OS](#), [TLBI VAE1OSNXXS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI VAE1OS](#), [TLBI VAE1OSNXXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

TLBIVMALLE1OS, bit [18]

When FEAT_TLBIOS is implemented:

TLBIVMALLE1OS

Trap execution of [TLBI VMALLE1OS](#), [TLBI VMALLE1OSNXXS](#) at EL1 using AArch64 to EL2.

If [FEAT_XS](#) is implemented and [HCRX_EL2.FGTnXS](#) == 0, this field also traps execution of [TLBI VMALLE1OSNXXS](#).

0b0 Execution of [TLBI VMALLE1OS](#), [TLBI VMALLE1OSNXXS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [TLBI VMALLE1OS](#), [TLBI VMALLE1OSNXXS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ATS1E1WP, bit [17]

When FEAT_PAN2 is implemented:

ATS1E1WP

Trap execution of [AT S1E1WP](#) at EL1 using AArch64 to EL2.

0b0 Execution of [AT S1E1WP](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [AT S1E1WP](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ATS1E1RP, bit [16]

When FEAT_PAN2 is implemented:

ATS1E1RP

Trap execution of [AT S1E1RP](#) at EL1 using AArch64 to EL2.

0b0 Execution of [AT S1E1RP](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [AT S1E1RP](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ATS1E0W, bit [15]

Trap execution of [AT S1E0W](#) at EL1 using AArch64 to EL2.

0b0 Execution of [AT S1E0W](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [AT S1E0W](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

ATS1E0R, bit [14]

Trap execution of [AT S1E0R](#) at EL1 using AArch64 to EL2.

0b0 Execution of [AT S1E0R](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [AT S1E0R](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

ATS1E1W, bit [13]

Trap execution of [AT S1E1W](#) at EL1 using AArch64 to EL2.

0b0 Execution of [AT S1E1W](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [AT S1E1W](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

ATS1E1R, bit [12]

Trap execution of [AT S1E1R](#) at EL1 using AArch64 to EL2.

0b0 Execution of [AT S1E1R](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution of [AT S1E1R](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DCZVA, bit [11]

Trap execution of multiple instructions. Enables a trap on execution at EL1 and EL0 using AArch64 of any of the following AArch64 instructions to EL2:

- [DC ZVA](#).
- [DC GVA](#), if [FEAT_MTE](#) is implemented.
- [DC GZVA](#), if [FEAT_MTE](#) is implemented.

———— Note ————

Unlike [HCR_EL2.TDZ](#), this field has no effect on [DCZID_EL0.DZP](#).

0b0 Execution of the instructions listed above is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution at EL1 and EL0 using AArch64 of any of the instructions listed above is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DCCIVAC, bit [10]

Trap execution of multiple instructions. Enables a trap on execution at EL1 and EL0 using AArch64 of any of the following AArch64 instructions to EL2:

- [DC CIVAC](#).
- [DC CIGVAC](#), if [FEAT_MTE](#) is implemented.
- [DC CIGDVAC](#), if [FEAT_MTE](#) is implemented.

0b0 Execution of the instructions listed above is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution at EL1 and EL0 using AArch64 of any of the instructions listed above is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DCCVADP, bit [9]

When FEAT_DPB2 is implemented:

DCCVADP

Trap execution of multiple instructions. Enables a trap on execution at EL1 and EL0 using AArch64 of any of the following AArch64 instructions to EL2:

- [DC CVADP](#).
- [DC CGVADP](#), if [FEAT_MTE](#) is implemented.

- [DC CGDVADP](#), if [FEAT_MTE](#) is implemented.

0b0 Execution of the instructions listed above is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then execution at EL1 and EL0 using AArch64 of any of the instructions listed above is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

DCCVAP, bit [8]

Trap execution of multiple instructions. Enables a trap on execution at EL1 and EL0 using AArch64 of any of the following AArch64 instructions to EL2:

- [DC CVAP](#).
- [DC CGVAP](#), if [FEAT_MTE](#) is implemented.
- [DC CGDVAP](#), if [FEAT_MTE](#) is implemented.

0b0 Execution of the instructions listed above is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then execution at EL1 and EL0 using AArch64 of any of the instructions listed above is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DCCVAU, bit [7]

Trap execution of [DC CVAU](#) at EL1 and EL0 using AArch64 to EL2.

0b0 Execution of [DC CVAU](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then execution of [DC CVAU](#) at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DCCISW, bit [6]

Trap execution of multiple instructions. Enables a trap on execution at EL1 using AArch64 of any of the following AArch64 instructions to EL2:

- [DC CISW](#).
- [DC CIGSW](#), if [FEAT_MTE](#) is implemented.
- [DC CIGDSW](#), if [FEAT_MTE](#) is implemented.

0b0 Execution of the instructions listed above is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then execution at EL1 using AArch64 of any of the instructions listed above is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DCCSW, bit [5]

Trap execution of multiple instructions. Enables a trap on execution at EL1 using AArch64 of any of the following AArch64 instructions to EL2:

- [DC CSW](#).
- [DC CGSW](#), if [FEAT_MTE](#) is implemented.
- [DC CGDSW](#), if [FEAT_MTE](#) is implemented.

0b0 Execution of the instructions listed above is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution at EL1 using AArch64 of any of the instructions listed above is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DCISW, bit [4]

Trap execution of multiple instructions. Enables a trap on execution at EL1 using AArch64 of any of the following AArch64 instructions to EL2:

- [DC ISW](#).
- [DC IGSW](#), if [FEAT_MTE](#) is implemented.
- [DC IGDSW](#), if [FEAT_MTE](#) is implemented.

0b0 Execution of the instructions listed above is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution at EL1 using AArch64 of any of the instructions listed above is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

DCIVAC, bit [3]

Trap execution of multiple instructions. Enables a trap on execution at EL1 using AArch64 of any of the following AArch64 instructions to EL2:

- [DC IVAC](#).
- [DC IGVAC](#), if [FEAT_MTE](#) is implemented.
- [DC IGDVAC](#), if [FEAT_MTE](#) is implemented.

0b0 Execution of the instructions listed above is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then execution at EL1 using AArch64 of any of the instructions listed above is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

ICIVAU, bit [2]

Trap execution of [IC IVAU](#) at EL1 and EL0 using AArch64 to EL2.

0b0 Execution of [IC IVAU](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then execution of [IC IVAU](#) at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

ICIALLU, bit [1]

Trap execution of [IC IALLU](#) at EL1 using AArch64 to EL2.

0b0 Execution of [IC IALLU](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then execution of [IC IALLU](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

ICIALLUIS, bit [0]

Trap execution of [IC IALLUIS](#) at EL1 using AArch64 to EL2.

0b0 Execution of [IC IALLUIS](#) is not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3](#).FGTEn == 1, then execution of [IC IALLUIS](#) at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Accessing HFGITR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HFGITR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b110

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
        return NVMem[0x1C8];

```

D13.2.53 HFGRTR_EL2, Hypervisor Fine-Grained Read Trap Register

The HFGRTR_EL2 characteristics are:

Purpose

Provides controls for traps of MRS and MRC reads of System registers.

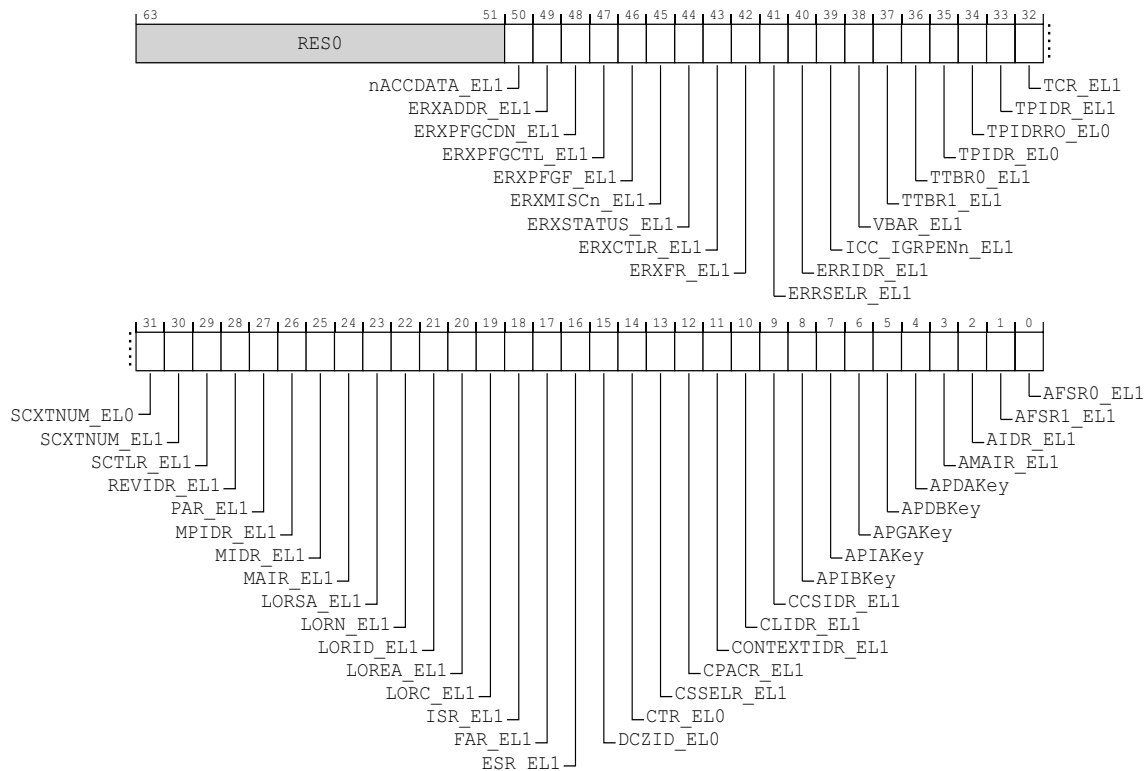

Configurations

This register is present only when FEAT_FGT is implemented. Otherwise, direct accesses to HFGRTR_EL2 are UNDEFINED.

Attributes

HFGRTR_EL2 is a 64-bit register.

Field descriptions

Bits [63:51]

Reserved, RES0.

nACCDATA_EL1, bit [50]

When FEAT_LS64 is implemented:

nACCDATA_EL1

Trap MRS reads of [ACCDATA_EL1](#) at EL1 using AArch64 to EL2.

0b0 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ACCDATA_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

0b1 MRS reads of [ACCDATA_EL1](#) are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXADDR_EL1, bit [49]

When FEAT_RAS is implemented:

ERXADDR_EL1

Trap MRS reads of [ERXADDR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ERXADDR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ERXADDR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXPFGCDN_EL1, bit [48]

When FEAT_RASv1p1 is implemented:

ERXPFGCDN_EL1

Trap MRS reads of [ERXPFGCDN_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ERXPFGCDN_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ERXPFGCDN_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXPFGCTL_EL1, bit [47]

When FEAT_RASv1p1 is implemented:

ERXPFGCTL_EL1

Trap MRS reads of [ERXPFGCTL_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ERXPFGCTL_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ERXPFGCTL_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXPFGF_EL1, bit [46]

When FEAT_RAS is implemented:

ERXPFGF_EL1

Trap MRS reads of [ERXPFGF_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ERXPFGF_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ERXPFGF_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXMISCN_EL1, bit [45]

When FEAT_RAS is implemented:

ERXMISCN_EL1

Trap MRS reads of [ERXMISCN_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ERXMISCN_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ERXMISCN_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXSTATUS_EL1, bit [44]

When FEAT_RAS is implemented:

ERXSTATUS_EL1

Trap MRS reads of [ERXSTATUS_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ERXSTATUS_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ERXSTATUS_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXCTLR_EL1, bit [43]

When FEAT_RAS is implemented:

ERXCTLR_EL1

Trap MRS reads of [ERXCTLR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ERXCTLR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ERXCTLR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXFR_EL1, bit [42]

When FEAT_RAS is implemented:

ERXFR_EL1

Trap MRS reads of [ERXFR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ERXFR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ERXFR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERRSELR_EL1, bit [41]

When FEAT_RAS is implemented:

ERRSELR_EL1

Trap MRS reads of [ERRSELR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ERRSELR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ERRSELR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERRIDR_EL1, bit [40]

When FEAT_RAS is implemented:

ERRIDR_EL1

Trap MRS reads of [ERRIDR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ERRIDR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ERRIDR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ICC_IGRPENn_EL1, bit [39]

When FEAT_GICv3 is implemented:

ICC_IGRPENn_EL1

Trap MRS reads of ICC_IGRPEN<n>_EL1 at EL1 using AArch64 to EL2.

0b0 MRS reads of ICC_IGRPEN<n>_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of ICC_IGRPEN<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

VBAR_EL1, bit [38]

Trap MRS reads of [VBAR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [VBAR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [VBAR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TTBR1_EL1, bit [37]

Trap MRS reads of [TTBR1_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [TTBR1_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [TTBR1_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TTBR0_EL1, bit [36]

Trap MRS reads of [TTBR0_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [TTBR0_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `TTBR0_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

TPIDR_EL0, bit [35]

Trap MRS reads of `TPIDR_EL0` at EL1 and EL0 using AArch64 and MRC reads of `TPIDRURW` at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MRS reads of `TPIDR_EL0` at EL1 and EL0 using AArch64 and MRC reads of `TPIDRURW` at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, `HCR_EL2.{E2H, TGE} != {1, 1}`, EL1 is using AArch64, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then, unless the read generates a higher priority exception:

- MRS reads of `TPIDR_EL0` at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`.
- MRC reads of `TPIDRURW` at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value `0x03`.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

TPIDRRO_EL0, bit [34]

Trap MRS reads of `TPIDRRO_EL0` at EL1 and EL0 using AArch64 and MRC reads of `TPIDRURO` at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MRS reads of `TPIDRRO_EL0` at EL1 and EL0 using AArch64 and MRC reads of `TPIDRURO` at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, `HCR_EL2.{E2H, TGE} != {1, 1}`, EL1 is using AArch64, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then, unless the read generates a higher priority exception:

- MRS reads of `TPIDRRO_EL0` at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`.
- MRC reads of `TPIDRURO` at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value `0x03`.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

TPIDR_EL1, bit [33]

Trap MRS reads of `TPIDR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `TPIDR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `TPIDR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

TCR_EL1, bit [32]

Trap MRS reads of `TCR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `TCR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `TCR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

SCXTNUM_EL0, bit [31]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

SCXTNUM_EL0

Trap MRS reads of `SCXTNUM_EL0` at EL1 and EL0 using AArch64 to EL2.

0b0 MRS reads of `SCXTNUM_EL0` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, `HCR_EL2.{E2H, TGE} != {1, 1}`, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `SCXTNUM_EL0` at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

SCXTNUM_EL1, bit [30]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

SCXTNUM_EL1

Trap MRS reads of `SCXTNUM_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `SCXTNUM_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `SCXTNUM_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

SCTLR_EL1, bit [29]

Trap MRS reads of `SCTLR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `SCTLR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `SCTLR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

REVIDR_EL1, bit [28]

Trap MRS reads of [REVIDR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [REVIDR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [REVIDR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

PAR_EL1, bit [27]

Trap MRS reads of [PAR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [PAR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [PAR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

MPIDR_EL1, bit [26]

Trap MRS reads of [MPIDR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [MPIDR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [MPIDR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

MIDR_EL1, bit [25]

Trap MRS reads of [MIDR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [MIDR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [MIDR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

MAIR_EL1, bit [24]

Trap MRS reads of [MAIR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [MAIR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [MAIR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

LORSA_EL1, bit [23]

When FEAT_LOR is implemented:

LORSA_EL1

Trap MRS reads of LORSA_EL1 at EL1 using AArch64 to EL2.

0b0 MRS reads of LORSA_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of LORSA_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

LORN_EL1, bit [22]

When FEAT_LOR is implemented:

LORN_EL1

Trap MRS reads of LORN_EL1 at EL1 using AArch64 to EL2.

0b0 MRS reads of LORN_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of LORN_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

LORID_EL1, bit [21]

When FEAT_LOR is implemented:

LORID_EL1

Trap MRS reads of LORID_EL1 at EL1 using AArch64 to EL2.

0b0 MRS reads of LORID_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of LORID_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

LOREA_EL1, bit [20]

When FEAT_LOR is implemented:

LOREA_EL1

Trap MRS reads of [LOREA_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [LOREA_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [LOREA_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

LORC_EL1, bit [19]

When FEAT_LOR is implemented:

LORC_EL1

Trap MRS reads of [LORC_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [LORC_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [LORC_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ISR_EL1, bit [18]

Trap MRS reads of [ISR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ISR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [ISR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

FAR_EL1, bit [17]

Trap MRS reads of [FAR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [FAR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [FAR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

ESR_EL1, bit [16]

Trap MRS reads of [ESR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [ESR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `ESR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

DCZID_EL0, bit [15]

Trap MRS reads of `DCZID_EL0` at EL1 and EL0 using AArch64 to EL2.

0b0 MRS reads of `DCZID_EL0` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, `HCR_EL2.{E2H, TGE} != {1, 1}`, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `DCZID_EL0` at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

CTR_EL0, bit [14]

Trap MRS reads of `CTR_EL0` at EL1 and EL0 using AArch64 to EL2.

0b0 MRS reads of `CTR_EL0` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, `HCR_EL2.{E2H, TGE} != {1, 1}`, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `CTR_EL0` at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

CSSELR_EL1, bit [13]

Trap MRS reads of `CSSELR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `CSSELR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `CSSELR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

CPACR_EL1, bit [12]

Trap MRS reads of `CPACR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `CPACR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `CPACR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to `0`.

CONTEXTIDR_EL1, bit [11]

Trap MRS reads of `CONTEXTIDR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `CONTEXTIDR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `CONTEXTIDR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

CLIDR_EL1, bit [10]

Trap MRS reads of `CLIDR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `CLIDR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `CLIDR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

CCSIDR_EL1, bit [9]

Trap MRS reads of `CCSIDR_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `CCSIDR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `CCSIDR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

APIBKey, bit [8]

When FEAT_PAuth is implemented:

APIBKey

Trap MRS reads of multiple System registers. Enables a trap on MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- `APIBKeyHi_EL1`.
- `APIBKeyLo_EL1`.

0b0 MRS reads of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

APIAKey, bit [7]

When FEAT_PAuth is implemented:

APIAKey

Trap MRS reads of multiple System registers. Enables a trap on MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- [APIAKeyHi_EL1](#).
- [APIAKeyLo_EL1](#).

0b0 MRS reads of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) = 1, then MRS reads at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

APGAKey, bit [6]

When FEAT_PAuth is implemented:

APGAKey

Trap MRS reads of multiple System registers. Enables a trap on MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- [APGAKeyHi_EL1](#).
- [APGAKeyLo_EL1](#).

0b0 MRS reads of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) = 1, then MRS reads at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

APDBKey, bit [5]

When FEAT_PAuth is implemented:

APDBKey

Trap MRS reads of multiple System registers. Enables a trap on MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- [APDBKeyHi_EL1](#).
- [APDBKeyLo_EL1](#).

0b0 MRS reads of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) = 1, then MRS reads at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

APDAKey, bit [4]

When FEAT_PAuth is implemented:

APDAKey

Trap MRS reads of multiple System registers. Enables a trap on MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- [APDAKeyHi_EL1](#).
- [APDAKeyLo_EL1](#).

0b0 MRS reads of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

AMAIR_EL1, bit [3]

Trap MRS reads of [AMAIR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [AMAIR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [AMAIR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

AIDR_EL1, bit [2]

Trap MRS reads of [AIDR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [AIDR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [AIDR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

AFSR1_EL1, bit [1]

Trap MRS reads of [AFSR1_EL1](#) at EL1 using AArch64 to EL2.

0b0 MRS reads of [AFSR1_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MRS reads of [AFSR1_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

AFSR0_EL1, bit [0]

Trap MRS reads of `AFSR0_EL1` at EL1 using AArch64 to EL2.

0b0 MRS reads of `AFSR0_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MRS reads of `AFSR0_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Accessing HFGTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HFGTR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b100

```

if PSTATE.EL == EL0 then
    UNDEFINED;

D13.2.54 HFGWTR_EL2, Hypervisor Fine-Grained Write Trap Register

The HFGWTR_EL2 characteristics are:

Purpose

Provides controls for traps of MSR and MCR writes of System registers.

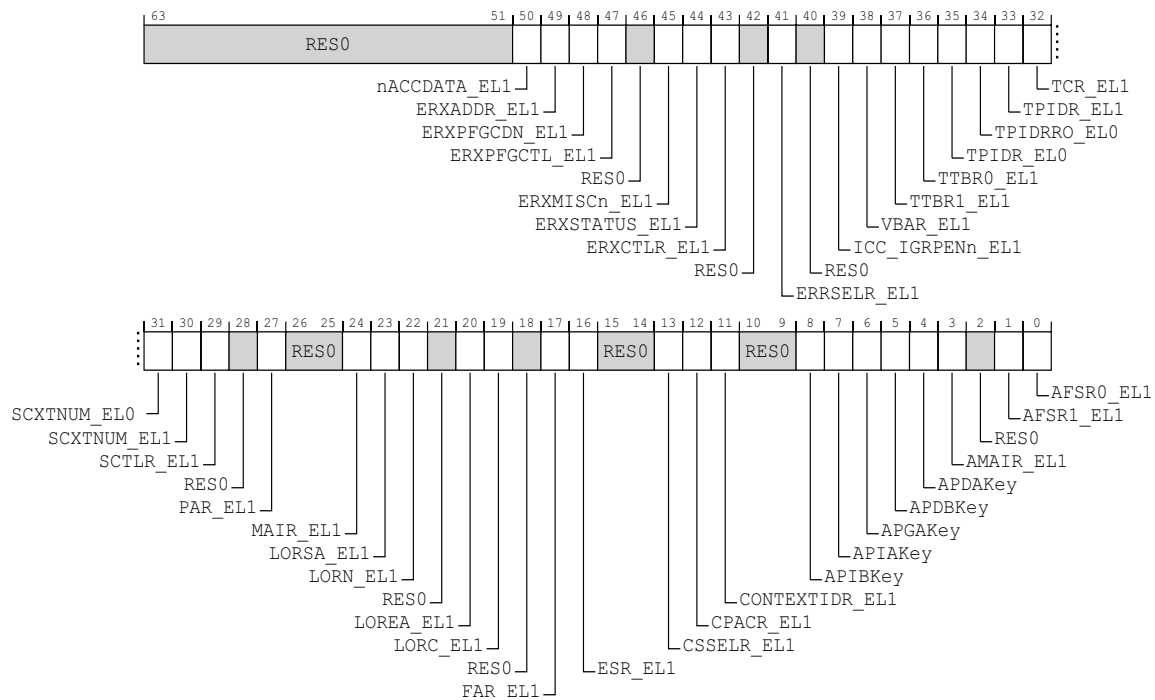

Configurations

This register is present only when FEAT_FGT is implemented. Otherwise, direct accesses to HFGWTR_EL2 are UNDEFINED.

Attributes

HFGWTR_EL2 is a 64-bit register.

Field descriptions

Bits [63:51]

Reserved, RES0.

nACCDATA_EL1, bit [50]

When FEAT_LS64 is implemented:

nACCDATA_EL1

Trap MSR writes of [ACCDATA_EL1](#) at EL1 using AArch64 to EL2.

0b0 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [ACCDATA_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

0b1 MSR writes of [ACCDATA_EL1](#) are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXADDR_EL1, bit [49]

When FEAT_RAS is implemented:

ERXADDR_EL1

Trap MSR writes of [ERXADDR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [ERXADDR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [ERXADDR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXPFGCDN_EL1, bit [48]

When FEAT_RASv1p1 is implemented:

ERXPFGCDN_EL1

Trap MSR writes of [ERXPFGCDN_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [ERXPFGCDN_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [ERXPFGCDN_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXPFGCTL_EL1, bit [47]

When FEAT_RASv1p1 is implemented:

ERXPFGCTL_EL1

Trap MSR writes of [ERXPFGCTL_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [ERXPFGCTL_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [ERXPFGCTL_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [46]

Reserved, RES0.

ERXMISCN_EL1, bit [45]

When FEAT_RAS is implemented:

ERXMISCN_EL1

Trap MSR writes of ERXMISCN<n>_EL1 at EL1 using AArch64 to EL2.

0b0 MSR writes of ERXMISCN<n>_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of ERXMISCN<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXSTATUS_EL1, bit [44]

When FEAT_RAS is implemented:

ERXSTATUS_EL1

Trap MSR writes of ERXSTATUS_EL1 at EL1 using AArch64 to EL2.

0b0 MSR writes of ERXSTATUS_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of ERXSTATUS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

ERXCTLR_EL1, bit [43]

When FEAT_RAS is implemented:

ERXCTLR_EL1

Trap MSR writes of ERXCTLR_EL1 at EL1 using AArch64 to EL2.

0b0 MSR writes of ERXCTLR_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of ERXCTLR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [42]

Reserved, RES0.

ERRSELR_EL1, bit [41]

When FEAT_RAS is implemented:

ERRSELR_EL1

Trap MSR writes of [ERRSELR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [ERRSELR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [ERRSELR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [40]

Reserved, RES0.

ICC_IGRPENn_EL1, bit [39]

When FEAT_GICv3 is implemented:

ICC_IGRPENn_EL1

Trap MSR writes of [ICC_IGRPEN<n>_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [ICC_IGRPEN<n>_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [ICC_IGRPEN<n>_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

VBAR_EL1, bit [38]

Trap MSR writes of [VBAR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [VBAR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [VBAR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TTBR1_EL1, bit [37]

Trap MSR writes of [TTBR1_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [TTBR1_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [TTBR1_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TTBR0_EL1, bit [36]

Trap MSR writes of [TTBR0_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [TTBR0_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [TTBR0_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TPIDR_EL0, bit [35]

Trap MSR writes of [TPIDR_EL0](#) at EL1 and EL0 using AArch64 and MCR writes of [TPIDRURW](#) at EL0 using AArch32 when EL1 is using AArch64 to EL2.

0b0 MSR writes of [TPIDR_EL0](#) at EL1 and EL0 using AArch64 and MCR writes of [TPIDRURW](#) at EL0 using AArch32 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, [HCR_EL2](#).{E2H, TGE} != {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then, unless the write generates a higher priority exception:

- MSR writes of [TPIDR_EL0](#) at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18.
- MCR writes of [TPIDRURW](#) at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TPIDRRO_EL0, bit [34]

Trap MSR writes of [TPIDRRO_EL0](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [TPIDRRO_EL0](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [TPIDRRO_EL0](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TPIDR_EL1, bit [33]

Trap MSR writes of [TPIDR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [TPIDR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `TPIDR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

TCR_EL1, bit [32]

Trap MSR writes of `TCR_EL1` at EL1 using AArch64 to EL2.

0b0 MSR writes of `TCR_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `TCR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

SCXTNUM_EL0, bit [31]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

SCXTNUM_EL0

Trap MSR writes of `SCXTNUM_EL0` at EL1 and EL0 using AArch64 to EL2.

0b0 MSR writes of `SCXTNUM_EL0` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, `HCR_EL2.{E2H, TGE} != {1, 1}`, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `SCXTNUM_EL0` at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

SCXTNUM_EL1, bit [30]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

SCXTNUM_EL1

Trap MSR writes of `SCXTNUM_EL1` at EL1 using AArch64 to EL2.

0b0 MSR writes of `SCXTNUM_EL1` are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `SCXTNUM_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

SCTLR_EL1, bit [29]

Trap MSR writes of [SCTLR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [SCTLR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [SCTLR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Bit [28]

Reserved, RES0.

PAR_EL1, bit [27]

Trap MSR writes of [PAR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [PAR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [PAR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Bits [26:25]

Reserved, RES0.

MAIR_EL1, bit [24]

Trap MSR writes of [MAIR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [MAIR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [MAIR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

LORSA_EL1, bit [23]

When FEAT_LOR is implemented:

LORSA_EL1

Trap MSR writes of [LORSA_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [LORSA_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [LORSA_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

LORN_EL1, bit [22]

When FEAT_LOR is implemented:

LORN_EL1

Trap MSR writes of LORN_EL1 at EL1 using AArch64 to EL2.

0b0 MSR writes of LORN_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of LORN_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [21]

Reserved, RES0.

LOREA_EL1, bit [20]

When FEAT_LOR is implemented:

LOREA_EL1

Trap MSR writes of LOREA_EL1 at EL1 using AArch64 to EL2.

0b0 MSR writes of LOREA_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of LOREA_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

LORC_EL1, bit [19]

When FEAT_LOR is implemented:

LORC_EL1

Trap MSR writes of LORC_EL1 at EL1 using AArch64 to EL2.

0b0 MSR writes of LORC_EL1 are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of LORC_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

Bit [18]

Reserved, RES0.

FAR_EL1, bit [17]

Trap MSR writes of [FAR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [FAR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [FAR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

ESR_EL1, bit [16]

Trap MSR writes of [ESR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [ESR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [ESR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Bits [15:14]

Reserved, RES0.

CSSELR_EL1, bit [13]

Trap MSR writes of [CSSELR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [CSSELR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [CSSELR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

CPACR_EL1, bit [12]

Trap MSR writes of [CPACR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [CPACR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [CPACR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

CONTEXTIDR_EL1, bit [11]

Trap MSR writes of [CONTEXTIDR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [CONTEXTIDR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes of `CONTEXTIDR_EL1` at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Bits [10:9]

Reserved, RES0.

APIBKey, bit [8]

When FEAT_PAuth is implemented:

APIBKey

Trap MSR writes of multiple System registers. Enables a trap on MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- `APIBKeyHi_EL1`.
- `APIBKeyLo_EL1`.

0b0 MSR writes of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

APIAKey, bit [7]

When FEAT_PAuth is implemented:

APIAKey

Trap MSR writes of multiple System registers. Enables a trap on MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- `APIAKeyHi_EL1`.
- `APIAKeyLo_EL1`.

0b0 MSR writes of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or `SCR_EL3.FGTEn == 1`, then MSR writes at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

APGAKey, bit [6]

When FEAT_PAuth is implemented:

APGAKey

Trap MSR writes of multiple System registers. Enables a trap on MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- [APGAKeyHi_EL1](#).
- [APGAKeyLo_EL1](#).

0b0 MSR writes of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

APDBKey, bit [5]

When FEAT_PAuth is implemented:

APDBKey

Trap MSR writes of multiple System registers. Enables a trap on MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- [APDBKeyHi_EL1](#).
- [APDBKeyLo_EL1](#).

0b0 MSR writes of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

APDAKey, bit [4]

When FEAT_PAuth is implemented:

APDAKey

Trap MSR writes of multiple System registers. Enables a trap on MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- [APDAKeyHi_EL1](#).
- [APDAKeyLo_EL1](#).

0b0 MSR writes of the System registers listed above are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes at EL1 using AArch64 of any of the System registers listed above are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Otherwise:

Reserved, RES0.

AMAIR_EL1, bit [3]

Trap MSR writes of [AMAIR_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [AMAIR_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [AMAIR_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Bit [2]

Reserved, RES0.

AFSR1_EL1, bit [1]

Trap MSR writes of [AFSR1_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [AFSR1_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [AFSR1_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

AFSR0_EL1, bit [0]

Trap MSR writes of [AFSR0_EL1](#) at EL1 using AArch64 to EL2.

0b0 MSR writes of [AFSR0_EL1](#) are not trapped by this mechanism.

0b1 If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or [SCR_EL3.FGTEn](#) == 1, then MSR writes of [AFSR0_EL1](#) at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Accessing HFGWTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HFGWTR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b101

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
        return NVMem[0x1C0];
    elseif EL2Enabled() && HCR_EL2.NV == '1' then

```

```

    AArch64.SystemAccessTrap(EL2, 0x18);
else
    UNDEFINED;
elseif PSTATE.EL == EL2 then
    if Halted() && HaveEL(EL3) && EDSCR.SDD == '1' && boolean IMPLEMENTATION_DEFINED "EL3 trap priority
when SDD == '1'" && SCR_EL3.FGTEn == '0' then
        UNDEFINED;
    elseif HaveEL(EL3) && SCR_EL3.FGTEn == '0' then

```

D13.2.55 HPFAR_EL2, Hypervisor IPA Fault Address Register

The HPFAR_EL2 characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to EL2.

Configurations

AArch64 System register HPFAR_EL2 bits [31:0] are architecturally mapped to AArch32 System register [HPFAR](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

The HPFAR_EL2 is written for:

- Translation or Access faults in the second stage of translation.
- An abort in the second stage of translation performed during the translation table walk of a first stage translation, caused by a Translation fault, an Access flag fault, or a Permission fault.
- A stage 2 Address size fault.

For all other exceptions taken to EL2, this register is UNKNOWN.

———— Note ————

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lowest address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

Attributes

HPFAR_EL2 is a 64-bit register.

Field descriptions

Execution at EL1 or EL0 makes HPFAR_EL2 become UNKNOWN.

NS, bit [63]

When FEAT_SEL2 is implemented:

NS

Faulting IPA address space.

0b0 Faulting IPA is from the Secure IPA space.

0b1 Faulting IPA is from the Non-secure IPA space.

For Data Aborts or Instruction Aborts taken to Non-secure EL2, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [62:44]

Reserved, RES0.

FIPA, bits [43:4]

When FEAT_LPA is implemented:

FIPA, bits [38:0]

Faulting Intermediate Physical Address.

When 52-bit addresses are in use for stage 1 translation, FIPA[38:35] forms the upper part of the address value.

When 52-bit addresses are not in use for stage 1 translation, FIPA[38:35] is RES0.

The reset behavior of this field is:
