Release Information

The following releases of this document have been made.

Release history			
Date	Issue	Confidentiality	Change
30 April 2013	A.a-1	Confidential-Beta Draft	Beta draft of first issue, limited circulation
12 June 2013	A.a-2	Confidential-Beta Draft	Second beta draft of first issue, limited circulation
04 September 2013	A.a	Non-Confidential Beta	Beta release
24 December 2013	A.b	Non-Confidential Beta	Second beta release
18 July 2014	A.c	Non-Confidential Beta	Third beta release
09 October 2014	A.d	Non-Confidential Beta	Fourth beta release
17 December 2014	A.e	Non-Confidential Beta	Fifth beta release
25 March 2015	A.f	Non-Confidential Beta	Sixth beta release
10 July 2015	A.g	Non-Confidential Beta	Seventh beta release
30 September 2015	A.h	Non-Confidential Beta	Eighth beta release
28 January 2016	A.i	Non-Confidential Beta	Ninth beta release
03 June 2016	A.j	Non-Confidential EAC	EAC release
30 September 2016	A.k	Non-Confidential Armv8.0 EAC	Updated EAC release
31 March 2017	B.a	Non-Confidential Armv8.1 EAC, v8.2 Beta	Initial release incorporating Armv8.1 and Armv8.2
26 September 2017	B.b	Non-Confidential Armv8.2 EAC	Initial Armv8.2 EAC release, incorporating SPE
20 December 2017	C.a	Non-Confidential Armv8.3 EAC	Initial Armv8.3 EAC release
31 October 2018	D.a	Non-Confidential Armv8.4 EAC	Initial Armv8.4 EAC release
29 April 2019	D.b	Non-Confidential Armv8.4 EAC	Updated Armv8.4 EAC release incorporating accessibility changes
05 July 2019	E.a	Non-Confidential Armv8.5 EAC	Initial Armv8.5 EAC release
20 February 2020	F.a	Non-Confidential Armv8.6 Beta	Initial Armv8.6 Beta release
31 March 2020	F.b	Non-Confidential Armv8.5 EAC, v8.6 Beta	Armv8.5 EAC release, initial Armv8.6 Beta release
17 July 2020	F.c	Non-Confidential Armv8.6 EAC	Initial Armv8.6 EAC release
22 January 2021	G.a	Non-Confidential Armv8.7 EAC	Initial Armv8.7 EAC release
22 July 2021	G.b	Non-Confidential Armv8.7 EAC	Updated Armv8.7 EAC release

Arm Limited. Company 02557590 registered in England.
110 Fulbourn Road, Cambridge, England CB1 9NJ.

(LES-PRE-20349 version 21.0)

In this document, where the term Arm is used to refer to the company it means “Arm or any of its affiliates as appropriate”.

Note

- The term Arm can refer to versions of the Arm architecture, for example Armv8 refers to version 8 of the Arm architecture. The context makes it clear when the term is used in this way.
- This document describes only the Armv8-A architecture profile. For the behaviors required by the previous version of this architecture profile, ARMv7-A, see the *ARM Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

Confidentiality Status

This document is Non-Confidential. The right to use, copy and disclose this document may be subject to license restrictions in accordance with the terms of the agreement entered into by Arm and the party that Arm delivered this document to.

Product Status

The information in this document is final, that is for a developed product.

The information in this manual is at EAC quality, which means that all features of the specification are described in the manual.

Web Address

<http://www.arm.com>

Limitations of this issue

This issue of the Armv8 Architecture Reference Manual contains many improvements and corrections. Validation of this document has identified the following issues that Arm will address in future issues:

- [PE state on reset to AArch64 state on page D1-2472](#) and [PE state on reset into AArch32 state on page G1-6100](#) require further update. Since the reset information is present in the register descriptions, this does not affect the quality status of the release.
- [Appendix K14 Arm Pseudocode Definition](#) requires further review and update. Since this appendix is informative, rather than being part of the architecture specification, this does not affect the quality status of this release.

- For a list of the known issues in this Manual, please refer to the Known Issues document on <https://developer.arm.com/documentation/102105/latest>.
- For a list of the known issues in the System register and instruction XML content, please refer to the Release Notes on <https://developer.arm.com/architectures/cpu-architecture/a-profile/exploration-tools>.

Arm Architecture Reference Manual Armv8, for A-profile architecture

Preface

About this Manual	xviii
Using this Manual	xx
Conventions	xxvi
Additional reading	xxviii
Feedback	xxx

Part A

Armv8 Architecture Introduction and Overview

Chapter A1

Introduction to the Armv8 Architecture

A1.1	About the Arm architecture	A1-34
A1.2	Architecture profiles	A1-36
A1.3	Armv8 architectural concepts	A1-37
A1.4	Supported data types	A1-40
A1.5	Advanced SIMD and floating-point support	A1-52
A1.6	The Arm memory model	A1-62

Chapter A2

Armv8-A Architecture Extensions

A2.1	Armv8.0 architecture extensions	A2-64
A2.2	Architectural features within Armv8.0 architecture	A2-68
A2.3	The Armv8 Cryptographic Extension	A2-72
A2.4	The Armv8.1 architecture extension	A2-74
A2.5	The Armv8.2 architecture extension	A2-78
A2.6	The Armv8.3 architecture extension	A2-87
A2.7	The Armv8.4 architecture extension	A2-91
A2.8	The Armv8.5 architecture extension	A2-96

A2.9	The Armv8.6 architecture extension	A2-100
A2.10	The Armv8.7 architecture extension	A2-103
A2.11	The Performance Monitors Extension	A2-107
A2.12	The Reliability, Availability, and Serviceability Extension	A2-108
A2.13	The Statistical Profiling Extension (SPE)	A2-109
A2.14	The Scalable Vector Extension (SVE)	A2-110
A2.15	The Activity Monitors Extension (AMU)	A2-111
A2.16	The Memory Partitioning and Monitoring (MPAM) Extension	A2-112

Part B The AArch64 Application Level Architecture

Chapter B1 The AArch64 Application Level Programmers' Model

B1.1	About the Application level programmers' model	B1-116
B1.2	Registers in AArch64 Execution state	B1-117
B1.3	Software control features and EL0	B1-122

Chapter B2 The AArch64 Application Level Memory Model

B2.1	About the Arm memory model	B2-126
B2.2	Atomicity in the Arm architecture	B2-128
B2.3	Definition of the Armv8 memory model	B2-133
B2.4	Caches and memory hierarchy	B2-155
B2.5	Alignment support	B2-160
B2.6	Endian support	B2-162
B2.7	Memory types and attributes	B2-165
B2.8	Mismatched memory attributes	B2-176
B2.9	Synchronization and semaphores	B2-179

Part C The AArch64 Instruction Set

Chapter C1 The A64 Instruction Set

C1.1	About the A64 instruction set	C1-194
C1.2	Structure of the A64 assembler language	C1-195
C1.3	Address generation	C1-202
C1.4	Instruction aliases	C1-205

Chapter C2 About the A64 Instruction Descriptions

C2.1	Understanding the A64 instruction descriptions	C2-208
C2.2	General information about the A64 instruction descriptions	C2-211

Chapter C3 A64 Instruction Set Overview

C3.1	Branches, Exception generating, and System instructions	C3-216
C3.2	Loads and stores	C3-224
C3.3	Data processing - immediate	C3-242
C3.4	Data processing - register	C3-247
C3.5	Data processing - SIMD and floating-point	C3-255

Chapter C4 A64 Instruction Set Encoding

C4.1	A64 instruction set encoding	C4-284
------	------------------------------------	--------

Chapter C5 The A64 System Instruction Class

C5.1	The System instruction class encoding space	C5-394
C5.2	Special-purpose registers	C5-408
C5.3	A64 System instructions for cache maintenance	C5-506
C5.4	A64 System instructions for address translation	C5-567
C5.5	A64 System instructions for TLB maintenance	C5-592
C5.6	A64 System instructions for prediction restriction	C5-860

Chapter C6	A64 Base Instruction Descriptions	
C6.1	About the A64 base instructions	C6-872
C6.2	Alphabetical list of A64 base instructions	C6-875

Chapter C7	A64 Advanced SIMD and Floating-point Instruction Descriptions	
C7.1	About the A64 SIMD and floating-point instructions	C7-1522
C7.2	Alphabetical list of A64 Advanced SIMD and floating-point instructions	C7-1524

Part D The AArch64 System Level Architecture

Chapter D1	The AArch64 System Level Programmers' Model	
D1.1	Exception levels	D1-2454
D1.2	Exception terminology	D1-2455
D1.3	Execution state	D1-2457
D1.4	Security state	D1-2458
D1.5	Virtualization	D1-2460
D1.6	Registers for instruction processing and exception handling	D1-2463
D1.7	Process state, PSTATE	D1-2466
D1.8	Program counter and stack pointer alignment	D1-2469
D1.9	Reset	D1-2471
D1.10	Exception entry	D1-2475
D1.11	Exception return	D1-2485
D1.12	Synchronous exception types, routing and priorities	D1-2489
D1.13	Asynchronous exception types, routing, masking and priorities	D1-2500
D1.14	Configurable instruction enables and disables, and trap controls	D1-2510
D1.15	System calls	D1-2535
D1.16	Mechanisms for entering a low-power state	D1-2536
D1.17	Self-hosted debug	D1-2542
D1.18	Event monitors	D1-2544
D1.19	Interprocessing	D1-2545
D1.20	The effect of implementation choices on the programmers' model	D1-2558

Chapter D2	AArch64 Self-hosted Debug	
D2.1	About self-hosted debug	D2-2564
D2.2	The debug exception enable controls	D2-2568
D2.3	Routing debug exceptions	D2-2569
D2.4	Enabling debug exceptions from the current Exception level	D2-2571
D2.5	The effect of powerdown on debug exceptions	D2-2573
D2.6	Summary of the routing and enabling of debug exceptions	D2-2574
D2.7	Pseudocode description of debug exceptions	D2-2576
D2.8	Breakpoint Instruction exceptions	D2-2577
D2.9	Breakpoint exceptions	D2-2579
D2.10	Watchpoint exceptions	D2-2598
D2.11	Vector Catch exceptions	D2-2612
D2.12	Software Step exceptions	D2-2613
D2.13	Synchronization and debug exceptions	D2-2626

Chapter D3	AArch64 Self-hosted Trace	
D3.1	About self-hosted trace	D3-2628
D3.2	Prohibited regions in self-hosted trace	D3-2629
D3.3	Self-hosted trace timestamps	D3-2631
D3.4	Synchronization in self-hosted trace	D3-2632

Chapter D4	The AArch64 System Level Memory Model	
D4.1	About the memory system architecture	D4-2634
D4.2	Address space	D4-2635
D4.3	Mixed-endian support	D4-2636

D4.4	Cache support	D4-2637
D4.5	External aborts	D4-2666
D4.6	Memory barrier instructions	D4-2668
D4.7	Pseudocode description of general memory System instructions	D4-2669
Chapter D5	The AArch64 Virtual Memory System Architecture	
D5.1	About the Virtual Memory System Architecture (VMSA)	D5-2674
D5.2	The VMSAv8-64 address translation system	D5-2682
D5.3	VMSAv8-64 Translation Table format descriptors	D5-2739
D5.4	Memory access control	D5-2754
D5.5	Memory region attributes	D5-2776
D5.6	Virtualization Host Extensions	D5-2787
D5.7	Nested virtualization	D5-2793
D5.8	VMSAv8-64 memory aborts	D5-2800
D5.9	Translation Lookaside Buffers (TLBs)	D5-2810
D5.10	TLB maintenance requirements and the TLB maintenance instructions	D5-2816
D5.11	Caches in a VMSAv8-64 implementation	D5-2835
Chapter D6	Memory Tagging Extension	
D6.1	Introduction	D6-2840
D6.2	Allocation Tags	D6-2841
D6.3	Tag checking	D6-2842
D6.4	Tagged and Untagged Addresses	D6-2843
D6.5	PE access to Allocation Tags	D6-2844
D6.6	Enabling the Memory Tagging Extension	D6-2845
D6.7	PE handling of Tag Check Fault	D6-2846
D6.8	PE generation of Tag Checked and Tag Unchecked accesses	D6-2848
Chapter D7	The Performance Monitors Extension	
D7.1	About the Performance Monitors	D7-2850
D7.2	Accuracy of the Performance Monitors	D7-2853
D7.3	Behavior on overflow	D7-2855
D7.4	Attributability	D7-2857
D7.5	Controlling the PMU counters	D7-2859
D7.6	Multithreaded implementations	D7-2863
D7.7	Event filtering	D7-2865
D7.8	Performance Monitors and Debug state	D7-2867
D7.9	Counter access	D7-2868
D7.10	PMU events and event numbers	D7-2869
D7.11	Performance Monitors Extension registers	D7-2940
Chapter D8	The Activity Monitors Extension	
D8.1	About the Activity Monitors Extension	D8-2942
D8.2	Properties and behavior of the activity monitors	D8-2943
D8.3	AMU events and event numbers	D8-2945
Chapter D9	The Statistical Profiling Extension	
D9.1	About the Statistical Profiling Extension	D9-2948
D9.2	Defining the sample population	D9-2950
D9.3	Controlling when an operation is sampled	D9-2951
D9.4	Enabling profiling	D9-2954
D9.5	Filtering sample records	D9-2956
D9.6	The profiling data	D9-2958
D9.7	The Profiling Buffer	D9-2968
D9.8	Profiling Buffer management	D9-2973
D9.9	Synchronization and Statistical Profiling	D9-2977

Chapter D10	Statistical Profiling Extension Sample Record Specification	
D10.1	About the Statistical Profiling Extension Sample Records	D10-2980
D10.2	Alphabetical list of Statistical Profiling Extension packets	D10-2983
Chapter D11	The Generic Timer in AArch64 state	
D11.1	About the Generic Timer	D11-3008
D11.2	The AArch64 view of the Generic Timer	D11-3012
Chapter D12	AArch64 System Register Encoding	
D12.1	The System register encoding space	D12-3020
D12.2	op0==0b10, Moves to and from debug and trace System registers	D12-3021
D12.3	op0==0b11, Moves to and from non-debug System registers, Special-purpose registers D12-3023	
Chapter D13	AArch64 System Register Descriptions	
D13.1	About the AArch64 System registers	D13-3040
D13.2	General system control registers	D13-3049
D13.3	Debug registers	D13-3810
D13.4	Performance Monitors registers	D13-3929
D13.5	Activity Monitors registers	D13-4001
D13.6	Statistical Profiling Extension registers	D13-4042
D13.7	RAS registers	D13-4091
D13.8	Generic Timer registers	D13-4139

Part E The AArch32 Application Level Architecture

Chapter E1	The AArch32 Application Level Programmers' Model	
E1.1	About the Application level programmers' model	E1-4248
E1.2	The Application level programmers' model in AArch32 state	E1-4249
E1.3	Advanced SIMD and floating-point instructions	E1-4260
E1.4	About the AArch32 System register interface	E1-4278
E1.5	Exceptions	E1-4279
Chapter E2	The AArch32 Application Level Memory Model	
E2.1	About the Arm memory model	E2-4282
E2.2	Atomicity in the Arm architecture	E2-4284
E2.3	Definition of the Armv8 memory model	E2-4288
E2.4	Ordering of translation table walks	E2-4306
E2.5	Caches and memory hierarchy	E2-4307
E2.6	Alignment support	E2-4312
E2.7	Endian support	E2-4314
E2.8	Memory types and attributes	E2-4318
E2.9	Mismatched memory attributes	E2-4328
E2.10	Synchronization and semaphores	E2-4331

Part F The AArch32 Instruction Sets

Chapter F1	About the T32 and A32 Instruction Descriptions	
F1.1	Format of instruction descriptions	F1-4344
F1.2	Standard assembler syntax fields	F1-4348
F1.3	Conditional execution	F1-4349
F1.4	Shifts applied to a register	F1-4351
F1.5	Memory accesses	F1-4353
F1.6	Encoding of lists of general-purpose registers and the PC	F1-4354
F1.7	General information about the T32 and A32 instruction descriptions	F1-4355
F1.8	Additional pseudocode support for instruction descriptions	F1-4368

F1.9	Additional information about Advanced SIMD and floating-point instructions ..	F1-4369
------	---	---------

Chapter F2

The AArch32 Instruction Sets Overview

F2.1	Support for instructions in different versions of the Arm architecture	F2-4376
F2.2	Unified Assembler Language	F2-4377
F2.3	Branch instructions	F2-4379
F2.4	Data-processing instructions	F2-4380
F2.5	PSTATE and banked register access instructions	F2-4388
F2.6	Load/store instructions	F2-4389
F2.7	Load/store multiple instructions	F2-4392
F2.8	Miscellaneous instructions	F2-4393
F2.9	Exception-generating and exception-handling instructions	F2-4395
F2.10	System register access instructions	F2-4397
F2.11	Advanced SIMD and floating-point load/store instructions	F2-4398
F2.12	Advanced SIMD and floating-point register transfer instructions	F2-4400
F2.13	Advanced SIMD data-processing instructions	F2-4401
F2.14	Floating-point data-processing instructions	F2-4412

Chapter F3

T32 Instruction Set Encoding

F3.1	T32 instruction set encoding	F3-4416
F3.2	About the T32 Advanced SIMD and floating-point instructions and their encoding	F3-4491

Chapter F4

A32 Instruction Set Encoding

F4.1	A32 instruction set encoding	F4-4494
F4.2	About the A32 Advanced SIMD and floating-point instructions and their encoding	F4-4562

Chapter F5

T32 and A32 Base Instruction Set Instruction Descriptions

F5.1	Alphabetical list of T32 and A32 base instruction set instructions	F5-4564
F5.2	Encoding and use of banked register transfer instructions	F5-5282

Chapter F6

T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions

F6.1	Alphabetical list of Advanced SIMD and floating-point instructions	F6-5288
------	--	---------

Part G

The AArch32 System Level Architecture

Chapter G1

The AArch32 System Level Programmers' Model

G1.1	About the AArch32 System level programmers' model	G1-6012
G1.2	Exception levels	G1-6013
G1.3	Exception terminology	G1-6014
G1.4	Execution state	G1-6016
G1.5	Instruction Set state	G1-6018
G1.6	Security state	G1-6019
G1.7	Security state, Exception levels, and AArch32 execution privilege	G1-6022
G1.8	Virtualization	G1-6024
G1.9	AArch32 state PE modes, and general-purpose and Special-purpose registers	G1-6026
G1.10	Process state, PSTATE	G1-6035
G1.11	Instruction set states	G1-6041
G1.12	Handling exceptions that are taken to an Exception level using AArch32	G1-6043
G1.13	Routing of aborts taken to AArch32 state	G1-6062
G1.14	Exception return to an Exception level using AArch32	G1-6065
G1.15	Asynchronous exception behavior for exceptions taken from AArch32 state ..	G1-6070
G1.16	AArch32 state exception descriptions	G1-6078
G1.17	Reset into AArch32 state	G1-6100
G1.18	Mechanisms for entering a low-power state	G1-6104
G1.19	The AArch32 System register interface	G1-6109
G1.20	Advanced SIMD and floating-point support	G1-6112
G1.21	Configurable instruction enables and disables, and trap controls	G1-6117

Chapter G2	AArch32 Self-hosted Debug	
G2.1	About self-hosted debug	G2-6154
G2.2	The debug exception enable controls	G2-6158
G2.3	Routing debug exceptions	G2-6159
G2.4	Enabling debug exceptions from the current Privilege level and Security state	G2-6161
G2.5	The effect of powerdown on debug exceptions	G2-6163
G2.6	Summary of permitted routing and enabling of debug exceptions	G2-6164
G2.7	Pseudocode description of debug exceptions	G2-6166
G2.8	Breakpoint Instruction exceptions	G2-6167
G2.9	Breakpoint exceptions	G2-6170
G2.10	Watchpoint exceptions	G2-6195
G2.11	Vector Catch exceptions	G2-6209
G2.12	Synchronization and debug exceptions	G2-6217
Chapter G3	AArch32 Self-hosted Trace	
G3.1	About self-hosted trace	G3-6220
G3.2	Prohibited regions in self-hosted trace	G3-6221
G3.3	Self-hosted trace timestamps	G3-6222
G3.4	Synchronization in self-hosted trace	G3-6223
Chapter G4	The AArch32 System Level Memory Model	
G4.1	About the memory system architecture	G4-6226
G4.2	Address space	G4-6227
G4.3	Mixed-endian support	G4-6228
G4.4	AArch32 cache and branch predictor support	G4-6229
G4.5	System register support for IMPLEMENTATION DEFINED memory features	G4-6254
G4.6	External aborts	G4-6255
G4.7	Memory barrier instructions	G4-6257
G4.8	Pseudocode description of general memory System instructions	G4-6258
Chapter G5	The AArch32 Virtual Memory System Architecture	
G5.1	About VMSAv8-32	G5-6262
G5.2	The effects of disabling address translation stages on VMSAv8-32 behavior	G5-6270
G5.3	Translation tables	G5-6274
G5.4	The VMSAv8-32 Short-descriptor translation table format	G5-6279
G5.5	The VMSAv8-32 Long-descriptor translation table format	G5-6288
G5.6	Memory access control	G5-6308
G5.7	Memory region attributes	G5-6319
G5.8	Translation Lookaside Buffers (TLBs)	G5-6332
G5.9	TLB maintenance requirements	G5-6336
G5.10	Caches in VMSAv8-32	G5-6351
G5.11	VMSAv8-32 memory aborts	G5-6354
G5.12	Exception reporting in a VMSAv8-32 implementation	G5-6367

Chapter G8

AArch32 System Register Descriptions

G8.1	About the AArch32 System registers	G8-6438
G8.2	General system control registers	G8-6454
G8.3	Debug registers	G8-6945
G8.4	Performance Monitors registers	G8-7074
G8.5	Activity Monitors registers	G8-7155
G8.6	RAS registers	G8-7192
G8.7	Generic Timer registers	G8-7253

Part H

External Debug

Chapter H1

About External Debug

H1.1	Introduction to external debug	H1-7334
H1.2	External debug	H1-7335
H1.3	Required debug authentication	H1-7336

Chapter H2

Debug State

H2.1	About Debug state	H2-7338
H2.2	Halting the PE on debug events	H2-7339
H2.3	Entering Debug state	H2-7345
H2.4	Behavior in Debug state	H2-7348
H2.5	Exiting Debug state	H2-7375

Chapter H3

Halting Debug Events

H3.1	Introduction to Halting debug events	H3-7378
H3.2	Halting Step debug events	H3-7380
H3.3	Halt Instruction debug event	H3-7390
H3.4	Exception Catch debug event	H3-7391
H3.5	External Debug Request debug event	H3-7395
H3.6	OS Unlock Catch debug event	H3-7396
H3.7	Reset Catch debug events	H3-7397
H3.8	Software Access debug event	H3-7398
H3.9	Synchronization and Halting debug events	H3-7399

Chapter H4

The Debug Communication Channel and Instruction Transfer Register

H4.1	Introduction	H4-7402
H4.2	DCC and ITR registers	H4-7403
H4.3	DCC and ITR access modes	H4-7406
H4.4	Flow control of the DCC and ITR registers	H4-7410
H4.5	Synchronization of DCC and ITR accesses	H4-7413
H4.6	Interrupt-driven use of the DCC	H4-7418
H4.7	Pseudocode description of the operation of the DCC and ITR registers	H4-7419

Chapter H5

The Embedded Cross-Trigger Interface

H5.1	About the Embedded Cross-Trigger (ECT)	H5-7422
H5.2	Basic operation on the ECT	H5-7424
H5.3	Cross-triggers on a PE in an Armv8 implementation	H5-7428
H5.4	Description and allocation of CTI triggers	H5-7429
H5.5	CTI registers programmers' model	H5-7433
H5.6	Examples	H5-7434

Chapter H6

Debug Reset and Powerdown Support

H6.1	About Debug over powerdown	H6-7438
H6.2	Power domains and debug	H6-7439
H6.3	Core power domain power states	H6-7440
H6.4	Powerup request mechanism	H6-7442
H6.5	Emulating low-power states	H6-7444

H6.6	Debug OS Save and Restore sequences	H6-7446
H6.7	Reset and debug	H6-7452
Chapter H7	The PC Sample-based Profiling Extension	
H7.1	About the PC Sample-based Profiling Extension	H7-7456
Chapter H8	About the External Debug Registers	
H8.1	Relationship between external debug and System registers	H8-7460
H8.2	Endianness and supported access sizes	H8-7461
H8.3	Synchronization of changes to the external debug registers	H8-7462
H8.4	Memory-mapped accesses to the external debug interface	H8-7466
H8.5	External debug interface register access permissions	H8-7468
H8.6	External debug interface registers	H8-7472
H8.7	Cross-trigger interface registers	H8-7479
H8.8	External debug register resets	H8-7481
Chapter H9	External Debug Register Descriptions	
H9.1	About the debug registers	H9-7486
H9.2	External debug registers	H9-7487
H9.3	Cross-Trigger Interface registers	H9-7599
Part I	Memory-mapped Components of the Armv8 Architecture	
Chapter I1	Requirements for Memory-mapped Components	
I1.1	Supported access sizes	I1-7656
I1.2	Synchronization of memory-mapped registers	I1-7658
I1.3	Access requirements for reserved and unallocated registers	I1-7660
Chapter I2	System Level Implementation of the Generic Timer	
I2.1	About the Generic Timer specification	I2-7662
I2.2	Memory-mapped counter module	I2-7664
I2.3	Memory-mapped timer components	I2-7668
Chapter I3	Recommended External Interface to the Performance Monitors	
I3.1	About the external interface to the Performance Monitors registers	I3-7674
Chapter I4	Recommended External Interface to the Activity Monitors	
I4.1	About the external interface to the Activity Monitors Extension registers	I4-7680
Chapter I5	External System Control Register Descriptions	
I5.1	About the external system control register descriptions	I5-7684
I5.2	External Performance Monitors registers summary	I5-7686
I5.3	Performance Monitors external register descriptions	I5-7689
I5.4	External Activity Monitors Extension registers summary	I5-7765
I5.5	Activity Monitors external register descriptions	I5-7767
I5.6	Generic Timer memory-mapped registers overview	I5-7804
I5.7	Generic Timer memory-mapped register descriptions	I5-7805
I5.8	RAS register descriptions	I5-7849
Part J	Architectural Pseudocode	
Chapter J1	Armv8 Pseudocode	
J1.1	Pseudocode for AArch64 operation	J1-7960
J1.2	Pseudocode for AArch32 operation	J1-8134
J1.3	Shared pseudocode	J1-8221

Part K

Appendixes

Appendix K1	Architectural Constraints on UNPREDICTABLE Behaviors	
K1.1	AArch32 CONSTRAINED UNPREDICTABLE behaviors	K1-8386
K1.2	AArch64 CONSTRAINED UNPREDICTABLE behaviors	K1-8408
Appendix K2	Recommended External Debug Interface	
K2.1	About the recommended external debug interface	K2-8426
K2.2	PMUEVENT bus	K2-8430
K2.3	Recommended authentication interface	K2-8431
K2.4	Management registers and CoreSight compliance	K2-8432
Appendix K3	Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events	
K3.1	Arm recommendations for IMPLEMENTATION DEFINED event numbers	K3-8446
K3.2	Summary of events for exceptions taken to an Exception level using AArch64	K3-8462
Appendix K4	Recommendations for Reporting Memory Attributes on an Interconnect	
K4.1	Arm recommendations for reporting memory attributes on an interconnect ...	K4-8466
Appendix K5	Additional Information for Implementations of the Generic Timer	
K5.1	Providing a complete set of features in a system level implementation	K5-8468
K5.2	Gray-count scheme for timer distribution scheme	K5-8470
Appendix K6	Legacy Instruction Syntax for AArch32 Instruction Sets	
K6.1	Legacy Instruction Syntax	K6-8472
Appendix K7	Address Translation Examples	
K7.1	AArch64 Address translation examples	K7-8480
K7.2	AArch32 Address translation examples	K7-8492
Appendix K8	Example OS Save and Restore Sequences	
K8.1	Save Debug registers	K8-8502
K8.2	Restore Debug registers	K8-8504
Appendix K9	Recommended Upload and Download Processes for External Debug	
K9.1	Using memory access mode in AArch64 state	K9-8508
Appendix K10	Software Usage Examples	
K10.1	Use of the Advanced SIMD complex number instructions	K10-8512
K10.2	Use of the Armv8.2 extensions to the Cryptographic Extension	K10-8514
Appendix K11	Barrier Litmus Tests	
K11.1	Introduction	K11-8522
K11.2	Load-Acquire, Store-Release and barriers	K11-8525
K11.3	Load-Acquire Exclusive, Store-Release Exclusive and barriers	K11-8529
K11.4	Using a mailbox to send an interrupt	K11-8534
K11.5	Cache and TLB maintenance instructions and barriers	K11-8535
K11.6	Armv7 compatible approaches for ordering, using DMB and DSB barriers ..	K11-8547
Appendix K12	Random Number Generation	
K12.1	Properties of the generated random number	K12-8562
Appendix K13	Legacy Feature Naming Convention	
K13.1	The Armv8.0 architecture	K13-8564

K13.2	The Armv8.1 architecture extension	K13-8565
K13.3	The Armv8.2 architecture extension	K13-8566
K13.4	The Armv8.3 architecture extension	K13-8568
K13.5	The Armv8.4 architecture extension	K13-8569
K13.6	The Armv8.5 architecture extension	K13-8570
K13.7	The Armv8.6 architecture extension	K13-8571

Appendix K14 Arm Pseudocode Definition

K14.1	About the Arm pseudocode	K14-8574
K14.2	Pseudocode for instruction descriptions	K14-8575
K14.3	Data types	K14-8577
K14.4	Operators	K14-8582
K14.5	Statements and control structures	K14-8588
K14.6	Built-in functions	K14-8593
K14.7	Miscellaneous helper procedures and functions	K14-8596
K14.8	Arm pseudocode definition index	K14-8598

Appendix K15 Registers Index

K15.1	Introduction and register disambiguation	K15-8602
K15.2	Alphabetical index of AArch64 registers and System instructions	K15-8607
K15.3	Functional index of AArch64 registers and System instructions	K15-8624
K15.4	Alphabetical index of AArch32 registers and System instructions	K15-8640
K15.5	Functional index of AArch32 registers and System instructions	K15-8650
K15.6	Alphabetical index of memory-mapped registers	K15-8662
K15.7	Functional index of memory-mapped registers	K15-8669

Glossary

Preface

This preface introduces the *Arm Architecture Reference Manual, Armv8, for Armv8-A architecture profile*. It contains the following sections:

- *About this Manual* on page xviii.
- *Using this Manual* on page xx.
- *Conventions* on page xxvi.
- *Additional reading* on page xxviii.
- *Feedback* on page xxx.

About this Manual

This manual describes the Arm® architecture v8, Armv8. The architecture describes the operation of an Armv8-A *Processing element (PE)*, and this Manual includes descriptions of:

- The two Execution states, AArch64 and AArch32.
- The instruction sets:
 - In AArch32 state, the A32 and T32 instruction sets, that are compatible with earlier versions of the Arm architecture.
 - In AArch64 state, the A64 instruction set.
- The states that determine how a PE operates, including the current Exception level and Security state, and in AArch32 state the PE mode.
- The Exception model.
- The interprocessing model, that supports transitioning between AArch64 state and AArch32 state.
- The memory model, that defines memory ordering and memory management. This manual covers a single architecture profile, Armv8-A, that defines a *Virtual Memory System Architecture (VMSA)*.
- The programmers' model, and its interfaces to System registers that control most PE and memory system features, and provide status information.
- The Advanced SIMD and floating-point instructions, that provide high-performance:
 - Single-precision, half-precision, and double-precision floating-point operations.
 - Conversions between double-precision, single-precision, and half-precision floating-point values.
 - Integer, single-precision floating-point, and half-precision floating-point vector operations in all instruction sets.
 - Double-precision floating-point vector operations in the A64 instruction set.
- The security model, that provides two Security states to support Secure applications.
- The virtualization model.
- The Debug architecture, that provides software access to debug features.

This manual gives the assembler syntax for the instructions it describes, meaning that it describes instructions in textual form. However, this Manual is not a tutorial for Arm assembler language, nor does it describe Arm assembler language, except at a very basic level. To make effective use of Arm assembler language, read the documentation supplied with the assembler being used.

This manual is organized into parts:

- | | |
|---------------|--|
| Part A | Provides an introduction to the Armv8-A architecture, and an overview of the AArch64 and AArch32 Execution states. |
| Part B | Describes the application level view of the AArch64 Execution state, meaning the view from EL0. It describes the application level view of the programmers' model and the memory model. |
| Part C | Describes the A64 instruction set, that is available in the AArch64 Execution state. The descriptions for each instruction also include the precise effects of each instruction when executed at EL0, described as <i>unprivileged</i> execution, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate Arm machine code. |
| Part D | Describes the system level view of the AArch64 Execution state. It includes details of the System registers, most of which are not accessible from EL0, and the system level view of the programmers' model and the memory model. This part includes the description of self-hosted debug. |

Part E Describes the application level view of the AArch32 Execution state, meaning the view from the EL0. It describes the application level view of the programmers' model and the memory model.

———— **Note** —————

In AArch32 state, execution at EL0 is execution in User mode.

Part F Describes the T32 and A32 instruction sets, that are available in the AArch32 Execution state. These instruction sets are backwards-compatible with earlier versions of the Arm architecture. This part describes the precise effects of each instruction when executed in User mode, described as *unprivileged* execution or execution at EL0, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate Arm machine code.

———— **Note** —————

User mode is the only mode where software execution is unprivileged.

Part G Describes the system level view of the AArch32 Execution state, that is generally compatible with earlier versions of the Arm architecture. This part includes details of the System registers, most of which are not accessible from EL0, and the instruction interface to those registers. It also describes the system level view of the programmers' model and the memory model.

Part H Describes the Debug architecture for external debug. This provides configuration, breakpoint and watchpoint support, and a *Debug Communications Channel* (DCC) to a debug host.

Part I Describes additional features of the architecture that are not closely coupled to a *processing element* (PE), and therefore are accessed through memory-mapped interfaces. Some of these features are OPTIONAL.

Part J Provides pseudocode that describes various features of the Armv8 architecture.

Part K, Appendixes

Provide additional information. Some appendixes give information that is not part of the Armv8 architectural requirements. The cover page of each appendix indicates its status.

Glossary Defines terms used in this document that have a specialized meaning.

———— **Note** —————

Terms that are generally well understood in the microelectronics industry are not included in the Glossary.

Using this Manual

The information in this Manual is organized into parts, as described in this section.

Part A, Introduction and Architecture Overview

Part A gives an overview of the Armv8-A architecture profile, including its relationship to the other Arm PE architectures. It introduces the terminology used to describe the architecture, and gives an overview of the Executions states, AArch64 and AArch32. It contains the following chapter:

Chapter A1 *Introduction to the Armv8 Architecture*

Read this for an introduction to the Armv8 architecture.

Chapter A2 *Armv8-A Architecture Extensions*

Read this for an introduction to the Armv8 architecture extensions.

Part B, The AArch64 Application Level Architecture

Part B describes the AArch64 state application level view of the architecture. It contains the following chapters:

Chapter B1 *The AArch64 Application Level Programmers' Model*

Read this for an application level description of the programmers' model for software executing in AArch64 state. It describes execution at EL0 when EL0 is using AArch64 state.

Chapter B2 *The AArch64 Application Level Memory Model*

Read this for an application level description of the memory model for software executing in AArch64 state. It describes the memory model for execution in EL0 when EL0 is using AArch64 state. It includes information about Arm memory types, attributes, and memory access controls.

Part C, The A64 Instruction Set

Part C describes the A64 instruction set, that is used in AArch64 state. It contains the following chapters:

Chapter C1 *The A64 Instruction Set*

Read this for a description of the A64 instruction set and common instruction operation details.

Chapter C2 *About the A64 Instruction Descriptions*

Read this to understand the format of the A64 instruction descriptions.

Chapter C3 *A64 Instruction Set Overview*

Read this for an overview of the individual A64 instructions, that are divided into five functional groups.

Chapter C4 *A64 Instruction Set Encoding*

Read this for a description of the A64 instruction set encoding.

Chapter C5 *The A64 System Instruction Class*

Read this for a description of the AArch64 System instructions and register descriptions, and the System instruction class encoding space.

Chapter C6 *A64 Base Instruction Descriptions*

Read this for information on key aspects of the A64 base instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*

Read this for information on key aspects of the A64 Advanced SIMD and floating-point instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Part D, The AArch64 System Level Architecture

Part D describes the AArch64 state system level view of the architecture. It contains the following chapters:

Chapter D1 *The AArch64 System Level Programmers' Model*

Read this for a description of the AArch64 state system level view of the programmers' model.

Chapter D2 *AArch64 Self-hosted Debug*

Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

Chapter D3 *AArch64 Self-hosted Trace*

Read this for an introduction to, and a description of, self-hosted trace in AArch64 state.

Chapter D4 *The AArch64 System Level Memory Model*

Read this for a description of the AArch64 state system level view of the general features of the memory system.

Chapter D5 *The AArch64 Virtual Memory System Architecture*

Read this for a system level view of the AArch64 Virtual Memory System Architecture (VMSA), the memory system architecture of an Armv8 implementation executing in AArch64 state.

Chapter D7 *The Performance Monitors Extension*

Read this for a description of an implementation of the Arm Performance Monitors, an optional non-invasive debug component.

Chapter D8 *The Activity Monitors Extension*

Read this for a description of an implementation of the Arm Activity Monitors, an optional non-invasive component.

Chapter D9 *The Statistical Profiling Extension*

Read this for a description of an implementation of the Statistical Profiling Extension, an optional AArch64 state non-invasive debug component.

Chapter D10 *Statistical Profiling Extension Sample Record Specification*

Read this for a description the sample records generated by the Statistical Profiling Extension.

Chapter D11 *The Generic Timer in AArch64 state*

Read this for a description of the AArch64 view of an implementation of the Arm Generic Timer.

Chapter D12 *AArch64 System Register Encoding*

Read this for a description of the encoding of the AArch64 System registers, and the other uses of the AArch64 System registers encoding space.

Chapter D13 *AArch64 System Register Descriptions*

Read this for an introduction to, and description of, each of the AArch64 System registers.

Part E, The AArch32 Application Level Architecture

Part E describes the AArch32 state application level view of the architecture. It contains the following chapters:

Chapter E1 *The AArch32 Application Level Programmers' Model*

Read this for an application level description of the programmers' model for software executing in AArch32 state. It describes execution at EL0 when EL0 is using AArch32 state.

Chapter E2 *The AArch32 Application Level Memory Model*

Read this for an application level description of the memory model for software executing in AArch32 state. It describes the memory model for execution in EL0 when EL0 is using AArch32 state. It includes information about Arm memory types, attributes, and memory access controls.

Part F, The AArch32 Instruction Sets

Part F describes the T32 and A32 instruction sets, that are used in AArch32 state. It contains the following chapters:

Chapter F1 *About the T32 and A32 Instruction Descriptions*

Read this to understand the format of the T32 and A32 instruction descriptions.

Chapter F2 *The AArch32 Instruction Sets Overview*

Read this for an overview of the T32 and A32 instruction sets.

Chapter F3 *T32 Instruction Set Encoding*

Read this for a description of the T32 instruction set encoding. This includes the T32 encoding of the Advanced SIMD and floating-point instructions.

Chapter F4 *A32 Instruction Set Encoding*

Read this for a description of the A32 instruction set encoding. This includes the A32 encoding of the Advanced SIMD and floating-point instructions.

Chapter F5 *T32 and A32 Base Instruction Set Instruction Descriptions*

Read this for a description of each of the T32 and A32 base instructions.

Chapter F6 *T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions*

Read this for a description of each of the T32 and A32 Advanced SIMD and floating-point instructions.

Part G, The AArch32 System Level Architecture

Part G describes the AArch32 state system level view of the architecture. It contains the following chapters:

Chapter G1 *The AArch32 System Level Programmers' Model*

Read this for a description of the AArch32 state system level view of the programmers' model for execution in an Exception level that is using AArch32.

Chapter G2 *AArch32 Self-hosted Debug*

Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

Chapter G3 *AArch32 Self-hosted Trace*

Read this for an introduction to, and a description of, self-hosted trace in AArch64 state.

Chapter G4 *The AArch32 System Level Memory Model*

Read this for a system level view of the general features of the memory system.

Chapter G5 *The AArch32 Virtual Memory System Architecture*

Read this for a description of the AArch32 Virtual Memory System Architecture (VMSA).

Chapter G6 *The Generic Timer in AArch32 state*

Read this for a description of the AArch32 view of an implementation of the Arm Generic Timer.

Chapter G7 *AArch32 System register Encoding*

Read this for a description of the encoding of the AArch32 System registers, including the System instructions that are part of the AArch32 System registers encoding space.

Chapter G8 *AArch32 System Register Descriptions*

Read this for a description of each of the AArch32 System registers.

Part H, External Debug

Part H describes the architecture for external debug. It contains the following chapters:

Chapter H1 *About External Debug*

Read this for an introduction to external debug, and a definition of the scope of this part of the manual.

Chapter H2 *Debug State*

Read this for a description of Debug state, which the PE might enter as the result of a Halting debug event.

Chapter H3 *Halting Debug Events*

Read this for a description of the external debug events referred to as Halting debug events.

Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*

Read this for a description of the communication between a debugger and the PE debug logic using the Debug Communications Channel and the Instruction Transfer register.

Chapter H5 *The Embedded Cross-Trigger Interface*

Read this for a description of the embedded cross-trigger interface.

Chapter H6 *Debug Reset and Powerdown Support*

Read this for a description of reset and powerdown support in the Debug architecture.

Chapter H7 *The PC Sample-based Profiling Extension*

Read this for a description of the PC Sample-based Profiling Extension that is an OPTIONAL extension to an Armv8 implementation.

Chapter H8 *About the External Debug Registers*

Read this for some additional information about the external debug registers.

Chapter H9 *External Debug Register Descriptions*

Read this for a description of each external debug register.

Part I, Memory-mapped Components of the Armv8 Architecture

Part I describes the memory-mapped components in the architecture. It contains the following chapters:

Chapter I1 *Requirements for Memory-mapped Components*

Read this for descriptions of some general requirements for memory-mapped components within a system that complies with the Armv8 Architecture.

Chapter I2 *System Level Implementation of the Generic Timer*

Read this for a definition of a system level implementation of the Generic Timer.

Chapter I3 *Recommended External Interface to the Performance Monitors*

Read this for a description of the recommended memory-mapped and external debug interfaces to the Performance Monitors.

Chapter I4 *Recommended External Interface to the Activity Monitors*

Read this for a description of the recommended memory-mapped interface to the Activity Monitors.

Chapter I5 *External System Control Register Descriptions*

Read this for a description of each memory-mapped system control register.

Part J, Architectural Pseudocode

Part J contains pseudocode that describes various features of the Arm architecture. It contains the following chapter:

Chapter J1 *Armv8 Pseudocode*

Read this for the pseudocode definitions that describe various features of the Armv8 architecture, for operation in AArch64 state and in AArch32 state.

Part K, Appendixes

This manual contains the following appendixes:

Appendix K1 *Architectural Constraints on UNPREDICTABLE Behaviors*

Read this for a description of the architecturally-required constraints on UNPREDICTABLE behaviors in the Armv8 architecture, including AArch32 behaviors that were UNPREDICTABLE in previous versions of the architecture.

Appendix K2 *Recommended External Debug Interface*

Read this for a description of the recommended external debug interface.

———— **Note** —————

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K3 *Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events*

Read this for a description of Arm recommendations for the use of the IMPLEMENTATION DEFINED event numbers.

———— **Note** —————

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K4 *Recommendations for Reporting Memory Attributes on an Interconnect*

Read this for the Arm recommendations about how the architectural memory attributes are reported on an interconnect.

Appendix K5 *Additional Information for Implementations of the Generic Timer*

Read this for additional information about implementations of the Arm Generic Timer. This information does not form part of the architectural definition of the Generic Timer.

Appendix K6 *Legacy Instruction Syntax for AArch32 Instruction Sets*

Read this for information about the pre-UAL syntax of the AArch32 instruction sets, which can still be valid for the A32 instruction set.

Appendix K7 *Address Translation Examples*

Read this for examples of translation table lookups using the translation regimes described in [Chapter D5 *The AArch64 Virtual Memory System Architecture*](#) and [Chapter G5 *The AArch32 Virtual Memory System Architecture*](#).

Appendix K8 *Example OS Save and Restore Sequences*

Read this for software examples that perform the OS Save and Restore sequences for an Armv8 debug implementation.

Note

Chapter H6 *Debug Reset and Powerdown Support* describes the OS Save and Restore mechanism.

Appendix K9 Recommended Upload and Download Processes for External Debug

Read this for information about implementing and using the Arm architecture.

Note

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K10 Software Usage Examples

Read this for software examples that help understanding of some aspects of the Arm architecture.

Note

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K11 Barrier Litmus Tests

Read this for examples of the use of barrier instructions provided by the Armv8 architecture.

Note

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K14 Arm Pseudocode Definition

Read this for definitions of the AArch32 pseudocode.

Appendix K15 Registers Index

Read this for an alphabetic and functional index of AArch32 and AArch64 registers, and memory-mapped registers.

Glossary

Defines terms used in this document that have a specialized meaning.

Note

Terms that are generally well understood in the microelectronics industry are not included in the Glossary.

Conventions

The following sections describe conventions that this book can use:

- *Typographic conventions* on page xxvi.
- *Signals* on page xxvii.
- *Numbers* on page xxvii.
- *Pseudocode descriptions* on page xxvii.
- *Assembler syntax descriptions* on page xxvii.

Typographic conventions

The typographical conventions are:

italic Introduces special terminology, and denotes citations.

bold Denotes signal names, and is used for terms in descriptive lists, where appropriate.

monospace Used for assembler syntax descriptions, pseudocode, and source code examples.
Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

SMALL CAPITALS

Used in body text for a few terms that have specific technical meanings, and are defined in the *Glossary*.

Colored text Indicates a link. This can be:

- A URL, for example <https://developer.arm.com>.
- A cross-reference, that includes the page number of the referenced information if it is not on the current page, for example, [Assembler syntax descriptions on page xxvii](#).
- A link, to a chapter or appendix, or to a glossary entry, or to the section of the document that defines the colored term, for example [Simple sequential execution](#) or [SCTLR](#).

{ and } Braces, { and }, have two distinct uses:

Optional items

In syntax descriptions braces enclose optional items. In the following example they indicate that the `<shift>` parameter is optional:

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

Similarly they can be used in generalized field descriptions, for example `TCR_ELx.{I}PS` refers to a field in the `TCR_ELx` registers that is called either `IPS` or `PS`.

Sets of items

Braces can be used to enclose sets. For example, `HCR_EL2.{E2H, TGE}` refers to a set of two register fields, `HCR_EL2.E2H` and `HCR_EL2.TGE`

Notes Notes are formatted as:

———— **Note** —————

This is a Note.

In this Manual, Notes are used only to provide additional information, usually to help understanding of the text. While a Note may repeat architectural information given elsewhere in the Manual, a Note never provides any part of the definition of the architecture.

Signals

In general this specification does not define hardware signals, but it does include some signal examples and recommendations. The signal conventions are:

- Signal level** The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:
- HIGH for active-HIGH signals.
 - LOW for active-LOW signals.
- Lowercase n** At the start or end of a signal name denotes an active-LOW signal.

Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a monospace font, for example `0xFFFF0000`. To improve readability, long numbers can be written with an underscore separator between every four characters, for example `0xFFFF_0000_0000_0000`. Ignore any underscores when interpreting the value of a number.

Pseudocode descriptions

This manual uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in monospace font, and is described in [Appendix K14 Arm Pseudocode Definition](#).

Assembler syntax descriptions

This manual contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a monospace font, and use the conventions described in [Structure of the A64 assembler language on page C1-195](#), and [Appendix K14 Arm Pseudocode Definition](#).

Additional reading

This section lists relevant publications from Arm and third parties.

See Arm Developer, <https://developer.arm.com>, for access to Arm documentation.

Feedback

Arm welcomes feedback on its documentation.

Feedback on this Manual

If you have comments on the content of this Manual, send email to errata@arm.com. Give:

- The title, *Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile*.
- The number, ARM DDI 0487G.b.
- The section name to which your comments refer.
- The page numbers to which your comments refer.
- A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

———— **Note** —————

Arm tests PDFs only in Adobe Acrobat and Acrobat Reader, and cannot guarantee the appearance or behavior of any document when viewed with any other PDF reader.

Progressive Terminology Commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive. Arm strives to lead the industry and create change.

Previous issues of this document included terms that can be offensive. We have replaced these terms. If you find offensive terms in this document, please contact terms@arm.com.

Part A

Armv8 Architecture Introduction and Overview

Chapter A1

Introduction to the Armv8 Architecture

This chapter introduces the Arm architecture. It contains the following sections:

- *About the Arm architecture* on page A1-34.
- *Architecture profiles* on page A1-36.
- *Armv8 architectural concepts* on page A1-37.
- *Supported data types* on page A1-40.
- *Advanced SIMD and floating-point support* on page A1-52.
- *The Arm memory model* on page A1-62.

A1.1 About the Arm architecture

The Arm architecture described in this Architecture Reference Manual defines the behavior of an abstract machine, referred to as a *processing element*, often abbreviated to *PE*. Implementations compliant with the Arm architecture must conform to the described behavior of the processing element. It is not intended to describe how to build an implementation of the PE, nor to limit the scope of such implementations beyond the defined behaviors.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with the Arm architecture must be the same as a simple sequential execution of the program on the processing element. This programmer-visible behavior does not include the execution time of the program.

The Arm Architecture Reference Manual also describes rules for software to use the processing element.

The Arm architecture includes definitions of:

- An associated debug architecture, see:
 - [Chapter D2 AArch64 Self-hosted Debug](#).
 - [Chapter G2 AArch32 Self-hosted Debug](#).
 - [Part H](#) of this Manual, [External Debug](#) on page [Part H-7331](#).
- Associated trace architectures that define PE Trace Units that implementers can implement with the associated processor hardware. For more information, see:
 - [The Embedded Trace Macrocell Architecture Specification](#).
 - [Chapter D3 AArch64 Self-hosted Trace](#).
 - [Chapter G3 AArch32 Self-hosted Trace](#).

The Arm architecture is a *Reduced Instruction Set Computer* (RISC) architecture with the following RISC architecture features:

- A large uniform register file.
- A *load/store* architecture, where data-processing operations only operate on register contents, not directly on memory contents.
- Simple addressing modes, with all load/store addresses determined from register contents and instruction fields only.

The architecture defines the interaction of the PE with memory, including caches, and includes a memory translation system. It also describes how multiple PEs interact with each other and with other observers in a system.

This document defines the Armv8-A architecture *profile*. See [Architecture profiles](#) on page [A1-36](#) for more information.

The Arm architecture supports implementations across a wide range of performance points. Implementation size, performance, and very low power consumption are key attributes of the Arm architecture.

An important feature of the Armv8 architecture is backwards compatibility, combined with the freedom for optimal implementation in a wide range of standard and more specialized use cases. The Armv8 architecture supports:

- A 64-bit Execution state, AArch64.
- A 32-bit Execution state, AArch32, that is compatible with previous versions of the Arm architecture.

———— **Note** —————

The AArch32 Execution state is compatible with the Armv7-A architecture profile, and enhances that profile to support some features included in the AArch64 Execution state.

Features that are optional are explicitly defined as such in this Manual.

———— **Note** —————

The presence of an ID register field for a feature does not imply that the feature is optional.

Both Execution states support SIMD and floating-point instructions:

- AArch32 state provides:
 - SIMD instructions in the base instruction sets that operate on the 32-bit general-purpose registers.
 - Advanced SIMD instructions that operate on registers in the *SIMD and floating-point register* (SIMD&FP register) file.
 - Floating-point instructions that operate on registers in the SIMD&FP register file.
- AArch64 state provides:
 - Advanced SIMD instructions that operate on registers in the SIMD&FP register file.
 - Floating-point instructions that operate on registers in the SIMD&FP register file.

Note

See [Conventions on page xxvi](#) for information about conventions used in this Manual, including the use of SMALL CAPITALS for particular terms that have Arm-specific meanings that are defined in the [Glossary](#).

A1.2 Architecture profiles

The Arm architecture has evolved significantly since its introduction, and Arm continues to develop it. Eight major versions of the architecture have been defined to date, denoted by the version numbers 1 to 8. Of these, the first three versions are now obsolete.

The generic names AArch64 and AArch32 describe the 64-bit and 32-bit Execution states:

AArch64 Is the 64-bit Execution state, meaning addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

AArch32 Is the 32-bit Execution state, meaning addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

———— **Note** —————

The *Base instruction set* comprises the supported instructions other than the Advanced SIMD and floating-point instructions.

See sections [Execution state on page A1-37](#) and [The Armv8 instruction sets on page A1-38](#) for more information.

Arm defines three architecture profiles:

A Application profile, described in this Manual:

- Supports a *Virtual Memory System Architecture* (VMSA) based on a *Memory Management Unit* (MMU).

———— **Note** —————

An Armv8-A implementation can be called an AArchv8-A implementation.

- Supports the A64, A32, and T32 instruction sets.

R Real-time profile:

- Supports a *Protected Memory System Architecture* (PMSA) based on a *Memory Protection Unit* (MPU).
- Supports the A32 and T32 instruction sets.

M Microcontroller profile:

- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
- Implements a variant of the R-profile PMSA.
- Supports a variant of the T32 instruction set.

———— **Note** —————

This Architecture Reference Manual describes only the Armv8-A profile.

For information about the R and M architecture profiles, and earlier Arm architecture versions see:

- The *ARM® Architecture Reference Manual Supplement, ARMv8, for the ARMv8-R AArch32 architecture profile*.
- The *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.
- The *Arm®v8-M Architecture Reference Manual*.
- The *ARM®v7-M Architecture Reference Manual*.
- The *ARM®v6-M Architecture Reference Manual*.

A1.3 Armv8 architectural concepts

Armv8 introduces major changes to the Arm architecture, while maintaining a high level of consistency with previous versions of the architecture. The Armv8 Architecture Reference Manual includes significant changes in the terminology used to describe the architecture, and this section introduces both the Armv8 architectural concepts and the associated terminology.

The following subsections describe key Armv8 architectural concepts. Each section introduces the corresponding terms that are used to describe the architecture:

- [Execution state on page A1-37.](#)
- [The Armv8 instruction sets on page A1-38.](#)
- [System registers on page A1-38.](#)
- [Armv8 Debug on page A1-39.](#)

A1.3.1 Execution state

The Execution state defines the PE execution environment, including:

- The supported register widths.
- The supported instruction sets.
- Significant aspects of:
 - The Exception model.
 - The *Virtual Memory System Architecture (VMSA)*.
 - The programmers' model.

The Execution states are:

- AArch64** The 64-bit Execution state. This Execution state:
- Provides 31 64-bit general-purpose registers, of which X30 is used as the procedure link register.
 - Provides a 64-bit *Program Counter (PC)*, *stack pointers (SPs)*, and *Exception Link Registers (ELRs)*.
 - Provides 32 128-bit registers for SIMD vector and scalar floating-point support.
 - Provides a single instruction set, A64. For more information, see [The Armv8 instruction sets on page A1-38.](#)
 - Defines the Armv8 Exception model, with up to four Exception levels, EL0 - EL3, that provide an *execution privilege* hierarchy, see [Exception levels on page D1-2454.](#)
 - Provides support for 64-bit *virtual addressing*. For more information, including the limits on address ranges, see [Chapter D5 The AArch64 Virtual Memory System Architecture.](#)
 - Defines a number of *Process state (PSTATE)* elements that hold PE state. The A64 instruction set includes instructions that operate directly on various *PSTATE* elements.
 - Names each System register using a suffix that indicates the lowest Exception level at which the register can be accessed.
- AArch32** The 32-bit Execution state. This Execution state:
- Provides 13 32-bit general-purpose registers, and a 32-bit PC, SP, and *Link Register (LR)*. The LR is used as both an ELR and a procedure link register. Some of these registers have multiple *banked* instances for use in different PE *modes*.
 - Provides a single ELR, for exception returns from Hyp mode.
 - Provides 32 64-bit registers for Advanced SIMD vector and scalar floating-point support.
 - Provides two instruction sets, A32 and T32. For more information, see [The Armv8 instruction sets on page A1-38.](#)
 - Supports the Armv7-A Exception model, based on *PE modes*, and maps this onto the Armv8 Exception model, that is based on the Exception levels.
 - Provides support for 32-bit virtual addressing.

- Defines a number of *Process state* (PSTATE) elements that hold PE state. The A32 and T32 instruction sets include instructions that operate directly on various PSTATE elements, and instructions that access PSTATE by using the *Application Program Status Register* (APSR) or the *Current Program Status Register* (CPSR).

Later subsections give more information about the different properties of the Execution states.

Transferring control between the AArch64 and AArch32 Execution states is known as *interprocessing*. The PE can move between Execution states only on a change of Exception level, and subject to the rules given in [Interprocessing on page D1-2545](#). This means different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.

A1.3.2 The Armv8 instruction sets

In Armv8 the possible instruction sets depend on the Execution state:

AArch64 AArch64 state supports only a single instruction set, called A64. This is a fixed-length instruction set that uses 32-bit instruction encodings.

For information on the A64 instruction set, see [Chapter C3 A64 Instruction Set Overview](#).

AArch32 AArch32 state supports the following instruction sets:

A32 This is a fixed-length instruction set that uses 32-bit instruction encodings.

T32 This is a variable-length instruction set that uses both 16-bit and 32-bit instruction encodings.

In previous documentation, these instruction sets were called the ARM and Thumb instruction sets. Armv8 extends each of these instruction sets. In AArch32 state, the Instruction set state determines the instruction set that the PE executes.

For information on the A32 and T32 instruction sets, see [Chapter F2 The AArch32 Instruction Sets Overview](#).

The Armv8 instruction sets support SIMD and scalar floating-point instructions. See [Advanced SIMD and floating-point support on page A1-52](#).

A1.3.3 System registers

System registers provide control and status information of architected features.

The System registers use a standard naming format: <register_name>.<bit_field_name> to identify specific registers as well as control and status bits within a register.

Bits can also be described by their numerical position in the form <register_name>[x:y] or the generic form bits[x:y].

In addition, in AArch64 state, most register names include the lowest Exception level that can access the register as a suffix to the register name:

- <register_name>_ELx, where x is 0, 1, 2, or 3.

For information about Exception levels, see [Exception levels on page D1-2454](#).

The System registers comprise:

- The following registers that are described in this Manual:
 - General system control registers.
 - Debug registers.
 - Generic Timer registers.
 - Optionally, Performance Monitor registers.
 - Optionally, the Activity Monitors registers.

- Optionally, one or more of the following groups of registers that are defined in other Arm architecture specifications:
 - Trace System registers, as defined in the *Embedded Trace Macrocell Architecture Specification, ETMv4*.
 - Scalable Vector Extension System registers, as defined in the Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A.
 - *Generic Interrupt Controller (GIC) System registers*, see *The Arm Generic Interrupt Controller System registers* on page A1-39.
- RAS Extension System registers, as defined in the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*. The RAS Extension is a mandatory extension to the Armv8.2 architecture, and an OPTIONAL extension to the Armv8.0 and the Armv8.1 architectures.

For information about the AArch64 System registers, see [Chapter D13 AArch64 System Register Descriptions](#).

For information about the AArch32 System registers, see [Chapter G8 AArch32 System Register Descriptions](#).

The Arm Generic Interrupt Controller System registers

From version 3 of the Arm Generic Interrupt Controller architecture, GICv3, the GIC architecture specification defines a System register interface to some of its functionality. The System register summaries in this Manual include these registers, see:

- [About the GIC System registers on page D12-3037](#), for more information about the AArch64 GIC System registers.
- [About the GIC System registers on page G7-6434](#), for more information about the AArch32 GIC System registers.

These sections give only short overviews of the GIC System registers. For more information, including descriptions of the registers, see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* (ARM IHI 0069).

————— **Note** —————

The programmers' model for earlier versions of the GIC architecture is wholly memory-mapped.

A1.3.4 Armv8 Debug

Armv8 supports the following:

Self-hosted debug

In this model, the PE generates *debug exceptions*. Debug exceptions are part of the Armv8 Exception model.

External debug

In this model, *debug events* cause the PE to enter *Debug state*. In Debug state, the PE is controlled by an external debugger.

All Armv8 implementations support both models. The model chosen by a particular user depends on the debug requirements during different stages of the design and development life cycle of the product. For example, external debug might be used during debugging of the hardware implementation and OS bring-up, and self-hosted debug might be used during application development.

For more information about self-hosted debug:

- In AArch64 state, see [Chapter D2 AArch64 Self-hosted Debug](#).
- In AArch32 state, see [Chapter G2 AArch32 Self-hosted Debug](#).

For more information about external debug, see [Part H External Debug on page Part H-7331](#).

A1.4 Supported data types

The Armv8 architecture supports the following integer data types:

Byte	8 bits.
Halfword	16 bits.
Word	32 bits.
Doubleword	64 bits.
Quadword	128 bits.

The architecture also supports the following floating-point data types:

- Half-precision, see [Half-precision floating-point formats on page A1-44](#) for details.
- Single-precision, see [Single-precision floating-point format on page A1-46](#) for details.
- Double-precision, see [Double-precision floating-point format on page A1-47](#) for details.
- BFloat16, see [BFloat16 floating-point format on page A1-48](#) for details.

It also supports:

- Fixed-point interpretation of words and doublewords. See [Fixed-point format on page A1-50](#).
- Vectors, where a register holds multiple elements, each of the same data type. See [Vector formats on page A1-41](#) for details.

The Armv8 architecture provides two register files:

- A general-purpose register file.
- A SIMD&FP register file.

In each of these, the possible register widths depend on the Execution state.

In AArch64 state:

- A general-purpose register file contains 64-bit registers:
 - Many instructions can access these registers as 64-bit registers or as 32-bit registers, using only the bottom 32 bits.
- A SIMD&FP register file contains 128-bit registers:
 - The quadword integer data types only apply to the SIMD&FP register file.
 - The floating-point data types only apply to the SIMD&FP register file.
 - While the AArch64 vector registers support 128-bit vectors, the effective vector length can be 64-bits or 128-bits depending on the A64 instruction encoding used, see [Instruction Mnemonics on page C1-197](#).

For more information on the register files in AArch64 state, see [Registers in AArch64 Execution state on page B1-117](#).

In AArch32 state:

- A general-purpose register file contains 32-bit registers:
 - Two 32-bit registers can support a doubleword.
 - Vector formatting is supported, see [Figure A1-4 on page A1-44](#).
- A SIMD&FP register file contains 64-bit registers:
 - AArch32 state does not support quadword integer or floating-point data types.

———— **Note** —————

Two consecutive 64-bit registers can be used as a 128-bit register.

For more information on the register files in AArch32 state, see [The general-purpose registers, and the PC, in AArch32 state on page E1-4251](#).

A1.4.1 Vector formats

In an implementation that includes the SIMD instructions that operate on the SIMD&FP register file, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector.

Vector formats in AArch64 state

In AArch64 state, the SIMD&FP registers can be referred to as V_n , where n is a value from 0 to 31.

The SIMD&FP registers support three data formats for loads, stores, and data-processing operations:

- A single, scalar, element in the least significant bits of the register.
- A 64-bit vector of byte, halfword, or word elements.
- A 128-bit vector of byte, halfword, word, or doubleword elements.

The element sizes are defined in [Table A1-1 on page A1-41](#) with the vector format described as:

- For a 128-bit vector: $V_n\{.2D, .4S, .8H, .16B\}$.
- For a 64-bit vector: $V_n\{.1D, .2S, .4H, .8B\}$.

Table A1-1 SIMD elements in AArch64 state

Mnemonic	Size
B	8 bits
H	16 bits
S	32 bits
D	64 bits

[Figure A1-1 on page A1-42](#) shows the SIMD vectors in AArch64 state.

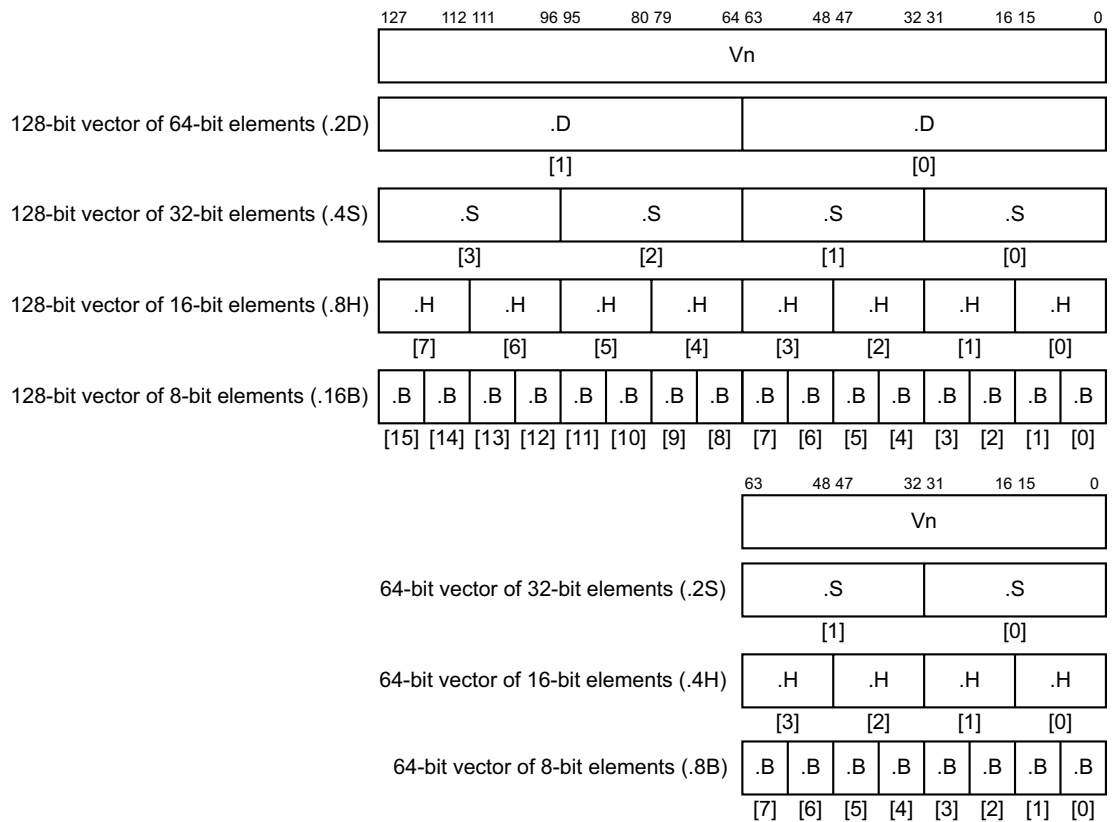

Figure A1-1 SIMD vectors in AArch64 state

Vector formats in AArch32 state

Table A1-2 on page A1-42 shows the available formats. Each instruction description specifies the data types that the instruction supports.

Table A1-2 Advanced SIMD data types in AArch32 state

Data type specifier	Meaning
<code>.<size></code>	Any element of <code><size></code> bits
<code>.F<size></code>	Floating-point number of <code><size></code> bits
<code>.I<size></code>	Signed or unsigned integer of <code><size></code> bits
<code>.P<size></code>	Polynomial over <code>{0, 1}</code> of degree less than <code><size></code>
<code>.S<size></code>	Signed integer of <code><size></code> bits
<code>.U<size></code>	Unsigned integer of <code><size></code> bits

Polynomial arithmetic over {0, 1} on page A1-50 describes the polynomial data type.

The `.F16` data type is the half-precision data type selected by the `FPSCR.AHP` bit, see *Half-precision floating-point formats* on page A1-44.

The `.F32` data type is the Arm standard single-precision floating-point data type, see *Single-precision floating-point format* on page A1-46.

The instruction definitions use a data type specifier to define the data types appropriate to the operation. [Figure A1-2 on page A1-43](#) shows the hierarchy of the Advanced SIMD data types.

.8	.i8	.S8

† Output format only. See VMULL instruction description.

‡ Available only if the Cyptographic Extension is implemented. See VMULL instruction description.

Figure A1-2 Advanced SIMD data type hierarchy in AArch32 state

For example, a multiply instruction must distinguish between integer and floating-point data types.

An integer multiply instruction that generates a double-width (long) result must specify the input data types as signed or unsigned. However, some integer multiply instructions use modulo arithmetic, and therefore do not have to distinguish between signed and unsigned inputs.

[Figure A1-3 on page A1-44](#) shows the Advanced SIMD vectors in AArch32 state.

———— **Note** —————

In AArch32 state, a pair of even and following odd numbered doubleword registers can be concatenated and treated as a single quadword register.

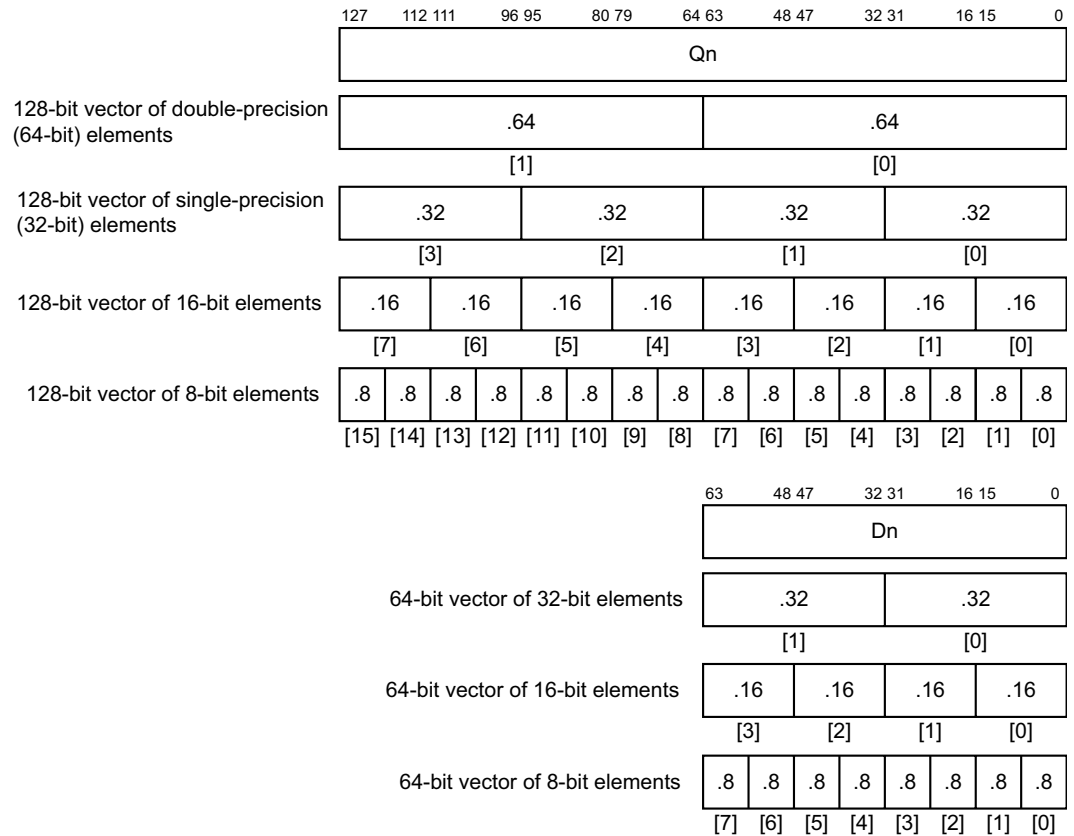

Figure A1-3 Advanced SIMD vectors in AArch32 state

The AArch32 general-purpose registers support vectors formats for use by the SIMD instructions in the Base instruction set. Figure A1-4 on page A1-44 shows these formats, that means that a general-purpose register can be treated as either 2 halfwords or 4 bytes.

Figure A1-4 Vector formatting in AArch32 state

A1.4.2 Half-precision floating-point formats

Armv8 supports two half-precision floating-point formats:

- IEEE half-precision, as described in the IEEE 754-2008 standard.
- Arm *alternative half-precision* format.

———— **Note** ————

BFloat16 is not a half-precision floating-point format, see *BFloat16 floating-point format* on page A1-48.

Both formats can be used for conversions to and from other floating-point formats. [FPCR.AHP](#) controls the format in AArch64 state and [FPSCR.AHP](#) controls the format in AArch32 state. [FEAT_FP16](#) adds half-precision data-processing instructions, which always use the IEEE format. These instructions ignore the value of the relevant AHP field, and behave as if it has an *Effective value* of 0.

The description of IEEE half-precision includes Arm-specific details that are left open by the standard, and is only an introduction to the formats and to the values they can contain. For more information, especially on the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

For both half-precision floating-point formats, the layout of the 16-bit format is the same. The format is:

The interpretation of the format depends on the value of the exponent field, bits[14:10] and on which half-precision format is being used.

0 < exponent < 0x1F

The value is a normalized number and is equal to:

$$(-1)^S \times 2^{(\text{exponent}-15)} \times (1.\text{fraction})$$

The minimum positive normalized number is 2^{-14} , or approximately $6.104 \cdot 10^{-5}$.

The maximum positive normalized number is $(2 - 2^{-10}) \times 2^{15}$, or 65504.

Larger normalized numbers can be expressed using the alternative format when the exponent == 0x1F.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

- +0** when S==0
- 0** when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$$(-1)^S \times 2^{-14} \times (0.\text{fraction})$$

The minimum positive denormalized number is 2^{-24} , or approximately 5.960×10^{-8} .

Half-precision denormalized numbers are not flushed to zero by default. When [FEAT_FP16](#) is implemented, the [FPCR.FZ16](#) bit controls whether flushing denormalized numbers to zero is enabled for half-precision data-processing instructions. For details, see [Flushing denormalized numbers to zero](#) on page A1-54.

exponent == 0x1F

The value depends on which half-precision format is being used:

IEEE half-precision

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

- +infinity** When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.
- infinity** When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[9]:

bit[9] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[9] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

Alternative half-precision

The value is a normalized number and is equal to:

$$-1^S \times 2^{16} \times (1.\text{fraction})$$

The maximum positive normalized number is $(2-2^{-10}) \times 2^{16}$ or 131008.

A1.4.3 Single-precision floating-point format

The single-precision floating-point format is as defined by the IEEE 754 standard.

This description includes Arm-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A single-precision value is a 32-bit word with the format:

The interpretation of the format depends on the value of the exponent field, bits[30:23]:

0 < exponent < 0xFF

The value is a *normalized number* and is equal to:

$$(-1)^S \times 2^{(\text{exponent} - 127)} \times (1.\text{fraction})$$

The minimum positive normalized number is 2^{-126} , or approximately 1.175×10^{-38} .

The maximum positive normalized number is $(2 - 2^{-23}) \times 2^{127}$, or approximately 3.403×10^{38} .

exponent == 0

The value is either a zero or a *denormalized number*, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 When S==0.

-0 When S==1.

These usually behave identically. In particular, the result is *equal* if +0 and -0 are compared as floating-point numbers. However, they yield different results in some circumstances. For example, the sign of the infinity produced as the result of dividing by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer comparison of the two words.

fraction != 0

The value is a denormalized number and is equal to:

$$(-1)^S \times 2^{-126} \times (0.\text{fraction})$$

The minimum positive denormalized number is 2^{-149} , or approximately 1.401×10^{-45} .

Denormalized numbers are always flushed to zero in Advanced SIMD processing in AArch32 state. They are optionally flushed to zero in floating-point processing and in Advanced SIMD processing in AArch64 state. For details, see [Flushing denormalized numbers to zero on page A1-54](#).

exponent == 0xFF

The value is either an *infinity* or a *Not a Number* (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When $S=0$. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When $S=1$. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[22]:

bit[22] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[22] == 1

The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

For details of the *default NaN*, see [The Default NaN on page A1-57](#).

———— **Note** ————

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.4 Double-precision floating-point format

The double-precision floating-point format is as defined by the IEEE 754 standard. Double-precision floating-point is supported by both SIMD and floating-point instructions in AArch64 state, and only by floating-point instructions in AArch32 state.

This description includes implementation-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A double-precision value is a 64-bit doubleword, with the format:

Double-precision values represent numbers, infinities, and NaNs in a similar way to single-precision values, with the interpretation of the format depending on the value of the exponent:

0 < exponent < 0x7FF

The value is a normalized number and is equal to:

$$(-1)^S \times 2^{(\text{exponent}-1023)} \times (1.\text{fraction})$$

The minimum positive normalized number is 2^{-1022} , or approximately 2.225×10^{-308} .

The maximum positive normalized number is $(2 - 2^{-52}) \times 2^{1023}$, or approximately 1.798×10^{308} .

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave in the same way as the two single-precision zeros:

- +0 when S==0
- 0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$$(-1)^S \times 2^{-1022} \times (0.\text{fraction})$$

The minimum positive denormalized number is 2^{-1074} , or approximately 4.941×10^{-324} .

Optionally, denormalized numbers are flushed to zero in floating-point calculations. For details, see [Flushing denormalized numbers to zero on page A1-54](#).

exponent == 0x7FF

The value is either an infinity or a NaN, depending on the fraction bits:

fraction == 0

The value is an infinity. As for single-precision, there are two infinities:

- +infinity When S==0.
- infinity When S==1.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[51] of the doubleword:

bit[51] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[51] == 1

The NaN is a quiet NaN. The sign bit and the remaining fraction bits can take any value.

For details of the *default NaN*, see [The Default NaN on page A1-57](#).

———— **Note** ————

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.5 BFloat16 floating-point format

BFloat16, or BF16, is a 16-bit floating-point storage format. The BF16 format inherits many of its properties and behaviors from the single-precision format defined by the IEEE 754 standard, as described in [Single-precision floating-point format on page A1-46](#).

For the BFloat16 floating-point format, the layout is:

0 < exponent < 0xFF

The value is a normalized number and is equal to:

$$(-1)^S \times 2^{(\text{exponent}-127)} \times (1.\text{fraction})$$

The minimum positive normalized number is 2^{-126} , or approximately $1.175 \cdot 10^{-38}$.

The maximum positive normalized number is $(2 - 2^{-7}) \times 2^{127}$, or approximately $3.390 \cdot 10^{38}$.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

- +0** when $S=0$
- 0** when $S=1$.

These usually behave identically. However, they yield different results in some circumstances. For example, the sign of the result produced as the result of multiplying by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer bitwise comparison of the two halfwords.

fraction != 0

The value is a denormalized number and is equal to:

$$(-1)^S \times 2^{-126} \times (0.\text{fraction})$$

The minimum positive denormalized number is 2^{-133} , or approximately 9.184×10^{-41} .

If *Flushing denormalized numbers to zero* on page A1-54 is enabled, for the conversion instructions that generate a BF16 result, a result will be flushed to zero if it satisfies the condition $0 < \text{Abs}(\text{result}) < 2^{-126}$.

Denormalized numbers are unconditionally flushed to zero by the BF16 arithmetic instructions, and by Advanced SIMD floating-point instructions in AArch32 state. They might be flushed to zero by other floating-point instructions, see *Flushing denormalized numbers to zero* on page A1-54.

For the conversion instructions that generate a BF16 result, flushing denormalized numbers to zero is enabled by the **FPCR.FZ** and **FPCR.FIZ** bits in AArch64 state and the **FPSCR.FZ** bit in AArch32 state.

exponent == 0xFF

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

- +infinity** When $S=0$. This represents all positive numbers that are too big to be represented accurately as a normalized number.
- infinity** When $S=1$. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[6]:

bit[6] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[6] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

In the arithmetic instructions that accept BF16 inputs, there is no distinction between quiet and signaling input NaNs, since these instructions cannot signal a floating-point exception, and any type of input NaN generates the same Default NaN result.

BF16 values are 16-bit halfwords that software can convert to single-precision format, by appending 16 zero bits, so that single-precision arithmetic instructions can be used. A single-precision value can be converted to BF16 format if required, either by:

- Truncating, by removing the least significant 16 bits.
- Using the BFloat16 conversion instructions, see *BFloat16 floating-point instructions* on page C3-262.

A1.4.6 Fixed-point format

Fixed-point formats are used only for conversions between floating-point and fixed-point values. They apply to general-purpose registers.

Fixed-point values can be signed or unsigned, and can be 16-bit or 32-bit. Conversion instructions take an argument that specifies the number of fraction bits in the fixed-point number. That is, it specifies the position of the binary point.

A1.4.7 Conversion between floating-point and fixed-point values

Armv8 supports the conversion of a scalar floating-point to or from a signed or unsigned fixed-point value in a general-purpose register.

The instruction argument `#fbits` indicates that the general-purpose register holds a fixed-point number with `fbits` bits after the binary point, where `fbits` is in the range 1 to 64 for a 64-bit general-purpose register, or 1 to 32 for a 32-bit general-purpose register.

More specifically:

- For a 64-bit register X_d :
 - The integer part is $X_d[63:\#fbits]$.
 - The fractional part is $X_d[(\#fbits-1):0]$.
- For a 32-bit register W_d or R_d :
 - The integer part is $W_d[31:\#fbits]$ or $R_d[31:\#fbits]$.
 - The fractional part is $W_d[(\#fbits-1):0]$ or $R_d[(\#fbits-1):0]$.

These instructions can cause the following floating-point exceptions:

Invalid Operation	When the floating-point input is NaN or Infinity or when a numerical value cannot be represented within the destination register.
Inexact	When the numeric result differs from the input value.
Input Denormal	When flushing denormalized numbers to zero is enabled and the denormal input is replaced by a zero, see Flushing denormalized numbers to zero on page A1-54 and Input Denormal exceptions on page D1-2495 .

———— **Note** —————

An out of range fixed-point result is saturated to the destination size.

For more information, see [Floating-point exceptions and exception traps on page D1-2495](#).

A1.4.8 Polynomial arithmetic over {0, 1}

Some SIMD instructions that operate on SIMD&FP registers can operate on polynomials over {0, 1}, see [Supported data types on page A1-40](#). The polynomial data type represents a polynomial in x of the form $b_{n-1}x^{n-1} + \dots + b_1x + b_0$ where b_k is bit[k] of the value.

The coefficients 0 and 1 are manipulated using the rules of Boolean arithmetic:

- $0 + 0 = 1 + 1 = 0$.
- $0 + 1 = 1 + 0 = 1$.
- $0 \times 0 = 0 \times 1 = 1 \times 0 = 0$.
- $1 \times 1 = 1$.

That is:

- Adding two polynomials over {0, 1} is the same as a bitwise exclusive OR.
- Multiplying two polynomials over {0, 1} is the same as integer multiplication except that partial products are exclusive-ORed instead of being added.

A64, A32, and T32 provide instructions for performing polynomial multiplication of 8-bit values.

- For AArch32, see [VMUL \(integer and polynomial\)](#) on page F6-5694 and [VMULL \(integer and polynomial\)](#) on page F6-5700.
- For AArch64, see [PMUL](#) on page C7-2019 and [PMULL](#), [PMULL2](#) on page C7-2021.

The Cryptographic Extension adds the ability to perform long polynomial multiplies of 64-bit values. See [PMULL](#), [PMULL2](#) on page C7-2021.

Pseudocode description of polynomial multiplication

In pseudocode, polynomial addition is described by the EOR operation on bitstrings.

Polynomial multiplication is described by the `PolynomialMult()` function defined in [Chapter J1 Armv8 Pseudocode](#).

A1.5 Advanced SIMD and floating-point support

Note

In AArch32 state, the SIMD instructions that operate on SIMD&FP registers are always described as the Advanced SIMD instructions, to distinguish them from the SIMD instructions in the base instruction sets, that operate on the 32-bit general-purpose registers. The A64 instruction set does not provide any SIMD instructions that operate on the general-purpose registers, and therefore some AArch64 state descriptions use SIMD as a synonym for Advanced SIMD. Unless the context clearly indicates otherwise, this section describes the support for SIMD instructions that operate on SIMD&FP registers.

Armv8 can support the following levels of support for Advanced SIMD and floating-point instructions:

- Full SIMD and floating-point support without exception trapping.
- Full SIMD and floating-point support with exception trapping.
- No floating-point or SIMD support. This option is licensed only for implementations targeting specialized markets.

Note

All systems that support standard operating systems with rich application environments provide hardware support for Advanced SIMD and floating-point. It is a requirement of the ARM Procedure Call Standard for AArch64, see *Procedure Call Standard for the Arm 64-bit Architecture*.

Armv8 supports single-precision (32-bit) and double-precision (64-bit) floating-point data types and arithmetic as defined by the IEEE 754 floating-point standard. It also supports the half-precision (16-bit) floating-point data type for data storage, by supporting conversions between single-precision and half-precision data types and double-precision and half-precision data types. When **FEAT_FP16** is implemented, it also supports the half-precision floating-point data type for data-processing operations.

The SIMD instructions provide packed *Single Instruction Multiple Data (SIMD)* and single-element scalar operations, and support:

- Single-precision and double-precision arithmetic in AArch64 state.
- Single-precision arithmetic only in AArch32 state.
- When **FEAT_FP16** is implemented, half-precision arithmetic is supported in AArch64 and AArch32 states.

Floating-point support in AArch64 state SIMD is IEEE 754-2008 compliant with:

- Configurable rounding modes.
- Configurable Default NaN behavior.
- Configurable flushing to zero of denormalized numbers.

Floating-point computation using AArch32 Advanced SIMD instructions remains unchanged from Armv7. A32 and T32 Advanced SIMD floating-point always uses Arm standard floating-point arithmetic and performs IEEE 754 floating-point arithmetic with the following restrictions:

- Denormalized numbers are flushed to zero, see *Flushing denormalized numbers to zero on page A1-54*.
- Only default NaNs are supported, see *The Default NaN on page A1-57*.
- The Round to Nearest rounding mode is used.
- Untrapped floating-point exception handling is used for all floating-point exceptions.

If floating-point exception trapping is supported, floating-point exceptions, such as Overflow or Divide by Zero, can be handled without trapping. This applies to both SIMD and floating-point operations. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. For more information about floating-point exceptions, see *Floating-point exceptions and exception traps on page D1-2495*.

In AArch64 state, the following registers control floating-point operation and return floating-point status information:

- The Floating-Point Control Register, **FPCR**, controls:
 - The half-precision format where applicable, **FPCR.AHP** bit.

- Default NaN behavior, [FPCR.DN](#) bit.
- Flushing of denormalized numbers to zero, [FPCR.{FZ, FZ16}](#) bits. If [FEAT_FP16](#) is not implemented, [FPCR.FZ16](#) is RES0.
- Rounding mode support, [FPCR.Rmode](#) field.
- Len and Stride fields associated with execution in AArch32 state, and only supported for a context save and restore from AArch64 state. These fields are obsolete in Armv8 and can be implemented as RAZ/WI. If they are implemented as RW and are programmed to a nonzero value, they make some AArch32 floating-point instructions UNDEFINED.
- Floating-point exception trap controls, the [FPCR.{IDE, IXE, UFE, OFE, DZE, IOE}](#) bits, see [Floating-point exceptions and exception traps on page D1-2495](#).
- The Floating-Point Status Register, [FPSR](#), provides:
 - Cumulative floating-point exceptions flags, [FPSR.{IDC, IXC, UFC, OFC, DZC, IOC and QC}](#).
 - The AArch32 floating-point comparison flags {N,Z,C,V}. These bits are RES0 if AArch32 floating-point is not implemented.

———— **Note** —————

In AArch64 state, the process state flags, [PSTATE.{N,Z,C,V}](#) are used for all data-processing compares and any associated conditional execution.

If [FEAT_FlagM2](#) is implemented, the instructions [AXFLAG](#) and [XAFLAG](#) convert between the Arm condition flag format and an alternative format shown in [Relationship between ARM format and alternative format PSTATE condition flags on page C6-874](#).

AArch32 state provides a single Floating-Point Status and Control Register, [FPSCR](#), combining the [FPCR](#) and [FPSR](#) fields.

For system level information about the SIMD and floating-point support, see [Advanced SIMD and floating-point support on page G1-6112](#).

A1.5.1 Instruction support

The Advanced SIMD and floating-point instructions support:

- Load and store for single elements and vectors of multiple elements.

———— **Note** —————

Single elements are also referred to as scalar elements.

- Data processing on single and multiple elements for both integer and floating-point data types.
- When [FEAT_FCMA](#) is implemented, complex number arithmetic.
- Floating-point conversion between different levels of precision.
- Conversion between floating-point, fixed-point integer, and integer data types.
- Floating-point rounding.

For more information on the SIMD and floating-point instructions in AArch64 state, see [Chapter C3 A64 Instruction Set Overview](#).

For more information on the Advanced SIMD and floating-point instructions in AArch32 state, see [Chapter F2 The AArch32 Instruction Sets Overview](#).

A1.5.2 Floating-point standards, and terminology

The Arm architecture includes support for all the required features of ANSI/IEEE Std 754-2008, *IEEE Standard for Binary Floating-Point Arithmetic*, referred to as IEEE 754-2008. However, some terms in this Manual are based on the 1985 version of this standard, referred to as IEEE 754-1985:

- Arm floating-point terminology generally uses the IEEE 754-1985 terms. This section summarizes how IEEE 754-2008 changes these terms.
- References to IEEE 754 that do not include the issue year apply to either issue of the standard.

Table A1-3 on page A1-54 shows how the terminology in this Manual differs from that used in IEEE 754-2008.

Table A1-3 Floating-point terminology

This manual	IEEE 754-2008
Normalized ^a	Normal
Denormal, or denormalized	Subnormal
Round towards Minus Infinity (RM)	roundTowardsNegative
Round towards Plus Infinity (RP)	roundTowardsPositive
Round towards Zero (RZ)	roundTowardZero
Round to Nearest (RN)	roundTiesToEven
Round to Nearest with Ties to Away	roundTiesToAway
Rounding mode	Rounding-direction attribute

a. *Normalized number* is used in preference to *normal number*, because of the other specific uses of *normal* in this Manual.

A1.5.3 Arm standard floating-point input and output values

Armv8 provides full IEEE 754 floating-point arithmetic support. In AArch32 state, floating-point operations performed using Advanced SIMD instructions are limited to *Arm standard floating-point operation*, regardless of the selected rounding mode in the `FPSCR`. Unlike AArch32, AArch64 SIMD floating point arithmetic is performed using the rounding mode selected by the `FPCR`.

Arm standard floating-point arithmetic supports the following input formats defined by the IEEE 754 floating-point standard:

- Zeros.
- Normalized numbers.
- Denormalized numbers are flushed to 0 before floating-point operations, see [Flushing denormalized numbers to zero on page A1-54](#).
- NaNs.
- Infinities.

Arm standard floating-point arithmetic supports the Round to Nearest (`roundTiesToEven`) rounding mode defined by the IEEE 754 standard.

Arm standard floating-point arithmetic supports the following output result formats defined by the IEEE 754 standard:

- Zeros.
- Normalized numbers.
- Results that are less than the minimum normalized number are flushed to zero, see [Flushing denormalized numbers to zero on page A1-54](#).
- NaNs produced in floating-point operations are always the default NaN, see [The Default NaN on page A1-57](#).
- Infinities.

A1.5.4 Flushing denormalized numbers to zero

For this section if `FEAT_AFP` is not implemented, the behavior is the same as if `FPCR.AH == 0`, `FPCR.FZ == 0` and `FPCR.NEP == 0`.

Calculations involving denormalized numbers and Underflow exceptions can reduce the performance of floating-point processing. For many algorithms, replacing the denormalized operands and Intermediate results with zeros can recover this performance, without significantly affecting the accuracy of the final result. Arm floating-point implementations allow denormalized numbers to be flushed to zero to permit this optimization.

If a number value satisfies the condition $0 < \text{Abs}(\text{value}) < \text{MinNorm}$, it is treated as a denormalized number.

`MinNorm` is defined as follows:

- For half-precision numbers, `MinNorm` is 2^{-14} .
- For single-precision and BFloat16 numbers, `MinNorm` is 2^{-126} .
- For double-precision numbers, `MinNorm` is 2^{-1022} .

Flushing denormals to zero is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Enabling flushing of denormals to zero must be done with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application-dependent:

- On many algorithms, it has no noticeable effect, because the algorithm does not usually process denormalized numbers.
- On other algorithms, it can cause exceptions to occur and can seriously reduce the accuracy of the results of the algorithm.

Flushing denormalized inputs to zero

If flushing denormalized inputs to zero is enabled for an instruction and a data type, and an input to that instruction is a denormalized number of that data type, the input operand is flushed to zero, and its sign bit is not changed.

If a floating-point operation has an input denormalized number that is flushed to zero, for all purposes within the instruction other than calculating Input Denormal floating-point exceptions, all inputs that are denormalized numbers are treated as though they were zero with the same sign as the input.

For Advanced SIMD and floating-point instructions, if the instruction processes half-precision inputs, flushing denormalized inputs to zero can be controlled as follows:

- If `FPCR.FZ16` == 0, denormalized half-precision inputs are not flushed to zero.
- If `FPCR.FZ16` == 1, for half-precision data-processing instructions, flushing of input denormalized numbers to zero occurs as follows:
 - If an instruction does not convert a half-precision input to a higher precision output, all input denormalized numbers are flushed to zero.
 - If an instruction converts a half-precision input to a higher precision output, input denormalized numbers are not flushed to zero.

If `FPCR.FIZ` == 1, or both `FPCR.AH` == 0 and `FPCR.FZ` == 1, for Advanced SIMD, floating-point and BF16 instructions other than FABS and FNEG, all single-precision, double-precision and BF16 input operands that are denormalized numbers are flushed to zero. Half-precision input operands are not flushed to zero.

If `FPCR.FZ` == 0, for Advanced SIMD, floating-point and BF16 instructions, for single-precision, double-precision and BF16 inputs, the `FPCR.FZ` setting does not cause denormalized inputs to be flushed to zero, although other factors might cause denormalized numbers to be flushed to zero.

If `FPCR.AH` == 1, regardless of the value of `FPCR.FIZ`, all of the following instructions flush all input denormal numbers to zero:

- BFloat instructions: `BFCVT`, `BFCVTN`, `BFCVTN2`, `BFMLALB`, `BFMLALT (by element)`, `BFMLALB`, `BFMLALT (vector)`, and `BFCVTNT`.
- Single-precision and double-precision instructions: `FRECPE`, `FRECPS`, `FRECPX`, `FRSQRT`, and `FRSQRTS`.

Flushing to zero of denormalized numbers as Intermediate results of some BF16 instructions

BF16 arithmetic instructions [BFDOT \(by element\)](#), [BFDOT \(vector\)](#), [BFMMLA](#) in AArch64, and [VDOT \(by element\)](#), [VDOT \(vector\)](#), [VMMLA](#) in AArch32 when working with BF16 inputs, convert BF16 input values to IEEE single-precision format, and calculate N-way dot-products, accumulating the products in single-precision accumulators.

If a BF16 arithmetic instruction processes an Intermediate result that is a single-precision denormalized number, the Intermediate result is unconditionally flushed to zero.

Flushing denormalized outputs to zero

If a denormalized output is flushed to zero, the output is returned as zero with the same sign bit as the denormalized output value.

If [FPCR.AH](#) == 0, for half-precision, single-precision and double-precision numbers, the test for a denormalized number for the purpose of flushing the output to zero occurs before rounding.

If [FPCR.AH](#) == 1, and if output flushing is caused by [FPCR.FZ](#) == 1 or [FPCR.FZ16](#) == 1, for half-precision, single-precision and double-precision numbers, the test for a denormalized number for the purpose of flushing the output to zero occurs after rounding using an unbounded exponent.

If [FPCR.AH](#) == 1, and if [FPCR.FZ](#) == 0, Advanced SIMD, floating-point and BF16 instructions, for single-precision, double-precision and BF16 outputs, the [FPCR.FZ](#) setting does not cause denormalized outputs to be flushed to zero, although other factors might cause denormalized outputs to be flushed to zero.

[BFDOT \(by element\)](#), [BFDOT \(vector\)](#), and [BFMMLA](#) instructions unconditionally flush denormalized output numbers to zero.

If [FPCR.AH](#) == 0, for Advanced SIMD, floating-point, and BF16 instructions, for single-precision, double-precision and BF16 outputs, flushing denormalized numbers to zero can be controlled as follows:

- If [FPCR.FZ](#) == 0, the [FPCR.FZ](#) setting does not cause denormalized output numbers to be flushed to zero, although other factors might cause denormalized output numbers to be flushed to zero.
- If [FPCR.FZ](#) == 1, for all Advanced SIMD, floating-point and BF16 instructions other than [FABS](#) and [FNEG](#), all single-precision, double-precision, and BF16 outputs that are denormalized numbers are flushed to zero.

If [FPCR.FZ16](#) == 0 denormalized half-precision output numbers are not flushed to zero.

If [FPCR.FZ16](#) == 1, for Advanced SIMD and floating-point instructions other than [FABS](#), [FNEG](#), [FMAX*](#), and [FMIN*](#), if the instruction processes half-precision numbers, flushing denormalized output numbers to zero can be controlled as follows:

- Instructions that convert between half-precision and single-precision numbers do not flush denormalized half-precision output numbers to zero.
- Instructions that convert between half-precision and double-precision numbers do not flush denormalized half-precision output numbers to zero.
- All other half-precision data-processing instructions flush all denormalized half-precision output numbers to zero.

If [FPCR.AH](#) == 1 and [FPCR.FZ](#) == 1, for Advanced SIMD, floating-point and BF16 instructions, all of the following apply:

- For all floating-point operations other than [FABS](#), [FNEG](#), [FMAX*](#), and [FMIN*](#), all single-precision and double-precision denormalized output operands are flushed to zero.
- For [FABS](#), [FNEG](#), [FMAX*](#), and [FMIN*](#), denormalized output operands are not flushed to zero.

If `FPCR.AH == 1`, regardless of the value of `FPCR.FZ` bit, for both Advanced SIMD and SVE, all of the following instructions flush all output denormal numbers to zero:

- BFloat instructions: `BFCVT`, `BFCVTN`, `BFCVTN2`, `BFMLALB`, `BFMLALT` (by element), `BFMLALB`, `BFMLALT` (vector), and `BFCVTNT`.
- Single-precision and double-precision instructions: `FRECPE`, `FRECPS`, `FRECPX`, `FRSQRTS`, and `FRSQRTS`.

A1.5.5 NaN handling and the Default NaN

The IEEE 754 standard defines a NaN as a number with all exponent bits set to 1 and a nonzero number in the mantissa. The Arm architecture additionally defines a Default NaN which does not follow this format.

The IEEE 754 standard specifies that the sign bit of a NaN has no significance.

For a quiet NaN output derived from a signaling NaN operand, the most significant fraction bit is set to 1.

The Default NaN

The Default NaN is encoded as described in [Table A1-4 on page A1-57](#).

Table A1-4 Default NaN encoding

	Half-precision, IEEE Format	Single-precision	Double-precision	BFloat16
Sign bit If <code>FPCR.AH == 0</code>	0	0	0	0
Sign bit If <code>FPCR.AH == 1</code>	1	1	1	1
Exponent	0x1F	0xFF	0x7FF	0xFF
Fraction	Bit[9] == 1, bits[8:0] == 0	Bit[22] == 1, bits[21:0] == 0	Bit[51] == 1, bits[50:0] == 0	Bit[6] == 1, bits[5:0] == 0

If `FPCR.DN == 1`, for Advanced SIMD and floating-point instructions other than `FABS`, `FMAX*`, `FMIN*` and `FNEG`, if any input to a floating-point operation performed by the instruction is a NaN, the output of the floating-point operation is the Default NaN.

For `FABS`, `FNEG`, `FMAX*`, and `FMIN*`, Default NaN behavior is explained in the instruction description.

If `FPCR.DN == 0`, for floating-point processing the Default NaN is not used for NaN propagation.

If a floating-point instruction performs a floating-point operation, and that instruction generates an untrapped Invalid Operation floating-point exception for a reason other than one of the inputs being a signaling NaN, the output is the Default NaN.

NaN handling

The IEEE 754 standard does not specify which input NaN is used as the output NaN. Therefore, where the Arm architecture specifies which input NaN to use, this is an addition to the requirements in the IEEE 754 standard.

Depending on the operation, the exact value of a derived quiet NaN output might have both a different sign and a different number of fraction bits from its source. See instruction descriptions for details.

NaN propagation

If an output NaN is derived from one of the operands, how the input NaN propagates to the output depends on the instruction and the number of operands.

If an output NaN is derived from an input NaN and if the size of the output format is the same as the input format, then all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN.
- If the input NaN is a signaling NaN, the output NaN is derived as follows:
 - If the handling of a signaling NaN by the instruction generates an Invalid Operation exception, the output NaN is the quieted version of the input NaN.
 - If the handling of a signaling NaN by the instruction does not generate an Invalid Operation exception, the output NaN is the same as the input NaN. This case applies for FABS, FNEG, and FTSSSEL instructions.

If an output NaN is derived from an input NaN and if the size of the output format is larger than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is zero-extended in the low-order bit to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN, except that the mantissa is zero-extended in the low-order bits and the exponent field is set to all ones.

If an output NaN is derived from an input NaN and if the size of the output format is smaller than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.

For the following descriptions, the term “first operand” and “second operand” relate to the left-to-right ordering of the arguments of the pseudocode function that describes the operation.

If `FPCR.DN == 0`, for Advanced SIMD, floating-point, or BF16 instructions that perform a floating-point operation, other than FABS, FNEG, `FMAX*`, and `FMIN*`, NaN outputs that derive from NaN inputs are derived as follows:

- If all of the following apply, an instruction outputs a quiet NaN derived from the first signaling NaN operand:
 - `FPCR.AH == 0`.
 - At least one operand is a signaling NaN.
 - The instruction is not trapped.
- If all of the following apply, an instruction outputs a quiet NaN derived from the first NaN operand:
 - `FPCR.AH == 0`.
 - At least one operand is a NaN, but none of the operands is a signaling NaN.
 - The instruction is not trapped.
- If all of the following apply, the output is a quiet NaN derived from the NaN operand:
 - `FPCR.AH == 1`.
 - The operation has two floating-point inputs.
 - The operation has only one NaN operand.
- If all of the following apply, the output is a NaN derived from the `<Vn>`, `<Hn>`, `<Sn>`, or `<Dn>` register:
 - `FPCR.AH == 1`.
 - The operation has two floating-point inputs.
 - The operation has two NaN operands.

- If all of the following apply, the output is a NaN derived from the NaN held in the <Vn>, <Hn>, <Sn>, or <Dn> register:
 - `FPCR.AH == 1`
 - The instruction is one of: `BFMLALB`, `BFMLALT` (by element), `BFMLALB`, `BFMLALT` (vector), `FCMLA`, `FMADD`, `FMLA` (by element), `FMLA` (vector), `FMLAL`, `FMLAL2` (by element), `FMLAL`, `FMLAL2` (vector), `FMLS` (by element), `FMLS` (vector), `FMLSL`, `FMLSL2` (by element), `FMLSL`, `FMLSL2` (vector), `FMSUB`, `FMADD`, and `FNMSUB`.
 - One of the following applies:
 - The operation has three NaN operands.
 - The operation has two NaN operands and the <Vn>, <Hn>, <Sn> or <Dn> register holds a NaN.
- If all of the following apply, the output is a NaN derived from the NaN held in the <Vm>, <Hm>, <Sm>, or <Dm> register:
 - `FPCR.AH == 1`
 - The instruction is one of: `BFMLALB`, `BFMLALT` (by element), `BFMLALB`, `BFMLALT` (vector), `FCMLA`, `FMADD`, `FMLA` (by element), `FMLA` (vector), `FMLAL`, `FMLAL2` (by element), `FMLAL`, `FMLAL2` (vector), `FMLS` (by element), `FMLS` (vector), `FMLSL`, `FMLSL2` (by element), `FMLSL`, `FMLSL2` (vector), `FMSUB`, `FMADD`, and `FNMSUB`.
 - The operation has two NaN operands and the <Vn>, <Hn>, <Sn> or <Dn> register does not hold a NaN.

If `FPCR.AH == 0`, and an output NaN is derived from an input NaN, the pseudocode functions `FPAbs()`, `FPNeg()`, `FPtrigMAdd()`, and `FPtrigSSel()` can change the sign of the NaN,

If `FPCR.AH == 1`, and an output NaN is derived from an input NaN, for all cases, the sign bit of the NaN is unchanged.

For `FMAX*` and `FMIN*`, the NaN handling is described in the instruction.

A1.5.6 Rounding

The rounding mode specifies how the exact result of a floating-point operation is rounded to a value in the destination format.

The rounding mode is either determined by the rounding mode control field `FPCR.RMode` or by the instruction.

If `FPCR.AH == 1`, for any value of `FPCR.RMode`, the following instructions use Round to Nearest on outputs:

- BF16 instructions `BFCVT`, `BFCVTN`, `BFCVTN2`, `BFMLALB`, `BFMLALT` (by element), `BFMLALB`, `BFMLALT` (vector), and the SVE instruction `BFCVTNT`.
- Single-precision and double-precision instructions `FRECPE`, `FRECPS`, `FRECPX`, `FRSQRT`, and `FRSQRTS`.
- Half-precision instructions `FRECPE`, `FRECPS`, `FRECPX`, `FRSQRT`, and `FRSQRTS`.

The rounding mode control field `FPCR.RMode` can select the following rounding modes:

- Round to Nearest (RN) mode.
- Round towards Plus Infinity (RP) mode.
- Round towards Minus Infinity (RM) mode.
- Round towards Zero (RZ) mode.

The following two additional rounding modes are not selected by `FPCR.RMode`, but are used by some instructions:

- Round to Odd mode.
- Round to Nearest with ties to away mode.

Round to Nearest mode

Round to Nearest rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity. The sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
 - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the number with an even least significant digit.
 - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

Round towards Plus Infinity mode

Round towards Plus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not less than the value before rounding. The result can be plus infinity.

Round towards Minus Infinity mode

Round towards Minus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the number in the output format that is closest to and not greater than the value before rounding. The result can be minus infinity.

Round towards Zero mode

Round towards Zero rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not greater in absolute value than the value before rounding.

Round to Nearest with Ties to Away

Round to Nearest with Ties to Away rounding mode is used by the [FCVTAS \(scalar\)](#), [FCVTAS \(vector\)](#), [FCVTAU \(scalar\)](#), [FCVTAU \(vector\)](#), [FRINTA \(scalar\)](#), and [FRINTA \(vector\)](#) instructions.

Round to Nearest with Ties to Away rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity, the sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
 - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the larger number.
 - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

Round to Odd mode

Round to Odd mode is not defined by IEEE 754, and differs between the [FCVTXN](#), [FCVTXN2](#) instructions, and the [BFDOT \(by element\)](#), [BFDOT \(vector\)](#), and [BFMMLA](#) instructions.

The [FCVTXN](#), [FCVTXN2](#) instructions use Round to Odd rounding mode. If the result of the rounding is inexact, the least significant bit of the mantissa is forced to 1.

Round to Odd rounding mode can avoid double rounding errors when a floating-point value is converted to a lower precision destination format through an intermediate precision format.

Example A1-1 Converting 64-bit floating-point format to 16-bit floating-point format

A 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value using the following steps:

1. Use an FCVTXN instruction to produce a 32-bit value.
 2. Use another instruction with the required rounding mode to convert the 32-bit value to the final 16-bit floating-point value.
-

For [BFDDOT \(by element\)](#), [BFDDOT \(vector\)](#), and [BFDDMLA](#) instructions, if the intermediate format has at least two more bits of precision than the result format, Round to Odd mode is used and operates as follows:

- If the rounded value is inexact, the least significant bit of the fraction is set to 1.
- If the value is too large to represent in the single-precision format, the rounded value is a single-precision Infinity, the sign of the rounded value is the same as the sign of the value before rounding.

A1.6 The Arm memory model

The Arm memory model supports:

- Generating an exception on an unaligned memory access.
- Restricting access by applications to specified areas of memory.
- Translating *virtual addresses* (VAs) provided by executing instructions to *physical addresses* (PAs).
- Altering the interpretation of multi-byte data between big-endian and little-endian.
- Controlling the order of accesses to memory.
- Controlling caches and address translation structures.
- Synchronizing access to shared memory by multiple PEs.
- Barriers that control and prevent speculative access to memory.

VA support depends on the Execution state, as follows:

AArch64 state

Supports 64-bit virtual addressing, with the Translation Control Register determining the supported VA range. Execution at EL1 and EL0 supports two independent VA ranges, each with its own translation controls.

AArch32 state

Supports 32-bit virtual addressing, with the Translation Control Register determining the supported VA range. For execution at EL1 and EL0, system software can split the VA range into two subranges, each with its own translation controls.

The supported PA space is IMPLEMENTATION DEFINED, and can be discovered by system software.

Regardless of the Execution state, the *Virtual Memory System Architecture* (VMSA) can translate VAs to blocks or pages of memory anywhere within the supported PA space.

For more information, see:

For execution in AArch64 state

- [Chapter B2 The AArch64 Application Level Memory Model.](#)
- [Chapter D4 The AArch64 System Level Memory Model.](#)
- [Chapter D5 The AArch64 Virtual Memory System Architecture.](#)

For execution in AArch32 state

- [Chapter E2 The AArch32 Application Level Memory Model.](#)
- [Chapter G4 The AArch32 System Level Memory Model.](#)
- [Chapter G5 The AArch32 Virtual Memory System Architecture.](#)

Chapter A2

Armv8-A Architecture Extensions

This chapter introduces the Arm architecture versions and extensions. It contains the following sections:

- *Armv8.0 architecture extensions* on page A2-64.
- *Architectural features within Armv8.0 architecture* on page A2-68.
- *The Armv8 Cryptographic Extension* on page A2-72.
- *The Armv8.1 architecture extension* on page A2-74.
- *The Armv8.2 architecture extension* on page A2-78.
- *The Armv8.3 architecture extension* on page A2-87.
- *The Armv8.4 architecture extension* on page A2-91.
- *The Armv8.5 architecture extension* on page A2-96.
- *The Armv8.6 architecture extension* on page A2-100.
- *The Armv8.7 architecture extension* on page A2-103.
- *The Performance Monitors Extension* on page A2-107.
- *The Reliability, Availability, and Serviceability Extension* on page A2-108.
- *The Statistical Profiling Extension (SPE)* on page A2-109.
- *The Scalable Vector Extension (SVE)* on page A2-110.
- *The Activity Monitors Extension (AMU)* on page A2-111.
- *The Memory Partitioning and Monitoring (MPAM) Extension* on page A2-112.

A2.1 Armv8.0 architecture extensions

The original Armv8-A architecture is called Armv8.0. The following sections of this manual describe or summarize permitted extensions to Armv8.0:

- [The Armv8 Cryptographic Extension on page A2-72.](#)
- [The Reliability, Availability, and Serviceability Extension on page A2-108.](#)
- [Event monitors on page D1-2544.](#)
- [The IVIPT Extension on page D5-2837.](#)
- [Chapter H7 The PC Sample-based Profiling Extension.](#)

Note

The naming convention of features in the Arm architecture has been redefined. For more information on how these names map to the legacy convention, see [Appendix K13 Legacy Feature Naming Convention](#).

In addition to describing Armv8.0, this manual describes the following architectural extensions:

Features added to Armv8.0 in later releases

Architectural features and architectural requirements have been added to the original Armv8-A architecture. For more information, see:

- [Additional functionality added to Armv8.0 in later releases on page A2-68.](#)
- [Architectural requirements within Armv8.0 architecture on page A2-71.](#)

For more information, see [Architectural features within Armv8.0 architecture on page A2-68.](#)

The Armv8.1 architectural extension

The Armv8.1 architecture extension adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is Armv8.1 compliant if all of the following apply:

- It includes all of the Armv8.1 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.1 compliant implementation includes the optional architecture component or extension. See [Architectural features added by Armv8.1 on page A2-74](#) for all of the Armv8.1 architectural features.
- It includes all of the Armv8.1 architectural requirements. [Additional requirements of Armv8.1 on page A2-76](#) lists these requirements.

For more information, see [The Armv8.1 architecture extension on page A2-74.](#)

The Armv8.2 architectural extension

The Armv8.2 architecture extension is an extension to Armv8.1. It adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is Armv8.2 compliant if all of the following apply:

- It is Armv8.1 compliant.
- It includes all of the Armv8.2 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.2 compliant implementation includes the optional architecture component or extension. The features are listed at:

— [Architectural features added by Armv8.2 on page A2-78](#), which lists the original Armv8.2 architectural features.

- [Features added to the Armv8.2 extension in later releases on page A2-84](#), which lists additional Armv8.2 architectural features.
 - It includes all of the Armv8.2 architectural requirements. [Additional requirements of Armv8.2 on page A2-84](#) lists these requirements.
- For more information, see [The Armv8.2 architecture extension on page A2-78](#).

The Armv8.3 architectural extension

The Armv8.3 architecture extension is an extension to Armv8.2. It adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is Armv8.3 compliant if all of the following apply:

- It is Armv8.2 compliant.
- It includes all of the Armv8.3 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.3 compliant implementation includes the optional architecture component or extension. The features are listed at:
 - [Architectural features added by Armv8.3 on page A2-87](#), which lists the original Armv8.3 architectural features.
 - [Features added to the Armv8.3 extension in later releases on page A2-89](#), which lists additional Armv8.3 architectural features.
- It includes all of the Armv8.3 architectural requirements. [Additional requirements of Armv8.3 on page A2-89](#) lists these requirements.

For more information, see [The Armv8.3 architecture extension on page A2-87](#).

The Armv8.4 architectural extension

The Armv8.4 architecture extension is an extension to Armv8.3. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.4 compliant if all of the following apply:

- It is Armv8.3 compliant.
- It includes all of the Armv8.4 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.4 compliant implementation includes the optional architecture component or extension. See [Architectural features added by Armv8.4 on page A2-91](#) for all of the Armv8.4 architectural features.

For more information, see [The Armv8.4 architecture extension on page A2-91](#).

The Armv8.5 architectural extension

The Armv8.5 architecture extension is an extension to Armv8.4. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.5 compliant if all of the following apply:

- It is Armv8.4 compliant.
- It includes all of the Armv8.5 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.5 compliant implementation includes the optional architecture component or extension. See [Architectural features added by Armv8.5 on page A2-96](#) for all of the Armv8.5 architectural features.
- It includes all of the Armv8.5 architectural requirements. [Additional requirements of Armv8.5 on page A2-98](#) lists these requirements.

For more information, see [The Armv8.5 architecture extension on page A2-96](#).

The Armv8.6 architectural extension

The Armv8.6 architecture extension is an extension to Armv8.5. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.6 compliant if all of the following apply:

- It is Armv8.5 compliant.
- It includes all of the Armv8.6 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.6 compliant implementation includes the optional architecture component or extension. See [Architectural features added by Armv8.6 on page A2-100](#) for all of the Armv8.6 architectural features.
- It includes all of the Armv8.6 architectural requirements. [Additional requirements of Armv8.6 on page A2-101](#) lists these requirements.

For more information, see [The Armv8.6 architecture extension on page A2-100](#).

The Armv8.7 architectural extension

The Armv8.7 architecture extension is an extension to Armv8.6. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.7 compliant if all of the following apply:

- It is Armv8.6 compliant.
- It includes all of the Armv8.7 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.7 compliant implementation includes the optional architecture component or extension. See [Architectural features added by Armv8.7 on page A2-103](#) for all of the Armv8.7 architectural features.
- It includes all of the Armv8.7 architectural requirements. [Additional requirements of Armv8.7 on page A2-106](#) lists these requirements.

For more information, see [The Armv8.7 architecture extension on page A2-103](#).

The Statistical Profiling Extension (SPE)

SPE is an optional extension to Armv8.2. That is, SPE requires the implementation of Armv8.2.

For more information, see [The Statistical Profiling Extension \(SPE\) on page A2-109](#).

The Scalable Vector Extension (SVE)

SVE is an optional extension to Armv8.2. That is, SVE requires the implementation of Armv8.2.

For more information, see [The Scalable Vector Extension \(SVE\) on page A2-110](#).

The Activity Monitors Extension (AMU)

AMU is an optional extension to Armv8.4. That is, AMU requires the implementation of Armv8.4.

For more information, see [The Activity Monitors Extension \(AMU\) on page A2-111](#).

The Memory Partitioning and Monitoring Extension (MPAM)

MPAM is an optional extension to Armv8.2. That is, MPAM requires the implementation of Armv8.2.

For more information, see [The Memory Partitioning and Monitoring \(MPAM\) Extension on page A2-112](#).

See also [Permitted implementation of subsets of Armv8.x and Armv8.\(x+1\) architectural features on page A2-66](#).

A2.1.1 Permitted implementation of subsets of Armv8.x and Armv8.(x+1) architectural features

An Armv8.x compliant implementation can include any arbitrary subset of the architectural features of Armv8.(x+1), subject only to those constraints that require that certain features be implemented together.

Unless this manual permits otherwise, an Armv8.x compliant implementation does not include any features of Armv8.(x+2) or later.

———— **Note** —————

The addition of Armv8.(x+1) features to an Armv8.x compliant implementation is permitted only if the implementer has a license to Armv8.(x+1) in addition to the license to Armv8.x.

A2.2 Architectural features within Armv8.0 architecture

This includes architectural features and architectural requirements that have been added to the Armv8.0 architecture since the initial release, that were not part of the original Armv8-A architecture, see:

- [Additional functionality added to Armv8.0 in later releases on page A2-68.](#)
- [Architectural requirements within Armv8.0 architecture on page A2-71.](#)

A2.2.1 Additional functionality added to Armv8.0 in later releases

An implementation of Armv8.0 can include any or all of the features that this section describes.

The Armv8.0 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_SB, Speculation Barrier

FEAT_SB introduces a barrier to control speculation.

This instruction is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.0 implementations and mandatory in Armv8.5 implementations.

The following fields identify the presence of FEAT_SB:

- [ID_AA64ISAR1_EL1.SB.](#)
- [ID_ISAR6_EL1.SB.](#)
- [ID_ISAR6.SB.](#)

For more information, see:

- [Speculation Barrier \(SB\) on page B2-148.](#)
- [Barriers and CLREX instructions on page C3-219.](#)
- [Speculation Barrier \(SB\) on page E2-4301.](#)
- [Miscellaneous instructions on page F2-4393.](#)

FEAT_SSBS, FEAT_SBSS2, Speculative Store Bypass Safe

FEAT_SSBS allows software to indicate whether hardware is permitted to load or store speculatively in a manner that could give rise to a cache timing side channel, which in turn could be used to derive an address from values loaded to a register from memory.

FEAT_SSBS2 provides controls for the MSR and MRS instructions to read and write the [PSTATE.SSBS](#) field.

FEAT_SSBS is supported in both AArch64 and AArch32 states. FEAT_SSBS2 is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.0 implementations and mandatory in Armv8.5 implementations.

The following fields identify the presence of FEAT_SSBS and FEAT_SSBS2:

- [ID_AA64PFR1_EL1.SSBS.](#)
- [ID_PFR2_EL1.SSBS.](#)
- [ID_PFR2.SSBS.](#)

For more information, see:

- [Speculative Store Bypass Safe \(SSBS\) on page B2-145.](#)
- [Speculative Store Bypass Safe \(SSBS\) on page E2-4298.](#)

FEAT_CSV2 and FEAT_CSV2_2, Cache Speculation Variant 2

FEAT_CSV2 adds a mechanism to identify if hardware cannot disclose information about whether branch targets trained in one hardware described context can control speculative execution in a different hardware described context.

FEAT_CSV2_2 adds the [SCXTNUM_ELx](#) registers, which provide a number that can be used to separate out different context numbers within their respective Exception levels for the purpose of protecting against side-channels using branch prediction and similar resources.

FEAT_CSV2 is supported in both AArch64 and AArch32 states.

FEAT_CSV2_2 is supported in AArch64 state only.

FEAT_CSV2 is OPTIONAL in Armv8.0 implementations and mandatory in Armv8.5 implementations.

FEAT_CSV2_2 is OPTIONAL in Armv8.0 implementations.

The following fields identify the presence of FEAT_CSV2:

- [ID_AA64PFR0_EL1.CSV2](#).
- [ID_PFR0_EL1.CSV2](#).
- [ID_PFR0.CSV2](#).

The [ID_AA64PFR0_EL1.CSV2](#) field identifies the presence of FEAT_CSV2_2.

For more information, see:

- [Restrictions on the effects of speculation on page B2-144](#).
- [Restrictions on the effects of speculation on page E2-4297](#).

FEAT_CSV2_1p1 and FEAT_CSV2_1p2, Cache Speculation Variant 2

For each of these features, within a hardware-described context, branch targets trained for branches situated at one address can control speculative execution of branches situated at different addresses only in a hard-to-determine way.

FEAT_CSV2_1p1 does not support the [SCXTNUM_ELx](#) registers, and the contexts do not include the [SCXTNUM_ELx](#) register contexts.

FEAT_CSV2_1p2 adds the [SCXTNUM_ELx](#) registers, but the contexts do not include the [SCXTNUM_ELx](#) register contexts.

These features are supported in AArch64 state only.

These features are OPTIONAL in Armv8.0 implementations.

The [ID_AA64PFR1_EL1.CSV2_frac](#) field identifies the presence of FEAT_CSV2_1p1 and FEAT_CSV2_1p2.

For more information, see:

- [Restrictions on the effects of speculation on page B2-144](#).
- [Restrictions on the effects of speculation on page E2-4297](#).

FEAT_CSV3, Cache Speculation Variant 3

FEAT_CSV3 adds a mechanism to identify if hardware cannot disclose information about whether data loaded under speculation with a permission or domain fault can be used to form an address, generate condition codes, or generate SVE predicate values, to be used by instructions newer than the load in the speculative sequence.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.0 implementations and mandatory in Armv8.5 implementations.

This feature is mandatory when FEAT_EOPD is implemented.

The following fields identify the presence of FEAT_CSV3:

- [ID_AA64PFR0_EL1.CSV3](#).
- [ID_PFR2_EL1.CSV3](#).
- [ID_PFR2.CSV3](#).

FEAT_SPECRES, Speculation restriction instructions

FEAT_SPECRES adds the [CFP RCTX](#), [CPP RCTX](#), [DVP RCTX](#), [CFPRCTX](#), [CPPRCTX](#), and [DVPRCTX](#) System instructions. These instructions prevent predictions based on information gathered from earlier execution within a particular execution context from affecting the later speculative execution within that context, to the extent that the speculative execution is observable through side channels.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.0 implementations and mandatory in Armv8.5 implementations.

The following fields identify the presence of FEAT_SPECRES:

- [ID_AA64ISAR1_EL1.SPECRES](#).
- [ID_ISAR6_EL1.SPECRES](#).
- [ID_ISAR6.SPECRES](#).

For more information, see:

- [Prediction restriction instructions on page C5-400](#).
- [Execution and data prediction restriction System instructions on page D4-2663](#).
- [Execution and data prediction restriction System instructions on page G4-6251](#).

FEAT_CP15SDISABLE2, CP15SDISABLE2

FEAT_CP15SDISABLE2 provides an implementation-defined mechanism, the **CP15SDISABLE2** signal, which when asserted HIGH prevents writes to a set of Secure CP15 registers. This signal is analogous to the existing **CP15SDISABLE** signal.

This feature is supported only when EL3 is executing in AArch32 state.

This feature is OPTIONAL in Armv8.0 implementations.

For more information, see [The CP15SDISABLE and CP15SDISABLE2 input signals on page G5-6400](#).

FEAT_DoubleLock, Double Lock

FEAT_DoubleLock is the mnemonic used for the OS Double Lock.

If [FEAT_DoPD](#) is not implemented and [FEAT_Debugv8p2](#) is implemented, this feature is OPTIONAL.

If [FEAT_DoPD](#) is not implemented and [FEAT_Debugv8p2](#) is not implemented, this feature is mandatory.

If [FEAT_DoPD](#) is implemented, this feature is not implemented.

The [ID_AA64DFR0_EL1.DoubleLock](#) field identifies that the OS Double Lock has been implemented.

FEAT_DGH, Data Gathering Hint

FEAT_DGH adds the Data Gathering Hint instruction to the hint space.

This instruction is added to the A64 instruction set only.

This feature is OPTIONAL in Armv8.0 implementations.

The [ID_AA64ISAR1_EL1.DGH](#) field identifies the presence of FEAT_DGH.

For more information, see [Hint instructions on page C3-219](#).

FEAT_ETS, Enhanced Translation Synchronization

FEAT_ETS adds support for enhanced memory access ordering requirements for translation table walks.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.0 implementations and mandatory in Armv8.7 implementations.

The following fields identify the presence of FEAT_ETS:

- [ID_AA64MMFR1_EL1.ETS](#).
- [ID_MMFR5_EL1.ETS](#).
- [ID_MMFR5.ETS](#).

For more information, see:

- [Ordering of memory accesses from translation table walks on page D5-2707](#).
- [Ordering of translation table walks on page E2-4306](#).

FEAT_nTLBPA, Intermediate caching of translation table walks

FEAT_nTLBPA adds a mechanism to identify if the intermediate caching of translation table walks does not include non-coherent caches of previous valid translation table entries since the last completed TLBI applicable to the PE.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.0 implementations.

The following fields identify the presence of FEAT_nTLBPA:

- [ID_AA64MMFR1_EL1.nTLBPA](#).
- [ID_MMFR5_EL1.nTLBPA](#).
- [ID_MMFR5.nTLBPA](#).

For more information, see:

- [General TLB maintenance requirements on page D5-2816](#).
- [General TLB maintenance requirements on page G5-6336](#).

FEAT_PCSRv8, PC Sample-based Profiling Extension

FEAT_PCSRv8 adds support for PC Sample-based Profiling Extension that provides coarse-grained, non-invasive profiling by an external debugger.

This feature is OPTIONAL in Armv8.0 implementations.

The following fields identify the presence of FEAT_PCSRv8:

- [EDDEVID.PCSample](#).
- [DBGDEVID.PCSample](#).
- [EDDEVID1.PCSROffset](#).
- [DBGDEVID1.PCSROffset](#).
- [PMDEVID.PCSample](#).

For more information, see [About the PC Sample-based Profiling Extension on page H7-7456](#).

A2.2.2 Architectural requirements within Armv8.0 architecture

The Armv8.0 architecture includes some mandatory changes, that have been added to the architecture at a later date, that are not associated with a feature. These are:

Prefetch speculation protection

When substituting a direct branch with another direct branch, or a NOP with a direct branch, by the modified PE, at around the time that the executing PE is executing the software being modified, prefetch speculation protection prevents the old instructions from accidentally being fetched to the executing PE. For further information on implementation of these requirements, see:

- [Ordering of instruction fetches on page B2-143](#).
- [Ordering of instruction fetches on page E2-4297](#).

An implementation of the Armv8.0 architecture must comply with all of the additional requirements. When combined with the mandatory architectural features that have been added to the Armv8.0 architecture, such an implementation is also called an implementation of the Armv8.0 architecture.

A2.3 The Armv8 Cryptographic Extension

The Armv8.0 Cryptographic Extension provides instructions for the acceleration of encryption and decryption, and includes the following features:

- FEAT_AES, which includes the AESD and AESE instructions.
- FEAT_PMULL, which includes the PMULL, PMULL2 instructions.
- FEAT_SHA1, which includes the SHA1* instructions.
- FEAT_SHA256, which includes the SHA256* instructions.

From Armv8.2, an implementation of the Armv8.0 Cryptographic Extension can include either or both of:

- The AES functionality, including support for multiplication of 64-bit polynomials. The ID_AA64ISAR0_EL1.AES field indicates whether this functionality is supported.
- The SHA1 and SHA2-256 functionality. The ID_AA64ISAR0_EL1.{SHA2, SHA1} fields indicate whether this functionality is supported.

The presence of the Cryptographic Extension in an implementation is subject to export license controls. The Cryptographic Extension is an extension of the SIMD support and operates on the vector register file.

The Cryptographic Extension also provides multiply instructions that operate on long polynomials.

The Cryptographic Extension provides this functionality in AArch64 state and AArch32 state, and an implementation that supports both AArch64 state and AArch32 state provides the same Cryptographic Extension functionality in both states.

For more information, see [The Cryptographic Extension on page C3-278](#) or [The Cryptographic Extension in AArch32 state on page F2-4410](#).

A2.3.1 Armv8.2 extensions to the Cryptographic Extension

Armv8.2 adds optional extensions to the Armv8 Cryptographic Extension, that provide cryptographic functionality in AArch64 state only. These optional features are:

FEAT_SHA512, Advanced SIMD SHA512 instructions

FEAT_SHA512 adds Advanced SIMD instructions that support SHA2-512 functionality.

These instructions are added to the A64 instruction set only.

Implementation of FEAT_SHA512 requires implementation of the Armv8.0 Cryptographic Extension FEAT_SHA1 and FEAT_SHA256 functionality.

The ID_AA64ISAR0_EL1.SHA2 field identifies the presence of FEAT_SHA512.

For more information, see [FEAT_SHA512, SHA2-512 functionality on page C3-279](#).

FEAT_SHA3, Advanced SIMD SHA3 instructions

FEAT_SHA3 adds Advanced SIMD instructions that support SHA3 functionality.

These instructions are added to the A64 instruction set only.

Implementation of FEAT_SHA3 requires implementation of the Armv8.0 Cryptographic Extension FEAT_SHA1 and FEAT_SHA256 functionality.

The ID_AA64ISAR0_EL1.SHA3 field identifies the presence of FEAT_SHA3.

For more information, see [FEAT_SHA3, SHA3 functionality on page C3-279](#).

FEAT_SM3, Advanced SIMD SM3 instructions

FEAT_SM3 adds Advanced SIMD instructions that support the Chinese cryptography algorithm SM3.

These instructions are added to the A64 instruction set only.

Implementation of FEAT_SM3 is independent of the implementation of any SHA functionality.

The ID_AA64ISAR0_EL1.SM3 field identifies the presence of FEAT_SM3.

For more information, see [FEAT_SM3, SM3 functionality on page C3-280](#).

FEAT_SM4, Advanced SIMD SM4 instructions

FEAT_SM4 adds Advanced SIMD instructions that support the Chinese cryptography algorithm SM4.

Implementation of FEAT_SM4 is independent of the implementation of any SHA functionality.

These instructions are added to the A64 instruction set only.

The `ID_AA64ISAR0_EL1.SM4` field identifies the presence of FEAT_SM4.

For more information, see [FEAT_SM4, SM4 functionality on page C3-281](#).

A2.4 The Armv8.1 architecture extension

The Armv8.1 architecture extension adds both architectural features and architectural requirements, see:

- [Architectural features added by Armv8.1](#) on page A2-74.
- [Additional requirements of Armv8.1](#) on page A2-76.
- [Features added to the Armv8.1 extension in later releases](#) on page A2-77.
- [Features made optional in Armv8.1 implementations](#) on page A2-77.

A2.4.1 Architectural features added by Armv8.1

An implementation of the Armv8.1 extension must include all of the features that this section describes as mandatory. Such an implementation, when combined with the additional requirements of Armv8.1, is also called an implementation of the Armv8.1 architecture.

The Armv8.1 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_LSE, Large System Extensions

FEAT_LSE introduces a set of atomic instructions:

- Compare and Swap instructions, CAS and CASP.
- Atomic memory operation instructions, LD<OP> and ST<OP>, where <OP> is one of ADD, CLR, EOR, SET, SMAX, SMIN, UMAX, and UMIN.
- Swap instruction, SWP.

These instructions are added only to the A64 instruction set.

This feature is mandatory in Armv8.1 implementations.

Implementations of FEAT_VHE require the implementation of FEAT_LSE.

The ID_AA64ISAR0_EL1.Atomic field identifies the presence of FEAT_LSE.

For more information, see:

- [Atomic memory operations](#) on page C3-236.
- [Swap](#) on page C3-239.
- [Compare and Swap](#) on page C3-239.

FEAT_RDM, Advanced SIMD rounding double multiply accumulate instructions

FEAT_RDM introduces Rounding Double Multiply Add/Subtract Advanced SIMD instructions.

For more information, see:

For the A64 instruction set

- [SQRDMLAH \(by element\)](#) on page C7-2181.
- [SQRDMLAH \(vector\)](#) on page C7-2184.
- [SQRDMLSH \(by element\)](#) on page C7-2187.
- [SQRDMLSH \(vector\)](#) on page C7-2190.

For the T32 and A32 instruction sets

- [VQRDMLAH](#) on page F6-5776.
- [VQRDMLSH](#) on page F6-5780.

This feature is mandatory in Armv8.1 implementations.

The following fields identify the presence of FEAT_RDM:

- ID_AA64ISAR0_EL1.RDM.
- ID_ISAR5_EL1.RDM.
- ID_ISAR5.RDM.

FEAT_LOR, Limited ordering regions

Limited ordering regions allow large systems to perform special Load-Acquire and Store-Release instructions that provide order between the memory accesses to a region of the PA map as observed by a limited set of observers.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.1 implementations.

The [ID_AA64MMFR1_EL1.LO](#) field identifies the presence of FEAT_LOR.

For more information, see:

- [Limited ordering regions on page B2-154](#).

FEAT_HPDS, Hierarchical permission disables

FEAT_HPDS introduces the facility to disable the hierarchical attributes, APTable, PXNTable, and UXNTable, in the translation tables. This disable has no effect on the NSTable bit.

This feature is mandatory in Armv8.1 implementations.

This feature is added only to the VMSAv8-64 translation regimes. Armv8.2 extends this to the AArch32 translation regimes, see [FEAT_AA32HPD](#).

The [ID_AA64MMFR1_EL1.HPDS](#) field identifies the presence of FEAT_HPDS.

FEAT_HAFDBS, Hardware management of the Access flag and dirty state

In Armv8.0, all updates to the translation tables are performed by software. From Armv8.1, for the VMSAv8-64 translation regimes only, hardware can perform updates to the translation tables in two contexts:

- Hardware management of the Access flag.
- Hardware management of dirty state, with updates to a dirty state in the translation tables.

The dirty state is introduced in Armv8.1.

Hardware management of dirty state can only be enabled when hardware management of the Access flag is also enabled.

This feature is OPTIONAL in Armv8.1 implementations. It is IMPLEMENTATION DEFINED whether this is implemented.

The [ID_AA64MMFR1_EL1.HAFDBS](#) field identifies the presence of FEAT_HAFDBS.

For more information, see:

- [The dirty state on page D5-2766](#).
- [Hardware management of the Access flag and dirty state on page D5-2767](#).

FEAT_PAN, Privileged access never

FEAT_PAN adds a bit to [PSTATE](#). When the value of this PAN state bit is 1, any privileged data access from EL1, or EL2 when [HCR_EL2.E2H](#) is 1, to a virtual memory address that is accessible to data accesses at EL0, generates a Permission fault.

This feature is mandatory in Armv8.1 implementations.

This feature is supported in both AArch64 and AArch32 states.

The following fields identify the presence of FEAT_PAN:

- [ID_AA64MMFR1_EL1.PAN](#).
- [ID_MMFR3_EL1.PAN](#).
- [ID_MMFR3.PAN](#).

For more information, see:

- [About PSTATE.PAN on page D5-2755](#).
- [About the PAN bit on page G5-6311](#).

FEAT_VMID16, 16-bit VMID

In an Armv8.1 implementation, when EL2 is using AArch64, the *virtual machine identifier (VMID)* size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits.

This feature is OPTIONAL in Armv8.1 implementations.

When implemented, this feature is supported only when EL2 is using AArch64.

The `ID_AA64MMFR1_EL1.VMIDBits` field identifies the supported VMID size.

For more information, see:

- [VMID size on page D5-2812](#).

FEAT_VHE, Virtualization Host Extensions

Armv8.1 introduces the *Virtualization Host Extensions* (VHE) that provide enhanced support for Type 2 hypervisors in Non-secure state.

This feature is mandatory in Armv8.1 implementations.

An implementation that includes `FEAT_VHE` requires `FEAT_LSE` to be implemented.

The `ID_AA64MMFR1_EL1.VH` field identifies the presence of `FEAT_VHE`.

The following fields indicate the presence of the Virtualization Host Extensions for debug, including the changes for the PC Sample-based Profiling Extension and the Performance Monitors Extension:

- `ID_AA64DFR0_EL1.DebugVer`.
- `ID_DFR0_EL1`.{CopSDBG, CopDBG}.

For more information, see:

- [Virtualization Host Extensions on page D5-2787](#).

FEAT_PMUv3p1, PMU Extensions v3.1

Armv8.1 makes the following enhancements to the Performance Monitors Extension:

- The event number space is extended to 16 bits to allow additional IMPLEMENTATION DEFINED event types, and the reserved space for future additions to the architecturally-defined event types is extended.
- The HPMD bit is added to `MDCR_EL2`. This bit disables event counting at EL2.
- The `STALL_FRONTEND` and `STALL_BACKEND` events are required to be implemented. For more information, see [Required events on page D7-2937](#).

The Performance Monitors Extension is an OPTIONAL feature, but if it is implemented, an Armv8.1 implementation must include `FEAT_PMUv3p1`.

The following fields identify the presence of `FEAT_PMUv3p1`:

- `ID_AA64DFR0_EL1.PMUVer`.
- `ID_DFR0_EL1.PerfMon`.
- `ID_DFR0.PerfMon`.

A2.4.2 Additional requirements of Armv8.1

The Armv8.1 architecture includes some mandatory changes that are not associated with a feature. These are:

Changes to CRC32 instructions

All implementations of the Armv8.1 architecture are required to implement the CRC32* instructions. These are OPTIONAL in Armv8.0.

The following fields identify the presence of the CRC32* instructions:

- `ID_AA64ISAR0_EL1.CRC32`.
- `ID_ISAR5_EL1.CRC32`.
- `ID_ISAR5.CRC32`.

An implementation of the Armv8.1 extension must comply with all of the additional requirements. Such an implementation, when combined with the mandatory architectural features of Armv8.1, is also called an implementation of the Armv8.1 architecture.

A2.4.3 Features added to the Armv8.1 extension in later releases

FEAT_PAN3, Support for SCTLR_ELx.EPAN

FEAT_PAN3 adds a bit to [SCTLR_EL1](#) and [SCTLR_EL2](#), EPAN, to support using Privileged Access Never with instruction accesses for stage 1 translation regimes.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.1 implementations and mandatory in Armv8.7 implementations.

The [ID_AA64MMFR1_EL1.PAN](#) field identifies the presence of FEAT_PAN3.

For more information, see [About PSTATE.PAN on page D5-2755](#).

A2.4.4 Features made OPTIONAL in Armv8.1 implementations

The feature that has been made OPTIONAL in Armv8.1 implementations is [FEAT_PAN2 on page A2-78](#).

A2.5 The Armv8.2 architecture extension

The Armv8.2 architecture extension adds both architectural features and architectural requirements, see:

- [Architectural features added by Armv8.2](#) on page A2-78.
- [Additional requirements of Armv8.2](#) on page A2-84.
- [Features added to the Armv8.2 extension in later releases](#) on page A2-84.
- [Features made optional in Armv8.2 implementations](#) on page A2-86.

The Armv8.2 architecture extension also adds functionality to the Cryptographic Extension, see [Armv8.2 extensions to the Cryptographic Extension](#) on page A2-72.

A2.5.1 Architectural features added by Armv8.2

An implementation of the Armv8.2 extension must include all of the features that this section describes as mandatory. Such an implementation, when combined with the additional requirements of Armv8.2, is also called an implementation of the Armv8.2 architecture.

The Armv8.2 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_ASMv8p2, Armv8.2 changes to the A64 ISA

FEAT_ASMv8p2 adds the BFC instruction to the A64 instruction set as an alias of BFM. It also requires that the BFC instruction and the A64 pseudo-instruction REV64 are implemented by assemblers.

————— Note —————

- In Armv8.0 and Armv8.1, the A64 pseudo-instruction REV64 is OPTIONAL.
- Because this feature relates to support for an instruction alias and for a pseudo-instruction, there are no corresponding feature ID register fields.

This change to the instruction set and assembler requirements is mandatory in an Armv8.2 implementation.

For more information, see:

- [BFC](#) on page C6-922.
- [REV64](#) on page C6-1290.

FEAT_PAN2, AT S1E1R and AT S1E1W instruction variants affected by PSTATE.PAN

FEAT_PAN2 adds variants of the AArch64 AT S1E1R and AT S1E1W instructions and the AArch32 ATS1CPR and ATS1CPW instructions. These instructions factor in the PSTATE.PAN bit when determining whether or not the location will generate a Permission fault for a privileged access, as is reported in the PAR. For more information, see:

For the AArch64 System instructions

- [AT S1E1RP, Address Translate Stage 1 EL1 Read PAN](#) on page C5-582.
- [AT S1E1WP, Address Translate Stage 1 EL1 Write PAN](#) on page C5-586.

For the AArch32 System instructions

- [ATS1CPRP, Address Translate Stage 1 Current state PL1 Read PAN](#) on page G8-6477.
- [ATS1CPWP, Address Translate Stage 1 Current state PL1 Write PAN](#) on page G8-6479.

This feature is OPTIONAL in Armv8.1 implementations and mandatory in Armv8.2 implementations.

These instructions are added to the A64 and A32/T32 instruction sets.

The following fields identify the presence of FEAT_PAN2:

- ID_AA64MMFR1_EL1.PAN.
- ID_MMFR3_EL1.PAN.
- ID_MMFR3.PAN.

For more information, see:

- [Address translation instructions on page D5-2735.](#)
- [ATSIC**, Address translation stage 1, current security state on page G5-6387.](#)
- [Encoding and availability of the address translation instructions on page G5-6388.](#)

FEAT_FP16, Half-precision floating-point data processing

FEAT_FP16 supports:

- Half-precision data-processing instructions for Advanced SIMD and floating-point in both AArch64 and AArch32 states.
- The [FPCR.FZ16](#) and [FPSCR.FZ16](#) bits, which enables flushing of denormalized numbers to zero for half-precision data-processing instructions.

This feature is OPTIONAL in Armv8.2 implementations, unless one of the following is implemented:

- [The Scalable Vector Extension \(SVE\).](#)
- [FEAT_FHM.](#)

If SVE or FEAT_FHM is implemented, FEAT_FP16 is implemented. From Armv8.4, if FEAT_FHM is not implemented, FEAT_FP16 is not implemented.

When this feature is implemented it is implemented in both Advanced SIMD and floating-point, and in AArch64 and AArch32 states.

The following fields identify the presence of FEAT_FP16:

- [ID_AA64PFR0_EL1](#).{FP, AdvSIMD}.
- [MVFR1_EL1](#).{FPHP, SIMDHP}.
- [MVFR1](#).{FPHP, SIMDHP}.

For more information, see:

- [Half-precision floating-point formats on page A1-44.](#)
- [Flushing denormalized numbers to zero on page A1-54.](#)
- [Modified immediate constants in A64 instructions on page C2-212.](#)

FEAT_DotProd, Advanced SIMD dot product instructions

FEAT_DotProd provides instructions to perform the dot product of two 32-bit vectors, accumulating the result in a third 32-bit vector. This can be performed using signed or unsigned arithmetic.

This feature is OPTIONAL in Armv8.2 implementations and mandatory in Armv8.4 implementations.

These instructions are added to the A64 and A32/T32 instruction sets.

The following fields identify the presence of FEAT_DotProd:

- [ID_AA64ISAR0_EL1](#).DP.
- [ID_ISAR6_EL1](#).DP.
- [ID_ISAR6](#).DP.

For more information, see:

- [SIMD dot product on page C3-275.](#)
- [Advanced SIMD dot product instructions on page F2-4407.](#)

FEAT_FHM, Floating-point half-precision multiplication instructions

FEAT_FHM adds floating-point multiplication instructions.

These instructions are added to the A64 and A32/T32 instruction sets.

This feature is OPTIONAL in Armv8.2 implementations, and can only be implemented when [FEAT_FP16](#) is implemented. This feature is mandatory in Armv8.4 implementations when [FEAT_FP16](#) is implemented. This feature is not implemented in Armv8.4 implementations when [FEAT_FP16](#) is not implemented.

The following fields identify the presence of FEAT_FHM:

- [ID_AA64ISAR0_EL1](#).FHM.
- [ID_ISAR6_EL1](#).FHM.

- [ID_ISAR6.FHM](#).

For more information, see:

- [SIMD arithmetic](#) on page C3-262.
- [SIMD by element arithmetic](#) on page C3-270.
- [Advanced SIMD multiply instructions](#) on page F2-4406.

FEAT_LSMAOC, AArch32 Load/Store Multiple instruction atomicity and ordering controls

FEAT_LSMAOC adds controls that disable legacy behavior of AArch32 load multiple and store multiple instructions, and provide a trap of one aspect of this legacy behavior.

Implementation of FEAT_LSMAOC is OPTIONAL. When implemented it provides:

- LSMAOE fields in the [SCTLR_EL1](#), [SCTLR_EL2](#), [HSCTLR](#), and [SCTLR](#) registers. These fields can have the following effects on the behavior of AArch32 load multiple and store multiple instructions:
 - An interrupt can be taken between two memory accesses made by a single load multiple or store multiple instruction.
 - The memory accesses made by a single load multiple or store multiple instruction to Device memory with the non-Reordering attribute can be reordered.
- nTLSMD fields in the [SCTLR_EL1](#), [SCTLR_EL2](#), [HSCTLR](#), and [SCTLR](#) registers. These fields can cause an access to Device-nGRE, Device-nGnRE, or Device-nGnRnE memory by an AArch32 load multiple and store multiple instruction to generate an Alignment fault.

Note

Armv8.2 deprecates software dependence on the legacy behavior of AArch32 load multiple and store multiple instructions, and these fields disable this behavior.

The following fields identify the presence of FEAT_LSMAOC:

- [ID_AA64MMFR2_EL1.LSM](#).
- [ID_MMFR4_EL1.LSM](#).
- [ID_MMFR4.LSM](#).

For more information, see the register field descriptions and:

- [Generation of Alignment faults by load/store multiple accesses to Device memory](#) on page E2-4313.
- [Multi-register loads and stores that access Device memory](#) on page E2-4326.
- [Taking an interrupt or other exception during a multiple-register load or store](#) on page G1-6077.

FEAT_UAO, Unprivileged Access Override control

Armv8.2 adds a bit to [PSTATE](#). When the value of [PSTATE.UAO](#) is 1, and when executed at EL1 or at EL2 with [HCR_EL2](#).{E2H, TGE} == {1, 1}, the memory accesses made by the load/store unprivileged instructions behave as if they were made by the load/store register instructions. See [Load/store unprivileged](#) on page C3-228 and [Load/store register](#) on page C3-224.

This feature is mandatory in Armv8.2 implementations.

This feature is supported in AArch64 state only.

The [ID_AA64MMFR2_EL1.UAO](#) field identifies the presence of FEAT_UAO.

For more information, see [About PSTATE.UAO](#) on page D5-2756.

FEAT_DPB, DC CVAP instruction

FEAT_DPB introduces a mechanism to identify and manage persistent memory locations in a shared memory hierarchy, including adding the [DC CVAP](#) instruction.

This feature is mandatory in Armv8.2 implementations.

This feature is supported in AArch64 state only.

The [ID_AA64ISAR1_EL1.DPB](#) field identifies the presence of FEAT_DPB.

For more information about FEAT_DPB, see [Memory hierarchy on page B2-155](#).

FEAT_VPIPT, VMID-aware PIPT instruction cache

FEAT_VPIPT supports a instruction cache type, described as the *VMID-aware PIPT* (VPIPT) instruction cache.

———— Note —————

Armv8.2 adds VPIPT to the set of supported cache types, meaning an Armv8.2 implementation is permitted to implement VPIPT caches, but is not required to do so.

This feature is supported in both AArch64 and AArch32 states.

The `CTR_EL0.L1Ip` and `CTR.L1Ip` fields identify the presence of FEAT_VPIPT.

For more information, see:

- [VPIPT \(VMID-aware PIPT\) instruction caches on page D5-2836](#).
- [VPIPT \(VMID-aware PIPT\) instruction caches on page G5-6352](#).

FEAT_AA32HPD, AArch32 hierarchical permission disables

FEAT_HPDS introduced the ability to disable the hierarchical attributes, APTable, PXNTable, and UXNTable, in the VMSAv8-64 translation regimes. FEAT_AA32HPD extends this functionality to the VMSAv8-32 translation regimes when those regimes are using the Long descriptor Translation Table format.

This feature is OPTIONAL in Armv8.2 implementations. It is IMPLEMENTATION DEFINED whether this is implemented.

The `ID_MMFR4_EL1.HPDS` and `ID_MMFR4.HPDS` fields identify the presence of FEAT_AA32HPD.

For more information, see [Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-6292](#).

FEAT_HPDS2, Translation table page-based hardware attributes

Armv8.2 provides a mechanism to allow operating systems or hypervisors to make up to four bits of Translation Table final-level descriptors available for IMPLEMENTATION DEFINED hardware use.

This functionality is available for all translation regimes in AArch64 state and for stages of translation in AArch32 state that use the Long descriptor Translation Table format.

FEAT_HPDS2 is OPTIONAL in Armv8.2 implementations, but implementation of FEAT_HPDS2 requires implementation of both:

- [FEAT_HPDS](#).
- [FEAT_AA32HPD](#), if any Exception level higher than EL0 can use AArch32.

———— Note —————

For stage 1 translations, page-based hardware attributes can only be used for a stage of translation for which the Hierarchical permission disables field has a value of 1.

The following fields identify the presence of FEAT_HPDS2:

- `ID_AA64MMFR1_EL1.HPDS`.
- `ID_MMFR4_EL1.HPDS`.
- `ID_MMFR4.HPDS`.

For more information, see:

- [Memory attribute fields in the VMSAv8-64 Translation Table format descriptors on page D5-2746](#).
- [Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-6292](#).

FEAT_LPA, Large PA and IPA support

FEAT_LPA:

- Allows a larger *intermediate physical address* (IPA) and PA space of up to 52 bits when using the 64KB translation granule.
- Allows a level 1 block size where the block covers a 4TB address range for the 64KB translation granule if the implementation support 52 bits of PA.

This is an OPTIONAL feature in Armv8.2 implementations. It is IMPLEMENTATION DEFINED whether it is implemented.

This feature is supported in AArch64 state only.

The `ID_AA64MMFR0_EL1.PARange` field identifies the presence of FEAT_LPA.

For more information about FEAT_LPA, see:

- [VMSA address types and address spaces on page D5-2675.](#)
- [Address size configuration on page D5-2689.](#)
- [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695.](#)
- [VMSAv8-64 translation table level -1, level 0, level 1, and level 2 descriptor formats on page D5-2739.](#)
- [Armv8 translation table level 3 descriptor formats on page D5-2744.](#)

FEAT_LVA, Large VA support

FEAT_LVA supports a larger VA space for each translation table base register of up to 52 bits when using the 64KB translation granule.

This feature is supported in AArch64 state only.

This is an OPTIONAL feature in Armv8.2 implementations. It is IMPLEMENTATION DEFINED whether it is implemented.

If FEAT_LVA is implemented, then any implemented trace macrocell must be at least ETMv4.2.

The `ID_AA64MMFR2_EL1.VARange` field identifies the presence of FEAT_LVA.

For more information about FEAT_LVA, see:

- [VMSA address types and address spaces on page D5-2675.](#)
- [Address size configuration on page D5-2689.](#)
- [Extending addressing above 48 bits when using the 64KB translation granule on page D5-2695.](#)
- [VMSAv8-64 translation table level -1, level 0, level 1, and level 2 descriptor formats on page D5-2739.](#)
- [Armv8 translation table level 3 descriptor formats on page D5-2744.](#)

FEAT_TTCNP, Translation table Common not private translations

FEAT_TTCNP permits multiple PEs in the same Inner Shareable domain to use the same translation tables for a given stage of address translation.

This feature is mandatory in Armv8.2 implementations.

This facility is available for all VMSAv8-64 translation regimes and for VMSAv8-32 translation stages that use the Long descriptor Translation Table format.

The following fields identify the presence of FEAT_TTCNP:

- `ID_AA64MMFR2_EL1.CnP.`
- `ID_MMFR4_EL1.CnP.`
- `ID_MMFR4.CnP.`

For more information, see:

- [Common not private translations on page D5-2811.](#)
- [Common not private translations in VMSAv8-32 on page G5-6341.](#)

FEAT_XNX, Translation table stage 2 Unprivileged Execute-never

FEAT_XNX extends the stage 2 translation table access permissions to provide control of whether memory is executable at EL0 independent of whether it is executable at EL1.

This feature is mandatory in Armv8.2 implementations that implement EL2.

This facility is available for stage 2 translation stages in VMSAv8-64 and VMSAv8-32.

The following fields identify the presence of FEAT_XNX:

- [ID_AA64MMFR1_EL1.XNX](#).
- [ID_MMFR4_EL1.XNX](#).
- [ID_MMFR4.XNX](#).

For more information, see:

- [Access permissions for instruction execution on page D5-2760](#).
- [Access permissions for instruction execution on page G5-6312](#).

FEAT_Debugv8p2, Debug v8.2

FEAT_Debugv8p2 covers a selection of mandatory changes, including:

- If the Core power domain is powered up and `DoubleLockStatus() == TRUE`, [EDPRSR.{DLK,SPD,PU}](#) is only permitted to read `{UNKNOWN, 0, 0}`.
- The definition of Exception Catch debug events is extended to include reset entry.
- All CONstrained UNPREDICTABLE cases that generate Exception Catch debug events are removed.
- Controls are added to [EDECCECR](#) to control Exception Catch debug event generation on exception return.
- All IMPLEMENTATION DEFINED control of external debug accesses to [OSLAR_EL1](#) is removed.
- `ExternalSecureNoninvasiveDebugEnabled()` cannot override software controls of counting attributable events in Secure state.

If [FEAT_Debugv8p2](#) is implemented, [FEAT_DoubleLock](#) is OPTIONAL.

The fields that identify the presence of FEAT_Debugv8p2 are:

- [ID_AA64DFR0_EL1.DebugVer](#) and [DBGDIDR.Version](#).
- [ID_DFR0_EL1.{CopSDBG, CopDBG}](#) and [ID_DFR0.{CopSDBG, CopDBG}](#).
- [EDDEVARCH.ARCHID](#).

For more information, see:

- [Exception Catch debug event on page H3-7391](#).
- [EDPRSR.{DLK, SPD, PU} and the Core power domain on page H6-7446](#).
- [Interaction with EL3 on page D7-2851](#).
- [External access disabled on page H8-7468](#).

FEAT_PCSRv8p2, PC Sample-based profiling

In Armv8.2, the control and implementation of the OPTIONAL PC Sample-based Profiling extension is moved from ED*SR Debug registers to PM*SR registers in the Performance Monitors address space. See [Chapter H7 The PC Sample-based Profiling Extension](#).

The PC Sample-based Profiling Extension is an OPTIONAL feature. If it is implemented, an Arm8.2 implementation must also include FEAT_PCSRv8p2.

If Secure EL2 and PC Sample-based Profiling are both implemented, FEAT_PCSRv8p2 is mandatory.

The following fields identify the presence of FEAT_PCSRv8p2:

- [EDDEVID.PCSample](#).
- [DBGDEVID.PCSample](#).
- [EDDEVID1.PCSROffset](#).
- [DBGDEVID1.PCSROffset](#).

- [PMDEVID.PCSample](#).

FEAT_IESB, Implicit Error Synchronization event

FEAT_IESB adds an implicit error synchronization event at exception entry and return, controlled by the added [SCTLR_ELx.IESB](#) fields. An IESB field is added to the [ESR_ELx](#) syndrome registers.

The implicit error synchronization events affect the same synchronizable asynchronous events that are synchronized by the ESB instruction, see [The Reliability, Availability, and Serviceability Extension on page A2-108](#).

This feature is OPTIONAL in Armv8.2 implementations.

This feature is supported in AArch64 state only.

The [ID_AA64MMFR2_EL1.IESB](#) field identifies the presence of FEAT_IESB.

For more information, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*.

Extensions to the Arm Cryptographic Extensions

See the description of the [FEAT_SHA512](#) and [FEAT_SM3](#) features in [Armv8.2 extensions to the Cryptographic Extension on page A2-72](#).

A2.5.2 Additional requirements of Armv8.2

The Armv8.2 architecture includes some mandatory changes that are not associated with a feature. These are:

Change to ACTLR2 and HCTLR2 registers

In AArch32 state, the [ACTLR2](#) and [HACTLR2](#) registers become mandatory.

Implementation of RAS Extension

The RAS Extension must be implemented, see [The Reliability, Availability, and Serviceability Extension on page A2-108](#).

An implementation of the Armv8.2 extension must comply with all of the additional requirements. Such an implementation, when combined with the mandatory architectural features of Armv8.2, is also called an implementation of the Armv8.2 architecture.

If [FEAT_PMUv3](#) is implemented, the feature [FEAT_PMUv3p4](#) is OPTIONAL in Armv8.2 implementations.

A2.5.3 Features added to the Armv8.2 extension in later releases

FEAT_EVT, Enhanced Virtualization Traps

FEAT_EVT introduces additional traps for EL1 and EL0 Cache controls. These traps are independent of existing controls.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.2 implementations and is mandatory in Armv8.5.

[ID_AA64MMFR2_EL1.EVT](#) identifies the presence of the AArch64 traps controls.

[ID_MMFR4_EL1.EVT](#) and [ID_MMFR4.EVT](#) identify the presence of the AArch32 traps.

For more information, see:

- [HCR_EL2.{TTLBIS, TTLBOS, TICAB, TOCU, TID4}](#).
- [HCR2.{TTLBIS, TICAB, TOCU, TID4}](#).

FEAT_DPB2, DC CVADP instruction

FEAT_DPB2 allows two levels of cache clean to the [Point of Persistence](#) by:

- Redefining [Point of Persistence](#), which changes the scope of DC CVAP.
- Defining a [Point of Deep Persistence](#).
- Adding the [DC CVADP](#) System instruction.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.2 implementations and is mandatory in Armv8.5 implementations.

The [ID_AA64ISAR1_EL1.DPB](#) field identifies the presence of FEAT_DPB2.

For further information, see [Terminology for Clean, Invalidate, and Clean and Invalidate instructions](#) on page D4-2645.

FEAT_BF16, AArch64 BFloat16 instructions

FEAT_BF16 supports the BFloat16, or BF16, 16-bit floating-point storage format in AArch64 state. This format supports:

- The BFloat16 floating-point data type.
- Arithmetic instructions to accelerate dot products and matrix multiplications of BF16 values.
- Instructions to convert single-precision floating-point values to BF16 format.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.2 implementations and mandatory in Armv8.6 implementations.

The [ID_AA64ISAR1_EL1.BF16](#) field identifies the presence of FEAT_BF16.

When both Advanced SIMD and SVE are implemented, the [ID_AA64ISAR1_EL1.BF16](#) and [ID_AA64ZFR0_EL1.BF16](#) fields must return the same value.

For further information, see:

- [BFloat16 floating-point format](#) on page A1-48.
- [BFloat16 floating-point instructions](#) on page C3-262.
- [SIMD BFloat16](#) on page C3-276.
- *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A.*

FEAT_AA32BF16, AArch32 BFloat16 instructions

FEAT_AA32BF16 supports the BFloat16, or BF16, 16-bit floating-point storage format in AArch32 state. This format supports:

- The BFloat16 floating-point data type.
- Arithmetic instructions to accelerate dot products and matrix multiplications of BF16 values.
- Instructions to convert single-precision floating-point values to BF16 format.

This feature is supported in AArch32 state only.

This feature is OPTIONAL in Armv8.2 implementations.

The [ID_ISAR6_EL1.BF16](#) and [ID_ISAR6.BF16](#) fields identify the presence of FEAT_AA32BF16.

For further information, see:

- [BFloat16 floating-point format](#) on page A1-48.
- [Advanced SIMD BFloat16 instructions](#) on page F2-4408.
- [Floating-point data-processing](#) on page F3-4449.

FEAT_I8MM, AArch64 Int8 matrix multiplication instructions

FEAT_I8MM introduces integer matrix multiply-accumulate instructions and mixed sign dot product instructions.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.2 implementations and mandatory in Armv8.6 implementations.

The [ID_AA64ISAR1_EL1.I8MM](#) field identifies the presence of FEAT_I8MM.

When both Advanced SIMD and SVE are implemented, the [ID_AA64ISAR1_EL1.I8MM](#) and the [ID_AA64ZFR0_EL1.I8MM](#) fields must return the same value.

For further information, see:

- [SIMD dot product](#) on page C3-275.
- [SIMD matrix multiplication](#) on page C3-277.

- *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A.*

FEAT_AA32I8MM, AArch32 Int8 matrix multiplication instructions

FEAT_AA32I8MM introduces integer matrix multiply-accumulate instructions and mixed sign dot product instructions.

This feature is supported in AArch32 state only.

This feature is OPTIONAL in Armv8.2 implementations.

The [ID_ISAR6_EL1.I8MM](#) and [ID_ISAR6.I8MM](#) fields identify the presence of FEAT_AA32I8MM.

For further information, see:

- [Advanced SIMD dot product instructions on page F2-4407.](#)
- [Advanced SIMD matrix multiply instructions on page F2-4408.](#)

A2.5.4 Features made OPTIONAL in Armv8.2 implementations

The features that have been made OPTIONAL in Armv8.2 implementations are:

- [FEAT_FlagM on page A2-91.](#)
- [FEAT_LSE2 on page A2-91.](#)
- [FEAT_LRCPC2 on page A2-91.](#)

A2.6 The Armv8.3 architecture extension

The Armv8.3 architecture extension adds both architectural features and additional requirements, see:

- [Architectural features added by Armv8.3 on page A2-87.](#)
- [Additional requirements of Armv8.3 on page A2-89.](#)
- [Features added to the Armv8.3 extension in later releases on page A2-89.](#)

A2.6.1 Architectural features added by Armv8.3

An implementation of the Armv8.3 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.3 architecture.

The Armv8.3 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_FCMA, Floating-point complex number instructions

FEAT_FCMA introduces instructions for floating-point multiplication and addition of complex numbers.

These instructions are added to the A64 and A32/T32 instruction sets.

This feature is mandatory in Armv8.3 implementations.

The half-precision versions of these instructions are implemented only if FEAT_FP16 is implemented. Otherwise they are UNDEFINED.

The fields that identify the presence of FEAT_FCMA are:

- [ID_AA64ISAR1_EL1.FCMA.](#)
- [ID_ISAR5_EL1.VCMA.](#)
- [ID_ISAR5.VCMA.](#)

For more information, see:

- [SIMD complex number arithmetic on page C3-276.](#)
- [Advanced SIMD complex number arithmetic instructions on page F2-4407.](#)

FEAT_JSCVT, JavaScript conversion instructions

FEAT_JSCVT introduces instructions that perform a conversion from a double-precision floating point value to a signed 32-bit integer, with rounding to zero. For more information, see:

For the A64 instruction set

- [FJCVTZS on page C7-1754.](#)

For the A32/T32 instruction set

- [VJCVT on page F6-5538.](#)

These instructions are added to the A64 and A32/T32 instruction sets.

This feature is mandatory in Armv8.3 implementations.

The fields that identify the presence of FEAT_JSCVT are:

- [ID_AA64ISAR1_EL1.JSCVT.](#)
- [ID_ISAR6_EL1.JSCVT.](#)
- [ID_ISAR6.JSCVT.](#)

For more information, see:

- [Floating-point conversion on page C3-257.](#)
- [About the A64 SIMD and floating-point instructions on page C7-1522.](#)
- [Advanced SIMD and floating-point instructions on page E1-4260.](#)
- [Floating-point data-processing instructions on page F2-4412.](#)

FEAT_LRCPC, Load-Acquire RCpc instructions

FEAT_LRCPC introduces three instructions to support the weaker *Release Consistency processor consistent* (RCpc) model that enables the reordering of a Store-Release followed by a Load-Acquire to a different address:

- [LDAPR](#) on page C6-1048.
- [LDAPRB](#) on page C6-1050.
- [LDAPRH](#) on page C6-1052.

These instructions are added to the A64 instruction set.

The feature is mandatory in Armv8.3 implementations.

The [ID_AA64ISAR1_EL1.LRCPC](#) field identifies the presence of FEAT_LRCPC.

For more information, see:

- [Load-Acquire, Load-AcquirePC, and Store-Release](#) on page B2-152.
- [Load-Acquire/Store-Release](#) on page C3-229.

FEAT_NV, Nested virtualization support

FEAT_NV provides support for a Guest Hypervisor to run in Non-secure EL1 and ensures that the Guest Hypervisor is unaware that it is running at that Exception level. A Guest Hypervisor is supported regardless of the value of [HCR_EL2.E2H](#).

This feature is supported in AArch64 state only.

The feature is OPTIONAL in Armv8.3 implementations. This feature must be implemented if [FEAT_NV2](#) is implemented.

The [ID_AA64MMFR2_EL1.NV](#) field identifies the presence of FEAT_NV.

For more information, see [Nested virtualization](#) on page D5-2793.

FEAT_CCIDX, Extended cache index

FEAT_CCIDX introduces the following registers to allow caches to be described with greater numbers of sets and greater associativity:

- A 64-bit format of [CCSIDR_EL1](#).
- [CCSIDR2_EL1](#).
- [CCSIDR2](#).

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.3 implementations.

The following fields identify the presence of FEAT_CCIDX:

- [ID_AA64MMFR2_EL1.CCIDX](#).
- [ID_MMFR4_EL1.CCIDX](#).
- [ID_MMFR4.CCIDX](#).

For more information, see:

- [Possible formats of the Cache Size Identification Register, CCSIDR_EL1](#) on page D4-2639.
- [Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2](#) on page G4-6231.

FEAT_PAuth, Pointer authentication

FEAT_PAuth adds functionality that supports address authentication of the contents of a register before that register is used as the target of an indirect branch, or as a load.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.3 implementations.

The fields [ID_AA64ISAR1_EL1](#).{GPI, GPA, API, APA} identify the presence of FEAT_PAuth.

For more information, see [Pointer authentication in AArch64 state](#) on page D5-2678.

A2.6.2 Additional requirements of Armv8.3

If [FEAT_PMUv3](#) is implemented, [FEAT_PMUv3p4](#) is OPTIONAL in Armv8.3 implementations.

A2.6.3 Features added to the Armv8.3 extension in later releases

FEAT_SPEv1p1, Armv8.3 Statistical Profiling Extensions

[FEAT_SPEv1p1](#) adds an Alignment Flag in the [Events packet](#) and filtering on this event using [PMSEVFR_EL1](#), together with support for the profiling of Scalable Vector Extension operations.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.3 implementations. An Armv8.5 implementation that includes the [Statistical Profiling Extension](#) must include [FEAT_SPEv1p1](#).

The fields in [ID_AA64DFR0_EL1.PMSVer](#) identify the presence of [FEAT_SPEv1p1](#).

For more information, see [Chapter D9 The Statistical Profiling Extension](#) and [Chapter D10 Statistical Profiling Extension Sample Record Specification](#).

FEAT_DoPD, Debug over Powerdown

[FEAT_DoPD](#) provides a debug programmers' model where all debug and PMU registers are in the Core power domain, all CTI registers are in the Debug power domain. Power control is provided by a CoreSight *Granular Power Requestor* (GPR) component.

When the OPTIONAL powerup mechanism is implemented and this feature is implemented, the debugger makes power control requests for the Core power domain using a CoreSight Class 0x9 ROM Table block, instead of using [EDRCR.COREPURQ](#). [EDRCR.COREPURQ](#) is not implemented. Refer to the *ARM® CoreSight Architecture Specification* for more information.

This feature is OPTIONAL in Armv8.3 implementations.

When [FEAT_DoPD](#) is implemented:

- [FEAT_DoubleLock](#) is not implemented.
- [FEAT_Debugv8p2](#) must be implemented.
- If PC Sample-based profiling is implemented, [FEAT_PCSRv8p2](#) must be implemented.
- The optional Software Lock is not implemented by the architecturally defined debug components in the PE Core power domain.
- If an ETMv4 PE Trace Unit is implemented, the ETM must implement:
 - ETMv4.2 or later.
 - The Unified Power Domain Model.

The fields that identify the presence of [FEAT_DoPD](#) are:

- [EDDEVID.DebugPower](#).
- [CTIDEVARCH.REVISION](#).

For more information, see [Chapter H6 Debug Reset and Powerdown Support](#).

FEAT_PAuth2, Enhancements to pointer authentication

[FEAT_PAuth2](#) adds enhanced pointer authentication functionality that changes the mechanism by which a PAC is added to the pointer.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.3 implementations and mandatory in Armv8.6 implementations.

The [ID_AA64ISAR1_EL1.APA](#) and [ID_AA64ISAR1_EL1.API](#) fields identify the presence of [FEAT_PAuth2](#).

For more information, see [Pointer authentication in AArch64 state on page D5-2678](#).

FEAT_FPAC, Faulting on AUT* instructions

[FEAT_FPAC](#) introduces faulting on an AUT* instruction and, optionally, on the combined instructions that perform pointer authentication. [FEAT_FPAC](#) is added as a further extension to [FEAT_PAuth2](#).

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.3 implementations, and can be implemented only if [FEAT_PAuth2](#) is implemented.

The [ID_AA64ISAR1_EL1.APA](#) and [ID_AA64ISAR1_EL1.API](#) fields identify the presence of FEAT_FPAC.

For more information, see [Faulting on pointer authentication](#) on page D5-2681.

A2.7 The Armv8.4 architecture extension

The Armv8.4 architecture extension adds architectural features, see [Architectural features added by Armv8.4 on page A2-91](#). It also adds features to earlier architecture extensions, see [Features added to earlier extensions on page A2-95](#).

A2.7.1 Architectural features added by Armv8.4

An implementation of the Armv8.4 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.4 architecture.

The Armv8.4 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_DIT, Data Independent Timing instructions

FEAT_DIT provides independent timing for data processing instructions with the addition of the [PSTATE.DIT](#) and [CPSR.DIT](#) fields.

This feature is supported in both AArch64 and AArch32 states.

This feature is mandatory in Armv8.4 implementations.

The following fields identify the presence of FEAT_DIT:

- [ID_AA64PFR0_EL1.DIT](#).
- [ID_PFR0_EL1.DIT](#).
- [ID_PFR0.DIT](#).

For more information, see:

- [About PSTATE.DIT on page B1-123](#).
- [About the DIT bit on page E1-4259](#).

FEAT_FlagM, Flag manipulation instructions v2

FEAT_FlagM provides instructions which manipulate the [PSTATE.{N,Z,C,V}](#) flags.

These instructions are added to the A64 instruction set only.

This feature is OPTIONAL in Armv8.2 implementations.

This feature is mandatory in Armv8.4 implementations.

The [ID_AA64ISAR0_EL1.TS](#) field identifies the presence of FEAT_FlagM.

For more information, see [Flag manipulation instructions on page C3-249](#).

FEAT_LRCPC2, Load-Acquire RCpc instructions v2

FEAT_LRCPC2 provides versions of LDAPR and STLR with a 9-bit unscaled signed immediate offset.

These instructions are added to the A64 instruction set only.

This feature is OPTIONAL in Armv8.2 implementations.

This feature is mandatory in Armv8.4 implementations.

The [ID_AA64ISAR1_EL1.LRCPC](#) field identifies the presence of FEAT_LRCPC2.

For more information, see:

- [Changes to single-copy atomicity in Armv8.4 on page B2-129](#).
- [Non-exclusive Load-Acquire and Store-Release instructions on page C3-230](#).
- [A64 instructions that are changed in Debug state on page H2-7349](#).

FEAT_LSE2, Large System Extensions v2

FEAT_LSE2 introduces changes to single-copy atomicity requirements for loads and stores, and changes to alignment requirements for loads and stores.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.2 implementations.

This feature is mandatory in Armv8.4 implementations.

The `ID_AA64MMFR2_EL1.AT` field identifies the presence of `FEAT_LSE2`.

For more information, see:

- [Requirements for single-copy atomicity on page B2-128.](#)
- [Alignment of data accesses on page B2-160.](#)

FEAT_TLBIOS, TLB invalidate instructions in Outer Shareable domain

`FEAT_TLBIOS` provides TLBI maintenance instructions that extend to the Outer Shareable domain.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations.

The field `ID_AA64ISAR0_EL1.TLB` identifies the presence of `FEAT_TLBIOS`.

For more information, see:

- [TLB maintenance instruction syntax on page D5-2820.](#)

FEAT_TLBIRANGE, TLB invalidate range instructions

`FEAT_TLBIRANGE` provides TLBI maintenance instructions that apply to a range of input addresses. `FEAT_TLBIRANGE` being implemented implies that `FEAT_TLBIOS` is implemented.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations.

The field `ID_AA64ISAR0_EL1.TLB` identifies the presence of `FEAT_TLBIRANGE`.

For more information, see:

- [TLB maintenance instruction syntax on page D5-2820.](#)
- [TLB range maintenance instructions on page D5-2828.](#)

FEAT_TTL, Translation Table Level

`FEAT_TTL` provides the TTL field to indicate the level of translation table walk holding the leaf entry for the address that is being invalidated. This field is provided in all TLB maintenance instructions that take a VA or an IPA argument.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations.

The field `ID_AA64MMFR2_EL1.TTL` identifies the presence of `FEAT_TTL`.

For more information, see:

- [TLB maintenance instruction syntax on page D5-2820.](#)
- [TLB range maintenance instructions on page D5-2828.](#)

FEAT_S2FWB, Stage 2 forced Write-Back

`FEAT_S2FWB` reduces the requirement of additional cache maintenance instructions in systems where the data Cacheability attributes used by the Guest operating system are different from those expected by the Hypervisor.

This feature is supported in AArch64 state.

This feature is mandatory in Armv8.4 implementations that implement EL2.

The `ID_AA64MMFR2_EL1.FWB` field identifies the presence of `FEAT_S2FWB`.

For more information, see:

- [Memory region attributes on page D5-2776.](#)
- [The stage 2 memory region attributes, EL1&0 translation regime on page D5-2778.](#)

FEAT_TTST, Small translation tables

`FEAT_TTST` relaxes the lower limit on the size of translation tables, by increasing the maximum permitted value of the T1SZ and T0SZ fields in `TCR_EL1`, `TCR_EL2`, `TCR_EL3`, `VTCR_EL2` and `VSTCR_EL2`.

This feature is supported in AArch64 state only.

This feature is mandatory if FEAT_SEL2 is implemented.

This feature is OPTIONAL if FEAT_SEL2 is not implemented.

The ID_AA64MMFR2_EL1.ST field identifies the presence of FEAT_TTST.

For more information, see:

- [Input address size on page D5-2691](#).
- [Overview of the VMSAv8-64 address translation stages on page D5-2708](#).

FEAT_BBM, Translation table break-before-make levels

FEAT_BBM provides support to identify the requirements of hardware to have break-before-make sequences when changing between block size for a translation.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations.

The ID_AA64MMFR2_EL1.BBM field identifies the presence of FEAT_BBM.

For more information, see:

- [Memory attribute fields in the VMSAv8-64 Translation Table format descriptors on page D5-2746](#).
- [Support levels for changing block size on page D5-2818](#).

FEAT_SEL2, Secure EL2

FEAT_SEL2 permits EL2 to be implemented in Secure state. When Secure EL2 is enabled, a translation regime is introduced that follows the same format as the other Secure translation regimes.

This feature is not supported if EL2 is using AArch32.

This feature is mandatory in Armv8.4 implementations that implement both EL2 and Secure state.

The ID_AA64PFR0_EL1.SEL2 field identifies the presence of FEAT_SEL2.

For more information, see:

- [Virtualization on page D1-2460](#).
- [The VMSAv8-64 address translation system on page D5-2682](#).

FEAT_NV2, Enhanced nested virtualization support

FEAT_NV2 supports nested virtualization by redirecting register accesses that would be trapped to EL1 and EL2 to access memory instead. The address of the memory access depends on information held in introduced register, VNCR_EL2.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.4 implementations.

The ID_AA64MMFR2_EL1.NV field identifies the presence of FEAT_NV2.

For more information, see [Enhanced support for nested virtualization on page D5-2795](#).

FEAT_IDST, ID space trap handling

FEAT_IDST causes all AArch64 read accesses to the feature ID space when exceptions are generated to be reported in ESR_ELx using the EC code 0x18.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations.

The ID_AA64MMFR2_EL1.IDS field identifies the presence of FEAT_IDST.

FEAT_CNTSC, Generic Counter Scaling

FEAT_CNTSC adds a scaling register to the memory-mapped counter module that allows the frequency of the counter that is generated to be scaled from the basic frequency reported in the counter ID mechanisms.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.4 implementations.

The **CNTID.CNTSC** field identifies the presence of **FEAT_CNTSC**.

For more information, see:

- [CNTCR, Counter Control Register on page I5-7808](#).

FEAT_Debugv8p4, Debug v8.4

FEAT_Debugv8p4 covers a selection of mandatory changes:

- The fields **MDCR_EL3**.{**EPMA**, **EDAD**} control Non-secure access to the debug and PMU registers. The bus Requester is responsible for other debug authentication.
- The Software Lock is obsolete.
- Non-invasive Debug controls are relaxed.
- Secure and Non-secure views of the debug registers are enabled.

This feature is mandatory if **FEAT_SEL2** is implemented.

The fields that identify the presence of **FEAT_Debugv8p4** are:

- **ID_AA64DFR0_EL1**.DebugVer.
- **DBGDIDR**.Version.
- **ID_DFR0_EL1**.{CopSDBG, CopDBG}.
- **ID_DFR0**.{CopSDBG, CopDBG}.
- **EDDEVARCH**.ARCHID.

For more information, see:

- [Definition and constraints of a debugger in the context of external debug on page H1-7334](#)
- [External debug interface register access permissions on page H8-7468](#)

FEAT_TRF, Self-hosted Trace Extensions

FEAT_TRF adds controls of trace in a self-hosted system through System registers.

The feature provides:

- Control of Exception levels and Security states where trace generation is prohibited.
- Control of whether an offset is used for the timestamp recorded with trace information.
- A context synchronization instruction **TSB CSYNC** which can be used to prevent reordering of trace operation accesses with respect to other accesses of the same System registers.

If an ETM Architecture PE Trace Unit is implemented and the ETM PE Trace Unit includes System register access to its control registers, this feature is mandatory. If a different PE Trace Unit is implemented or the ETM PE Trace Unit does not include System register access to its control registers, this feature is OPTIONAL.

The reset state of the PE has prohibited regions controlled by the feature and not the external authentication signals. An external trace controller must override the internal controls before enabling trace, including trace from reset. This is a change from previous trace architectures and is not backwards-compatible.

The fields that identify the presence of **FEAT_TRF** are:

- **ID_AA64DFR0_EL1**.TraceFilt.
- **ID_DFR0_EL1**.TraceFilt.
- **ID_DFR0**.TraceFilt.
- **EDDFR**.TraceVer.
- **ID_AA64DFR0_EL1**.TraceVer.

For more information, see:

- [Chapter D3 AArch64 Self-hosted Trace](#).
- [Chapter G3 AArch32 Self-hosted Trace](#).

FEAT_PMUv3p4, PMU Extensions v3.4

FEAT_PMUv3p4 introduces the **PMMIR_EL1** and **PMMIR** registers.

This feature is supported in both AArch64 and AArch32 states.

The Performance Monitors Extension is an OPTIONAL feature, but if it is implemented, an Armv8.4 implementation must include FEAT_PMUv3p4.

The fields that identify the presence of FEAT_PMUv3p4 are:

- [ID_AA64DFR0_EL1.PMUVer](#).
- [ID_DFR0_EL1.PerfMon](#).
- [ID_DFR0.PerfMon](#).
- [EDDFR.PMUVer](#).

For more information, see [PMU events and event numbers on page D7-2869](#).

FEAT_RASv1p1, RAS Extension v1.1

FEAT_RASv1p1 implements RAS System Architecture v1.1 and adds support for:

- Simplifications to ERR<n>STATUS.
- Additional ERR<n>MISC<m> registers.
- The OPTIONAL RAS Common Fault Injection Model Extension.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.2 implementations and mandatory in Armv8.4 implementations.

The following fields identify the complete or partial presence of FEAT_RASv1p1:

- [ID_AA64PFR0_EL1.RAS](#).
- [ID_AA64PFR1_EL1.RAS_frac](#).
- [ID_PFR0_EL1.RAS](#).
- [ID_PFR2_EL1.RAS_frac](#).
- [ID_PFR0.RAS](#).
- [ID_PFR2.RAS_frac](#).

For more information, see:

- [The Reliability, Availability, and Serviceability Extension on page A2-108](#).
- *Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.*

FEAT_DoubleFault, Double Fault Extension

FEAT_DoubleFault provides two controls:

- [SCR_EL3.EASE](#).
- [SCR_EL3.NMEA](#).

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations if EL3 is implemented and EL3 uses AArch64. Otherwise, it is not implemented.

This feature is implemented if [ID_AA64PFR0_EL1.RAS](#) $\geq 0b0010$ and the implementation includes EL3 using AArch64.

For more information, see:

- [The Reliability, Availability, and Serviceability Extension on page A2-108](#).
- *Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.*

A2.7.2 Features added to earlier extensions

The existing functionality of OS Double Lock is added as a feature mnemonic in Armv8.0, see [FEAT_DoubleLock on page A2-70](#).

A2.8 The Armv8.5 architecture extension

The Armv8.5 architecture extension adds architectural features and additional requirements, see:

- [Architectural features added by Armv8.5 on page A2-96.](#)
- [Additional requirements of Armv8.5 on page A2-98.](#)
- [Features added to earlier extensions on page A2-99.](#)
- [Architectural requirements added to earlier extensions on page A2-99.](#)
- [Features added to the Armv8.5 extension in later releases on page A2-99.](#)

A2.8.1 Architectural features added by Armv8.5

An implementation of the Armv8.5 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.5 architecture.

The Armv8.5 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_FlagM2, Enhancements to flag manipulation instructions

FEAT_FlagM2 provides instructions that convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format described in [Relationship between ARM format and alternative format PSTATE condition flags on page C6-874.](#)

These instructions are added to the A64 instruction set only.

This feature is mandatory in Armv8.5 implementations.

The ID_AA64ISAR0_EL1.TS field identifies the presence of FEAT_FlagM2.

For more information, see:

- [Flag manipulation instructions on page C3-249.](#)
- [Relationship between ARM format and alternative format PSTATE condition flags on page C6-874.](#)

FEAT_FRINTTS, Floating-point to integer instructions

FEAT_FRINTTS provides instructions that round a floating-point number to an integral valued floating-point number that fits in a 32-bit or 64-bit integer number range.

These instructions are added to the A64 instruction set only.

This feature requires SIMD&FP, and is mandatory in Armv8.5 implementations when SIMD&FP is implemented.

The ID_AA64ISAR1_EL1.FRINTTS identifies the presence of FEAT_FRINTTS.

For more information, see [Floating-point round to integral value on page C3-258.](#)

FEAT_ExS, Context synchronization and exception handling

FEAT_ExS provides a mechanism to control whether exception entry and exception return are context synchronization events. Fields in the SCTLR_ELx registers enable and disable context synchronization at exception entry and return at an Exception level.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.5 implementations.

The ID_AA64MMFR0_EL1.ExS identifies the presence of FEAT_ExS.

For more information, see:

- [SCTLR_EL1, System Control Register \(EL1\) on page D13-3621, SCTLR_EL2 and SCTLR_EL3.](#)
- [Context synchronization event on page Glossary-8678](#)

FEAT_GTG, Guest translation granule size

FEAT_GTG allows a hypervisor to support different granule sizes for stage 2 and stage 1 translation, and allows a nested hypervisor to determine what stage 2 granule sizes are available.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.5 implementations.

The `ID_AA64MMFR0_EL1`.{TGran16_2, TGran64_2, TGran4_2} fields identify whether each of the granule sizes is supported for stage 2 translation. The `ID_AA64MMFR0_EL1`.{TGran16, TGran64, TGran4} fields identify whether each of the granule sizes is supported for stage 1 translations.

For more information, see [Memory translation granule size on page D5-2698](#).

FEAT_BTI, Branch Target Identification

FEAT_BTI allows memory pages to be guarded against the execution of instructions that are not the intended target of a branch. To do this, it introduces:

- The GP field, which denotes the blocks and pages in stage 1 translation tables that are guarded pages.
- The `PSTATE.BTYPE` field, which is used to determine whether an access to a guarded memory region will generate a Branch Target exception.
- The `BTI` instruction, which is used to guard against the execution of instructions that are not the intended target of a branch.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.5 implementations.

The `ID_AA64PFR1_EL1`.BT field identifies the presence of FEAT_BTI.

For more information, see:

- [Exception entry on page D1-2475](#).
- [Synchronous exception types, routing and priorities on page D1-2489](#).
- [VMSAv8-64 translation table level -1, level 0, level 1, and level 2 descriptor formats on page D5-2739](#).
- [About PSTATE.BTYPE on page D5-2756](#).
- [Effect of entering Debug state on PSTATE on page H2-7346](#).

FEAT_E0PD, Preventing EL0 access to halves of address maps

FEAT_E0PD prevents access at EL0 to half of the addresses in the memory map.

This feature is supported in AArch64 state only. When EL1 is using AArch64 state, this feature affects access to EL0, in either Execution state.

This feature is mandatory in Armv8.5 implementations.

Implementations that support FEAT_E0PD must also support FEAT_CSV3.

The `ID_AA64MMFR2_EL1`.E0PD field identifies presence of FEAT_E0PD.

For more information, see:

- [Preventing EL0 access to halves of the address map on page D5-2758](#).
- `TCR_EL1`.{E0PD0, E0PD1}.
- `TCR_EL2`.{E0PD0, E0PD1}.

FEAT_RNG, Random number generator

FEAT_RNG introduces the `RNDR` and `RNDRRS` registers. Reads to these registers return a 64-bit random number. A read to `RNDRRS` will cause a reseeding of the random number before the generation of the random number that is returned.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.5 implementations.

The `ID_AA64ISAR0_EL1`.RNDR field identifies presence of FEAT_RNG.

- [Effect of random number generation instructions on Condition flags on page C6-874](#).
- [Appendix K12 Random Number Generation](#).

FEAT_MTE and FEAT_MTE2, Memory Tagging Extension

FEAT_MTE and FEAT_MTE2 provide architectural support for runtime, always-on detection of various classes of memory error to aid with software debugging to eliminate vulnerabilities arising from memory-unsafe languages.

These features are supported in AArch64 state only.

These features are OPTIONAL in Armv8.5 implementations.

The `ID_AA64PFR1_EL1.MTE` field identifies the presence of FEAT_MTE and FEAT_MTE2.

For more information, see:

- [Chapter D6 Memory Tagging Extension](#).
- [Chapter B2 The AArch64 Application Level Memory Model](#).
- [PMU events and event numbers on page D7-2869](#).
- [Chapter D9 The Statistical Profiling Extension](#).
- [Chapter H2 Debug State](#).

FEAT_PMUv3p5, PMU Extensions v3.5

FEAT_PMUv3p5 extends event counters to 64-bit event counters, and adds mechanisms to disable the cycle counter in Secure state and in EL2.

FEAT_PMUv3p5 relaxes the behavior of `PMCR`.{`IMP`, `IDCODE`}, and deprecates use of these fields.

This feature is supported in both AArch64 and AArch32 states.

The Performance Monitors Extension is an OPTIONAL feature, but if it is implemented, an Armv8.5 implementation must include FEAT_PMUv3p5.

The fields that identify the presence of FEAT_PMUv3p5 are:

- `ID_AA64DFR0_EL1.PMUVer`.
- `ID_DFR0_EL1.PerfMon`.
- `ID_DFR0.PerfMon`.
- `EDDFR.PMUVer`.

For more information, see:

- [Behavior on overflow on page D7-2855](#)
- [Controlling the PMU counters on page D7-2859](#).
- [PMU events and event numbers on page D7-2869](#).

A2.8.2 Additional requirements of Armv8.5

The Armv8.5 architecture includes some mandatory changes that are not associated with a feature. These are:

Restrictions on effects of speculation

Further restrictions are placed on execution for:

- Execution prediction instructions that predict addresses or register values.
- Data loaded under speculation with a permission or domain fault.
- Any System register read under speculation to a register that is not architecturally accessible from the current Exception level.

For more information, see:

- [Restrictions on the effects of speculation on page B2-144](#).
- [Restrictions on the effects of speculation on page E2-4297](#).

Changes to CTIDEVARCH, CTIDEVAFF0, and CTIDEVAFF1

`CTIDEVARCH`, `CTIDEVAFF0`, and `CTIDEVAFF1` must be implemented.

Changes to the input channel gate function

If the *Cross Trigger Matrix* (CTM) is implemented, the input channel gate function must be implemented.

Deprecation of EDPRCR.CWRR

EDPRCR.CWRR is deprecated.

Mandatory changes are also made to earlier architectural extensions, see [Architectural requirements added to earlier extensions](#) on page A2-99.

A2.8.3 Features added to earlier extensions

The features that have been added to earlier architectural extensions are:

- [FEAT_SB](#) on page A2-68.
- [FEAT_SSBS](#) on page A2-68.
- [FEAT_CSV2](#) on page A2-68.
- [FEAT_CSV3](#) on page A2-69.
- [FEAT_SPECRES](#) on page A2-69.
- [FEAT_CPI5SDISABLE2](#) on page A2-70.
- [FEAT_EVT](#) on page A2-84.
- [FEAT_DPB2](#) on page A2-84.
- [FEAT_SPEv1p1](#) on page A2-89.
- [FEAT_DoPD](#) on page A2-89.

A2.8.4 Architectural requirements added to earlier extensions

The additional architectural requirement that has been added to earlier extensions is [Prefetch speculation protection](#) on page A2-71.

A2.8.5 Features added to the Armv8.5 extension in later releases

FEAT_MTE3, MTE Asymmetric Fault Handling

FEAT_MTE3 introduces support for asymmetric Tag Check Fault handling.

This feature is OPTIONAL in Armv8.5 implementations.

This feature is mandatory from Armv8.7 when FEAT_MTE2 is implemented.

This feature is supported in AArch64 state.

The ID_AA64PFR1_EL1.MTE field identifies the presence of FEAT_MTE3.

For more information, see [Chapter D6 Memory Tagging Extension](#).

A2.9 The Armv8.6 architecture extension

The Armv8.6 architecture extension adds architectural features and additional requirements, see:

- [Architectural features added by Armv8.6 on page A2-100](#).
- [Additional requirements of Armv8.6 on page A2-101](#).

Features are also added to earlier architecture extensions, see [Features added to earlier extensions on page A2-102](#).

A2.9.1 Architectural features added by Armv8.6

An implementation of the Armv8.6 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.6 architecture.

The Armv8.6 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_ECV, Enhanced Counter Virtualization

FEAT_ECV enhances the Generic Timer architecture.

When executing in AArch64 state or AArch32 state, FEAT_ECV provides:

- Self-synchronizing views of the virtual and physical timers in AArch64 and AArch32 state.
- The ability to scale the generation of the event stream.

When EL2 is using AArch64 state, FEAT_ECV provides:

- An optional offset between the EL1 or EL0 view of physical time, and the EL2 or EL3 view of physical time.
- Traps configurable in [CNTHTL_EL2](#) that trap EL0 and EL1 access to the virtual counter or timer registers, and accesses to the physical timer registers when they are accessed using an EL02 descriptor.

The optional offset to views of physical time, and the configurable traps in [CNTHTL_EL2](#), both apply to EL1 and EL0 whether EL1 and EL0 are in AArch64 state or AArch32 state.

This feature is mandatory in Armv8.6 implementations.

The [ID_AA64MMFR0_EL1.ECV](#) field identifies the presence of FEAT_ECV. The [ID_PFR1_EL1.GenTimer](#) and [ID_PFR1.GenTimer](#) fields identify support for self-synchronized counter views in AArch32 state.

For more information, see:

- [Self-hosted trace timestamps on page D3-2631](#).
- [The profiling data on page D9-2958](#).
- [The AArch64 view of the Generic Timer on page D11-3012](#).
- [The AArch32 view of the Generic Timer on page G6-6408](#).

FEAT_FGT, Fine Grain Traps

FEAT_FGT introduces additional traps to EL2 of EL1 and EL0 access to individual or small groups of System registers and instructions, and traps to EL3 and EL2 of the Debug Communications Channel registers. The traps are independent of existing controls.

This feature is supported in AArch64, and when EL1 is using AArch64, EL0 accesses using AArch32 are also trapped.

This feature is mandatory in Armv8.6 implementations.

The [ID_AA64MMFR0_EL1.FGT](#) field identifies the presence of FEAT_FGT.

For more information, see:

- [Traps to EL3 of EL2 accesses to fine-grained trap registers on page D1-2532](#).
- [Traps to EL2 of EL0 and EL1 accesses to the Debug Communications Channel registers on page D1-2527](#).
- [Traps to EL3 of EL2, EL1, and EL0 accesses to Debug Communication Channel registers on page D1-2531](#).

- [Fine-grained traps to EL2 of EL0 and EL1 accesses to System registers on page D1-2525.](#)
- [Fine-grained traps to EL2 of EL0 and EL1 accesses to the debug, trace, and PMU registers on page D1-2525.](#)
- [Fine-grained Traps to EL2 of EL0 and EL1 accesses to instructions on page D1-2525.](#)
- [Fine-grained traps to EL2 of EL0 and EL1 read accesses to Activity Monitors registers on page D1-2520.](#)

FEAT_TWED, Delayed Trapping of WFE

FEAT_TWED introduces support for configurable delayed trapping of the WFE instruction.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.6 implementations.

The `ID_AA64MMFR1_EL1.TWED` field identifies the presence of FEAT_TWED.

For more information, see [The Wait For Event and Wait for Event with Timeout instructions on page D1-2537.](#)

FEAT_AMUv1p1, AMU Extensions v1.1

FEAT_AMUv1p1 introduces support for virtualization of Activity Monitors event counters, and introduces controls to disable access to auxiliary event counters below the highest Exception level.

This feature is supported in AArch32 state and AArch64 state, if the hypervisor is using AArch64.

This feature is OPTIONAL in Armv8.6 implementations if the OPTIONAL `FEAT_AMUv1` is implemented.

The fields `ID_AA64PFR0_EL1.AMU`, `ID_PFR0_EL1.AMU`, and `ID_PFR0.AMU` identify the presence of `FEAT_AMUv1p1`.

For more information, see [Chapter D8 The Activity Monitors Extension.](#)

FEAT_MTPMU, Multi-threaded PMU Extensions

FEAT_MTPMU introduces controls to disable `PMEVTYPER<n>_EL0.MT`.

This feature requires at least one of EL2 and EL3. If neither is implemented, this feature is not implemented.

If EL2 or EL3 is implemented, the feature is OPTIONAL if `FEAT_PMUv3` is implemented.

Multithreaded Armv8.6 implementations with `FEAT_PMUv3` implemented must implement `FEAT_MTPMU` to enable any multithreaded event counting.

This feature is supported in both AArch64 and AArch32 states.

The fields `ID_AA64DFR0_EL1.MTPMU` and `ID_DFR1.MTPMU` identify the presence of `FEAT_MTPMU`.

For more information, see:

- [Multithreaded implementations on page D7-2863.](#)
- `MDCR_EL3.MTPME`, `SDCR.MTPME`, `MDCR_EL2.MTPME`, and `HDCR.MTPME`.
- [Common event numbers on page D7-2876.](#)

A2.9.2 Additional requirements of Armv8.6

The Armv8.6 architecture includes some mandatory changes that are not associated with a feature. These are:

Changes to the frequency of the physical counter

The frequency of `CNTFRQ_EL0` is standardized to a frequency of 1GHz. This means that the system counter must be implemented at 64 bits. For more information, see:

- [The system counter on page D11-3010.](#)
- [The system counter on page G6-6406.](#)

A2.9.3 Features added to earlier extensions

The features that have been added to earlier architectural extensions are:

- [FEAT_DGH](#) on page A2-70.
- [FEAT_ETS](#) on page A2-70.
- [FEAT_BF16](#) on page A2-85.
- [FEAT_AA32BF16](#) on page A2-85.
- [FEAT_I8MM](#) on page A2-85.
- [FEAT_AA32I8MM](#) on page A2-86.
- [FEAT_PAuth2](#) on page A2-89.
- [FEAT_FPAC](#) on page A2-89.

A2.10 The Armv8.7 architecture extension

The Armv8.7 architecture extension adds architectural features and additional requirements, see:

- [Architectural features added by Armv8.7 on page A2-103](#).
- [Additional requirements of Armv8.7 on page A2-106](#).

Features are also added to earlier architecture extensions, see [Features added to earlier extensions on page A2-106](#).

A2.10.1 Architectural features added by Armv8.7

An implementation of the Armv8.7 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.7 architecture.

The Armv8.7 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_AFP, Alternate floating-point behavior

FEAT_AFP allows alternate behavior for specified floating-point instructions including:

- Flushing of denormalized numbers to zero can be controlled separately on inputs and outputs.
- Alternate NaN propagation rules can apply.
- Output elements for specified scalar Advanced SIMD instructions can be determined using alternate rules.
- Changes to floating-point exception generation.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.7 implementations that implement floating-point support.

The `ID_AA64MMFR1_EL1.AFP` field identifies the presence of FEAT_AFP.

For more information, see:

- [Flushing denormalized numbers to zero on page A1-54](#).
- [NaN handling and the Default NaN on page A1-57](#).
- [Rounding on page A1-59](#).
- [Floating-point exceptions and exception traps on page D1-2495](#).

FEAT_RPRES, Increased precision of Reciprocal Estimate and Reciprocal Square Root Estimate

FEAT_RPRES allows an increase in the precision of the Reciprocal Estimate and Reciprocal Square Root Estimate from an 8-bit mantissa to a 12-bit mantissa.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.7 implementations. This feature requires implementation of [FEAT_AFP](#).

The `ID_AA64ISAR2_EL1.RPRES` field identifies the presence of FEAT_RPRES.

For more information, see `RecipEstimate()` and `RecipSqrtEstimate()`.

FEAT_LS64, FEAT_LS64_V, FEAT_LS64_ACCDATA, Support for 64 byte loads/stores

FEAT_LS64 introduces support for atomic single-copy 64-byte loads and stores without return and adds the following instructions:

- [LD64B on page C6-1040](#).
- [ST64B on page C6-1325](#).

FEAT_LS64_V introduces support for atomic single-copy 64-byte stores with return and adds [ST64BV on page C6-1326](#).

This feature also introduces the `ACCDATA_EL1` register.

FEAT_LS64 introduces support for atomic single-copy 64-byte EL0 stores with return and adds the following:

- [LD64B on page C6-1040](#).
- The `ACCDATA_EL1` register.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.7 implementations.

The [ID_AA64ISAR1_EL1.LS64](#) field identifies the presence of FEAT_LS64, FEAT_LS64_V, and FEAT_LS64_ACCDATA.

For more information, see [Single-copy atomic 64-byte load/store on page C3-238](#).

FEAT_WFxF and FEAT_WFxF2, WFE and WFI instructions with timeout

FEAT_WFxF introduces [WFET](#) and [WFIT](#). These instructions support the generation of a local timeout event to act as a wake-up event for the PE when the virtual count in [CNTVCT_ELO](#) equals or exceeds the value supplied by the instruction for the first time.

FEAT_WFxF2 adds a mechanism to report the register number that holds the timeout value in [ESR_ELx](#) for trapped [WFET](#) and [WFIT](#) instructions.

These instructions are added to the A64 instruction set only.

FEAT_WFxF is mandatory in Armv8.7 implementations. FEAT_WFxF2 is OPTIONAL in Armv8.7 implementations.

———— Note ————

Arm deprecates not implementing FEAT_WFxF2.

The [ID_AA64ISAR2_EL1.WFxF](#) field identifies the presence of FEAT_WFxF and FEAT_WFxF2.

For more information, see:

- [Instructions with register argument on page C3-218](#).
- [WFET on page C6-1513](#).
- [WFIT on page C6-1515](#).
- [Wait for Event mechanism and Send event on page D1-2536](#).
- [Wait For Interrupt on page D1-2540](#).

FEAT_HCX, Support for the HCRX_EL2 register

FEAT_HCX introduces the Extended Hypervisor Configuration Register, [HCRX_EL2](#), that provides configuration controls for virtualization in addition to those provided by [HCR_EL2](#), including defining whether various operations are trapped to EL2.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.7 implementations.

The [ID_AA64MMFR1_EL1.HCX](#) field identifies the presence of FEAT_HCX.

For more information, see [Configurable instruction enables and disables, and trap controls on page D1-2510](#).

FEAT_LPA2, Larger physical address for 4KB and 16KB translation granules

FEAT_LPA2:

- Allows a larger VA space for each translation table base register of up to 52 bits when using the 4KB or 16KB translation granules.
- Allows a larger intermediate physical address (IPA) and PA space of up to 52 bits when using the 4KB or 16KB translation granules.
- Allows a level 0 block size where the block covers a 512GB address range for the 4KB translation granule if the implementation supports 52 bits of PA.
- Allows a level 1 block size where the block covers a 64GB address range for the 16KB translation granule if the implementation supports 52 bits of PA.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.7 implementations. This feature requires implementation of [FEAT_LPA](#) and [FEAT_LVA](#).

The `ID_AA64MMFR0_EL1`.{`TGRAN4_2`, `TGRAN16_2`, `TGRAN4`, `TGRAN16`} fields identify the presence of `FEAT_LPA2`.

For more information, see:

- [VMSA address types and address spaces on page D5-2675](#).
- [Address size configuration on page D5-2689](#).
- [Extending addressing above 48 bits when using the 4KB or 16KB translation granule on page D5-2696](#).
- [VMSAv8-64 translation table level -1, level 0, level 1, and level 2 descriptor formats on page D5-2739](#).
- [Armv8 translation table level 3 descriptor formats on page D5-2744](#).

FEAT_XS, XS attribute

`FEAT_XS` introduces the XS attribute for memory to indicate that an access could take a long time to complete. This feature provides variants of DSB instructions and TLB maintenance instructions, the completion of which does not depend on the completion of memory accesses with the XS attribute.

`FEAT_XS` adds:

- A mechanism to define the XS attribute for memory.
- An optional nXS variant to the AArch64 DSB instruction and optional nXS qualifier to each AArch64 TLBI instruction to handle memory accesses with the XS attribute.
- The `FGTnXS` bit to `HCRX_EL2` to determine the behavior of fine-grained traps in `HFGITR_EL2` for TLB maintenance instructions with the nXS qualifier.
- The `FnXS` bit to `HCRX_EL2` to determine the behavior of pre-existing TLB maintenance instructions in relation to the XS attribute.

This feature is supported in AArch64 state only, but the XS attribute also impacts AArch32 state execution.

This feature is mandatory in Armv8.7 implementations.

The `ID_AA64ISARI_EL1.XS` field identifies the presence of `FEAT_XS`.

For more information, see:

- [Data Synchronization Barrier \(DSB\) on page B2-150](#).
- [Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors on page D5-2751](#).
- [The stage 1 memory region attributes on page D5-2776](#).
- [Ordering and completion of TLB maintenance instructions on page D5-2831](#).
- [Data Synchronization Barrier \(DSB\) on page E2-4301](#).
- [Overview of memory region attributes for stage 1 translations on page G5-6319](#).
- [Ordering and completion of TLB maintenance instructions on page G5-6339](#).

FEAT_PMUv3p7, Armv8.7 PMU extensions

`FEAT_PMUv3p7` adds the following features to the Performance Monitors Extension:

- PMU counters can be frozen when an event counter has an unsigned overflow.
- Event counters can be prohibited from counting events at EL3 without affecting the rest of Secure state.
- The cycle counter can be prohibited from counting cycles at EL3 without affecting the rest of Secure state.

This feature is supported in both AArch64 and AArch32 states.

The Performance Monitors Extension is an OPTIONAL feature, but if it is implemented, an Armv8.7 implementation must include `FEAT_PMUv3p7`.

The fields that identify the presence of `FEAT_PMUv3p7` are:

- `ID_AA64DFR0_EL1.PMUVer`.
- `ID_DFR0_EL1.PerfMon`.

- [ID_DFR0.PerfMon.](#)
- [EDDFR.PMUVer.](#)

For more information, see:

- [Controlling the PMU counters on page D7-2859.](#)
- [Freezing event counters on page D7-2860.](#)
- [Common microarchitectural events on page D7-2884.](#)
- [PMMIR_EL1, Performance Monitors Machine Identification Register on page D13-3974.](#)

FEAT_SPEv1p2, Armv8.7 SPE features

FEAT_SPEv1p2 adds the following features to the Statistical Profiling Extension, [FEAT_SPE](#):

- Adds an inverse event filter control.
- Adds controls to freeze the PMU event counters after an SPE buffer management event occurs.
- Adds a discard mode that allows all SPE data to be discarded rather than written to memory.

This feature is mandatory from Armv8.7 when [FEAT_SPE](#) is implemented.

This feature is supported in AArch64 state.

FEAT_SPEv1p2 optionally enables support for a packet for each taken branch that provides the target address for the previous taken branch.

[ID_AA64DFR0_EL1.PMSVer](#) identifies the presence of FEAT_SPEv1p2.

If FEAT_SPEv1p2 is implemented, [PMSIDR_EL1.PBT](#) indicates support for the previous branch target packet.

For more information, see:

- [Freezing event counters on page D7-2860.](#)
- [Common event numbers on page D7-2876.](#)
- [Filtering sample records on page D9-2956.](#)
- [Last branch target on page D9-2959.](#)
- [About the Statistical Profiling Extension Sample Records on page D10-2980.](#)
- [Address packet on page D10-2983.](#)

A2.10.2 Additional requirements of Armv8.7

The Armv8.7 architecture includes some mandatory changes that are not associated with a feature. These are:

FEAT_ETS, Enhanced Translation Synchronization

All implementations of the Armv8.7 architecture are required to implement FEAT_ETS.

For more information, see [FEAT_ETS on page A2-70.](#)

A2.10.3 Features added to earlier extensions

The features that have been added to earlier architectural extensions are:

- [FEAT_PAN3 on page A2-77.](#)
- [FEAT_MTE3 on page A2-99](#)

A2.11 The Performance Monitors Extension

The Performance Monitors Extension, FEAT_PMUv3, is an OPTIONAL extension but Arm strongly recommends that Armv8-A implementations include version 3 of the Performance Monitors Extension.

[ID_AA64DFR0_EL1.PMUVer](#) indicates whether the Performance Monitors Extension is implemented.

For more information, see [Chapter D7 The Performance Monitors Extension](#).

Armv8.1 introduces the following architectural feature to the Performance Monitors Extension:

- [FEAT_PMUv3p1](#).

Armv8.4 introduces the following architectural feature to the Performance Monitors Extension:

- [FEAT_PMUv3p4](#).

Armv8.5 introduces the following architectural feature to the Performance Monitors Extension:

- [FEAT_PMUv3p5](#).

Armv8.6 introduces the following architectural feature to the Performance Monitors Extension:

- [FEAT_MTPMU](#).

Armv8.7 introduces the following architectural feature to the Performance Monitors Extension:

- [FEAT_PMUv3p7](#).

A2.12 The Reliability, Availability, and Serviceability Extension

The RAS Extension, FEAT_RAS, is a mandatory extension to the Armv8.2 architecture, and an OPTIONAL extension to the Armv8.0 and the Armv8.1 architectures.

The RAS Extension improves the dependability of a system by providing:

- Reliability, that is, the continuity of correct service.
- Availability, that is, the readiness for correct service.
- Serviceability, that is, the ability to undergo modifications and repairs.

[ID_AA64PFR0_EL1.RAS](#) in AArch64 state, and [ID_PFR0.RAS](#) in AArch32 state, indicate whether the RAS Extension is implemented.

The RAS Extension introduces a barrier instruction, the Error Synchronization Barrier (ESB), to the A32, T32, and A64 instruction sets.

System registers introduced by the RAS Extension are described in:

- For AArch64, [RAS registers on page D13-4091](#).
- For AArch32, [RAS registers on page G8-7192](#).

In addition, the RAS Extension introduces a number of memory-mapped registers. These are described in the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the Armv8-A architecture profile*.

Armv8.2 introduces the following architectural features to the RAS Extension:

- [FEAT_IESB](#).

Armv8.4 introduces the following architectural features to the RAS Extension:

- [FEAT_RASv1p1](#).
- [FEAT_DoubleFault](#).

A2.13 The Statistical Profiling Extension (SPE)

The Statistical Profiling Extension, FEAT_SPE, is an OPTIONAL extension introduced by the Armv8.2 architecture. Implementation of the Statistical Profiling Extension requires implementation of at least Armv8.1 of the Armv8-A architecture profile. The Statistical Profiling Extension is supported only in AArch64 state.

The Statistical Profiling Extension provides a non-invasive method of sampling software and hardware using randomized sampling of either architectural instructions, as defined by the instruction set architecture, or by microarchitectural operations.

[ID_AA64DFR0_EL1.PMSVer](#) indicates whether the Statistical Profiling Extension is implemented.

For more information, see [Chapter D9 The Statistical Profiling Extension](#).

Armv8.3 introduces the following architectural feature to the SPE:

- [FEAT_SPEv1p1](#).

Armv8.7 introduces the following architectural feature to the SPE:

- [FEAT_SPEv1p2](#).

A2.14 The Scalable Vector Extension (SVE)

The Scalable Vector Extension, FEAT_SVE, is an OPTIONAL extension introduced by the Armv8.2 architecture. SVE is supported in AArch64 state only.

The Scalable Vector Extension provides vector instructions that, primarily, support wider vectors than the Arm Advanced SIMD instruction set. The *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A* describes the SVE.

[ID_AA64PFR0_EL1](#).SVE indicates whether the Scalable Vector Extension is implemented.

The Scalable Vector Extension affects some AArch64 System registers, and those register changes are included in this issue of this Manual, where they are identified as SVE features. SVE also introduces AArch64 System registers, but these do not appear in this manual. For more information about the System registers introduced by SVE, see the *Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A*.

The SVE and Advanced SIMD events are documented in [Chapter D7 The Performance Monitors Extension](#).

The Scalable Vector Extension introduces the following System registers:

- [ID_AA64ZFR0_EL1](#).
- [ZCR_EL1](#), and an EL2 alias of this register, [ZCR_EL12](#).
- [ZCR_EL2](#).
- [ZCR_EL3](#).

The Scalable Vector Extension modifies the following existing System registers:

- [CPACR_EL1](#).
- [CPTR_EL2](#).
- [CPTR_EL3](#).
- [ESR_ELx](#).
- [ID_AA64PFR0_EL1](#).
- [TCR_EL1](#).
- [TCR_EL2](#).

A2.15 The Activity Monitors Extension (AMU)

The Activity Monitors Extension is an OPTIONAL extension introduced by the Armv8.4 architecture. AMU is supported in AArch64 and AArch32 states.

The Activity Monitors Extension implements version 1 of the Activity Monitors architecture, FEAT_AMUv1, which provides a function similar to a subset of the existing Performance Monitors Extension functionality, intended for system management use rather than debugging and profiling.

The Activity Monitors Extension implements a System register interface to the Activity Monitors registers, and supports an optional external memory-mapped interface.

The fields that identify the presence of the Activity Monitors Extension are:

- [ID_AA64PFR0_EL1](#).AMU.
- [ID_PFR0_EL1](#).AMU.
- [ID_PFR0](#).AMU.
- [EDPFR](#).AMU.

For more information, see [Chapter D8 The Activity Monitors Extension](#).

A2.16 The Memory Partitioning and Monitoring (MPAM) Extension

The MPAM Extension, FEAT_MPAM, is an OPTIONAL extension introduced by the Armv8.4 architecture and requires implementation of at least Armv8.2 of the Armv8-A architecture profile. MPAM is supported in AArch64 state only.

The MPAM Extension provides a framework for memory-system component controls that partition one or more of the performance resources of the component.

The fields that identify the presence of the MPAM Extension are:

- [ID_AA64PFR0_EL1](#).MPAM.
- [EDPFR](#).MPAM.

For more information, see *ARM® Architecture Reference Manual Supplement, Memory System Resource Partitioning and Monitoring (MPAM), for ARMv8-A*.

Part B

The AArch64 Application Level Architecture

Chapter B1

The AArch64 Application Level Programmers' Model

- *About the Application level programmers' model on page B1-116.*
- *Registers in AArch64 Execution state on page B1-117.*
- *Software control features and EL0 on page B1-122.*

B1.1 About the Application level programmers' model

This chapter contains the programmers' model information required for application development.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of the system information is needed to put the Application level programmers' model into context.

Depending on the implementation choices, the architecture supports multiple levels of execution privilege, indicated by different *Exception levels* that number upwards from EL0 to EL3. EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers' model is the programmers' model for software executing at EL0. For more information see [Exception levels on page D1-2454](#).

System software determines the Exception level, and therefore the level of privilege, at which software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged at EL0. This:

- Permits the operating system to allocate system resources to an application in a unique or shared manner.
- Provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some system level understanding is necessary, and where relevant it gives a reference to the system level description.

Execution at any Exception level above EL0 is often referred to as privileged execution.

For more information on the system level view of the architecture refer to [Chapter D1 The AArch64 System Level Programmers' Model](#).

B1.2 Registers in AArch64 Execution state

This section describes the registers and process state visible at EL0 when executing in the AArch64 state. It includes the following:

- [Registers in AArch64 state on page B1-117](#)
- [Process state, PSTATE on page B1-118](#)
- [System registers on page B1-120](#)

B1.2.1 Registers in AArch64 state

In the AArch64 application level view, an Arm processing element has:

R0-R30 31 general-purpose registers, R0 to R30. Each register can be accessed as:

- A 64-bit general-purpose register named X0 to X30.
- A 32-bit general-purpose register named W0 to W30.

See the register name mapping in [Figure B1-1 on page B1-117](#).

Figure B1-1 General-purpose register naming

The X30 general-purpose register is used as the procedure call link register.

———— **Note** ————

In instruction encodings, the value `0b11111` (31) is used to indicate the ZR (zero register). This indicates that the argument takes the value zero, but does not indicate that the ZR is implemented as a physical register.

SP A 64-bit dedicated Stack Pointer register. The least significant 32 bits of the stack pointer can be accessed using the register name WSP.

The use of SP as an operand in an instruction, indicates the use of the current stack pointer.

———— **Note** ————

Stack pointer alignment to a 16-byte boundary is configurable at EL1. For more information see the *Procedure Call Standard for the Arm 64-bit Architecture*.

PC A 64-bit Program Counter holding the address of the current instruction.

Software cannot write directly to the PC. It can only be updated on a branch, exception entry or exception return.

———— **Note** ————

Attempting to execute an A64 instruction that is not word-aligned generates a PC alignment fault, see [PC alignment checking on page D1-2469](#).

V0-V31 32 SIMD&FP registers, V0 to V31. Each register can be accessed as:

- A 128-bit register named Q0 to Q31.
- A 64-bit register named D0 to D31.
- A 32-bit register named S0 to S31.
- A 16-bit register named H0 to H31.
- An 8-bit register named B0 to B31.
- A 128-bit vector of elements.

- A 64-bit vector of elements.

Where the number of bits described by a register name does not occupy an entire SIMD&FP register, it refers to the least significant bits. See [Figure B1-2 on page B1-118](#).

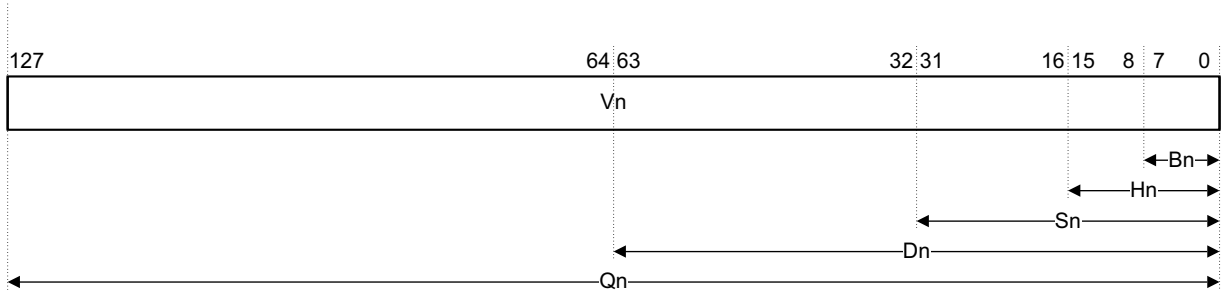

Figure B1-2 SIMD and floating-point register naming

For more information about data types and vector formats, see [Supported data types on page A1-40](#).

FPCR, FPSR Two SIMD and floating-point control and status registers, [FPCR](#) and [FPSR](#).

See [Registers for instruction processing and exception handling on page D1-2463](#) for more information on the registers.

Pseudocode description of registers in AArch64 state

In the pseudocode functions that access registers:

- The assignment form is used for register writes.
- The non-assignment for register reads.

The uses of the $X[]$ function are:

- Reading or writing $X0$ - $X30$, using n to index the required register.
- Reading the zero register ZR, accessed as $X[31]$.

———— **Note** —————

The pseudocode use of $X[31]$ to represent the zero register does not indicate that hardware must implement this register.

The AArch64 $SP[]$ function is used to read or write the current SP.

The AArch64 $PC[]$ function is used to read the PC.

The AArch64 $V[]$ function is used to read or write the Advanced SIMD and floating-point registers $V0$ - $V31$, using a parameter n to index the required register.

The AArch64 $Vpart[]$ function is used to read or write a part of one of $V0$ - $V31$, using a parameter n to index the required register, and a parameter $part$ to indicate the required part of the register, see the function description for more information.

The $SP[]$, $PC[]$, $V[]$, and $Vpart[]$ functions are defined in [Chapter J1 Armv8 Pseudocode](#).

B1.2.2 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

The following PSTATE information is accessible at EL0:

The Condition flags

Flag-setting instructions set these. They are:

- N** Negative Condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:
- 1 if the result is negative.
 - 0 if the result is positive or zero.
- Z** Zero Condition flag. Set to:
- 1 if the result of the instruction is zero.
 - 0 otherwise.
- A result of zero often indicates an equal result from a comparison.
- C** Carry Condition flag. Set to:
- 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
 - 0 otherwise.
- V** Overflow Condition flag. Set to:
- 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.
 - 0 otherwise.

Conditional instructions test the N, Z, C and V Condition flags, combining them with the Condition code for the instruction to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see [Condition flags and related instructions on page C6-873](#).

The exception masking bits

- D** Debug exception mask bit. When EL0 is enabled to modify the mask bits, this bit is visible and can be modified. However, this bit is architecturally ignored at EL0.
- A** SError interrupt mask bit.
- I** IRQ interrupt mask bit.
- F** FIQ interrupt mask bit.

For each bit, the values are:

- 0** Exception not masked.
- 1** Exception masked.

Access at EL0 using AArch64 state depends on `SCTLR_EL1.UMA`. See [Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks on page D1-2514](#).

See [Process state, PSTATE on page D1-2466](#) for the system level view of PSTATE.

Accessing PSTATE fields at EL0

At EL0 using AArch64 state, **PSTATE** fields can be accessed using Special-purpose registers that can be directly read using the **MRS** instruction and directly written using the **MSR (register)** instructions. [Table B1-1 on page B1-120](#) shows the Special-purpose registers that access the **PSTATE** fields that hold AArch64 state when the PE is at EL0 using AArch64. All other **PSTATE** fields do not have direct read and write access at EL0.

Table B1-1 Accessing PSTATE fields at EL0 using MRS and MSR (register)

Special-purpose register	PSTATE fields
NZCV	N, Z, C, V
DAIF	D, A, I, F

Software can also use the **MSR (immediate)** instruction to directly write to **PSTATE**.{D, A, I, F}. [Table B1-2 on page B1-120](#) shows the **MSR (immediate)** operands that can directly write to **PSTATE**.{D, A, I, F} when the PE is at EL0 using AArch64 state.

Table B1-2 Accessing PSTATE.{D, A, I, F} at EL0 using MSR (immediate)

Operand	PSTATE fields	Notes
DAIFSet	D, A, I, F	Directly sets any of the PSTATE .{D,A, I, F} bits to 1
DAIFClr	D, A, I, F	Directly clears any of the PSTATE .{D, A, I, F} bits to 0

However, access to the **PSTATE**.{D, A, I, F} fields at EL0 using AArch64 state depends on **SCTLR_EL1.UMA**. [Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks on page D1-2514](#).

Writes to the **PSTATE** fields have side-effects on various aspects of the PE operation. All of these side-effects, are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

B1.2.3 System registers

System registers provide support for execution control, status and general system configuration. The majority of the System registers are not accessible at EL0.

However, some System registers can be configured to allow access from software executing at EL0. Any access from EL0 to a System register with the access right disabled causes the instruction to behave as UNDEFINED. The registers that can be accessed from EL0 are:

Cache ID registers The **CTR_EL0** and **DCZID_EL0** registers provide implementation parameters for EL0 cache management support.

Debug registers A Debug Communications Channel is supported by the **MDCCSR_EL0**, **DBGDTR_EL0**, **DBGDTRRX_EL0** and **DBGDTRTX_EL0** registers.

Performance Monitors registers

The Performance Monitors Extension provides counters and configuration registers. Software executing at EL1 or a higher Exception level can configure some of these registers to be accessible at EL0.

For more details, see [Chapter D7 The Performance Monitors Extension](#).

Activity Monitors registers

The Activity Monitors Extension provides counters and configuration registers. Software executing at EL1 or a higher Exception level can configure these registers to be accessible at EL0.

For more details, see [Chapter D8 The Activity Monitors Extension](#).

Thread ID registers The [TPIDR_EL0](#) and [TPIDRRO_EL0](#) registers are two thread ID registers with different access rights.

Timer registers In Armv8 the following operations are performed:

- Read access to the system counter clock frequency using [CNTFRQ_EL0](#).
- Physical and virtual timer count registers, [CNTPCT_EL0](#) and [CNTVCT_EL0](#).
- Physical up-count comparison, down-count value and timer control registers, [CNTP_CVAL_EL0](#), [CNTP_TVAL_EL0](#), and [CNTP_CTL_EL0](#).
- Virtual up-count comparison, down-count value and timer control registers, [CNTV_CVAL_EL0](#), [CNTV_TVAL_EL0](#), and [CNTV_CTL_EL0](#).

B1.3 Software control features and EL0

The following sections describe the EL0 view of the Armv8 software control features:

- [Exception handling on page B1-122](#)
- [Wait for Interrupt and Wait for Event on page B1-122](#)
- [The YIELD instruction on page B1-122](#)
- [Application level cache management on page B1-123](#)
- [Instructions relating to Debug on page B1-123](#)
- [About PSTATE.DIT on page B1-123](#)

B1.3.1 Exception handling

In the Arm architecture, an *exception* causes a change of program flow. Execution of an exception handler starts, at an Exception level higher than EL0, from a defined vector that relates to the exception taken.

Exceptions include:

- Interrupts.
- Memory system aborts.
- Exceptions generated by attempting to execute an instruction that is UNDEFINED.
- System calls.
- Secure monitor or Hypervisor traps.
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in [Chapter D1 The AArch64 System Level Programmers' Model](#).

The SVC instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a system call to an operating system.

The BRK instruction generates a Breakpoint Instruction exception. This provides a mechanism for debugging software using debugger executing on the same PE, see [Breakpoint Instruction exceptions on page D2-2577](#).

———— **Note** —————

The BRK instruction is supported only in the A64 instruction set. The equivalent instruction in the T32 and A32 instruction sets is BKPT.

—————

B1.3.2 Wait for Interrupt and Wait for Event

Issuing a WFI instruction indicates that no further execution is required until a WFI wake-up event occurs, see [Wait For Interrupt on page D1-2540](#). This permits entry to a low-power state.

Issuing a WFE instruction indicates that no further execution is required until a WFE wake-up event occurs, see [Wait for Event mechanism and Send event on page D1-2536](#). This permits entry to a low-power state.

B1.3.3 The YIELD instruction

The YIELD instruction provides a hint that the task performed by a thread is of low importance so that it could yield, see [YIELD on page C6-1519](#). This mechanism can be used to improve overall performance in a *Symmetric Multithreading* (SMT) or *Symmetric Multiprocessing* (SMP) system.

Examples of when the YIELD instruction might be used include a thread that is sitting in a spin-lock, or where the arbitration priority of the snoop bit in an SMP system is modified. The YIELD instruction permits binary compatibility between SMT and SMP systems.

The YIELD instruction is a NOP hint instruction.

The YIELD instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use for future migration to a multiprocessor or multithreading system. Operating systems can use YIELD in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.

B1.3.4 Application level cache management

A small number of cache management instructions can be enabled at ELO from higher levels of privilege using the [SCTLR_EL1](#) System register. Any access from ELO to an operation with the access right disabled causes the instruction to behave as UNDEFINED.

About the available operations, see [Application level access to functionality related to caches on page B2-156](#).

B1.3.5 Instructions relating to Debug

[Exception handling on page B1-122](#) refers to the BRK instruction, which generates a Breakpoint Instruction exception. In addition, in both AArch64 state and AArch32 state, the HLT instruction causes the PE to halt execution and enter Debug state. This provides a mechanism for debugging software using a debugger that is external to the PE, see [Chapter H1 About External Debug](#).

———— **Note** ————

In AArch32 state, previous versions of the architecture defined the DBG instruction, that could provide a hint to the debug system. In Armv8, this instruction executes as a NOP. Arm deprecates the use of the DBG instruction.

B1.3.6 About PSTATE.DIT

When the value of [PSTATE.DIT](#) is 1:

- The instructions listed in [DIT](#) are required to have;
 - Timing which is independent of the values of the data supplied in any of its registers, and the values of the NZCV flags.
 - Responses to asynchronous exceptions which do not vary based on the values supplied in any of their registers, or the values of the NZCV flags.
- All loads and stores must have their timing insensitive to the value of the data being loaded or stored.

———— **Note** ————

- The use of value prediction for load data values when [PSTATE.DIT](#) is set, is not compatible with the requirement that the timing is insensitive to the data value being loaded.
- Arm recommends that the [FEAT_PAAuth](#) instructions do not have their timing dependent on the key value used in the pointer authentication, regardless of the [PSTATE.DIT](#) bit.
- When the value of [PSTATE.DIT](#) is 0, the architecture makes no statement about the timing properties of any instructions. However, it is likely that these instructions have timing that is invariant of the data in many situations.

A corresponding DIT bit is added to [PSTATE](#) in AArch64 state, and to [CPSR](#) in AArch32 state.

On an exception that is taken from AArch64 state to AArch64 state, [PSTATE.DIT](#) is copied to [SPSR_ELx.DIT](#).

On an exception that is taken from AArch32 state to AArch64 state, [CPSR.DIT](#) is copied to [SPSR_ELx.DIT](#).

On an exception return from AArch64 state:

- [SPSR_ELx.DIT](#) is copied to [PSTATE.DIT](#), when the target Exception level is in AArch64 state.
- [SPSR_ELx.DIT](#) is copied to [CPSR.DIT](#), when the target Exception level is in AArch32 state.

PSTATE.DIT can be written and read at all Exception levels.

———— **Note** ————

- PSTATE.DIT is unchanged on entry into Debug state.
 - PSTATE.DIT is not guaranteed to have any effect in Debug state.
-

Chapter B2

The AArch64 Application Level Memory Model

This chapter gives an application level view of the memory model. It contains the following sections:

- *About the Arm memory model* on page B2-126.
- *Atomicity in the Arm architecture* on page B2-128.
- *Definition of the Armv8 memory model* on page B2-133.
- *Caches and memory hierarchy* on page B2-155.
- *Alignment support* on page B2-160.
- *Endian support* on page B2-162.
- *Memory types and attributes* on page B2-165.
- *Mismatched memory attributes* on page B2-176.
- *Synchronization and semaphores* on page B2-179.

———— **Note** —————

In this chapter, System register names usually link to the description of the register in [Chapter D13 AArch64 System Register Descriptions](#), for example. [SCTLR_EL1](#).

B2.1 About the Arm memory model

The Arm architecture is a weakly ordered memory architecture that permits the observation and completion of memory accesses in a different order from the program order. The following sections of this chapter provide the complete definition of the Armv8 memory model, this introduction is not intended to contradict the definition found in those sections. In general, the basic principles of the Armv8 memory model are:

- To provide a memory model that has similar weaknesses to those found in the memory models used by high-level programming languages such as C or Java. For example, by permitting independent memory accesses to be reordered as seen by other observers.
- To avoid the requirement for multi-copy atomicity in the majority of memory types.
- The provision of instructions and memory barriers to compensate for the lack of multi-copy atomicity in the cases where it would be needed.
- The use of address, data, and control dependencies in the creation of order so as to avoid having excessive numbers of barriers or other explicit instructions in common situations where some order is required by the programmer or the compiler.
- If `FEAT_MTE2` is implemented, the definitions of the memory model which apply to data accesses and data apply to Allocation Tag accesses and Allocation tags.

This section contains:

- [Address space on page B2-126](#).
- [Memory type overview on page B2-126](#).

B2.1.1 Address space

Address calculations are performed using 64-bit registers. However, supervisory software can configure the top eight address bits for use as a tag, as described in [Address tagging in AArch64 state on page D5-2676](#). If this is done, address bits[63:56]:

- Are not considered when determining whether the address is valid.
- Are never propagated to the program counter.

Supervisory software determines the valid address range. Attempting to access an address that is not valid generates an MMU fault.

[Simple sequential execution](#) of instructions might overflow the valid address range. For more information, see [Virtual address space overflow on page D4-2635](#).

Memory accesses use the `Mem[]` function. This function makes an access of the required type. If supervisory software configures the top eight address bits for use as a tag, the top eight address bits are ignored.

The `AccType{}` enumeration defines the different access types.

————— Note —————

- [Chapter D4 The AArch64 System Level Memory Model](#) and [Chapter D5 The AArch64 Virtual Memory System Architecture](#) include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also include pseudocode descriptions of these operations.
- For information on the pseudocode that relates to memory accesses, see [Basic memory access on page D4-2669](#), [Unaligned memory access on page D4-2669](#), and [Aligned memory access on page D4-2669](#).

B2.1.2 Memory type overview

Armv8 provides the following mutually-exclusive memory types:

Normal This is generally used for bulk memory operations, both read/write and read-only operations.

Device The Arm architecture forbids *Speculative* reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive **Locations**.

Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See *Gathering* on page B2-171.
- They preserve the access order and synchronization requirements for accesses to a single peripheral. See *Reordering* on page B2-172.
- They indicate whether a write can be acknowledged other than at the end point. See *Early Write Acknowledgement* on page B2-173.

For more information on Normal memory and Device memory, see *Memory types and attributes* on page B2-165.

———— **Note** —————

Earlier versions of the Arm architecture defined a single Device memory type and a Strongly-ordered memory type. A *Note* in *Device memory* on page B2-169 describes how these memory types map onto the Armv8 memory types.

B2.2 Atomicity in the Arm architecture

Atomicity is a feature of memory accesses, described as *atomic* accesses. The Arm architecture description refers to two types of atomicity, *single-copy atomicity* and *multi-copy atomicity*. In the Armv8 architecture, the atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information, see:

- [Requirements for single-copy atomicity on page B2-128.](#)
- [Properties of single-copy atomic accesses on page B2-130.](#)
- [Multi-copy atomicity on page B2-130.](#)
- [Requirements for multi-copy atomicity on page B2-130.](#)
- [Concurrent modification and execution of instructions on page B2-130.](#)

For more information about the memory types, see [Memory type overview on page B2-126.](#)

B2.2.1 Requirements for single-copy atomicity

For explicit memory effects generated from an Exception level the following rules apply:

- A read that is generated by a load instruction that loads a single general-purpose register and is aligned to the size of the read in the instruction is single-copy atomic.
- A write that is generated by a store instruction that stores a single general-purpose register and is aligned to the size of the write in the instruction is single-copy atomic.
- Reads that are generated by a Load Pair instruction that loads two general-purpose registers and are aligned to the size of the load to each register are treated as two single-copy atomic reads, one for each register being loaded.
- Writes that are generated by a Store pair instruction that stores two general-purpose registers and are aligned to the size of the store of each register are treated as two single-copy atomic writes, one for each register being stored.
- Load-Exclusive Pair instructions of two 32-bit quantities and Store-Exclusive Pair instructions of 32-bit quantities are single-copy atomic.
- When the Store-Exclusive of a Load-Exclusive/Store-Exclusive pair instruction using two 64-bit quantities succeeds, it causes a single-copy atomic update of the entire memory location being updated.

———— **Note** —————

To atomically load two 64-bit quantities, perform a Load-Exclusive pair/Store-Exclusive pair sequence of reading and writing the same value for which the Store-Exclusive pair succeeds, and use the read values from the Load-Exclusive pair.

- Where translation table walks generate a read of a translation table entry, this read is single-copy atomic.
- For the atomicity of instruction fetches, see [Concurrent modification and execution of instructions on page B2-130.](#)
- Reads to SIMD and floating-point registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being loaded are treated as single-copy atomic reads.
- Writes from SIMD and floating-point registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being stored are treated as single-copy atomic writes.
- Element or Structure Reads to SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the element being loaded, have each element treated as a single-copy atomic read.
- Element or Structure Writes from SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the element being stored, have each element treated as a single-copy atomic store.

- Reads to SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit reads.
- Writes from SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit writes.
- When [FEAT_LS64](#) is implemented, a single-copy atomic load of a 64-byte value that is 64-byte aligned in memory is treated as an atomic 64-byte read from the target address.
- When [FEAT_LS64](#) is implemented, a single-copy atomic store of a 64-byte value that is 64-byte aligned in memory is treated as an atomic 64-byte write to the target address.
- For unaligned memory accesses, the single-copy atomicity is described in [Alignment of data accesses on page B2-160](#).
- The reads and writes of the two words or two double-words accessed by CASP instructions are single-copy atomic at the size of the two words or double-words.

All other memory accesses are regarded as streams of accesses to bytes, and no atomicity between accesses to different bytes is ensured by the architecture.

All accesses to any byte are single-copy atomic.

———— **Note** —————

In AArch64 state, no memory accesses from a DC ZVA have single-copy atomicity of any quantity greater than individual bytes.

If, according to these rules, an instruction is executed as a sequence of accesses, exceptions, including interrupts, can be taken during that sequence, regardless of the memory type being accessed. If any of these exceptions are returned from using their preferred return address, the instruction that generated the sequence of accesses is re-executed, and so any access performed before the exception was taken is repeated. See also [Taking an interrupt or other exception during a multi-access load or store on page D1-2509](#).

———— **Note** —————

The exception behavior for these multiple access instructions means that they are not suitable for use for writes to memory for the purpose of software synchronization.

Changes to single-copy atomicity in Armv8.4

Instructions that are introduced in [FEAT_LRCPC](#) are single-copy atomic when the following conditions are true:

- All bytes being accessed are within the same 16-byte quantity aligned to 16 bytes.
- Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

Otherwise it is IMPLEMENTATION DEFINED whether they are single-copy atomic.

If [FEAT_LSE2](#) is implemented, all loads and stores are single-copy atomic when the following conditions are true:

- Accesses are unaligned to their data size but are aligned within a 16-byte quantity that is aligned to 16 bytes.
- Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

Otherwise it is IMPLEMENTATION DEFINED whether loads and stores are single-copy atomic.

If [FEAT_LSE2](#) is implemented, LDP, LDNP, and STP instructions that load or store two 64-bit registers are single-copy atomic when the following conditions are true:

- The overall memory access is aligned to 16 bytes.
- Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

If [FEAT_LSE2](#) is implemented, LDP, LDNP, and STP instructions that access fewer than 16 bytes are single-copy atomic when the following conditions are true:

- All bytes being accessed are within a 16-byte quantity aligned to 16 bytes.
- Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

Otherwise it is IMPLEMENTATION DEFINED whether LDP, LDNP, or STP instructions that access fewer than 16 bytes are single-copy atomic.

B2.2.2 Properties of single-copy atomic accesses

A memory access instruction that is single-copy atomic has the following properties:

1. For a pair of overlapping single-copy atomic store instructions, all of the overlapping writes generated by one of the stores are **Coherence-after** the corresponding overlapping writes generated by the other store.
2. For a single-copy atomic load instruction L_1 that overlaps a single-copy atomic store instruction S_2 , if one of the overlapping reads generated by L_1 **Reads-from** one of the overlapping writes generated by S_2 , then none of the overlapping writes generated by S_2 are **Coherence-after** the corresponding overlapping reads generated by L_1 .

For more information, see [Definition of the Armv8 memory model on page B2-133](#).

B2.2.3 Multi-copy atomicity

In a multiprocessing system, writes to a memory location are *multi-copy atomic* if the following conditions are both true:

- All writes to the same location are *serialized*, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

———— **Note** —————

Writes that are not coherent are not multi-copy atomic.

B2.2.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory, writes are not required to be multi-copy atomic.

The Armv8 memory model is **Other-multi-copy atomic**. For more information, see [External ordering constraints on page B2-139](#).

B2.2.5 Concurrent modification and execution of instructions

The Armv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where each of the instruction before modification and the instruction after modification is one of a B, B.cond, BL, BRK, CBNZ, CBZ, HVC, ISB, NOP, SMC, SVC, TBNZ or TBZ instruction.

For the B, B.cond, BL, BRK, CBNZ, CBZ, HVC, ISB, NOP, SMC, SVC, TBNZ and TBZ instructions, the architecture guarantees that after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

For all other instructions, to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.
2. To ensure that the modified instructions are observable, a PE that is writing the instructions must issue the following sequence of instructions and operations:

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.  
; enter this code with <Wt> containing a new 32-bit instruction,  
; to be held in Cacheable space at a location pointed to by Xn.  
STR Wt, [Xn]  
DC CVAU, Xn          ; Clean data cache by VA to point of unification (PoU)  
DSB ISH              ; Ensure visibility of the data cleaned from cache  
IC IVAU, Xn          ; Invalidate instruction cache by VA to PoU  
DSB ISH
```

Note

- The DC CVAU operation is not required if the area of memory is either Non-cacheable or Write-Through Cacheable.
- If the contents of physical memory differ between the mappings, changing the mapping of VAs to PAs can cause the instructions to be concurrently modified by one PE and executed by another PE. If the modifications affect instructions other than those listed as being acceptable for modification, synchronization must be used to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.

3. In a multiprocessor system, the IC IVAU is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, when the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

```
ISB                      ; Synchronize fetched instruction stream
```

For more information about the required synchronization operation, see [Synchronization and coherency issues between data and instruction accesses on page B2-158](#).

For information about memory accesses caused by instruction fetches, see [Ordering relations on page B2-137](#).

B2.2.6 Possible implementation restrictions on using atomic instructions

In some implementations, and for some memory types, the properties of atomicity can be met only by functionality outside the PE. Some system implementations might not support atomic instructions for all regions of the memory. In particular, this can apply to:

- Any type of memory in the system that does not support hardware cache coherency.
- Device, Non-cacheable memory, or memory that is treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such implementations, it is defined by the system:

- Whether the atomic instructions are atomic in regard to other agents that access memory.
- If the atomic instructions are atomic in regard to other agents that access memory, which address ranges or memory types this applies to.

An implementation can choose which memory type is treated as Non-cacheable.

The memory types for which it is architecturally guaranteed that the atomic instructions will be atomic are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

The architecture only requires that [Conventional memory](#) that is mapped in this way supports this functionality.

If the atomic instructions are not atomic in regard to other agents that access memory, then performing an atomic instruction to such a location can have one or more of the following effects:

- The instruction generates a synchronous External abort.
- The instruction generates a System Error interrupt.

- The instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data Abort Fault status code of ESR_ELx.DFSC = 110101.
For the EL1&0 translation regime, if the atomic instruction is not supported because of the memory type that is defined in the first stage of translation, or the second stage of translation is not enabled, then this exception is a first stage abort and is taken to EL1. Otherwise, the exception is a second stage abort and is taken to EL2.
- The instruction is treated as a NOP.
- The instructions are performed, but there is no guarantee that the memory accesses were performed atomically in regard to other agents that access memory. In this case, the instruction might also generate a System Error interrupt.

B2.3 Definition of the Armv8 memory model

This section describes observation and ordering in the Armv8 memory model. It contains the following subsections:

- [Basic definitions](#) on page B2-133.
- [Dependency definitions](#) on page B2-136.
- [Ordering relations](#) on page B2-137.
- [Ordering constraints](#) on page B2-138.
- [Internal visibility requirement](#) on page B2-139.
- [External ordering constraints](#) on page B2-139.
- [Completion and endpoint ordering](#) on page B2-141.
- [Ordering of instruction fetches](#) on page B2-143.
- [Restrictions on the effects of speculation](#) on page B2-144.
- [Memory barriers](#) on page B2-146.
- [Limited ordering regions](#) on page B2-154.

For more information about endpoint ordering of memory accesses, see [Reordering](#) on page B2-172.

In the Armv8 memory model, the Shareability memory attribute indicates the degree to which hardware must ensure memory coherency between a set of observers, see [Memory types and attributes](#) on page B2-165.

The Armv8 architecture defines additional memory attributes and associated behaviors, which are defined in the system level section of this manual. See:

- [Chapter D4 The AArch64 System Level Memory Model](#).
- [Chapter D5 The AArch64 Virtual Memory System Architecture](#).

See also [Mismatched memory attributes](#) on page B2-176.

B2.3.1 Basic definitions

The Armv8 memory model provides a set of definitions that are used to construct conditions on the permitted sequences of accesses to memory.

Observer

An *Observer* refers to a processing element or mechanism in the system, such as a peripheral device, that can generate reads from, or writes to, memory.

Common Shareability Domain

For the purpose of this section, all *Observers* are assumed to belong to a *Common Shareability Domain*. All read and write effects access only Normal memory locations in a Common Shareability Domain, and excludes the situations described in [Mismatched memory attributes](#) on page B2-176.

Location

A *Location* is a byte that is associated with an address in the physical address space.

———— Note —————

It is expected that an operating system will present the illusion to the application programmer that is consistent with a location also being considered as a byte that is associated with an address in the virtual address space.

Effects

The *Effects* of an instruction can be:

- Register effects.
- Memory effects.
- Barrier effects.
- Tag effects.
- Branching effects.

The effects of an instruction I_1 are said to appear in program order before the effects of an instruction I_2 if and only if I_1 occurs before I_2 in the order specified by the program. Each effect generated by an instruction has a unique identifier, which characterizes it amongst the events generated by the same instruction.

Register effect

The *Register effects* of an instruction are register reads or register writes of that instruction. For an instruction that accesses registers, a register read effect is generated for each register read by the instruction and a register write effect is generated for each register written by the instruction. An instruction may generate both read and write Register effects.

Memory effect

The *Memory effects* of an instruction are the memory reads or writes generated by that instruction. For an instruction that accesses memory, a memory read effect is generated for each [Location](#) read by the instruction and a memory write effect is generated for each [Location](#) written by the instruction. An instruction may generate both read and write Memory effects.

Tag effect

The *Tag effects* of a Memory Tagging instruction are the memory read or write effects of that instruction that affect tag locations.

Tag-read

A *Tag-read* is a read of a tag location generated by an LDG instruction.

Tag-write

A *Tag-write* is a write of a tag location generated by an STG instruction.

Tag-Check-read

A *Tag-Check-read* is a read of a tag location that is generated by a checked memory access. All other reads and writes are considered Data accesses.

Branching effect

The *Branching effects* of an instruction are effects which correspond to a branching decision being taken.

————— Note —————

Conditional and compare-and-swap instructions do not create Branching effects.

Intrinsic order

There is a per-instruction *Intrinsic order* relation that provides a partial order over the effects of that instruction, according to the operation of that instruction.

The operation of an instruction is defined by the pseudocode in [Chapter C6 A64 Base Instruction Descriptions](#).

Reads-from-register

The *Reads-from-register* relation couples register read and write effects to the same register such that each register read effect is paired with exactly one register write effect in the execution of a program. A register read effect R_2 Reads-from-register a register write effect W_1 to the same register if and only if R_2 takes its data from W_1 . By construction W_1 must be in program order before R_2 and there must be no intervening write to the same register in program order between W_1 and R_2 .

Reads-from

The *Reads-from* relation couples memory read and write effects to the same [Location](#) such that each memory read effect is paired with exactly one memory write effect in the execution of a program. A memory read effect R_2 from a [Location](#) Reads-from a memory write effect W_1 to the same [Location](#) if and only if R_2 takes its data from W_1 .

Coherence order

There is a per-location *Coherence order* relation that provides a total order over all memory write effects from all coherent **Observers** to that **Location**, starting with a notional memory write effect of the initial value. The Coherence order of a **Location** represents the order in which memory write effects to the **Location** arrive at memory.

Local read successor

A memory read effect R_2 of a **Location** is the *Local read successor* of a memory write effect W_1 from the same **Observer** to the same **Location** if and only if W_1 appears in program order before R_2 and there is not a memory write effect W_3 from the same **Observer** to the same **Location** appearing in program order between W_1 and R_2 .

Local write successor

A memory write effect W_2 of a **Location** is a *Local write successor* of a memory read or write effect RW_1 from the same **Observer** to the same **Location** if and only if RW_1 appears in program order before W_2 .

Coherence-after

A memory write effect W_2 to a **Location** is *Coherence-after* another memory write effect W_1 to the same **Location** if and only if W_2 is sequenced after W_1 in the *Coherence order* of the **Location**.

A memory write effect W_2 to a **Location** is *Coherence-after* a memory read effect R_1 of the same location if and only if R_1 *Reads-from* a memory write effect W_3 to the same **Location** and W_2 is *Coherence-after* W_3 .

Observed-by

A memory read or write effect RW_1 from an **Observer** is *Observed-by* a memory write effect W_2 from a different **Observer** if and only if W_2 is *coherence-after* RW_1 .

A memory write effect W_1 from an **Observer** is *Observed-by* a memory read effect R_2 from a different **Observer** if and only if R_2 *Reads-from* W_1 .

———— Note —————

The *Observed-by* relation only relates **Memory effects** generated by different **Observers**.

Overlapping accesses

Two **Memory effects** overlap if and only if they access the same **Location**. Two instructions overlap if and only if one or more of their generated **Memory effects** overlap.

Single-copy-atomic-ordered-before

A memory read effect R_1 is *Single-copy-atomic-ordered-before* another memory read effect R_2 if and only if all of the following statements are true:

- R_1 and R_2 are memory read effects generated by the same instruction.
- R_1 is not a **Local read successor** of a memory write effect.
- R_2 is a **Local read successor** of a memory write effect.

DMB FULL

A **DMB FULL** is a **DMB** with neither the **LD** or the **ST** qualifier.

Where this section refers to **DMB** without any qualification, then it is referring to all types of **DMB**. Unless a specific shareability domain is defined, a **DMB** applies to the **Common Shareability Domain**.

All properties that apply to **DMB** also apply to the corresponding **DSB**.

Context synchronization instruction

A *Context synchronization instruction* is one of the following:

- An **ISB** instruction.
- An instruction that generates a synchronous exception.

- An exception return instruction.
- A DCPS or DRPS instruction.

B2.3.2 Dependency definitions

Dependency through registers

A *Dependency through registers* from a first effect E_1 to a second effect E_2 exists within a PE if and only if at least one of the following applies:

- E_1 is a register write effect W_1 which has not been generated by a Store Exclusive, E_2 is a register read effect R_2 and R_2 [Reads-from-register](#) W_1 .
- E_1 and E_2 have been generated by the same instruction and E_1 is before E_2 in the [Intrinsic order](#) of that instruction.
- There is a [Dependency through registers](#) from E_1 to a third effect E_3 , and there is a [Dependency through registers](#) from E_3 to E_2 .

Address dependency

An *Address dependency* from a memory read effect R_1 to a [Memory effect](#) RW_2 exists if and only if there is a [Dependency through registers](#) from R_1 to a [Register effect](#) E_3 generated by RW_2 , and E_3 affects the address part of RW_2 , and either:

- RW_2 is a memory write effect W_2 .
- RW_2 is a memory read effect R_2 and there is no [Branching effect](#) D_4 such that there is a [Dependency through registers](#) from R_1 to D_4 and from D_4 to R_2 .

———— **Note** —————

An Address dependency exists from a memory read effect R_1 to a [Tag-Check-read](#) R_2 if and only if there is a [Dependency through registers](#) from R_1 to the address part of R_2 .

Data dependency

A *Data dependency* from a memory read effect R_1 to a memory write effect W_2 exists if and only if there is a [Dependency through registers](#) from R_1 to a [Register effect](#) E_3 generated by W_2 , and E_3 affects the data part of W_2 .

Control dependency

A *Control dependency* from a memory read effect R_1 to a [Memory effect](#) RW_2 exists if and only if either:

- There is a [Dependency through registers](#) from R_1 to a [Branching effect](#) B_3 and B_3 is in program order before RW_2 .
- There is a [Dependency through registers](#) from R_1 to the determination of a synchronous exception on an instruction generating an effect RW_3 , and RW_2 appears in program order after RW_3 .

———— **Note** —————

This notion is under review. Arm's intent is that a branch instruction between a read and a write, where the branch condition is dependent on the read, will provide order, regardless of whether the branch is taken. This only applies to branch instructions and not to conditional selection or other conditional data processing instructions. A formal definition of this change will be issued soon as an erratum to the Armv8 Architecture Reference Manual.

B2.3.3 Ordering relations

Dependency-ordered-before

A dependency creates externally-visible order between a memory read effect and another [Memory effect](#) generated by the same [Observer](#). A memory read effect R_1 is *Dependency-ordered-before* a memory read or write effect RW_2 from the same [Observer](#) if and only if R_1 appears in program order before RW_2 and any of the following cases apply:

- There is an [Address dependency](#) or a [Data dependency](#) from R_1 to RW_2 .
- RW_2 is a memory write effect W_2 and there is a [Control dependency](#) from R_1 to W_2 .
- RW_2 is a memory read effect R_2 generated by an instruction appearing in program order after an instruction that generates a [Context synchronization event](#) E_3 , and there is a [Dependency through registers](#) from R_1 to E_3 .
- RW_2 is a memory write effect W_2 appearing in program order after a memory read or write effect RW_3 and there is an [Address dependency](#) from R_1 to RW_3 .
- RW_2 is a [Local read successor](#) R_2 of a memory write effect W_3 and there is an [Address dependency](#) or a [Data dependency](#) from R_1 to W_3 .

Atomic-ordered-before

Load-Exclusive and Store-Exclusive instructions provide some ordering guarantees, even in the absence of dependencies. A memory read or write effect RW_1 is *Atomic-ordered-before* a memory read or write effect RW_2 from the same [Observer](#) if and only if RW_1 appears in program order before RW_2 and either of the following cases apply:

- RW_1 is a memory read effect R_1 and RW_2 is a memory write effect W_2 such that R_1 and W_2 are generated by an atomic instruction or a successful Load-Exclusive/Store-Exclusive instruction pair to the same [Location](#).
- RW_1 is a memory write effect W_1 generated by an atomic instruction or a successful Store-Exclusive instruction and RW_2 is a memory read effect R_2 generated by an instruction with Acquire or AcquirePC semantics such that R_2 is a [Local read successor](#) of W_1 .

For more information, see [Synchronization and semaphores](#) on page B2-179.

Barrier-ordered-before

Barrier instructions order prior [Memory effects](#) before subsequent [Memory effects](#) generated by the same [Observer](#). A memory read or write effect RW_1 is *Barrier-ordered-before* a memory read or write effect RW_2 from the same [Observer](#) if and only if RW_1 appears in program order before RW_2 and any of the following cases apply:

- RW_1 appears in program order before a DMB FULL that appears in program order before RW_2 .
- RW_1 is a memory write effect W_1 and is generated by an atomic instruction with both Acquire and Release semantics.
- RW_1 is a memory write effect W_1 generated by an instruction with Release semantics and RW_2 is a memory read effect R_2 , except a [Tag-Check-read](#), generated by an instruction with Acquire semantics.
- RW_1 is a memory read effect R_1 and appears in program order before a DMB LD that appears in program order before RW_2 .
- RW_1 is a memory read effect R_1 , except a [Tag-Check-read](#), and is generated by an instruction with Acquire or AcquirePC semantics.
- RW_1 is a memory write effect W_1 and RW_2 is a memory write effect W_2 appearing in program order before a DMB ST that appears in program order before W_2 .
- RW_2 is a memory write effect W_2 and is generated by an instruction with Release semantics.

Tag-ordered-before

If FEAT_MTE2 is implemented, a Tag read R_1 is *Tag-ordered-before* a memory read or write effect Checked data access RW_2 generated by the same instruction if and only if all of the following apply:

- R_1 is in the **Intrinsic order** of that instruction before RW_2 .
- R_1 reads the Allocation Tag at a tag physical address and compares it with the physical address Tag of the instruction. If the result of the comparison can cause a precise exception and the result is negative, then RW_2 does not architecturally occur.

Tag-Location-Ordered

Tag-Check-reads R_1 and R_2 are *Tag-Location-Ordered* if and only if all the following apply:

- R_1 is **Tag-ordered-before** a Checked data access RW_3 .
- R_2 is **Tag-ordered-before** a Checked data access RW_4 .
- RW_3 and RW_4 are to the same **Location**.

Locally-ordered-before

Dependencies, **Local write successor**, load/store-exclusive, atomic and barrier instructions can be composed within an **Observer** to create externally-visible order. A memory read or write effect RW_1 is *Locally-ordered-before* a memory read or write effect RW_2 from the same **Observer** if and only if any of the following cases apply:

- RW_1 is a memory write effect W_1 and RW_2 is a memory write effect W_2 that is equal to or generated by the same instruction as a **Local write successor** of RW_1 .
- RW_1 is **Dependency-ordered-before** RW_2 .
- RW_1 is **Atomic-ordered-before** RW_2 .
- RW_1 is **Barrier-ordered-before** RW_2 .
- RW_1 is **Tag-ordered-before** RW_2 .
- RW_1 is **Locally-ordered-before** a memory read or write effect that is **Locally-ordered-before** RW_2 .

B2.3.4 Ordering constraints

The Armv8 memory model is described as being **Other-multi-copy atomic**. The definition of Other-multi-copy atomic is as follows:

Other-multi-copy atomic

In an *Other-multi-copy atomic* system, it is required that a memory write effect from an **Observer**, if observed by a different **Observer**, is then observed by all other **Observers** that access the **Location** coherently. It is, however, permitted for an **Observer** to observe its own writes prior to making them visible to other observers in the system.

The **Other-multi-copy atomic** property of the Armv8 memory model is enforced by placing constraints on the possible executions of a program. Those executions that meet the constraints given by the ordering model are said to be **Architecturally well-formed**. An implementation that is executing a program is only permitted to exhibit behavior consistent with an **Architecturally well-formed** execution.

Architecturally well-formed

An *Architecturally well-formed* execution must satisfy both the **Internal visibility requirement** and any of the three alternative **External ordering constraints**.

B2.3.5 Internal visibility requirement

For a memory read or write effect RW_1 that appears in program order before a memory read or write effect RW_2 to the same [Location](#):

- Where one or more of the following statements is true:
 - RW_1 is not a [Tag-Check-read](#).
 - RW_2 is not a [Tag-Check-read](#).
 - RW_1 and RW_2 are both [Tag-Check-reads](#) R_1 and R_2 that are [Tag-Location-Ordered](#).
- The *Internal visibility requirement* requires that exactly one of the following statements is true:
 - RW_2 is a memory write effect W_2 that is [Coherence-after](#) RW_1 .
 - RW_1 is a memory write effect W_1 , RW_2 is a memory read effect R_2 and either:
 - R_2 [Reads-from](#) W_1 .
 - R_2 [Reads-from](#) a memory write effect that is [Coherence-after](#) W_1 .
 - RW_1 and RW_2 are both reads R_1 , R_2 , R_1 [Reads-from](#) a memory write effect W_3 and either:
 - R_2 [Reads-from](#) W_3 .
 - R_2 [Reads-from](#) a memory write effect that is [Coherence-after](#) W_3 .

Informally, if a [Memory effect](#) M_1 from an [Observer](#) appears in program order before a [Memory effect](#) M_2 from the same [Observer](#), then M_1 will be seen to occur before M_2 by that [Observer](#).

B2.3.6 External ordering constraints

The Armv8 memory model offers the following three alternative representations of the *External ordering constraint*:

- [External visibility requirement](#).
- [External completion requirement](#).
- [External global completion requirement](#).

An [Architecturally well-formed](#) execution must satisfy both the [Internal visibility requirement](#) and one of the three alternative representations in the External ordering constraints.

External visibility requirement

Ordered-before

An arbitrary pair of [Memory effects](#) is ordered if it can be linked by a chain of ordered accesses consistent with external observation. A memory read or write effect RW_1 is *Ordered-before* a memory read or write effect RW_2 if and only if any of the following cases apply:

- RW_1 is [Observed-by](#) a memory read or write effect RW_3 which is generated by the same instruction as RW_2 .
- RW_1 is [Locally-ordered-before](#) RW_2 .
- RW_1 is Ordered-before a memory read or write effect that is Ordered-before RW_2 .

For a memory read or write effect RW_1 from an [Observer](#) that is Ordered-before a memory read or write effect RW_2 from a different [Observer](#), the External visibility requirement requires that RW_2 is not [Observed-by](#) RW_1 . This means that an [Architecturally well-formed](#) execution must not exhibit a cycle in the Ordered-before relation.

Informally, if a [Memory effect](#) M_1 from an [Observer](#) appears in program order before a [Memory effect](#) M_2 from the same [Observer](#), then M_1 will be seen to occur before M_2 by all [Observers](#) in the system.

Completes-before order

The *Completes-before order* is a total order that corresponds to the order in which [Memory effects](#) complete within the system. The following effects constitute a single entry in the Completes-before order:

- Writes from the same instruction.

- Reads from the same instruction which read from external writes.
- Reads from the same instruction which read from the same internal write.

All other reads constitute distinct entries in the Completes-before order.

Completes-before

A memory read or write effect RW_1 *Completes-before* a memory read or write effect RW_2 if and only if RW_1 appears in the Completes-before order before RW_2 .

Deriving Reads-from and Coherence order from the Completes-before order

The [Completes-before order](#) can be used to resolve the [Reads-from](#) and [Coherence order](#) relations for every memory access in the system as follows:

- For a memory read effect R_1 of a memory location by an [Observer](#), then:
 - If there is a memory write effect W_2 to the same [Location](#) from the same [Observer](#) and all of the following are true:
 - W_2 appears in program order before R_1 .
 - R_1 [Completes-before](#) W_2 .
 - There are no writes to the [Location](#) appearing in program order between W_2 and R_1 then R_1 [Reads-from](#) W_2 .
 - Otherwise, R_1 [Reads-from](#) its closest preceding write in the [Completes-before order](#) to the same [Location](#). If no such write exists, then R_1 [Reads-from](#) the initial value of the memory location.
- The [Coherence order](#) of writes to a memory location is the order in which those writes appear in the [Completes-before order](#). The final value of each memory location is therefore determined by the final write to each [Location](#) in the [Completes-before order](#). If no such write exists for a given [Location](#), the final value is the initial value of that [Location](#).

External completion requirement

A memory read or write effect RW_1 [Completes-before](#) a memory read or write effect RW_2 if and only if any of the following statements are true:

- RW_1 is [Locally-ordered-before](#) RW_2 .
- RW_1 is a memory read effect R_1 and RW_2 is a memory read effect R_2 and R_1 is [Single-copy-atomic-ordered-before](#) R_2 .

Globally-completes-before order

The *Globally-completes-before order* is a total order that corresponds to the order in which [Memory effects](#) globally-complete within the system. The following effects constitute a single entry in the Globally-completes-before order:

- Writes from the same instruction.
- Reads from the same instruction which read from external writes.
- Reads from the same instruction which read from the same internal write.

All other reads constitute distinct entries in the Globally-completes-before order.

Globally-completes-before

A memory read or write effect RW_1 *Globally-completes-before* a memory read or write effect RW_2 if and only if RW_1 appears in the Globally-completes-before order before RW_2 .

Deriving Reads-from and Coherence order from the Globally-completes-before order

The [Globally-completes-before order](#) can be used to resolve the [Reads-from](#) and [Coherence order](#) relations for every memory access in the system as follows:

- A memory read effect R_1 of a memory location by an [Observer Reads-from](#) its closest preceding write in the [Globally-completes-before order](#) to the same [Location](#). If no such write exists, then R_1 [Reads-from](#) the initial value of the memory location.
- The [Coherence order](#) of writes to a memory location is the order in which those writes appear in the [Globally-completes-before order](#). The final value of each memory location is therefore determined by the final write to each [Location](#) in the [Globally-completes-before order](#). If no such write exists for a given [Location](#), the final value is the initial value of that [Location](#).

External global completion requirement

The *External global completion* requirement requires that a memory read or write effect RW_1 [Globally-completes-before](#) a memory read or write effect RW_2 if and only if any of the following statements are true:

- RW_1 is [Locally-ordered-before](#) RW_2 and either:
 - RW_1 is a memory write effect.
 - RW_1 is a memory read effect R_1 and either:
 - R_1 is not a [Local read successor](#) of a memory write effect.
 - R_1 is a [Local read successor](#) of a memory write effect that is [Locally-ordered-before](#) RW_2 .
- RW_1 is a memory read effect R_1 and RW_2 is a memory read effect R_2 and R_1 is [Single-copy-atomic-ordered-before](#) R_2 .

B2.3.7 Completion and endpoint ordering

Interaction between [Observers](#) in a system is not restricted to communication via shared variables in coherent memory. For example, an [Observer](#) could configure an interrupt controller to raise an interrupt on another [Observer](#) as a form of message passing. These interactions typically involve an additional agent, which defines the instruction sequence that is required to establish communication links between different [Observers](#). When these forms of interaction are used in conjunction with shared variables, a DSB instruction can be used to enforce ordering between them.

For all memory, the completion rules are defined as:

- A memory read effect R_1 to a [Location](#) is complete for a shareability domain when all of the following are true:
 - Any write to the same [Location](#) by an [Observer](#) within the shareability domain will be [Coherence-after](#) R_1 .
 - Any translation table walks associated with R_1 are complete for that shareability domain.
- A memory write effect W_1 to a [Location](#) is complete for a shareability domain when all of the following are true:
 - Any write to the same [Location](#) by an [Observer](#) within the shareability domain will be [Coherence-after](#) W_1 .
 - Any read to the same [Location](#) by an [Observer](#) within the shareability domain will either [Reads-from](#) W_1 or [Reads-from](#) a memory write effect that is [Coherence-after](#) W_1 .
 - Any translation table walks associated with the write are complete for that shareability domain.
- A translation table walk is complete for a shareability domain when the memory accesses, including the updates to translation table entries, associated with the translation table walk are complete for that shareability domain, and the TLB is updated.

- A cache maintenance instruction is complete for a shareability domain when the memory effects of the instruction are complete for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.
- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.

The completion of any cache or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction.

———— **Note** —————

These completion rules mean that, for example, a cache maintenance instruction that operates by VA to the PoC completes only after memory at the PoC has been updated.

Additionally, for Device-nGnRnE memory, a read or write of a Location in a Memory-mapped peripheral that exhibits side-effects is complete only when the read or write both:

- Can begin to affect the state of the Memory-mapped peripheral.
- Can trigger all associated side-effects, whether they affect other peripheral devices, PEs, or memory.

———— **Note** —————

This requirement for Device-nGnRnE memory is consistent with the memory access having reached the peripheral endpoint.

Peripherals

This section defines a Memory-mapped peripheral and the total order of reads and writes to a peripheral which is defined as the Peripheral coherence order:

Memory-mapped peripheral

A Memory-mapped peripheral occupies a memory region of IMPLEMENTATION DEFINED size and can be accessed using load and store instructions. Memory effects to a Memory-mapped peripheral can have side-effects, such as causing the peripheral to perform an action. Values that are read from addresses within a Memory-mapped peripheral might not correspond to the last data value written to those addresses. As such, Memory effects to a Memory-mapped peripheral might not appear in the Reads-from or Coherence order relations.

Peripheral coherence order

The Peripheral coherence order of a Memory-mapped peripheral is a total order on all reads and writes to that peripheral.

———— **Note** —————

The Peripheral coherence order for a Memory-mapped peripheral signifies the order in which accesses arrive at the endpoint.

For a memory read or write effect RW_1 and a memory read or write effect RW_2 to the same peripheral, then RW_1 will appear in the Peripheral coherence order for the peripheral before RW_2 if either of the following cases apply:

- RW_1 and RW_2 are accesses using Non-cacheable or Device attributes and RW_1 is Ordered-before RW_2 .
- RW_1 and RW_2 are accesses using Device-nGnRE or Device-nGnRnE attributes, with the same XS attribute value, and RW_1 appears in program order before RW_2 .

———— **Note** —————

When **FEAT_XS** is implemented, if accesses marked with the Device-nGnRE or Device-nGnRnE attributes are within the same **Memory-mapped peripheral**, but the XS attribute is not the same on those accesses, the order of arrival at the endpoint is not defined by the architecture.

Out-of-band-ordered-before

A memory read or write effect RW_1 is *Out-of-band-ordered-before* a memory read or write effect RW_2 if and only if either of the following cases apply:

- RW_1 appears in program order before a DSB instruction that begins an IMPLEMENTATION DEFINED instruction sequence indirectly leading to the generation of RW_2 .
- RW_1 is **Ordered-before** a memory read or write effect RW_3 and RW_3 is Out-of-band-ordered-before RW_2 .

If a **Memory effect** M_1 is Out-of-band-ordered-before a memory read or write effect M_2 , then M_1 is seen to occur before M_2 by all **Observers**.

———— **Note** —————

Arm expects that, in most systems with early acknowledgments, those acknowledgments will come from a point at or after the point that establishes global visibility. This is expected in such systems to enable the acknowledgments to be used as part of the mechanisms to implement the ordering requirements of the Arm memory model.

B2.3.8 Ordering of instruction fetches

For two memory locations A and B, if A has been written to and been made coherent with the instruction fetches of the shareability domain, before an update to B by an observer in the same shareability domain, then the instruction stream of each observer in the shareability domain will not see the updated value of B without also seeing the updated value of A.

A write has been made coherent with an instruction fetch of a shareability domain when:

CTR_EL0.{DIC, IDC} == {0, 0}

The location written to has been cleaned to the *Point of unification (PoU)* from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the *Point of unification (PoU)* from the instruction cache, and that invalidation is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {1, 0}

The location written to has been cleaned to the *Point of unification (PoU)* from the data cache, and that clean is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {0, 1}

The write is complete for the shareability domain. Subsequently the location has been invalidated to the *Point of unification (PoU)* from the instruction cache, and that invalidation is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {1, 1}

The write is complete for the shareability domain.

———— **Note** —————

Microarchitecturally, this means that these situations cannot both be true in an implementation:

- After delays in fetching from memory, the instruction queue can have entries written into it out of order.
- For an implementation:
 - When **CTR_EL0**.DIC == 0, if there is an outstanding entry in the instruction queue, then later entries in the instruction queue are not impacted by the **IC IVAU** instructions of a different core.

- When `CTR_EL0.DIC == 1`, if there is a write to the location that is held in the queue when there is an outstanding entry in the instruction queue for an older entry, then the instruction queue does not have entries invalidated from it.
-

B2.3.9 Restrictions on the effects of speculation

This section covers restrictions on speculation effects, including:

- [Restrictions on the effects of speculation on page B2-144.](#)
- [Speculative Store Bypass Safe \(SSBS\) on page B2-145.](#)
- [Restrictions on exploitative control of speculative execution on page B2-145.](#)
- [Restrictions on the effects of speculation from Armv8.5 on page B2-145.](#)

Restrictions on the effects of speculation

The Arm architecture places certain restrictions on the effects of speculation. These are:

- Each load from a location using a particular VA after an exception return that is a [Context synchronization event](#) will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception exit.
- Each load from a location using a particular VA after an exception entry that is a [Context synchronization event](#) will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception entry.
- Any load from a location using a particular VA before an exception entry that is a [Context synchronization event](#) will not speculatively read data from a store to the same location using the same VA after the exception entry.
- Any load from a location using a particular VA before an exception return that is a [Context synchronization event](#) will not speculatively read data from a store to the same location using the same VA after the exception exit.
- When data is loaded under speculation with a Translation fault, it cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence.
- When data is loaded under speculation from a location without a translation for the translation regime being speculated in, the data cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence.
- Changes to System registers must not occur speculatively in a way that can affect a speculative memory access that can cause a change to the micro-architectural state.
- Changes to Special-purpose registers can occur speculatively.
- Execute-never controls apply to speculative instruction fetching. See [Access permissions for instruction execution on page D5-2760.](#)

Note

The prohibition of using data loaded under speculation with faults to form addresses, condition codes or SVE predicate values does not prohibit the use of value predicted data from such locations for such purposes, so long as the training of the data value prediction was from the hardware defined context that is using the prediction. A consequence of this is that training of value prediction cannot be based on data loaded under speculation with a translation or Permission fault.

Speculative Store Bypass Safe (SSBS)

When `FEAT_SSBS` is implemented, `PSTATE.SSBS` is a control that can be set by software to indicate whether hardware is permitted to use, in a manner that is potentially speculatively exploitable, a speculative value in a register that has been loaded from memory using a load instruction that speculatively read the location being loaded from, where the entry that is speculatively read is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

A speculative value in a register is used in a potentially speculatively exploitable manner if it is used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence or if the execution timing of any other instructions in the speculative sequence is a function of the data loaded under speculation.

When the value of `PSTATE.SSBS` is 0, hardware is not permitted to use speculative register values in a potentially speculatively exploitable manner if the speculative read that loads the register is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

When the value of `PSTATE.SSBS` is 1, hardware is permitted to use speculative register values in a potentially speculatively exploitable manner if the speculative read that loads the register is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

————— Note —————

- If speculation is permitted, then cache timing side channels can lead to addresses being derived using reads of address values that have been speculatively loaded from memory to a register.
- Software written for architectures from Armv8.0 to Armv8.4 will set `SPSR_ELx.SSBS` to 0. This means that `PSTATE.SSBS` will not set, so hardware will not be permitted to use speculative loads with outstanding memory disambiguation issues for any subsequent speculative memory accesses if there is any possibility of those subsequent memory accesses creating a cache timing side channel.

Restrictions on exploitative control of speculative execution

The execution of some code (code1) can exploitatively control speculative execution of some other code (code2) if and only if all of the following apply:

- The actions of code1 can influence the speculative execution of code2 to cause an irreversible change to the microarchitectural state of the PE that is indicative of some architectural state accessible to the execution context of code2.
- Code1 has control in determining the choice of the architecture state that causes the irreversible change to the microarchitectural state.
- The irreversible changes to the microarchitectural state of the PE can be measured by code executing in an execution context other than that of code2 to allow the retrieval of the architectural state in a computationally feasible manner.

Restrictions on the effects of speculation from Armv8.5

From Armv8.5, there are some further restrictions on the effects of speculation in addition to those in Armv8.0:

- Data loaded under speculation with a permission or domain fault cannot be used to form an address, to generate condition codes, or to generate SVE predicate values to be used by other instructions in the speculative sequence.
- Any System register read under speculation to a register that is not architecturally accessible from the current Exception level cannot be used to form an address, to generate condition codes, or to generate SVE predicate values to be used by other instructions in the speculative sequence.

Note

As the effects of speculation are not architecturally visible, this restriction requires that the effect of any speculation cannot give rise to side channels that will leak the values of memory locations, System registers, or Special-purpose registers to a level of privilege that would otherwise not be able to determine those values.

- Code running in one hardware-defined context cannot **exploitatively control speculative execution** of code in a different hardware-defined context as a result of the behavior of any execution prediction resources that predict address or register values. In the case of this definition, the hardware-defined context is determined by:
 - The Exception level.
 - The Security state.
 - When executing at EL1, if EL2 is implemented and enabled in the current Security state, the VMID.
 - When executing at EL0, whether the EL1&0 or the EL2&0 translation regime is in use.
 - When executing at EL0 and using the EL1&0 translation regime, the *address space identifier (ASID)* and, if EL2 is implemented and enabled in the current Security state, the VMID.
 - When executing at EL0 and using the EL2&0 translation regime, the ASID.
 - When in AArch64 state, the current `SCXTNUM_ELx` value if `SCXTNUM_ELx` is implemented and the hardware identifies that `SCXTNUM_ELx` is part of the context. Where `SCXTNUM_ELx` is not included as part of the hardware-indicated context, an implementation can further identify that branch targets trained for branches situated at one address can control speculative execution of branches situated at different addresses only in a hard-to-determine way.

Note

- The definition of “hard-to-determine manner” is left open to implementations. Examples could include the complete separation of prediction resources, or the isolation of the predictions using a cryptographic or pseudo-random mechanism to separate each context.
 - The architecture does not require that prediction resources that simply predict the direction of a branch are separated in this way.
-

- Changes to System registers must not occur speculatively in a way that can affect a speculative memory access that can cause a change to the micro-architectural state.
- Changes to Special-purpose registers can occur speculatively.

Note

If `SCR_EL3.EEL2` is changed, in order to remove all VMID tagging from Secure EL1 and Secure EL0 entries, each prediction resource should be invalidated by software for:

- Secure EL0 for all ASID and VMID values.
 - Secure EL1 for all VMID values.
-

B2.3.10 Memory barriers

Memory barrier is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring load/store instructions. The memory barriers defined by the Armv8 architecture provide a range of functionality, including:

- Ordering of load/store instructions.
- Completion of load/store instructions.
- Context synchronization.

The following subsections describe the Armv8 memory barrier instructions:

- [Instruction Synchronization Barrier \(ISB\)](#) on page B2-147
- [Data Memory Barrier \(DMB\)](#) on page B2-147.
- [Data Synchronization Barrier \(DSB\)](#) on page B2-150.

- [Speculation Barrier \(SB\)](#) on page B2-148.
- [Consumption of Speculative Data Barrier \(CSDB\)](#) on page B2-148.
- [Speculative Store Bypass Barrier \(SSBB\)](#) on page B2-148.
- [Profiling Synchronization Barrier \(PSB CSYNC\)](#) on page B2-149.
- [Physical Speculative Store Bypass Barrier \(PSSBB\)](#) on page B2-149.
- [Trace Synchronization Barrier \(TSB CSYNC\)](#) on page B2-149
- [Shareability and access limitations on the data barrier operations](#) on page B2-151.
- [Load-Acquire, Load-AcquirePC, and Store-Release](#) on page B2-152.
- [LoadLOAcquire, StoreLORelease](#) on page B2-153.

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are only available when software execution is at EL1 or higher.

DMB and DSB instructions affect reads and writes to the memory system generated by load/store instructions and data or unified cache maintenance instructions being executed by the PE.

Instruction Synchronization Barrier (ISB)

An ISB instruction ensures that all instructions that come after the ISB instruction in program order are fetched from the cache or memory after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction. Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to System registers.

Any context-changing operations appearing in program order after the ISB instruction only take effect after the ISB has been executed.

The pseudocode function for the operation of an ISB is [InstructionSynchronizationBarrier\(\)](#).

See also [Memory barriers](#) on page D4-2671.

Data Memory Barrier (DMB)

The DMB instruction is a memory barrier instruction that ensures the relative order of memory accesses before the barrier with memory accesses after the barrier. The DMB instruction does not ensure the completion of any of the memory accesses for which it ensures relative order.

The full definition of the DMB instruction is covered formally in the [Definition of the Armv8 memory model on page B2-133](#) and this introduction to the DMB instruction is not intended to contradict that section.

The basic principle of a DMB instruction is to introduce order between memory accesses that are specified to be affected by the DMB options supplied as arguments to the DMB instruction. The DMB instruction ensures that all affected memory accesses by the PE executing the DMB instruction that appear in program order before the DMB instruction and those which originate from a different PE, to the extent required by the DMB options, which have been [Observed-by](#) the PE before the DMB instruction is executed, are [Observed-by](#) each PE, to the extent required by the DMB options, before any affected memory accesses that appear in program order after the DMB instruction are [Observed-by](#) that PE.

The use of a DMB instruction creates order between the [Memory effects](#) of instructions as described in the definition of [Barrier-ordered-before](#).

The DMB instruction only affects memory accesses and the operation of data cache and unified cache maintenance instructions, see [A64 Cache maintenance instructions](#) on page D4-2648. It has no effect on the ordering of any other instructions executing on the PE.

The pseudocode function for the operation of a DMB instruction is [DataMemoryBarrier\(\)](#).

Speculation Barrier (SB)

An SB instruction is a memory barrier that prevents speculative execution of instructions until after the barrier has completed when those instructions could be observed through side-channels.

Until the barrier completes, the speculative execution of any instruction appearing later in the program order than the barrier:

- Cannot be performed to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be performed when predicting that an instruction that could generate an exception does not generate an exception.

Speculative execution of an SB instruction:

- Cannot be as a result of control flow speculation.
- Cannot be as a result of data value speculation.
- Can be as a result of predicting that an instruction that could generate an exception does not generate an exception.

An SB instruction can complete when:

- It is known that it is not speculative.
- All the predicted data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

———— Note ————

The SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched, so long as the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after the SB instruction.

Consumption of Speculative Data Barrier (CSDB)

The CSDB instruction is a memory barrier instruction that controls speculative execution and data value prediction. This includes:

- Data value predictions of any instructions.
- PSTATE. $\{N,Z,C,V\}$ predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
- Predictions of SVE predication state for any SVE instructions.

For purposes of the definition of CSDB, PSTATE. $\{N,Z,C,V\}$ is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB instruction.
- Speculative execution of conditional data processing instructions after the CSDB instruction, unless they use the results of data value or PSTATE. $\{N,Z,C,V\}$ predictions of instructions appearing in program order before the CSDB instruction that have not been architecturally resolved.

Speculative Store Bypass Barrier (SSBB)

The SSBB instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB instruction, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
 - The store is to the same location as the load.
 - The store uses the same virtual address as the load.
 - The store appears in program order before the SSBB instruction.
- When a load to a location appears in program order before the SSBB instruction, then the load does not speculatively read data from any store satisfying all of the following conditions:
 - The store is to the same location as the load.
 - The store uses the same virtual address as the load.
 - The store appears in program order after the SSBB instruction.

Profiling Synchronization Barrier (PSB CSYNC)

The PSB CSYNC instruction is a memory barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following DSB instruction completes when the writes to the profiling buffer have completed.

If the Statistical Profiling Extension is not implemented, this instruction executes as a NOP.

Physical Speculative Store Bypass Barrier (PSSBB)

The PSSBB instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB instruction, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
 - The store is to the same location as the load.
 - The store appears in program order before the PSSBB instruction.
- When a load to a location appears in program order before the PSSBB instruction, then the load does not speculatively read data from any store satisfying all of the following conditions:
 - The store is to the same location as the load.
 - The store appears in program order after the PSSBB instruction.

———— Note —————

The effect of this barrier applies to accesses to the same location even if they are accessed with different virtual addresses and from different Exception levels.

Trace Synchronization Barrier (TSB CSYNC)

The TSB CSYNC instruction is a memory barrier instruction that preserves the relative order of memory accesses to System registers due to trace operations and other memory accesses to the same registers.

A trace operation is an operation of the PE Trace Unit generating trace for an instruction when [FEAT_TRF](#) is implemented and enabled.

A TSB CSYNC instruction is not required to execute in program order with respect to other instructions. This includes being reordered with respect to other trace instructions. One or more Context synchronization events are required to ensure that TSB CSYNC instruction is executed in the necessary order.

If trace is generated between a Context synchronization event and a TSB CSYNC operation, these trace operations may be reordered with respect to the TSB CSYNC operation, and therefore may not be synchronized.

The following situations are synchronized using a TSB CSYNC operation:

- A direct write B to a System register is ordered after an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all of the following are true:
 - A is executed in program order before a Context synchronization event C.
 - C is in program order before a TSB CSYNC operation T.
 - B is executed in program order after T.
- A direct read B of a System register is ordered after an indirect write to the same register by a trace operation of a traced instruction A if all the following are true:
 - A is executed in program order before a Context synchronization event C1.
 - C1 is in program order before TSB CSYNC operation T.
 - T is executed in program order before a second Context synchronization event C2.
 - B is executed in program order after C2.

A TSB CSYNC operation is not needed to ensure a direct write B to a System register is ordered before an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all the following are true:

- A is executed in program order after a Context synchronization event C.
- B is executed in program order before C.

The pseudocode function for the operation of a TSB CSYNC instruction is `TraceSynchronizationBarrier()`.

Data Synchronization Barrier (DSB)

A DSB instruction is a memory barrier that ensures that memory accesses that occur before the DSB instruction have completed before the completion of the DSB instruction. In doing this, it acts as a stronger barrier than a DMB and all ordering that is created by a DMB with specific options is also generated by a DSB with the same options.

Execution of a DSB instruction:

- At EL2 ensures that any memory accesses caused by [Speculative](#) translation table walks from the EL1&0 translation regime have been observed.
- At EL3 ensures that any memory accesses caused by speculative translation table walks from the EL2, EL1&0 or EL2&0 translation regimes have been observed.

For more information, see [Use of out-of-context translation regimes on page D5-2697](#).

A DSB instruction executed by a PE, PEe, completes when all of the following apply:

- All explicit memory effects of the required access types appearing in program order before the DSB are complete for the set of observers in the required shareability domain.
- If the required access types of the DSB is reads and writes, the following instructions issued by PEe before the DSB are complete for the required shareability domain:
 - All cache maintenance instructions.
 - All TLB maintenance instructions.
 - All PSB SYNC instructions.
- When [FEAT_XS](#) is implemented, if the required access types of the DSB is reads and writes, completion of the DSB instruction with the nXS qualifier executed by a PE, PEe, ensures that:
 - All previous TLBInXS maintenance operations generated by AArch64 TLB maintenance instructions with the nXS qualifier executed by PEe are finished for all PEs in the shareability domain of the DSB instruction.
 - All previous TLBInXS maintenance operations generated by AArch32 or AArch64 TLB maintenance instructions executed at EL1 by PEe when [HCRX_EL2.FnXS](#) is 1 are finished for all PEs in the shareability domain of the DSB instruction.

Completion of the [DSB](#) instruction with the nXS qualifier executed by a PE, PEE, does not ensure that:

- All previous TLB maintenance operations generated by AArch32 or AArch64 TLB maintenance instructions executed at EL1 by PEE when [HCRX_EL2.FnXS](#) is 0 are finished for all PEs in the shareability domain of the [DSB](#) instruction.
- All previous TLB maintenance operations generated by AArch32 or AArch64 TLB maintenance instructions executed at EL2 or EL3 by PEE are finished for all PEs in the shareability domain of the [DSB](#) instruction.

In addition, no instruction that appears in program order after the [DSB](#) instruction can alter any state of the system or perform any part of its functionality until the [DSB](#) completes other than:

- Being fetched from memory and decoded.
- Reading the general-purpose, SIMD and floating-point, Special-purpose, or System registers that are directly or indirectly read without causing side-effects.

If [FEAT_MTE2](#) is implemented, on completion of a [DSB](#) instruction operating over the Non-shareable domain, all updates to [TFSR_ELx.TFx](#) or [TFSRE0_EL1.TFx](#) due to Tag Check fails caused by accesses for which the [DSB](#) operates will be complete. For more information on [FEAT_MTE2](#), see [Chapter D6 Memory Tagging Extension](#).

When [FEAT_XS](#) is implemented and [HCRX_EL2.FnXS](#) is 1, an AArch64 [DSB](#) instruction executed at EL1 or EL0 behaves in the same way as the corresponding [DSB](#) instruction with the nXS qualifier executed at EL1 or EL0.

The pseudocode function for the operation of a [DSB](#) is [DataSynchronizationBarrier\(\)](#).

See also:

- [Memory barriers on page D4-2671](#).
- [Ordering and completion of TLB maintenance instructions on page D5-2831](#).

Shareability and access limitations on the data barrier operations

The [DMB](#) and [DSB](#) instructions take an argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
 - Full system.
 - Outer Shareable.
 - Inner Shareable.
 - Non-shareable.

Full system applies to all the observers in the system and, as such, encompasses the Inner and Outer Shareable domains of the processor.

———— **Note** —————

The distinction between Full system and Outer Shareable is only applicable for Normal Non-cacheable memory accesses and Device memory accesses.

- The accesses for which the instruction operates. This is one of:
 - Read and write accesses, both before and after the barrier instruction.
 - Write accesses only, before and after the barrier instruction.
 - Read accesses before the barrier instruction, and read and write accesses after the barrier instruction.

———— **Note** —————

This form of a [DMB](#) or [DSB](#) instruction can be described as a load-load/store barrier.

For more information on whether an access is before or after a barrier instruction, see [Data Memory Barrier \(DMB\) on page B2-147](#) or [Data Synchronization Barrier \(DSB\) on page B2-150](#).

Table B2-1 on page B2-152 shows how these options are encoded in the <option> field of the instruction:

Table B2-1 Encoding of the DMB and DSB <option> parameter

Accesses		Shareability domain			
Before the barrier	After the barrier	Full system	Outer Shareable	Inner Shareable	Non-shareable
Reads and writes	Reads and writes	SY	OSH	ISH	NSH
Writes	Writes	ST	OSHST	ISHST	NSHST
Reads	Reads and writes	LD	OSHL	ISHL	NSHL

See the instruction descriptions for more information:

- [DMB on page C6-1013](#).
- [DSB on page C6-1016](#).

———— **Note** ————

ISB also supports an optional limitation argument that can only contain one value that corresponds to full system operation, see [ISB on page C6-1039](#).

Load-Acquire, Load-AcquirePC, and Store-Release

Armv8 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores. These instructions support the *Release Consistency sequentially consistent* (RCsc) model. In addition, [FEAT_LRCPC](#) provides Load-AcquirePC instructions. The combination of Load-AcquirePC and Store-Release can be used to support the weaker *Release Consistency processor consistent* (RCpc) model.

The full definitions of the Load-Acquire and Load-AcquirePC instructions are covered formally in the [Definition of the Armv8 memory model on page B2-133](#). This introduction to the Load-Acquire and Load-AcquirePC instructions is not intended to contradict that section.

The basic principle of both Load-Acquire and Load-AcquirePC instructions is to introduce order between:

- The memory access generated by the Load-Acquire or Load-AcquirePC instruction.
- The memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction, such that the memory access generated by the Load-Acquire or Load-AcquirePC instruction is **Observed-by** each PE to the extent that the PE is required to observe the access coherently, before any of the memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction are **Observed-by** that PE to the extent that the PE is required to observe the accesses coherently.

The use of a Load-Acquire or Load-AcquirePC instruction creates order between the **Memory effects** of instructions as described in the definition of **Barrier-ordered-before**.

The full definition of the Store-Release instruction is covered formally in the [Definition of the Armv8 memory model on page B2-133](#) and this introduction to the Store-Release instruction is not intended to contradict that section.

The basic principle of a Store-Release instruction is to introduce order between the following:

- A set of memory accesses, RWx, that are generated by the PE executing the Store-Release instruction and that appear in program order before the Store-Release instruction, together with those that originate from a different PE to the extent that the PE is required to observe them coherently, **Observed-by** the PE before executing the Store-release.
- The memory access generated by the Store-Release (Wrel), such that all of the memory accesses, RWx, are **Observed-by** each PE to the extent that the PE is required to observe those accesses coherently, before Wrel is **Observed-by** that PE to the extent that the PE is required to observe that access coherently.

The use of a Store-Release instruction creates order between the [Memory effects](#) of instructions as described in the definition of [Barrier-ordered-before](#).

Where a Load-Acquire appears in program order after a Store-Release, the memory access generated by the Store-Release instruction is [Observed-by](#) each PE to the extent that PE is required to observe the access coherently, before the memory access generated by the Load-Acquire instruction is [Observed-by](#) that PE, to the extent that the PE is required to observe the access coherently. In addition, the use of a Load-Acquire, Load-AcquirePC or a Store-Release instruction on accesses to a [Memory-mapped peripheral](#) introduces order between the [Memory effects](#) of the instructions that access that peripheral, as described in the definition of [Peripheral coherence order](#).

Load-Acquire, Load-AcquirePC and Store-Release, other than Load-Acquire Exclusive Pair and Store-Release-Exclusive Pair, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

Load-Acquire Exclusive Pair and Store-Release Exclusive Pair access two data elements. The address supplied to the instructions must be aligned to twice the size of the element being loaded, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the release semantics if the store is successful.

Note

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
 - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
 - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.
 - The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit DMB instruction.
-

LoadLOAcquire, StoreLORelease

For each PE, the Non-secure physical memory map is divided into a set of LORegions using a table that is held within the PE. Any PA in the Non-secure memory map can be a member of one LORegion. If a PA is assigned to more than one LORegion, then an implementation might treat it as if it has been assigned to fewer LORegions than that have been specified. A PA in the Secure physical memory map cannot be a member of any LORegion. For more information, see [Limited ordering regions on page B2-154](#).

Armv8.1 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores that apply in relation to the defined LORegions. The new variants of the Load-Acquire and Store-Release instructions are LoadLOAcquire and StoreLORelease. See [LoadLOAcquire/StoreLORelease on page C3-231](#).

For all memory types, these instructions have the following ordering requirements:

- LoadLOAcquire has the same semantics as Load-Acquire except that the memory accesses affected lie within the same LORegion as the address of the memory access generated by the LoadLOAcquire instruction. See [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).
- StoreLORelease has the same semantics as Store-Release except that the memory accesses affected lie within the same LORegion as the address of the memory access generated by the StoreLORelease instruction. See [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

In addition, for accesses to [Memory-mapped peripherals](#):

- LoadLOAcquire has the same semantics as Load-Acquire except that the affected [Memory effects](#) of instructions that access the peripheral lie within the same LORegion as the address of the memory access generated by the LoadLOAcquire instruction. See [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

- StoreLORelease has the same semantics as Store-Release except that the affected [Memory effects](#) of instructions that access the peripheral lie within the same LORegion as the address of the memory access generated by the StoreLORelease instruction. See [Load-Acquire](#), [Load-AcquirePC](#), and [Store-Release](#) on page B2-152.

———— **Note** —————

The LoadLOAcquire/StoreLORelease instructions can remove the requirement to use the explicit DMB instruction.

B2.3.11 Limited ordering regions

Armv8.1 introduces *limited ordering regions* (LORegions), which allow large systems to perform special load-acquire and store-release instructions that provide order between the memory accesses to a region of the PA map as observed by a set of observers.

This feature is supported in AArch64 state only.

Specification of the LORegions

The LORegions are defined in the Non-secure physical memory map using a set of LORegion descriptors. The number of LORegion descriptors is IMPLEMENTATION DEFINED, and can be discovered by reading the [LORID_EL1](#) register.

Each LORegion descriptor consists of:

- A tuple of the following values:
 - A Start Address.
 - An End Address.
 - An LORegion Number.
- Valid bit which indicates whether that LORegion descriptor is valid.

A memory location lies within the LORegion identified by the LORegion Number if the PA lies between the Start Address and the End Address, inclusive. The Start Address must be defined to be aligned to 64KB and the End Address must be defined as the top byte of a 64KB block of memory.

The LORegion descriptors are programmed using the [LORSA_EL1](#), [LOREA_EL1](#), [LORN_EL1](#), and [LORC_EL1](#) registers in the System register space. These registers only describe memory addresses in the Non-secure memory map. These registers are UNDEFINED if accessed when [SCR_EL3.NS](#) == 0.

If a LoadLOAcquire or a StoreLORelease does not match with any LORegion, then:

- The LoadLOAcquire will behave as a Load-Acquire, and will be ordered in the same way with respect to all accesses, independent of their LORegions.
- The StoreLORelease will behave as a Store-Release, and will be ordered in the same way with respect to all accesses, independent of their LORegions.

———— **Note** —————

If no LORegions are implemented, then the LoadLOAcquire and StoreLORelease will therefore behave as a Load-Acquire and Store-Release.

A new access type [AccType_LIMITEDORDERED](#) has been added for these limited ordering instructions to be identified.

B2.4 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. Armv8 defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- [Introduction to caches on page B2-155.](#)
- [Memory hierarchy on page B2-155.](#)
- [Application level access to functionality related to caches on page B2-156](#)
- [Implication of caches for the application programmer on page B2-157.](#)
- [Preloading caches on page B2-159.](#)

B2.4.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a *tag*.
- The associated data.

Caches increase the average speed of a memory access. Caching takes account of two principles of locality:

Spatial locality

An access to one [Location](#) is likely to be followed by accesses to adjacent [Locations](#). Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a *cache line*. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a *cache hit*, and other accesses are called *cache misses*.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. Armv8 permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

B2.4.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an Armv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. [Figure B2-1 on page B2-156](#) shows an example of such a system in an Armv8-A system that supports virtual addressing.

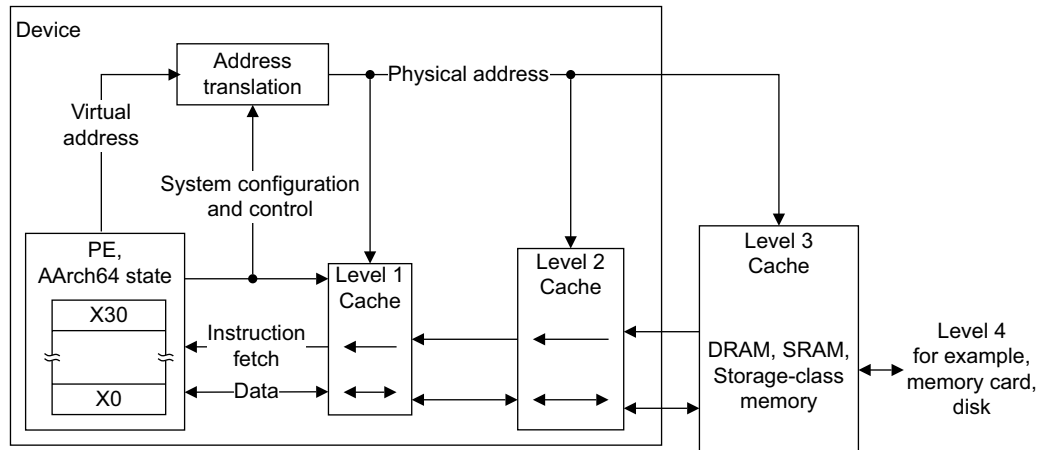

Figure B2-1 Multiple levels of cache in a memory hierarchy

Note

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the processing element, as shown in [Figure B2-1 on page B2-156](#).

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches that are located at the levels closest to the main memory. Memory coherency for cache topologies can be defined using the conceptual points [Point of Unification \(PoU\)](#), [Point of Coherency \(PoC\)](#), [Point of Persistence \(PoP\)](#), and [Point of Deep Persistence \(PoDP\)](#).

For more information, including the definitions of [PoU](#), [PoC](#), [PoP](#), and [PoDP](#), see [About cache maintenance in AArch64 state on page D4-2644](#).

If [FEAT_MTE2](#) is implemented, the behavior of cache maintenance instructions is modified. For more information, see [Allocation Tags on page D6-2841](#).

The cacheability and shareability memory attributes

Cacheability and shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

Cacheability This attribute defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.

Shareability This attribute defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about Cacheability and Shareability, see [Memory types and attributes on page B2-165](#).

B2.4.3 Application level access to functionality related to caches

As indicated in [About the Application level programmers' model on page B1-116](#), the application level corresponds to execution at EL0. The architecture defines a set of cache maintenance instructions that software can use to manage cache coherency. Software executing at a higher Exception level can enable use of some of this functionality from EL0, as follows:

When the value of [SCTLR_EL1.UCI](#) is 1

Software executing at EL0 can access:

- The data cache maintenance instructions, DC CVAU, DC CVAC, DC CVAP, DC CVADP, and DC CIVAC. See [The data cache maintenance instruction \(DC\) on page D4-2650](#).

- The instruction cache maintenance instruction IC IVAU. See [The instruction cache maintenance instruction \(IC\)](#) on page D4-2650.

Attempted execution of these instructions might generate a Permission fault as described in [Permission fault](#) on page D5-2801.

When the value of SCTLR_EL1.UCT is 1

Software executing at EL0 can access the cache type register. See [CTR_EL0](#).

When the value of SCTLR_EL1.DZE is 1

Software executing at EL0 can access the data cache zero instruction DC ZVA. See [Data cache zero instruction](#) on page D4-2661.

The [SCTLR_EL1](#).{UCI, UCT, DZE} control fields are only accessible by software executing at EL1 or higher.

When [HCR_EL2](#).{E2H, TGE} == 1 the controls {UCI, UCT and DZE} are found in [SCTLR_EL2](#).

This functionality is UNDEFINED at EL0 when the value of the corresponding [SCTLR_EL1](#) control field is 0, see:

- [Traps to EL1 of EL0 execution of cache maintenance instructions](#) on page D1-2514.
- [Traps to EL1 of EL0 accesses to the CTR_EL0](#) on page D1-2514.
- [Traps to EL1 of EL0 execution of DC ZVA instructions](#) on page D1-2514.

B2.4.4 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
 - Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
 - Not enabling caches in the system.
- By using cache maintenance instructions to manage the coherency issues in software. See [Application level access to functionality related to caches](#) on page B2-156.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see [Non-shareable Normal memory](#) on page B2-167 and [Shareable, Inner Shareable, and Outer Shareable Normal memory](#) on page B2-166.

———— **Note** ————

The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations, the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

———— **Note** ————

Not all these mechanisms are directly available to software operating at EL0 and might involve interaction with software operating at a higher Exception level.

Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last *Context synchronization event* on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being refetched from memory. In the absence of a *Context synchronization event*, there is no limit on the number of times such an instruction might be executed without being refetched from memory.

The Arm architecture requires the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory. A write has been made coherent with an instruction fetch of a shareability domain when:

CTR_EL0.{DIC, IDC} == {0, 0}

The location written to has been cleaned to the *Point of unification (PoU)* from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the *Point of unification (PoU)* from the instruction cache, and that invalidation is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {1, 0}

The location written to has been cleaned to the *Point of unification (PoU)* from the data cache, and that clean is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {0, 1}

The write is complete for the shareability domain. Subsequently the location has been invalidated to the *Point of unification (PoU)* from the instruction cache, and that invalidation is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {1, 1}

The write is complete for the shareability domain.

If software requires coherency between instruction execution and memory, it must manage this coherency using *Context synchronization events* and cache maintenance instructions. The following code sequence can be used to allow a PE to execute code that the same PE has written.

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.  
; Enter this code with <Wt> containing a new 32-bit instruction,  
; to be held in Cacheable space at a location pointed to by Xn.  
STR Wt, [Xn]  
DC CVAU, Xn      ; Clean data cache by VA to point of unification (PoU)  
DSB ISH          ; Ensure visibility of the data cleaned from cache  
IC IVAU, Xn      ; Invalidate instruction cache by VA to PoU  
DSB ISH          ; Ensure completion of the invalidations  
ISB              ; Synchronize the fetched instruction stream
```

Note

- If this sequence is not executed between writing data to a location and executing the instruction at that location, the lack of coherency between instruction caches and memory means that the instructions that are executed might be the old instruction or the updated instruction, and which is used can arbitrarily vary during execution. It must not be assumed by software, before the synchronization sequence is executed, that when the updated instruction has been seen, the old instruction will not be seen again.
- For Non-cacheable or Write-Through accesses, the clean data cache by VA instruction is not required. However, the invalidate instruction cache instruction is required because the Armv8-A AArch64 architecture allows Non-cacheable accesses to be held in an instruction cache. See [Non-cacheable accesses and instruction caches on page D4-2643](#).
- This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The Armv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See [Concurrent modification and execution of instructions on page B2-130](#).
- The system software controls whether these cache maintenance instructions are available to the application level by setting `SCTLR_ELI.UCI`.

B2.4.5 Preloading caches

The Arm architecture provides memory system hints PRFM, LDNP, and STNP that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring the data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as NOPs without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous External abort, which is taken using an SError interrupt exception. For more information, see [ISS encoding for an exception from a Data Abort on page D13-3172](#).

`PrefetchHint{}` defines the prefetch hint types.

The `Hint_Prefetch()` function signals to the memory system that memory accesses of the type hint to or from the specified address are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level target and non-temporal hint stream.

For more information on PRFM and load/store instructions that provide hints to the memory system, see [Prefetch memory on page C3-235](#) and [Load/store SIMD and floating-point non-temporal pair on page C3-233](#).

B2.5 Alignment support

This section describes alignment support. It contains the following subsections:

- [Instruction alignment](#) on page B2-160.
- [Alignment of data accesses](#) on page B2-160.

B2.5.1 Instruction alignment

A64 instructions must be word-aligned.

Attempting to fetch an instruction from a misaligned location results in a PC alignment fault. See [PC alignment checking](#) on page D1-2469.

B2.5.2 Alignment of data accesses

An unaligned access to any type of Device memory causes an Alignment fault.

Unaligned accesses to Normal memory

The behavior of unaligned accesses to Normal memory is dependent on all of the following:

- The instruction causing the memory access.
- The memory attributes of the accessed memory.
- The value of `SCTLR_ELx.{A, nAA}`.
- Whether or not `FEAT_LSE2` is implemented.

Load or Store of Single or Multiple registers

For all instructions that load or store single or multiple registers, but not Load-Exclusive, Store-Exclusive, Load-Acquire/Store-Release and Atomic instructions, if the address that is accessed is not aligned to the size of the data element being accessed, then:

When the value of `SCTLR_ELx.A` applicable to the current Exception level is 1, an Alignment fault is generated.

When the value of `SCTLR_ELx.A` applicable to the current Exception level is 0:

- An unaligned access is performed.
- If `FEAT_LSE2` is not implemented, the access is not guaranteed to be single-copy atomic except at the byte access level.
- If `FEAT_LSE2` is implemented:
 - If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable memory, the memory access is single-copy atomic. For a Load-Pair or Store-Pair, including load non-temporal pair, instructions the entire memory access will be single-copy atomic.
 - If all the bytes of the memory accessed do not lie within a 16-byte quantity aligned to 16 bytes or the access is not to Normal Inner Write-Back, Outer Write-Back Cacheable memory the access is not guaranteed to be single-copy atomic except at the byte access level.

For these instructions, the definition of an unaligned access is based on the size of the accessed elements, not the overall size of the memory access. This affects SIMD element and structure loads and stores, and also load/store pair instructions.

Load-Exclusive/ Store-Exclusive and Atomic instructions

For Load-Exclusive/Store-Exclusive, and Atomic instructions including those with acquire or acquire-release semantics:

When the value of `SCTLR_ELx.A` applicable to the current Exception level is 1, an Alignment fault is generated.

When the value of `SCTLR_ELx.A` applicable to the current Exception level is 0:

If [FEAT_LSE2](#) is not implemented, these instructions generate an Alignment fault if the address being accessed is not aligned to the size of the data structure being accessed.

If [FEAT_LSE2](#) is implemented, then:

- If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable memory, an unaligned access is performed.
- If all the bytes of the memory access do not lie within a 16-byte quantity aligned to 16-bytes, or the memory access is not to Normal Inner Write-Back, Outer Write-Back Cacheable memory, then it is a CONSTRAINED UNPREDICTABLE choice of either of the following:
 - An unaligned access is performed meeting all of the semantics of the instruction.
 - An Alignment fault is generated.

Where memory access is performed, then it is single-copy atomic.

For these instructions, the definition of an unaligned access is based on the overall access size.

If [FEAT_LS64](#) is implemented, when a single-copy atomic 64-byte instruction accesses a memory location that is not aligned to 64 bytes, an Alignment fault always occurs, regardless of the value of [SCTLR_ELx.A](#).

Non-atomic Load-Acquire/Store-Release instructions

For Load-Acquire/Store-Release instructions which do not have exclusive or atomic behaviors:

When the value of [SCTLR_ELx.A](#) applicable to the current Exception level is 1, an Alignment fault is generated.

When the value of [SCTLR_ELx.A](#) applicable to the current Exception level is 0:

If [FEAT_LSE2](#) is not implemented, then these instructions generate an Alignment fault if the address being accessed is not aligned to the size of the data structure being accessed.

If [FEAT_LSE2](#) is implemented, then:

- If the memory access is not to Normal Inner Write-Back or Outer Write-Back Cacheable memory, then it is a CONSTRAINED UNPREDICTABLE choice of either of the following:
 - An unaligned access is performed meeting all of the semantics of the instruction.
 - An Alignment fault is generated.
- If all of the bytes of the memory access do not lie within a 16-byte quantity aligned to 16 bytes then the following applies:
 - If [SCTLR_ELx.nAA](#) applicable to the current Exception level is 0 an Alignment fault is generated.
 - If [SCTLR_ELx.nAA](#) applicable to the current Exception level is 1 then an unaligned access is performed which is not guaranteed to be single-copy atomic except at the byte access level.

In this case, the architecture does not define the order of the different transactions of the access defined by the single instructions relative to each other.

Note

- Unaligned accesses typically take additional cycles to complete compared to a naturally-aligned access.
- An operation that is not single-copy atomic above the byte level can abort on any memory access that it makes and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the page boundary.

B2.6 Endian support

General description of endianness in the Arm architecture on page B2-162 describes the relationship between endianness and memory addressing in the Arm architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- *Instruction endianness* on page B2-163.
- *Data endianness* on page B2-163.
- *Endianness of memory-mapped peripherals* on page B2-164.

B2.6.1 General description of endianness in the Arm architecture

This section only describes memory addressing and the effects of endianness for data elements up to quadwords of 128 bits. However, this description can be extended to apply to larger data elements.

For an address A, *Figure B2-2 on page B2-162* shows, for big-endian and little-endian memory systems, the relationship between:

- The quadword at address A.
- The doubleword at address A and A+8.
- The words at addresses A, A+4, A+8, and A+12.
- The halfwords at addresses A, A+2, A+4, A+6, A+8, A+10, A+12, and A+14.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, A+7, A+8, A+9, A+10, A+11, A+12, A+13, A+14, and A+15.

The terms in *Figure B2-2 on page B2-162* have the following definitions:

- B_A** Byte at address A.
- HW_A** Halfword at address A.
- MSByte** Most significant byte.
- LSByte** Least significant byte.

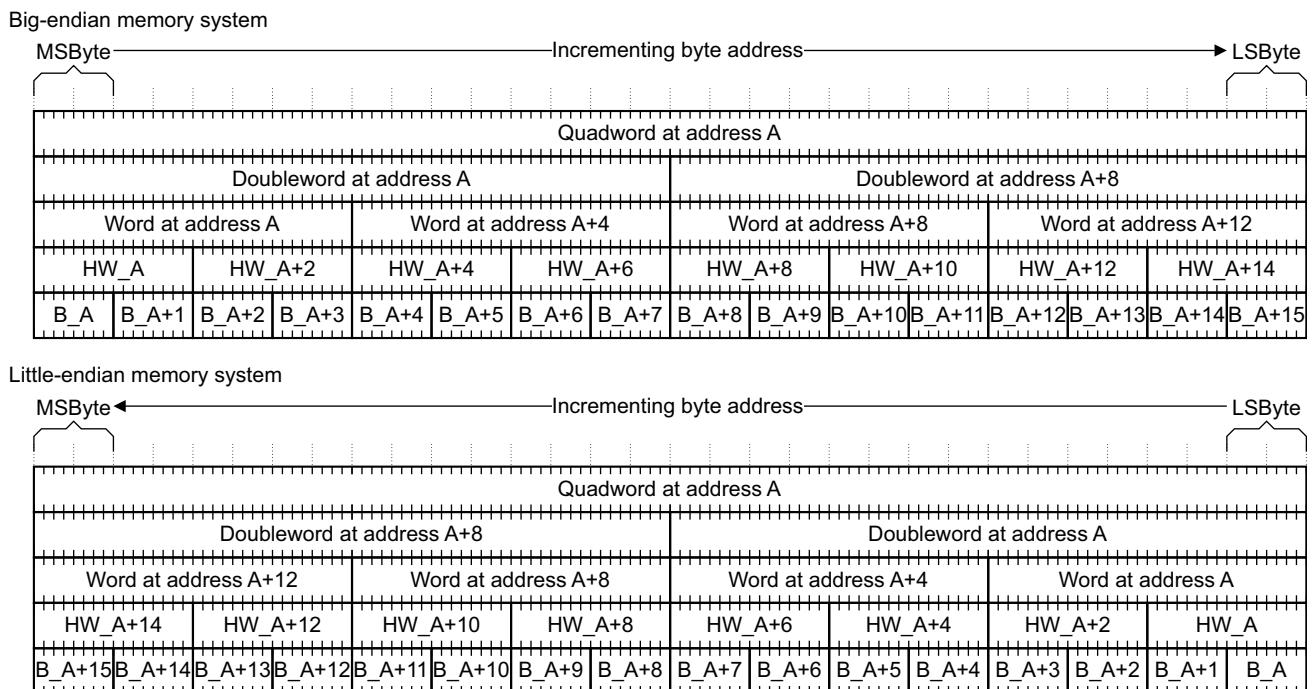

Figure B2-2 Endianness relationships

The big-endian and little-endian mapping schemes determine the order in which the bytes of a quadword, doubleword, word, or halfword are interpreted. For example, a load of a word from address 0x1000 always results in an access to the bytes at memory locations 0x1000, 0x1001, 0x1002, and 0x1003. The endianness mapping scheme determines the significance of these 4 bytes.

B2.6.2 Instruction endianness

In Armv8-A, A64 instructions have a fixed length of 32 bits and are always little-endian.

B2.6.3 Data endianness

[SCTLR_ELI.E0E](#), configurable at EL1 or higher, determines the data endianness for execution at EL0.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for SIMD element and data structure loads and stores. For more information, see [Endianness in SIMD operations on page B2-163](#).

———— Note ————

This means the Armv8 architecture introduces a requirement for 128-bit endian conversions.

Instructions to reverse bytes in a general-purpose register or a SIMD and floating-point register

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

[Table B2-2 on page B2-163](#) shows the instructions that provide this functionality:

Table B2-2 Byte reversal instructions

Function	Instructions	Notes
Reverse bytes in 32-bit word or words ^a	REV32	For use with general-purpose registers
Reverse bytes in whole register	REV	For use with general-purpose registers
Reverse bytes in 16-bit halfwords	REV16	For use with general-purpose registers
Reverse elements in doublewords, vector	REV64	For use with SIMD and floating-point registers
Reverse elements in words, vector	REV32	For use with SIMD and floating-point registers
Reverse elements in halfwords, vector	REV16	For use with SIMD and floating-point registers

a. Can operate on multiple words.

Endianness in SIMD operations

SIMD element load/store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used to load and store data correctly in both big-endian and little-endian systems.

For example:

```
LD1 {V0.4H}, [X1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in [Figure B2-3 on page B2-164](#). Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

Figure B2-3 SIMD byte order example

The `BigEndian()` pseudocode function determines the current endianness of the data.

The `BigEndianReverse()` pseudocode function reverses the endianness of a bitstring.

The `BigEndian()` and `BigEndianReverse()` functions are defined in [Chapter J1 Armv8 Pseudocode](#).

B2.6.4 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the Arm architecture must be little-endian.

Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a Cross Trigger Interface, see [Chapter H8 About the External Debug Registers](#).
- The memory-mapped register interface to the system level implementation of the Generic Timer, see [Chapter I2 System Level Implementation of the Generic Timer](#).
- A memory-mapped register interface to the Performance Monitors, see [Chapter I3 Recommended External Interface to the Performance Monitors](#).
- A memory-mapped register interface to the Activity Monitors, see [Chapter I4 Recommended External Interface to the Activity Monitors](#).
- Memory-mapped register interfaces to an Arm Generic Interface Controller, see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0*.
- The memory-mapped register interface to an Arm trace component. See, for example, the *ARM® Embedded Trace Macrocell Architecture Specification, ETMv4*.

B2.7 Memory types and attributes

In Armv8 the ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- [Normal memory on page B2-165](#).
- [Device memory on page B2-169](#).
- [Memory access restrictions on page B2-174](#).

B2.7.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform *Speculative* data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time.
- Writes to a memory location with the Normal memory type that is either Non-cacheable or Write-Through cacheable for both the Inner and Outer cacheability must reach the endpoint for that location in the memory system in finite time. Two writes to the same location, where at least one is using the Normal memory type, might be merged before they reach the endpoint unless there is an ordered-before relationship between the two writes.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register load/store instructions. See [Multi-register loads and stores that access Normal memory on page B2-169](#).

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
 - Read accesses can be repeated with no side-effects.
 - Repeated read accesses return the last value written to the resource being read.
 - Read accesses can fetch additional memory locations with no side-effects.
 - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
 - Unaligned accesses can be supported.
 - Accesses can be merged before accessing the target memory system.
- Normal memory allows speculative reads and may be affected by intermediate buffering and forwarding of data. If non-idempotent memory locations are mapped as Normal memory, the following may occur:
 - Memory accesses return UNKNOWN values.
 - UNPREDICTABLE effects on memory-mapped peripherals.
- An instruction that generates a sequence of accesses as described in [Atomicity in the Arm architecture on page B2-128](#) might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

For accesses to Normal memory, a DMB instruction is required to ensure the required ordering.

The following sections describe the other attributes for Normal memory:

- [Shareable Normal memory on page B2-166](#).

- [Non-shareable Normal memory](#) on page B2-167.
- [Cacheability attributes for Normal memory](#) on page B2-167.

See also:

- [Multi-register loads and stores that access Normal memory](#) on page B2-169.
- [Atomicity in the Arm architecture](#) on page B2-128.
- [Memory barriers](#) on page B2-146.
- [Concurrent modification and execution of instructions](#) on page B2-130.

Shareable Normal memory

A Normal memory location has a Shareability attribute that is one of:

- Inner Shareable, meaning it applies across the Inner Shareable shareability domain.
- Outer Shareable, meaning it applies across both the Inner Shareable and the Outer Shareable shareability domains.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, that hardware must enforce. They do not affect the coherency requirements of instruction fetches, see [Synchronization and coherency issues between data and instruction accesses](#) on page B2-158.

Note

- System designers can use the shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different processing elements.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

Shareable, Inner Shareable, and Outer Shareable Normal memory

The Arm architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
- The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

The details of the use of the shareability attributes are system-specific. [Example B2-1 on page B2-167](#) shows how they might be used.

Example B2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
 - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
 - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable shareability domain.

For shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

Cacheability attributes for Normal memory

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Through Cacheable.
- Write-Back Cacheable.
- Non-cacheable.

Also, for Write-Through Cacheable and Write-Back Cacheable Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

For more information, see [Cacheability, cache allocation hints, and cache transient hints on page D4-2640](#).

A memory location can be marked as having different cacheability attributes, for example when using aliases in a VA to PA mapping:

- If the attributes differ only in the cache allocation hint, this does not affect the behavior of accesses to that location.
- For other cases, see [Mismatched memory attributes on page B2-176](#).

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

- A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.
- A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.
- For accesses to Normal memory that is Non-cacheable, a DMB instruction introduces a [Barrier-ordered-before](#) relation on all accesses to a single peripheral or block of memory that is of IMPLEMENTATION DEFINED size. For more information, see [Ordering relations on page B2-137](#).

Note

Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the Arm architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the *inner* and the *outer* cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.
- An implementation might not have any outer cache.

[Example B2-2 on page B2-168](#), [Example B2-3 on page B2-169](#), and [Example B2-4 on page B2-169](#) describe the possible ways of implementing a system with three levels of cache, *level 1* (L1) to *level 3* (L3).

Note

- L1 cache is the level closest to the PE, see [Memory hierarchy on page B2-155](#).
- When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example B2-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 and L2 cache.
 - The Outer cacheability attribute applied to L3 cache.
-

Example B2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example B2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 cache.
 - The Outer cacheability attribute applied to L2 and L3 cache.
-

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more SIMD&FP registers from an Exception level, there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

B2.7.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for Armv8 Device memory are:

Gathering Identified as G or nG, see [Gathering on page B2-171](#).

Reordering Identified as R or nR, see [Reordering on page B2-172](#).

Early Write Acknowledgement

Identified as E or nE, see [Early Write Acknowledgement on page B2-173](#).

The Armv8 Device memory types are:

Device-nGnRnE Device non-Gathering, non-Reordering, No Early Write Acknowledgement.
Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.

Device-nGnRE Device non-Gathering, non-Reordering, Early Write Acknowledgement.
Equivalent to the Device memory type in earlier versions of the architecture.

Device-nGRE Device non-Gathering, Reordering, Early Write Acknowledgement.
Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.

Device-GRE Device Gathering, Reordering, Early Write Acknowledgement.
Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that [Speculative](#) accesses to Device-GRE memory is forbidden.

Collectively these are referred to as *any Device memory type*. Going down the list, the memory types are described as getting *weaker*; conversely the going up the list the memory types are described as getting *stronger*.

Note

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.
- The architecture does not require an implementation to distinguish between each of these memory types and Arm recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

The following exceptions to this apply:

- Reads generated by the SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.
- For Device memory with the Gathering attribute, reads generated by the LDNP instructions are permitted to access bytes that are not explicitly accessed by the instruction, provided that the bytes accessed are in a 128-byte window, aligned to 128-bytes, that contains at least one byte that is explicitly accessed by the instruction.
- Where a load or store instruction performs a sequence of memory accesses, as opposed to one single-copy atomic access as defined in the rules for single-copy atomicity, these accesses might occur multiple times as a result of executing the load or store instruction. See [Properties of single-copy atomic accesses on page B2-130](#).

Note

- An instruction that generates a sequence of accesses as described in [Atomicity in the Arm architecture on page B2-128](#) might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception, the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program only defines a single access. For this reason, Arm strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.
- Write speculation that is visible to other observers is prohibited for all memory types.

-
- A write to a memory location with any Device memory type completes in finite time.
 - If a value that would be returned from a read of a memory location with the Device memory type changes without an explicit memory write effect by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.
 - Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.
 - A memory location with any Device memory attribute cannot be allocated into a cache.
 - Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Two writes of Device memory type to the same location might be merged before they reach the endpoint, unless both writes have the non-Gathering attribute or there is an ordered-before relationship between the two writes.

- For accesses to any Device memory type, a DMB instruction introduces a [Barrier-ordered-before](#) relation on all accesses to a single peripheral or block of memory that is of implementation defined size. For more information, see [Ordering relations on page B2-137](#).
- If a memory location is not capable of supporting unaligned memory accesses, then an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.
- If a memory location is capable of supporting unaligned memory accesses, and such a memory location is marked as Device, then it is IMPLEMENTATION DEFINED whether an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.
- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as execute-never for all Exception levels.

———— **Note** —————

This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as execute-never for all Exception levels is a programming error.

———— **Note** —————

In the EL1&0 translation regime in systems where $HCR_EL2.TGE==1$ and $HCR_EL2.DC==0$, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes $ESR_EL2.ISS[24]$ to be 0.

See also [Memory access restrictions on page B2-174](#).

The memory types for translation table walks cannot be defined as any Device memory type within the TCR_ELx . For the EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the $HCR_EL2.PTW$ bit is 1, a stage 2 Permission fault is generated if a first stage translation table walk is made to any Device memory type.

———— **Note** —————

In general, making a translation table walk to any Device memory type is the result of a programming error.

For an instruction fetch from a memory location with the Device attribute that is not marked as execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

Gathering

In the Device memory attribute:

- G** Indicates that the location has the Gathering attribute.
- nG** Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

Note

This also applies to writebacks from the cache, whether caused by a *Natural eviction* or as a result of a cache maintenance instruction.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All accesses occur at their single-copy atomic sizes, except that there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by multi-register load/store instructions that generate more than one single-copy atomic access. See *Multi-register loads and stores that access Device memory* on page B2-174.

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

Note

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
 - The accesses are not separated by a DMB or DSB barrier that affects both of the accesses.
 - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
 - The accesses are not generated by a Store-Release instruction.
- The Arm architecture only defines programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the non-Gathering attribute.

An implementation is not permitted to perform an access with the non-Gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

Reordering

In the Device memory attribute:

- R** Indicates that the location has the Reordering attribute. Accesses to the location can be reordered within the same rules that apply to accesses to Normal Non-cacheable memory. All memory types with the Reordering attribute have the same ordering rules as accesses to Normal Non-cacheable memory, see *Ordering relations* on page B2-137.
- nR** Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

Note

Some interconnect fabrics, such as PCIe, perform very limited reordering, which is not important for the software usage. It is outside the scope of the Arm architecture to prohibit the use of a non-Reordering memory type with these interconnects.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.
- The Arm architecture only defines programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.
- The non-Reordering property is only required by the architecture to apply the order of arrival of accesses to a single memory-mapped peripheral of an IMPLEMENTATION DEFINED size, and is not required to have an impact on the order of observation of memory accesses to SDRAM. For this reason, there is no effect of the non-Reordering attribute on the ordering relations between accesses to different locations described in [Ordering relations on page B2-137](#) as part of the formal definition of the memory model.
- If the same memory location is mapped with different aliases, and different attribute values, these are a type of mismatched attribute. The different attributes could be:
 - A different Reordering attribute value.
 - A different Device memory attribute value.
 - When FEAT_XS is implemented, a different XS attribute value.

For information about the effects of accessing memory with mismatched attributes, see [Mismatched memory attributes on page B2-176](#).

An implementation:

- Is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.
- Is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses to one physical address with the non-Reordering attribute and accesses to a different physical address with the Reordering attribute.
- Access to one physical address with the non-Reordering attribute and access to a different physical address to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

The non-Reordering attribute has no effect on the ordering of cache maintenance instructions, even if the memory location specified in the instruction has the non-Reordering attribute.

Early Write Acknowledgement

In the Device memory attribute:

- E** Indicates that the location has the Early Write Acknowledgement attribute.
- nE** Indicates that the location has the No Early Write Acknowledgement attribute.

If the No Early Write Acknowledgement attribute is assigned for a Device memory location:

- For memory system endpoints where the system architecture in which the PE is operating requires that acknowledgement of a write comes from the endpoint, it is guaranteed that:
 - Only the endpoint of the write access returns a write acknowledgement of the access.

- No earlier point in the memory system returns a write acknowledgement.
- For memory system endpoints where the system architecture in which the PE is operating does not require that acknowledgement of a write comes from the endpoint, the acknowledgement of a write is not required to come from the endpoint.

———— **Note** —————

A write with the No Early Write Acknowledgement attribute assigned for a Device memory location is not expected to generate an abort in any situation where the equivalent write to the same location without the No Early Write Acknowledgement attribute assigned does not generate an abort.

This means that a DSB barrier instruction, executed by the PE that performed the write to the No Early Write Acknowledgement [Location](#), completes only after the write has reached its endpoint in the memory system.

Peripherals are an example of system endpoints that require that the acknowledgement of a write comes from the endpoint.

———— **Note** —————

- The Early Write Acknowledgement attribute only affects where the endpoint acknowledgement is returned from, and does not affect the ordering of arrival at the endpoint between accesses, which is determined by either the Device Reordering attribute, or the use of barriers to create order.
- The areas of the physical memory map for which write acknowledgement from the endpoint is required is outside the scope of the Arm Architecture definition and must be defined as part of the system architecture in which the PE is operating. In particular, regions of memory handled as PCIe configuration writes are expected to support write acknowledgement from the endpoint.
- Arm recognizes that not all areas of a physical memory map will be capable of supporting write acknowledgement from the endpoint. In particular, Arm expects that regions of memory handled as posted writes under PCIe will not support write acknowledgement from the endpoint.
- For maximum software compatibility, Arm strongly recommends that all peripherals for which standard software drivers expect that the use of a DSB instruction will determine that a write has reached its endpoint are placed in areas of the physical memory map that support write acknowledgement from the endpoint.

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register and generate more than one single-copy atomic access for that load or store, there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register, the order in which the registers are accessed is not defined by the architecture. This applies even to accesses to any type of Device memory.

For all instructions that load or store one or more SIMD and floating-point or SVE registers, and generate more than one single-copy atomic access for that load or store, there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by these load or store instructions, even for access to any type of Device memory.

B2.7.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For two explicit memory reads to any two adjacent bytes in memory, p and $p+1$, generated by the same instruction, and for two explicit writes to any two adjacent bytes in memory, p and $p+1$, that are generated by the same instruction:
 - The bytes p and $p+1$ must have the same memory type and Shareability attributes, otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an LD1, ST1, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.

- Except for possible differences in the cache allocation hints, Arm deprecates having different cacheability attributes for bytes p and $p+1$.

For the permitted CONSTRAINED UNPREDICTABLE behavior, see [Crossing a page boundary with different memory types or Shareability attributes on page K1-8413](#).

- If the accesses of an instruction that causes multiple accesses to any type of Device memory cross an address boundary that corresponds to the smallest implemented translation granule, then behavior is CONSTRAINED UNPREDICTABLE, and [Crossing a peripheral boundary with a Device access on page K1-8414](#) describes the permitted behaviors. For this reason, it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.

———— **Note** —————

- The boundary referred to is between two Device memory regions that are both of the size of the smallest implemented translation granule and aligned to the size of the smallest implemented translation granule.
 - This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.
 - Arm expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.
-

B2.8 Mismatched memory attributes

Memory attributes are controlled by privileged software. For more information, see [Chapter D5 The AArch64 Virtual Memory System Architecture](#).

Physical memory locations are accessed with *mismatched attributes* if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type: Device-nGnRnE, Device-nGnRE, Device-nGRE, Device-GRE or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.
- When [FEAT_XS](#) is implemented, XS attribute.

Collectively these are referred to as memory attributes.

If [FEAT_MTE2](#) is implemented, accesses to a location which use a common definition of the memory attributes but the Tagged attribute of that location differs do not cause a mismatched access to occur.

———— Note —————

In this document, the terms *location* and *memory location* refer to any byte within the current coherency granule and are used interchangeably.

When a memory [Location](#) is accessed with mismatched attributes, the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory [Location](#) might be lost. This means:
 - A read of the memory [Location](#) by one agent might not return the value most recently written to that memory [Location](#) by the same agent.
 - Multiple writes to the memory [Location](#) by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory [Location](#).
- There might be a loss of properties derived from the memory type, as described in later bullets in this section.
- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory [Location](#) do not use consistent memory attributes, the Exclusives monitor state becomes UNKNOWN.
- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of *Speculative* read accesses.
- Prohibition on Gathering.
- Prohibition on reordering.

For the following situations, when a physical memory [Location](#) is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. Any agent that reads that memory [Location](#) using the same common definition of the Memory type, Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:
 - All writes are performed to an alias of the memory [Location](#) that uses the same definition of the Memory type, Shareability and Cacheability attributes.
 - Either:
 - In the EL1&0 translation regime, [HCR_EL2.MI0CNCE](#) has a value of 0.
 - All aliases with write permission have the Inner Cacheability attribute the same as the Outer Cacheability attribute.

- Either:
 - All writes are performed to an alias of the memory [Location](#) that has Inner Cacheability and Outer Cacheability attributes both as Non-cacheable.
 - All aliases to a memory [Location](#) use a definition of the Shareability attributes that encompasses all the agents with permission to access the [Location](#).
- 2. The possible software-visible effects caused by mismatched attributes for a memory [Location](#) are defined more precisely if all of the mismatched attributes define the memory [Location](#) as one of:
 - Any Device memory type.
 - Inner Non-cacheable, Outer Non-cacheable Normal memory.

In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:

- Possible loss of properties derived from the memory type when multiple agents attempt to access the memory [Location](#).
- Possible reordering of memory transactions to the same memory [Location](#) with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting DMB barrier instructions between accesses to the same memory [Location](#) that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory location all assign the same shareability attribute to a [Location](#) that has a cacheable attribute, any loss of uniprocessor semantics, ordering, or coherency within a shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable [Locations](#) between agents in different shareability domains. This means:
 - Before writing to a cacheable [Location](#) not using the Write-Back attribute, software must invalidate, or clean, a [Location](#) from the caches if any agent might have written to the [Location](#) with the Write-Back attribute. This avoids the possibility of overwriting the [Location](#) with stale data.
 - After writing to a cacheable [Location](#) with the Write-Back attribute, software must clean the [Location](#) from the caches, to make the write visible to external memory.
 - Before reading the [Location](#) with a cacheable attribute, software must invalidate, or clean and invalidate, the [Location](#) from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.
 - Executing a DMB barrier instruction, with scope that applies to the common shareability of the accesses, between any accesses to the same cacheable [Location](#) that use different attributes.

In all cases:

- [Location](#) refers to any byte within the current coherency granule.
- A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
- In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see [Ordering and completion of data and instruction cache instructions on page D4-2656](#).

Note

With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same [Location](#), and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

2. If the mismatched attributes for a [Location](#) mean that multiple cacheable accesses to the [Location](#) might be made with different shareability attributes, then uniprocessor semantics, ordering, and coherency are guaranteed only if:
 - Software running on a PE cleans and invalidates a [Location](#) from cache before and after each read or write to that [Location](#) by that PE.
 - A DMB barrier with scope that covers the full shareability of the accesses is placed between any accesses to the same memory [Location](#) that use different attributes.

———— **Note** —————

The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a [Location](#), and the accesses from the different agents have different memory attributes associated with the [Location](#), the Exclusives monitor state becomes UNKNOWN.

Arm strongly recommends that software does not use mismatched attributes for aliases of the same [Location](#). An implementation might not optimize the performance of a system that uses mismatched aliases.

———— **Note** —————

As described in [Non-cacheable accesses and instruction caches on page D4-2643](#), a non-cacheable access is permitted to be cached in an instruction cache, despite the fact that a non-cacheable access is not permitted to be cached in a unified cache. Despite this, when cacheable and non-cacheable aliases exist for memory which is executable, these must be treated as mismatched aliases to avoid coherency issues from the data or unified caches that might hold entries that will be brought into the instruction caches.

B2.9 Synchronization and semaphores

Armv8 provides non-blocking synchronization of shared memory, using *synchronization primitives*. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal memory and to any type of Device memory.

———— **Note** —————

Use of the Armv8 synchronization primitives scales for multiprocessing system designs.

Table B2-3 on page B2-179 shows the synchronization primitives and the associated CLREX instruction.

Table B2-3 Synchronization primitives and associated instruction, A64 instruction set

Transaction size	Additional semantics	Load-Exclusive ^a	Store-Exclusive ^a	Other ^a
Byte	-	LDXRB	STXRB	-
	Load-Acquire/Store-Release	LDAXRB	STLXRB	-
Halfword	-	LDXRH	STXRH	-
	Load-Acquire/Store-Release	LDAXRH	STLXRH	-
Register ^b	-	LDXR	STXR	-
	Load-Acquire/Store-Release	LDAXR	STLXR	-
Pair ^b	-	LDXP	STXP	-
	Load-Acquire/Store-Release	LDAXP	STLXP	-
None	Clear-Exclusive	-	-	CLREX

a. Instruction in the A64 instruction set.

b. A register instruction operates on a doubleword if accessing an X register, or on a word if accessing a W register. A pair instruction operates on two doublewords if access X registers, or on two words if accessing W registers.

Except for the row showing the CLREX instruction, the two instructions in a single row are a Load-Exclusive/Store-Exclusive instruction pair. The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address x is:

- The Load-Exclusive instruction reads a value from memory address x .
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address x only if no other observer, process, or thread has performed a more recent store to address x . The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see *Marking and the size of the marked memory block* on page B2-185. A Store-Exclusive instruction to any address in the marked block clears the marking.

———— **Note** —————

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- *Exclusive access instructions and Non-shareable memory locations* on page B2-180.
- *Exclusive access instructions and Shareable memory locations* on page B2-181.
- *Marking and the size of the marked memory block* on page B2-185.
- *Context switch support* on page B2-186.

- [Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-186.](#)
- [Use of WFE and SEV instructions by spin-locks on page B2-189.](#)

B2.9.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the shareability attribute is Non-shareable, the exclusive access instructions rely on a *local Exclusives monitor*, or *local monitor*, that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
 - If the store took place, the status value is 0.
 - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

When an Exclusives monitor is in the Exclusive Access state, the monitor is *set*.

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

When an Exclusives monitor is in the Open Access state, the monitor is *clear*.

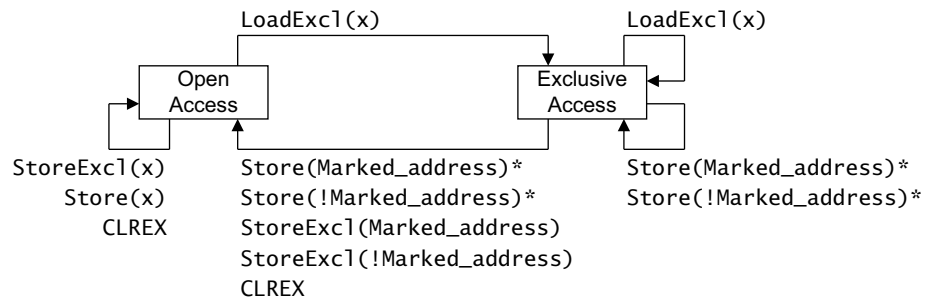

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a PA that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a PA that is marked as Exclusive Access by its local monitor, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked PA causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the PA to be marked.

Figure B2-4 on page B2-181 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.

Operations marked * are possible alternative IMPLEMENTATION DEFINED options.

In the diagram: LoadExc1 represents any Load-Exclusive instruction
StoreExc1 represents any Store-Exclusive instruction
Store represents any other store instruction.

Any LoadExc1 operation updates the marked address to the most significant bits of the address x used for the operation.

Figure B2-4 Local monitor state machine diagram

For more information about marking, see [Marking and the size of the marked memory block on page B2-185](#).

———— **Note** —————

For the local monitor state machine, as shown in [Figure B2-4 on page B2-181](#):

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any PA, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the Store or StoreExc1 is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in [Figure B2-4 on page B2-181](#).

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in [Figure B2-4 on page B2-181](#).
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in [Figure B2-4 on page B2-181](#) must not indefinitely delay forward progress of execution.

B2.9.2 Exclusive access instructions and Shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.

For shareable memory locations, exclusive access instructions rely on:

- A *local monitor* for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in *Exclusive access instructions and Non-shareable memory locations on page B2-180*, except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
 - Updating memory.
 - Returning a status value of 0.

The local monitor can ignore accesses from other PEs in the system.

- A *global monitor* that marks a PA as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
 - Can hold at least one marked block.
 - Maintains a state machine for each marked block it can hold.

———— **Note** —————

For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, see *Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-186*.

———— **Note** —————

The global monitor can either reside within the PE, or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

———— **Note** —————

If *FEAT_MTE2* is implemented, it is IMPLEMENTATION DEFINED whether a global monitor monitors access to the Tag PA space. For more information, see *Chapter D6 Memory Tagging Extension*.

———— **Note** —————

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all Arm PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport's Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global Exclusives monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

The architecture only requires that *Conventional memory* mapped in this way supports this functionality.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive or a Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an External abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Data Abort Fault status code of `ESR_ELx.DFSC = 110101`.

If the IMPLEMENTATION DEFINED MMU fault is generated for the EL1&0 translation regime then:

- If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.
- Otherwise, the fault is a second stage fault and the exception is taken to EL2.

The priority of this fault is IMPLEMENTATION DEFINED.

- The instruction is treated as a NOP.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN. In this case, if the store exclusive instruction is a store exclusive pair of 64-bit quantities, then the two quantities being stored might not be stored atomically.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by Arm PEs is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

Operation of the global Exclusives monitor

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the PA of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other PA that has been marked by the requesting PE.

————— **Note** —————

The global monitor only supports a single outstanding exclusive access to shareable memory per PE.

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the PA accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
 - A status value of 0 is returned to a register to acknowledge the successful store.
 - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.

- If the address accessed is marked for exclusive access in the global monitor state machine for any other PE, then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
 - A status value of 1 is returned to a register to indicate that the store failed.
 - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different PA is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
 - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
 - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means that it responds to:

- Accesses generated by PE(n).
- Accesses generated by the other observers in the shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

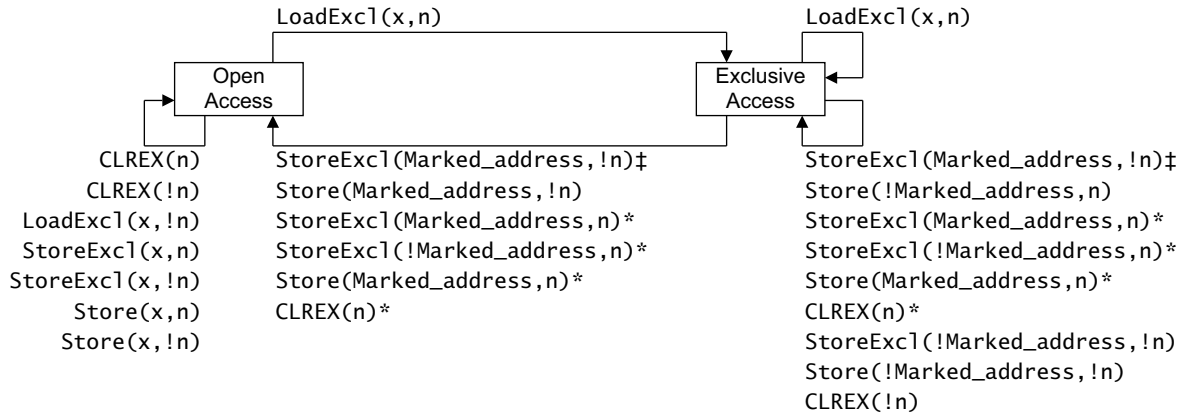

A global monitor:

- In the Exclusive Access state is *set*.
- In the Open Access state is *clear*.

Clear global monitor event

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see [Mechanisms for entering a low-power state on page D1-2536](#).

[Figure B2-5 on page B2-185](#) shows the state machine for PE(n) in a global monitor.

‡StoreExc1(Marked_address,!n) clears the monitor only if the StoreExc1 updates memory

Operations marked * are possible alternative IMPLEMENTATION DEFINED options.

In the diagram: LoadExc1 represents any Load-Exclusive instruction

StoreExc1 represents any Store-Exclusive instruction

Store represents any other store instruction.

Any LoadExc1 operation updates the marked address to the most significant bits of the address x used for the operation.

Figure B2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking, see [Marking and the size of the marked memory block](#) on page B2-185.

———— **Note** —————

For the global monitor state machine, as shown in [Figure B2-5 on page B2-185](#):

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, [Figure B2-5 on page B2-185](#) only shows how the operations by (!n) cause state transitions of the state machine for PE(n).
- A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.
- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.
- It is IMPLEMENTATION DEFINED:
 - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
 - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

B2.9.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size 2^a bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the *Exclusives reservation granule*. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4-512 words.

———— **Note** —————

This definition means that the Exclusives reservation granule is:

- 4 words in an implementation where a is 4.
- 512 words in an implementation where a is 11.

For example, in an implementation where a is 4, a successful LDXR of address 0x341B4 defines a marked block using bits[47:4] of the address. This means that the four words of memory from 0x341B0 to 0x341BF are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see [CTR_EL0](#). Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

B2.9.4 Context switch support

An exception return clears the local monitor. As a result, performing a CLREX instruction as part of a context switch is not required in most situations.

———— **Note** —————

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

B2.9.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDXP/STXP pair or a LDXR/STXR pair. To support different implementations of these functions, software must follow the notes and restrictions given here.

The following notes describe the use of a LoadExc1/StoreExc1 instruction pair, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in [Table B2-3 on page B2-179](#). In this context, a LoadExc1/StoreExc1 pair comprises two instructions in the same thread of execution:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the `IsExclusiveLocal()` function. If the target VA of a StoreExc1 is different from the VA of the preceding LoadExc1 instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
 - The StoreExc1 either passes or fails, the status value returned by the StoreExc1 is UNKNOWN, and the states of the local and global monitors for that PE are UNKNOWN.

———— **Note** —————

This means the StoreExc1 might pass for some instances of a LoadExc1/StoreExc1 pair with mismatched addresses, and fail for other instances of a LoadExc1/StoreExc1 pair with mismatched addresses.

- The data at the address accessed by the LoadExc1, and at the address accessed by the StoreExc1, is UNKNOWN.

This means software can rely on a LoadExc1/StoreExc1 pair to eventually succeed only if the LoadExc1 and the StoreExc1 are executed with the same VA.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a StoreExc1 instruction is the same as the transaction size of the preceding LoadExc1 instruction executed in that thread. If the transaction size of a StoreExc1 instruction is different from the preceding LoadExc1 instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
 - The StoreExc1 either passes or fails, and the status value returned by the StoreExc1 is UNKNOWN.

———— **Note** —————

This means the StoreExc1 might pass for some instances of a LoadExc1/StoreExc1 pair with mismatched transaction sizes, and fail for other instances of a LoadExc1/StoreExc1 pair with mismatched transaction sizes.

- The block of data of the size of the larger of the transaction sizes used by the LoadExc1/StoreExc1 pair at the address accessed by the LoadExc1/StoreExc1 pair, is UNKNOWN.

This means software can rely on a LoadExc1/StoreExc1 pair to eventually succeed only if the LoadExc1 and the StoreExc1 have the same transaction size.

- An implementation of the LoadExc1 and StoreExc1 instructions can require that, in any thread of execution, the StoreExc1 instruction accesses the same number of registers as the preceding LoadExc1 instruction executed in that thread. If the StoreExc1 instruction accesses a different number of registers than the preceding LoadExc1 instruction in the same thread of execution, behavior is *CONSTRAINED UNPREDICTABLE*. As a result, software can rely on an LoadExc1/StoreExc1 pair to eventually succeed only if they access the same number of registers. For more information, see *CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers* on page B2-189.
- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the Tag Checked property of a memory access due to a StoreExc1 instruction is the same as the Tag Checked property of a memory access by the preceding LoadExc1 instruction executed in that thread. If the Tag Checked property of memory accesses due to a LoadExc1/StoreExc1 pair in the same thread of execution differ, behavior can be *CONSTRAINED UNPREDICTABLE* with the following behavior:
 - The StoreExc1 either passes or fails, and the status value returned by the StoreExc1 is UNKNOWN.

———— **Note** —————

This means the StoreExc1 might pass for some instances of such a LoadExc1/StoreExc1 pair, and fail for other instances of such a LoadExc1/StoreExc1 pair.

- The data at the address accessed by the LoadExc1/StoreExc1 pair is UNKNOWN.

This means software can rely on a LoadExc1/StoreExc1 pair to eventually succeed only if the memory is accessed with the same Tag Checked property.

- LoadExc1/StoreExc1 loops are guaranteed to make forward progress only if, for any LoadExc1/StoreExc1 loop within a single thread of execution, the software meets all of the following conditions:
 - 1 Between the Load-Exclusive and the Store-Exclusive, there are no explicit memory effects, preloads, direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.
 - 2 Between the Store-Exclusive returning a failing result and the retry of the corresponding Load-Exclusive:
 - There are no stores or PRFM instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive.
 - There are no loads or preloads to any address within the Exclusives reservation granule accessed by the Store-Exclusive that use a different VA alias to that address.
 - There are no direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.
 - All loads and stores are to a block of contiguous virtual memory of not more than 512 bytes in size.

The Exclusives monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the Exclusives monitor. However, it is permissible for the LoadExc1/StoreExc1 loop not to make forward progress if a different thread is repeatedly doing any of the following in a tight loop:

- Performing stores to a PA covered by the Exclusives monitor.

- Prefetching with intent to write to a PA covered by the Exclusives monitor.
- Executing data cache clean, data cache invalidate, or data cache clean and invalidate instructions to a PA covered by the Exclusives monitor.
- Executing instruction cache invalidate all instructions.
- Executing instruction cache invalidate by VA instructions to a PA covered by the Exclusives monitor.
- Executing TLB maintenance to a PA covered by the Exclusives monitor.
- Implementations can benefit from keeping the LoadExc1 and StoreExc1 operations close together in a single thread of execution. This minimizes the likelihood of the Exclusives monitor state being cleared between the LoadExc1 instruction and the StoreExc1 instruction. Therefore, for best performance, Arm strongly recommends a limit of 128 bytes between LoadExc1 and StoreExc1 instructions in a single thread of execution.
- The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, Arm recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusives reservation granule. This is a performance guideline rather than a functional requirement.
- After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN.
- For the memory location accessed by a LoadExc1/StoreExc1 pair, if the memory attributes for a StoreExc1 instruction are different from the memory attributes for the preceding LoadExc1 instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. Where this occurs because the translation of the accessed address changes between the LoadExc1 instruction and the StoreExc1 instruction, the CONSTRAINED UNPREDICTABLE behavior is as follows:
 - The StoreExc1 either passes or fails, and the status value returned by the StoreExc1 is UNKNOWN.

———— **Note** —————

This means the StoreExc1 might pass for some instances of a LoadExc1/StoreExc1 pair with changed memory attributes, and fail for other instances of a LoadExc1/StoreExc1 pair with changed memory attributes.

—————
 - The data at the address accessed by the StoreExc1 is UNKNOWN.

———— **Note** —————

Another bullet point in this list covers the case where the memory attributes of a LoadExc1/StoreExc1 pair differ as a result of using different VAs with different attributes that point to the same PA.

—————
- The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same shareability domain as the PE executing the cache maintenance instruction, as determined by the shareability domain of the address being maintained.

———— **Note** —————

Arm strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

—————
- If the mapping of the VA to PA is changed between the LoadExc1 instruction and the STREX instruction, and the change is performed using a break-before-make sequence as described in [Using break-before-make when updating translation table entries on page D5-2818](#), if the StoreExc1 is performed after another write to the same PA as the StoreExc1, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the StoreExc1 will not pass its monitor check.

———— **Note** —————

 - The TLB invalidation will clear either the local or global monitor.
 - The PA will be checked between the LoadExc1 and StoreExc1.

—————

- The Exclusive Access state for an address accessed by a PE can be lost as a result of a PFRM PST* instruction to the same PA executed by another PE. This means that a very high rate of repeated PFRM PST* accesses to a memory location might impede the forward progress of another PE.
- If FEAT_MTE2 is implemented, and if a Tag Unchecked store exclusive instruction would not perform the store and return a status value of 1, it is CONSTRAINED UNPREDICTABLE whether:
 - The instruction is a Tag Checked access,
 - The instruction is an Tag Unchecked access.

For more information, see [Chapter D6 Memory Tagging Extension](#).

Note

In the event of repeatedly-contending LoadExc1/StoreExc1 instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers

As stated in this section, an implementation can require that the instructions of a Load-Exclusive/Store-Exclusive pair access the same number of registers. In such an implementation, this means behavior is CONSTRAINED UNPREDICTABLE if, in a single thread of execution, either:

- An LDXP instruction of two 32-bit quantities is followed by an STXR instruction of one 64-bit quantity at the same address.
- An LDXR instruction of one 64-bit quantity is followed by an STXP instruction of two 32-bit quantities at the same address.

In these cases, the CONSTRAINED UNPREDICTABLE behavior must be one of:

- The STXP or STXR instruction generates an external Data Abort.
- The STXP or STXR instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data Abort Fault status code of `ESR_ELx.DFSC = 0b110101`.
- The STXP or STXR instruction always fails, returning a status of 1.
- The STXP or STXR instruction always passes, returning a status of 0.
- This STXP or STXR instruction has the same pass or fail behavior that it would have had if the instruction had used the same size and number of registers as the preceding LDXR or LDXP instruction.

B2.9.6 Use of WFE and SEV instructions by spin-locks

Armv8 provides Wait For Event, Send Event, and Send Event Local instructions, WFE, SEV, and SEVL, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in [Wait for Event mechanism and Send event on page D1-2536](#). However, in Armv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

Note

This is equivalent to issuing an SEVL instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an SEV instruction after clearing a spinlock.

Part C

The AArch64 Instruction Set

Chapter C1

The A64 Instruction Set

This chapter describes the A64 instruction set. It contains the following sections:

- *About the A64 instruction set* on page C1-194.
- *Structure of the A64 assembler language* on page C1-195.
- *Address generation* on page C1-202.
- *Instruction aliases* on page C1-205.

C1.1 About the A64 instruction set

The A64 instruction set is the instruction set supported in the AArch64 Execution state.

All A64 instructions have a width of 32 bits. The A64 encoding structure breaks down into the following functional groups:

- A miscellaneous group of branch instructions, exception generating instructions, and System instructions.
- Data-processing instructions associated with general-purpose registers. These instructions are supported by two *functional groups*, depending on whether the operands:
 - Are all held in registers.
 - Include an operand with a constant immediate value.
- Load and store instructions associated with the general-purpose register file and the SIMD and floating-point register file.
- SIMD and scalar floating-point data-processing instructions that operate on the SIMD and floating-point registers.

The encoding hierarchy within a functional group breaks down as follows:

- A functional group consists of a set of related instruction classes. [A64 instruction set encoding on page C4-284](#) provides an overview of the instruction encodings in the form of a list of instruction classes within their functional groups.
- An instruction class consists of a set of related instruction forms. Instruction forms are documented in one of two alphabetic lists:
 - The load, store, and data-processing instructions associated with the general-purpose registers, together with those in the other instruction classes. See [Chapter C6 A64 Base Instruction Descriptions](#).
 - The load, store, and data-processing instructions associated with the SIMD and floating-point support. See [Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions](#).
- An instruction form might support a single instruction syntax. Where an instruction supports more than one syntax, each syntax is an *instruction variant*. Instruction variants can occur because of differences in:
 - The size or format of the operands.
 - The register file used for the operands.
 - The addressing mode used for load/load/store memory operands.

Instruction variants might also arise as the result of other factors.

Instruction variants are described in the instruction description for the individual instructions.

A64 instructions have a regular bit encoding structure:

- 5-bit register operand fields at fixed positions within the instruction. For general-purpose register operands, the values 0-30 select one of 31 registers. The value 31 is used as a special case that can:
 - Indicate use of the current stack pointer, when identifying a load/store base register or in a limited set of data-processing instructions. See [The stack pointer registers on page D1-2463](#).
 - Indicate the value zero when used as a source register operand.
 - Indicate discarding the result when used as a destination register operand.

For SIMD and floating-point register access, the value used selects one of 32 registers.

- Immediate bits that provide constant data-processing values or address offsets are placed in contiguous bitfields. Some computed values in instruction variants use one or more immediate bitfields together with the secondary encoding bitfields.

All encodings that are not fully defined are described as unallocated. An attempt to execute an unallocated instruction is UNDEFINED, unless the behavior is otherwise defined in this Manual.

C1.2 Structure of the A64 assembler language

The following sections describe the A64 assembler syntax:

- [General requirements on page C1-195.](#)
- [Common syntax terms on page C1-195.](#)
- [Instruction Mnemonics on page C1-197.](#)
- [Condition code on page C1-197.](#)
- [Register names on page C1-198.](#)

C1.2.1 General requirements

The letter W denotes a general-purpose register holding a 32-bit word, and X denotes a general-purpose register holding a 64-bit doubleword.

An A64 assembler recognizes both uppercase and lowercase variants of the instruction mnemonics and register names, but not mixed case variants. An A64 disassembler can output either uppercase or lowercase mnemonics and register names. Program and data labels are case-sensitive.

The A64 assembly language does not require the # character to introduce constant immediate operands, but an assembler must allow immediate values introduced with or without the # character.

In [Example C1-1 on page C1-197](#), the sequence // is used as a comment leader and A64 assemblers are encouraged to accept this syntax.

C1.2.2 Common syntax terms

The following syntax terms are used frequently throughout the A64 instruction set description.

UPPER	Text in upper-case letters is fixed. Text in lower-case letters is variable. This means that register name Xn indicates that the X is required, followed by a variable register number, for example X29.
< >	Any text enclosed by angle braces, < >, is a value that the user supplies. Subsequent text might supply additional information.
{ }	Any item enclosed by curly brackets, { }, is optional. A description of the item and how its presence or absence affects the instruction is normally supplied by subsequent text. In some cases curly braces are actual symbols in the syntax, for example when they surround a register list. These cases are called out in the surrounding text.
[]	Any items enclosed by square brackets, [], constitute a list of alternative characters. A single one of the characters can be used in that position and the subsequent text describes the meaning of the alternatives. In some case the square brackets are part of the syntax itself, such as addressing modes or vector elements. These cases are called out in the surrounding text.
a b	Alternative words are separated by a vertical bar, , and can be surrounded by parentheses to delimit them. For example, U(ADD SUB)W represents UADDW or USUBW.
±	This indicates an optional + or - sign. If neither is used then + is assumed.
uimmn	An n-bit unsigned, positive, immediate value.
simmn	An n-bit two's complement, signed immediate value, where n includes the sign bit.
SP	See Register names on page C1-198.
Wn	See Register names on page C1-198.
WSP	See Register names on page C1-198.
WZR	See Register names on page C1-198.
Xn	See Register names on page C1-198.

XZR See [Register names](#) on page C1-198

C1.2.3 Instruction Mnemonics

The A64 assembly language overloads instruction mnemonics and distinguishes between the different forms of an instruction based on the operand types. For example, the following ADD instructions all have different opcodes. However, the programmer must only remember one mnemonic, as the assembler automatically chooses the correct opcode based on the operands. The disassembler follows the same procedure in reverse.

Example C1-1 ADD instructions with different opcodes

```
ADD W0, W1, W2           // add 32-bit register
ADD X0, X1, X2           // add 64-bit register
ADD X0, X1, W2, SXTW    // add 64-bit extended register
ADD X0, X1, #42         // add 64-bit immediate
```

C1.2.4 Condition code

The A64 ISA has some instructions that set Condition flags or test Condition codes or both. For information about instructions that set the Condition flags or use the condition mnemonics, see [Condition flags and related instructions on page C6-873](#).

Table C1-1 on page C1-197 shows the available Condition codes.

Table C1-1 Condition codes

cond	Mnemonic	Meaning (integer)	Meaning (floating-point) ^a	Condition flags
0000	EQ	Equal	Equal	Z == 1
0001	NE	Not equal	Not equal or unordered	Z == 0
0010	CS or HS	Carry set	Greater than, equal, or unordered	C == 1
0011	CC or LO	Carry clear	Less than	C == 0
0100	MI	Minus, negative	Less than	N == 1
0101	PL	Plus, positive or zero	Greater than, equal, or unordered	N == 0
0110	VS	Overflow	Unordered	V == 1
0111	VC	No overflow	Ordered	V == 0
1000	HI	Unsigned higher	Greater than, or unordered	C == 1 && Z == 0
1001	LS	Unsigned lower or same	Less than or equal	!(C == 1 && Z == 0)
1010	GE	Signed greater than or equal	Greater than or equal	N == V
1011	LT	Signed less than	Less than, or unordered	N! = V
1100	GT	Signed greater than	Greater than	Z == 0 && N == V
1101	LE	Signed less than or equal	Less than, equal, or unordered	!(Z == 0 && N == V)
1110	AL	Always	Always	Any
1111	NV ^b	Always	Always	Any

a. Unordered means at least one NaN operand.

b. The Condition code NV exists only to provide a valid disassembly of the 0b1111 encoding, otherwise its behavior is identical to AL.

C1.2.5 Register names

This section describes the AArch64 registers. It contains the following subsections:

- [General-purpose register file and zero register and stack pointer on page C1-198.](#)
- [SIMD and floating-point register file on page C1-199.](#)
- [SIMD and floating-point scalar register names on page C1-199.](#)
- [SIMD vector register names on page C1-199.](#)
- [SIMD vector element names on page C1-200.](#)

General-purpose register file and zero register and stack pointer

The 31 general-purpose registers in the general-purpose register file are named R0-R30 and encoded in the instruction register fields with values 0-30. In a general-purpose register field the value 31 represents either the current stack pointer or the zero register, depending on the instruction and the operand position.

When the registers are used in a specific instruction variant, they must be qualified to indicate the operand data size, 32 bits or 64 bits, and the data size of the instruction.

When the data size is 32 bits, the lower 32 bits of the register are used and the upper 32 bits are ignored on a read and cleared to zero on a write.

[Table C1-2 on page C1-198](#) shows the qualified names for registers, where n is a register number 0-30.

Table C1-2 Naming of general-purpose registers, the zero register, and the stack pointer

Name	Size	Encoding	Description
Wn	32 bits	0-30	General-purpose register 0-30
Xn	64 bits	0-30	General-purpose register 0-30
WZR	32 bits	31	Zero register
XZR	64 bits	31	Zero register
WSP	32 bits	31	Current stack pointer
SP	64 bits	31	Current stack pointer

This list gives more information about the instruction arguments shown in [Table C1-2 on page C1-198](#):

- The names Xn and Wn both refer to the same general-purpose register, Rn.
- There is no register named W31 or X31.
- The name SP represents the stack pointer for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as a read or write of the current stack pointer. When instructions do not interpret this operand encoding as the stack pointer, use of the name SP is an error.
- The name WSP represents the current stack pointer in a 32-bit context.
- The name XZR represents the zero register for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as returning zero when read or discarding the result when written. When instructions do not interpret this operand encoding as the zero register, use of the name XZR is an error.
- The name WZR represents the zero register in a 32-bit context.
- The architecture does not define a specific name for general-purpose register R30 to reflect its role as the link register on procedure calls. However, an A64 assembler must always use W30 and X30 for this purpose, and additional software names might be defined as part of the Procedure Call Standard, see *Procedure Call Standard for the Arm 64-bit Architecture*.

SIMD and floating-point register file

The 32 registers in the SIMD and floating-point register file, V0-V31, hold floating-point operands for the scalar floating-point instructions, and both scalar and vector operands for the SIMD instructions. When they are used in a specific instruction form, the names must be further qualified to indicate the data shape, that is the data element size and the number of elements or lanes within the register. A similar requirement is placed on the general-purpose registers. See [General-purpose register file and zero register and stack pointer on page C1-198](#).

———— Note —————

The data type is described by the instruction mnemonics that operate on the data. The data type is not described by the register name. The data type is the interpretation of bits within each register or vector element, whether these are integers, floating-point values, polynomials, or cryptographic hashes.

SIMD and floating-point scalar register names

SIMD and floating-point instructions that operate on scalar data only access the lower bits of a SIMD and floating-point register. The unused high bits are ignored on a read and cleared to 0 on a write.

[Table C1-3 on page C1-199](#) shows the qualified names for accessing scalar SIMD and floating-point registers. The letter *n* denotes a register number between 0 and 31.

Table C1-3 SIMD and floating-point scalar register names

Size	Name
8 bits	B _n
16 bits	H _n
32 bits	S _n
64 bits	D _n
128 bits	Q _n

SIMD vector register names

If a register holds multiple data elements on which arithmetic is performed in a parallel, SIMD, manner, then a qualifier describes the vector shape. The vector shape is the element size and the number of elements or lanes. If the element size in bits multiplied by the number of lanes does not equal 128, then the upper 64 bits of the register are ignored on a read and cleared to zero on a write.

[Table C1-4 on page C1-199](#) shows the SIMD vector register names. The letter *n* denotes a register number between 0 and 31.

Table C1-4 SIMD vector register names

Shape	Name
8 bits × 8 lanes	V _n .8B
8 bits × 16 lanes	V _n .16B
16 bits × 4 lanes	V _n .4H
16 bits × 8 lanes	V _n .8H
32 bits × 2 lanes	V _n .2S

Table C1-4 SIMD vector register names (continued)

Shape	Name
32 bits × 4 lanes	Vn.4S
64 bits × 1 lane	Vn.1D
64 bits × 2 lanes	Vn.2D

SIMD vector element names

Appending a constant, zero-based element index to the register name inside square brackets indicates that a single element from a SIMD and floating-point register is used as a scalar operand. The number of lanes is not represented, as it is not encoded in the instruction and can only be inferred from the index value.

Table C1-5 on page C1-200 shows the vector register names and the element index. The letter *i* denotes the element index.

Table C1-5 Vector register names with element index

Size	Name
8 bits	Vn.B[i]
16 bits	Vn.H[i]
32 bits	Vn.S[i]
64 bits	Vn.D[i]

An assembler must accept a fully qualified SIMD register name if the number of lanes is greater than the index value. See *SIMD vector register names* on page C1-199. For example, an assembler must accept all of the following forms as the name for the 32-bit element in bits [63:32] of the SIMD and floating-point register V9:

```
V9.S[1]    //standard disassembly
V9.2S[1]   //optional number of lanes
V9.4S[1]   //optional number of lanes
```

———— Note —————

The SIMD and floating-point register element name Vn.S[0] is not equivalent to the scalar SIMD and floating-point register name Sn. Although they represent the same bits in the register, they select different instruction encoding forms, either the vector element or the scalar form.

SIMD vector register list

Where an instruction operates on multiple SIMD and floating-point registers, for example vector load/store structure and table lookup operations, the registers are specified as a list enclosed by curly braces. This list consists of either a sequence of registers separated by commas, or a register range separated by a hyphen. The registers must be numbered in increasing order, modulo 32, in increments of one. The hyphenated form is preferred for disassembly if there are more than two registers in the list and the register number are increasing. The following examples are equivalent representations of a set of four registers V4 to V7, each holding four lanes of 32-bit elements:

```
{ V4.4S - V7.4S }           //standard disassembly
{ V4.4S, V5.4S, V6.4S, V7.4S } //alternative representation
```

SIMD vector element list

Registers in a list can also have a vector element form. For example, the LD4 instruction can load one element into each of four registers, and in this case the index is appended to the list as follows:

```
{ V4.S - V7.S }[3]         //standard disassembly
```

{ V4.4S, V5.4S, V6.4S, V7.4S }[3] //alternative with optional number of lanes

C1.3 Address generation

The A64 instruction set supports 64-bit virtual addresses (VAs). The valid VA range is determined by the following factors:

- The size of the implemented virtual address space.
- *Memory Management Unit* (MMU) configuration settings.

Limits on the VA size mean that the most significant bits of the virtual address do not hold valid address bits. These unused bits can hold:

- A tag, see [Address tagging in AArch64 state on page D5-2676](#).
- If `FEAT_PAAuth` is implemented, a Pointer authentication code (PAC), see [Pointer authentication in AArch64 state on page D5-2678](#).

For more information on memory management and address translation, see [Chapter D5 The AArch64 Virtual Memory System Architecture](#).

C1.3.1 Register indexed addressing

The A64 instruction set allows a 64-bit index register to be added to the 64-bit base register, with optional scaling of the index by the access size. Additionally it allows for sign-extension or zero-extension of a 32-bit value within an index register, followed by optional scaling.

C1.3.2 PC-relative addressing

The A64 instruction set has support for position-independent code and data addressing:

- PC-relative literal loads have an offset range of $\pm 1\text{MB}$.
- Process state flag and compare based conditional branches have a range of $\pm 1\text{MB}$. Test bit conditional branches have a restricted range of $\pm 32\text{KB}$.
- Unconditional branches, including branch and link, have a range of $\pm 128\text{MB}$.

PC-relative load/store operations, and address generation with a range of $\pm 4\text{GB}$ can be performed using two instructions.

C1.3.3 Load/store addressing modes

Load/store addressing modes in the A64 instruction set require a 64-bit base address from a general-purpose register X0-X30 or the current stack pointer, SP, with an optional immediate or register offset. [Table C1-6 on page C1-202](#) shows the assembler syntax for the complete set of load/store addressing modes.

Table C1-6 A64 Load/store addressing modes

Addressing Mode	Offset		
	Immediate	Register	Extended Register
Base register only (no offset)	[base{, #0}]	-	-
Base plus offset	[base{, #imm}]	[base, Xm{, LSL #imm}]	[base, Wm, (S U)XT(X W) {#imm}]
Pre-indexed	[base, #imm]!	-	-
Post-indexed	[base], #imm	[base], Xm ^a	-
Literal (PC-relative)	label	-	-

a. The post-indexed by register offset mode can be used with the SIMD load/store structure instructions described in [Load/store Vector on page C3-233](#). Otherwise the post-indexed by register offset mode is not available.

Some types of load/store instruction support only a subset of the load/store addressing modes listed in [Table C1-6 on page C1-202](#). Details of the supported modes are as follows:

- Base plus offset addressing means that the address is the value in the 64-bit base register plus an offset.
- Pre-indexed addressing means that the address is the sum of the value in the 64-bit base register and an offset, and the address is then written back to the base register.
- Post-indexed addressing means that the address is the value in the 64-bit base register, and the sum of the address and the offset is then written back to the base register.
- Literal addressing means that the address is the value of the 64-bit program counter for this instruction plus a 19-bit signed word offset. This means that it is a 4 byte aligned address within $\pm 1\text{MB}$ of the address of this instruction with no offset. Literal addressing can only be used for loads of at least 32 bits and for prefetch instructions. The PC cannot be referenced using any other addressing modes. The syntax for labels is specific to individual toolchains.
- An immediate offset can be unsigned or signed, and scaled or unscaled, depending on the type of load/store instruction. When the immediate offset is scaled it is encoded as a multiple of the transfer size, although the assembly language always uses a byte offset, and the assembler or disassembler performs the necessary conversion. The usable byte offsets therefore depend on the type of load/store instruction and the transfer size.

[Table C1-7 on page C1-203](#) shows the offset and the type of load/store instruction.

Table C1-7 Immediate offsets and the type of load/store instruction

Offset bits	Sign	Scaling	Write-Back	Load/store type
0	-	-	-	Exclusive/acquire/release
7	Signed	Scaled	Optional	Register pair
9	Signed	Unscaled	Optional	Single register
12	Unsigned	Scaled	No	Single register

- A register offset means that the offset is the 64 bits from a general-purpose register, X_m , optionally scaled by the transfer size, in bytes, if `LSL #imm` is present and where `imm` must be equal to $\log_2(\text{transfer_size})$. The `SXTX` extend/shift option is functionally equivalent to `LSL`, but the `LSL` option is preferred in source code.
- An extended register offset means that offset is the bottom 32 bits from a general-purpose register W_m , sign-extended or zero-extended to 64 bits, and then scaled by the transfer size if so indicated by `#imm`, where `imm` must be equal to $\log_2(\text{transfer_size})$. An assembler must accept W_m or X_m as an extended register offset, but W_m is preferred for disassembly.
- Generating an address lower than the value in the base register requires a negative signed immediate offset or a register offset holding a negative value.
- When stack alignment checking is enabled by system software and the base register is the SP, the current stack pointer must be initially quadword aligned, that is aligned to 16 bytes. Misalignment generates a Stack Alignment fault. The offset does not have to be a multiple of 16 bytes unless the specific load/store instruction requires this. SP cannot be used as a register offset.

Address calculation

General-purpose arithmetic instructions can calculate the result of most addressing modes and write the address to a general-purpose register or, in most cases, to the current stack pointer.

Table C1-8 on page C1-204 shows the arithmetic instructions that can compute addressing modes.

Table C1-8 Arithmetic instructions to compute addressing modes

Addressing Form	Offset		
	Immediate	Register	Extended Register
Base register (no offset)	MOV Xd SP, base	-	-
Base plus offset	ADD Xd SP, base, #imm or SUB Xd SP, base, #imm	ADD <Xd SP>, base, Xm{, LSL#imm}	ADD <Xd SP>, base, Wm, (S U)XT(W H B X) {#imm}
Pre-indexed	-	-	-
Post-indexed	-	-	-
Literal (PC-relative)	ADR Xd, label	-	-

Note

- For the 64-bit base plus register offset form, the UXTX mnemonic is an alias for the LSL shift option, but LSL is preferred for disassembly. Similarly the SXTX extend/shift option is functionally equivalent to the LSL option, but the LSL option is preferred in source code.
- To calculate a base plus immediate offset the ADD instructions defined in [Arithmetic \(immediate\) on page C3-242](#) accept an unsigned 12-bit immediate offset, with an optional left shift by 12. This means that a single ADD instruction cannot support the full range of byte offsets available to a single register load/store with a scaled 12-bit immediate offset. For example, a quadword LDR effectively has a 16-bit byte offset. To calculate an address with a byte offset that requires more than 12 bits it is necessary to use two ADD instructions. The following example shows this:

```
ADD Xd, base, #(imm & 0xFFF)
ADD Xd, Xd, #(imm>>12), LSL #12
```
- To calculate a base plus extended register offset, the ADD instructions defined in [Arithmetic \(extended register\) on page C3-248](#) provide a superset of the addressing mode that also supports sign-extension or zero-extension of a byte or halfword value with any shift amount between 0 and 4, for example:

```
ADD Xd, base, Wm, SXTW #3 // Xd = base + (SignExtend(Wm) LSL 3)
ADD Xd, base, Wm, UXTH #4 // Xd = base + (ZeroExtend(Wm<15:0>) LSL 4)
```
- If the same extended register offset is used by more than one load/store instruction, then, depending on the implementation, it might be more efficient to calculate the extended and scaled intermediate result just once, and then reuse it as a simple register offset. The extend and scale calculation can be performed using the SBFIZ and UBFIZ bitfield instructions defined in [Bitfield move on page C3-244](#), for example:

```
SBFIZ Xd, Xm, #3, #32 //Xd = "Wm, SXTW #3"
UBFIZ Xd, Xm, #4, #16 //Xd = "Wm, UXTH #4"
```

C1.4 Instruction aliases

Some instructions have an associated *architecture alias* that is used for disassembly of the encoding when the associated conditions are met. Architecture alias instructions are included in the alphabetic lists of instruction types and clearly presented as an alias form in descriptions for the individual instructions.

Chapter C2

About the A64 Instruction Descriptions

This chapter describes the *instruction descriptions* contained in [Chapter C6 A64 Base Instruction Descriptions](#) and [Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions](#).

It contains the following sections:

- [Understanding the A64 instruction descriptions on page C2-208](#).
- [General information about the A64 instruction descriptions on page C2-211](#).

C2.1 Understanding the A64 instruction descriptions

Each instruction description in [Chapter C6](#) and [Chapter C7](#) has the following content:

1. A title.
2. An introduction to the instruction.
3. The instruction encoding or encodings.
4. Any alias conditions.
5. A list of the assembler symbols for the instruction.
6. Pseudocode describing how the instruction operates.
7. Notes, if applicable.

The following sections describe each of these.

C2.1.1 The title

The title of an instruction description includes the base mnemonic for the instruction.

If different forms of an instruction use the same base mnemonic, each form has its own description. In this case, the title is the mnemonic followed by a short description of the instruction form in parentheses. This is most often used when an operand is an immediate value in one instruction form, but is a register in another form.

For example, in [Chapter C6](#) there are the following titles for different forms of the ADD instruction:

- [ADD \(extended register\) on page C6-880.](#)
- [ADD \(immediate\) on page C6-883.](#)
- [ADD \(shifted register\) on page C6-885.](#)

C2.1.2 An introduction to the instruction

This briefly describes the function of the instruction. The introduction is not a complete description of the instruction, and it is not definitive. If there is any conflict between it and the more detailed information that follows it, the more detailed information takes priority.

C2.1.3 The instruction encoding or encodings

This shows the instruction encoding diagram, or if the instruction has more than one encoding, shows all of the encoding diagrams. Each diagram has a subheading.

For example, for load and store instructions, the subheadings might be:

- Post-index.
- Pre-index.
- Unsigned offset.

Each diagram numbers the bits from 31 to 0. The diagram for an instruction at address A shows, from left to right, the bytes at addresses $A+3$, $A+2$, $A+1$, and A .

There might be variants of an encoding, if the *assembler syntax prototype* differs depending on the value in one or more of the encoding fields. In this case, each variant has a subheading that describes the variant and shows the distinguishing field value or values in parentheses. For example, in [Chapter C6](#) there are the following subheadings for variants of the ADC instruction encoding:

- 32-bit variant (sf = 0).
- 64-bit variant (sf = 1).

The assembler syntax prototype for an encoding or variant of an encoding shows how to form a complete assembler source code instruction that assembles to the encoding. Unless otherwise stated, the prototype is also the preferred syntax for a disassembler to disassemble the encoding to. Disassemblers are permitted to omit optional symbols that represent the default value of a field or set of fields, to produce more readable disassembled code, provided that the output re-assembles to the same encoding.

Each encoding diagram, and its associated assembler syntax prototypes, is followed by encoding-specific pseudocode that translates the fields of that encoding into inputs for the encoding-independent pseudocode that describes the operation of the instruction. See [Pseudocode describing how the instruction operates on page C2-210](#).

C2.1.4 Any alias conditions, if applicable

This is an optional part of an instruction description. If included, it describes the set of conditions for which an alternative mnemonic and its associated assembler syntax prototypes are preferred for disassembly by a disassembler. It includes a link to the alias instruction description that defines the alternative syntax. The alias syntax and the original syntax can be used interchangeably in the assembler source code.

Arm recommends that if a disassembler outputs the alias syntax, it consistently outputs the alias syntax.

C2.1.5 A list of the assembler symbols for the instruction

The *Assembler symbols* subsection of the instruction description contains a list of the symbols that the assembler syntax prototype or prototypes use, if any.

In assembler syntax prototypes, the following conventions are used:

- < > Angle brackets. Any symbol enclosed by these is a name or a value that the user supplies. For each symbol, there is a description of what the symbol represents. The description usually also specifies which encoding field or fields encodes the symbol.
- { } Brace brackets. Any symbols enclosed by these are optional. For each optional symbol, there is a description of what the symbol represents and how its presence or absence is encoded.

In some assembler syntax prototypes, some brace brackets are mandatory, for example if they surround a register list. When the use of brace brackets is mandatory, they are separated from other syntax items by one or more spaces.
- # This usually precedes a numeric constant. All uses of # are optional in A64 assembler source code. Arm recommends that disassemblers output the # where the assembler syntax prototype includes it.
- +/- This indicates an optional + or - sign. If neither is coded, + is assumed.

Single spaces are used for clarity, to separate syntax items. Where a space is mandatory, the assembler syntax prototype shows two or more consecutive spaces.

Any characters not shown in this conventions list must be coded exactly as shown in the assembler syntax prototype. Apart from brace brackets, the characters shown are used as part of a meta-language to define the architectural assembler syntax for an instruction encoding or alias, but have no architecturally defined significance in the input to an assembler or in the output from a disassembler.

The following symbol conventions are used:

- <Xn> The 64-bit name of a general-purpose register (X0-X30) or the zero register (XZR).
- <Wn> The 32-bit name of a general-purpose register (W0-W30) or the zero register (WZR).
- <Xn|SP> The 64-bit name of a general-purpose register (X0-X30) or the current stack pointer (SP).
- <Wn|WSP> The 32-bit name of a general-purpose register (W0-W30) or the current stack pointer (WSP).
- <Bn>, <Hn>, <Sn>, <Dn>, <Qn> The 8, 16, 32, 64 or 128-bit name of a SIMD and floating-point register in a scalar context as described in section [Register names on page C1-198](#).
- <Vn> The name of a SIMD and floating-point register name in a vector context as described in [Register names on page C1-198](#).

If the description of a symbol specifies that the symbol is a register, the description might also specify that the range of permitted registers is extended or restricted. It also specifies any differences from the default rules for such fields.

———— **Note** —————

[Register names on page C1-198](#) provides the A64 register names.

C2.1.6 Pseudocode describing how the instruction operates

The *Operation* subsection of the instruction description contains this pseudocode.

It is encoding-independent pseudocode that provides a precise description of what the instruction does.

———— **Note** —————

For a description of Arm pseudocode, see [Appendix K14 Arm Pseudocode Definition](#). This appendix also describes the execution model for an instruction.

C2.1.7 Notes, if applicable

If applicable, other notes about the instruction appear under additional subheadings.

C2.2 General information about the A64 instruction descriptions

This section provides general information about the A64 instruction descriptions. Some of this information also applies to System register descriptions, for example the terms defined in [Fixed values in AArch64 instruction and System register descriptions on page C2-211](#) apply to the AArch64 descriptions throughout this manual. The following subsections provide this information:

- [Execution of instructions in debug state on page C2-211](#).
- [Fixed values in AArch64 instruction and System register descriptions on page C2-211](#).
- [Modified immediate constants in A64 instructions on page C2-212](#).

C2.2.1 Execution of instructions in debug state

In general, except for the instructions described in [Debug state on page C3-218](#), the A64 instruction descriptions do not indicate any differences in the behavior of the instruction if it is executed in Debug state. For this information, see [Executing instructions in Debug state on page H2-7349](#).

———— **Note** —————

For many instructions, execution is unchanged in Debug state. [Executing instructions in Debug state on page H2-7349](#) identifies these instructions,

C2.2.2 Fixed values in AArch64 instruction and System register descriptions

This section summarizes the terms used to describe fixed values in AArch64 register and instruction descriptions. The [Glossary](#) gives full descriptions of these terms, and each entry in this section includes a link to the corresponding [Glossary](#) entry.

———— **Note** —————

In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the [Glossary](#).

The following terms are used to describe bits or fields with fixed values:

RAZ Read-As-Zero. See [Read-As-Zero \(RAZ\)](#).

In diagrams, a RAZ bit can be shown as 0.

(0), RES0 Reserved, [Should-Be-Zero \(SBZ\)](#) or [RES0](#).

In instruction encoding diagrams, and sometimes in other descriptions, (0) indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 0.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (0)(0)(0) or as (000).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. See the [Glossary](#) definition of [RES0](#) for more information.

———— **Note** —————

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES0 fields,

The (0) and RES0 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The [Glossary](#) definitions cover these cases.

RAO Read-As-One. See [Read-As-One \(RAO\)](#).

In diagrams, a RAO bit can be shown as 1.

(1), RES1 Reserved, [Should-Be-One \(SBO\)](#) or [RES1](#).

In instruction encoding diagrams, and sometimes in other descriptions, (1) indicates an SBO bit. If the bit is set to 0, behavior is CONstrained UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 1.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (1)(1)(1) or as (111).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. See the [Glossary](#) definition of RES1 for more information.

———— **Note** —————

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES1 fields,

The (1) and RES1 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The [Glossary](#) definitions cover these cases.

C2.2.3 Modified immediate constants in A64 instructions

It contains the following subsections:

- [Modified immediate constants in A64 floating-point instructions on page C2-212.](#)

Modified immediate constants in A64 floating-point instructions

[Table C2-1 on page C2-212](#) shows the immediate constants available in FMOV (scalar, immediate) and FMOV (vector, immediate) floating-point instructions.

Table C2-1 A64 Floating-point modified immediate constants

Data type	immediate	Constant ^a
F16	abcdefgh	aBbbcdef gh000000
F32	abcdefgh	aBbbbbbc defgh000 00000000 00000000
F64	abcdefgh	aBbbbbbb bbcdefgh 00000000 00000000 00000000 00000000 00000000 00000000

a. In this column, B = NOT(b). The bit pattern represents the floating-point number $(-1)^S \times 2^{exp} \times mantissa$, where $S = \text{UInt}(a)$, $exp = \text{UInt}(\text{NOT}(b):c:d) - 3$ and $mantissa = (16 + \text{UInt}(e:f:g:h)) / 16$.

The immediate value shown in the table is either:

- The value of the imm8 field for an FMOV (scalar, immediate) instruction, see [FMOV \(scalar, immediate\) on page C7-1824.](#)
- The value obtained by concatenating the a:b:c:d:e:f:g:h fields for an FMOV (vector, immediate) instruction, see [FMOV \(vector, immediate\) on page C7-1817.](#)

Table C2-2 on page C2-213 shows the floating-point constant values encoded in the b:c:d:e:f:g:h fields of the FMOV (vector, immediate) instruction.

Table C2-2 Floating-point constant values

efgh	bcd							
	000	001	010	011	100	101	110	111
0000	2.0	4.0	8.0	16.0	0.125	0.25	0.5	1.0
0001	2.125	4.25	8.5	17.0	0.1328125	0.265625	0.53125	1.0625
0010	2.25	4.5	9.0	18.0	0.140625	0.28125	0.5625	1.125
0011	2.375	4.75	9.5	19.0	0.1484375	0.296875	0.59375	1.1875

Operation of modified immediate constants, floating-point instructions

For an A64 floating-point instruction that uses a modified immediate constant, the operation described by the [VFPEExpandImm\(\)](#) pseudocode function returns the value of the immediate constant.

Chapter C3

A64 Instruction Set Overview

This chapter provides an overview of the A64 instruction set. It contains the following sections:

- *Branches, Exception generating, and System instructions* on page C3-216.
- *Loads and stores* on page C3-224.
- *Data processing - immediate* on page C3-242.
- *Data processing - register* on page C3-247.
- *Data processing - SIMD and floating-point* on page C3-255.

For a structured breakdown of instruction groups by encoding, see [Chapter C4 A64 Instruction Set Encoding](#).

C3.1 Branches, Exception generating, and System instructions

This section describes the branch, exception generating, and System instructions. It contains the following subsections:

- [Conditional branch](#) on page C3-216.
- [Unconditional branch \(immediate\)](#) on page C3-216.
- [Unconditional branch \(register\)](#) on page C3-217.
- [Exception generation and return](#) on page C3-217.
- [System register instructions](#) on page C3-218.
- [System instructions](#) on page C3-218.
- [Hint instructions](#) on page C3-219.
- [Barriers and CLREX instructions](#) on page C3-219.
- [Pointer authentication instructions](#) on page C3-220.

For information about the encoding structure of the instructions in this instruction group, see [Branches, Exception Generating and System instructions](#) on page C4-289.

———— Note —————

Software must:

- Use only BLR or BL to perform a nested subroutine call when that subroutine is expected to return to the immediately following instruction, that is, the instruction with the address of the BLR or BL instruction incremented by four.
- Use only RET to perform a subroutine return, when that subroutine is expected to have been entered by a BL or BLR instruction.
- Use only B, BR, or the instructions listed in [Table C3-1 on page C3-216](#) to perform a control transfer that is not a subroutine call or subroutine return described in this *Note*.

C3.1.1 Conditional branch

Conditional branches change the flow of execution depending on the current state of the Condition flags or the value in a general-purpose register. See [Table C1-1 on page C1-197](#) for a list of the Condition codes that can be used for cond.

[Table C3-1 on page C3-216](#) shows the Conditional branch instructions.

Table C3-1 Conditional branch instructions

Mnemonic	Instruction	Branch offset range from the PC	See
B.cond	Branch conditionally	±1MB	B.cond on page C6-920
CBNZ	Compare and branch if nonzero	±1MB	CBNZ on page C6-954
CBZ	Compare and branch if zero	±1MB	CBZ on page C6-955
TBNZ	Test bit and branch if nonzero	±32KB	TBNZ on page C6-1485
TBZ	Test bit and branch if zero	±32KB	TBZ on page C6-1486

C3.1.2 Unconditional branch (immediate)

Unconditional branch (immediate) instructions change the flow of execution unconditionally by adding an immediate offset with a range of ±128MB to the value of the program counter that fetched the instruction. The BL instruction also writes the address of the sequentially following instruction to general-purpose register, X30.

Table C3-2 on page C3-217 shows the Unconditional branch instructions with an immediate branch offset.

Table C3-2 Unconditional branch instructions (immediate)

Mnemonic	Instruction	Immediate branch offset range from the PC	See
B	Branch unconditionally	±128MB	B on page C6-921
BL	Branch with link	±128MB	BL on page C6-934

C3.1.3 Unconditional branch (register)

Unconditional branch (register) instructions change the flow of execution unconditionally by setting the program counter to the value in a general-purpose register. The BLR instruction also writes the address of the sequentially following instruction to general-purpose register X30. The RET instruction behaves identically to BR, but provides an additional hint to the PE that this is a return from a subroutine. Table C3-3 on page C3-217 shows Unconditional branch instructions that jump directly to an address held in a general-purpose register.

Table C3-3 Unconditional branch instructions (register)

Mnemonic	Instruction	See
BLR	Branch with link to register	BLR on page C6-935
BR	Branch to register	BR on page C6-938
RET	Return from subroutine	RET on page C6-1282

C3.1.4 Exception generation and return

This section describes the following exceptions:

- [Exception generating on page C3-217.](#)
- [Exception return on page C3-218.](#)
- [Debug state on page C3-218.](#)

Exception generating

Table C3-4 on page C3-217 shows the Exception generating instructions.

Table C3-4 Exception generating instructions

Mnemonic	Instruction	See
BRK	Breakpoint Instruction	BRK on page C6-941
HLT	Halt Instruction	HLT on page C6-1034
HVC	Generate exception targeting Exception level 2	HVC on page C6-1035
SMC	Generate exception targeting Exception level 3	SMC on page C6-1316
SVC	Generate exception targeting Exception level 1	SVC on page C6-1470

Exception return

Table C3-5 on page C3-218 shows the Exception return instructions.

Table C3-5 Exception return instructions

Mnemonic	Instruction	See
ERET	Exception return using current ELR and SPSR	ERET on page C6-1026

Debug state

Table C3-6 on page C3-218 shows the Debug state instructions.

Table C3-6 Debug state instructions

Mnemonic	Instruction	See
DCPS1	Debug switch to Exception level 1	DCPS1 on page C6-1009
DCPS2	Debug switch to Exception level 2	DCPS2 on page C6-1010
DCPS3	Debug switch to Exception level 3	DCPS3 on page C6-1011
DRPS	Debug restore PE state	DRPS on page C6-1015

C3.1.5 System register instructions

For detailed information about the System register instructions, see [Chapter C5 The A64 System Instruction Class](#).
 Table C3-7 on page C3-218 shows the System register instructions.

Table C3-7 System register instructions

Mnemonic	Instruction	See
MRS	Move System register to general-purpose register	MRS on page C6-1236
MSR	Move general-purpose register to System register	MSR (register) on page C6-1240
	Move immediate to PE state field	MSR (immediate) on page C6-1237

C3.1.6 Instructions with register argument

For detailed information about instructions with register argument, see [Chapter C6 A64 Base Instruction Descriptions](#). Table C3-8 on page C3-218 shows the instructions with register argument.

Table C3-8 Instructions with register argument

Mnemonic	Instruction	See
WFET	Wait for event with Timeout	WFET on page C6-1513
WFIT	Wait for interrupt with Timeout	WFIT on page C6-1515

C3.1.7 System instructions

For detailed information about the System instructions, see [Chapter C5 The A64 System Instruction Class](#).

Table C3-9 on page C3-219 shows the System instructions.

Table C3-9 System instructions

Mnemonic	Instruction	See
SYS	System instruction	SYS on page C6-1482
SYSL	System instruction with result	SYSL on page C6-1484
IC	Instruction cache maintenance	IC on page C6-1036 and Table C5-1 on page C5-399
DC	Data cache maintenance	DC on page C6-1007 and Table C5-1 on page C5-399
AT	Address translation	AT on page C6-911 and Table C5-3 on page C5-401
TLBI	TLB Invalidate	TLBI on page C6-1487 and Table C5-4 on page C5-402

C3.1.8 Hint instructions

Table C3-10 on page C3-219 shows the Hint instructions.

Table C3-10 Hint instructions

Mnemonic	Instruction	See
NOP	No operation	NOP on page C6-1254
YIELD	Yield hint	YIELD on page C6-1519
WFE	Wait for event	WFE on page C6-1512
WFI	Wait for interrupt	WFI on page C6-1514
SEV	Send event	SEV on page C6-1312
SEVL	Send event local	SEVL on page C6-1313
HINT	Unallocated hint	HINT on page C6-1032
DGH	Data Gathering Hint	DGH on page C6-1012

C3.1.9 Barriers and CLREX instructions

Table C3-11 on page C3-219 shows the barrier and CLREX instructions.

Table C3-11 Barriers and CLREX instructions

Mnemonic	Instruction	See
CLREX	Clear Exclusives monitor	CLREX on page C6-970
DMB	Data memory barrier	DMB on page C6-1013
DSB	Data synchronization barrier	DSB on page C6-1016
ISB	Instruction synchronization barrier	ISB on page C6-1039

For more information about DSB, DMB, and ISB, see [Memory barriers on page B2-146](#).

Table C3-12 on page C3-220 shows the speculation and synchronization barriers. If these instructions are not implemented, then these instructions execute as a NOP.

Table C3-12 Speculation and synchronization barriers

Mnemonic	Instruction	See
CSDB	Consumption of Speculative Data Barrier	CSDB on page C6-994
ESB	Error synchronization barrier	ESB on page C6-1028
PSB CSYNC	Profiling synchronization barrier	PSB CSYNC on page C6-1278
PSSBB	Physical Speculative Store Bypass Barrier	PSSBB on page C6-1279
SB	Speculation Barrier	SB on page C6-1298
SSBB	Speculative Store Bypass Barrier	SSBB on page C6-1322
TSB CSYNC	Trace Synchronization Barrier	TSB CSYNC on page C6-1490

For more information about:

- CSDB, PSSBB, SB, SSBB, TSB CSYNC, see [Memory barriers on page B2-146](#).
- ESB, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*.
- PSB CSYNC, see [Chapter D9 The Statistical Profiling Extension](#).

C3.1.10 Pointer authentication instructions

FEAT_PAAuth adds support for pointer authentication, see [Pointer authentication in AArch64 state on page D5-2678](#). This functionality includes the A64 instructions described in this section. These instructions fall into two groups, see:

- [Basic pointer authentication instructions on page C3-220](#).
- [Combined instructions that include pointer authentication on page C3-222](#).

Basic pointer authentication instructions

Each of these instructions only performs an operation that supports pointer authentication.

Table C3-13 on page C3-220 shows the instructions that add a *Pointer Authentication Code* (PAC) to the address in a register:

Table C3-13 Instructions that add a PAC

Mnemonic	Instruction	See
PACIASP	Add PAC to instruction address using APIAKey_EL1 and SP	PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA on page C6-1264
PACIAZ	Add PAC to instruction address using APIAKey_EL1 and zero	
PACIA1716	Add PAC to instruction address X17 using APIAKey_EL1 and X16	
PACIBSP	Add PAC to instruction address using APIBKey_EL1 and SP	PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB on page C6-1267
PACIBZ	Add PAC to instruction address using APIBKey_EL1 and zero	
PACIB1716	Add PAC to instruction address X17 using APIBKey_EL1 and X16	
PACIA	Add PAC to instruction address using APIAKey_EL1 , registers	PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA on page C6-1264

Table C3-13 Instructions that add a PAC (continued)

Mnemonic	Instruction	See
PACDA	Add PAC to data address using APDAKey_EL1 , registers	PACDA , PACDZA on page C6-1261
PACIB	Add PAC to instruction address using APIBKey_EL1 , registers	PACIB , PACIB1716 , PACIBSP , PACIBZ , PACIZB on page C6-1267
PACDB	Add PAC to data address using APDBKey_EL1 , registers	PACDB , PACDZB on page C6-1262
PACIZA	Add PAC to instruction address using APIAKey_EL1 , register and zero	PACIA , PACIA1716 , PACIASP , PACIAZ , PACIZA on page C6-1264
PACDZA	Add PAC to data address using APDAKey_EL1 , register and zero	PACDA , PACDZA on page C6-1261
PACIZB	Add PAC to instruction address using APIBKey_EL1 , register and zero	PACIB , PACIB1716 , PACIBSP , PACIBZ , PACIZB on page C6-1267
PACDZB	Add PAC to data address using APDBKey_EL1 , register and zero	PACDB , PACDZB on page C6-1262
PACGA	Add generic PAC using APGAKey_EL1 , registers	PACGA on page C6-1263

[Table C3-14 on page C3-221](#) shows the instructions that authenticate a PAC in a register:

Table C3-14 Instructions that authenticate a PAC

Mnemonic	Instruction	See
AUTIASP	Authenticate PAC for instruction address using APIAKey_EL1 and SP	AUTIA , AUTIA1716 , AUTIASP , AUTIAZ , AUTIZA on page C6-915
AUTIAZ	Authenticate PAC for instruction address using APIAKey_EL1 and zero	
AUTIA1716	Authenticate PAC for instruction address X17 using APIAKey_EL1 and X16	
AUTIBSP	Authenticate PAC for instruction address using APIBKey_EL1 and SP	AUTIB , AUTIB1716 , AUTIBSP , AUTIBZ , AUTIZB on page C6-917
AUTIBZ	Authenticate PAC for instruction address using APIBKey_EL1 and zero	
AUTIB1716	Authenticate PAC for instruction address X17 using APIBKey_EL1 and X16	
AUTIA	Authenticate PAC for instruction address using APIAKey_EL1 , registers	AUTIA , AUTIA1716 , AUTIASP , AUTIAZ , AUTIZA on page C6-915
AUTDA	Authenticate PAC for data address using APDAKey_EL1 , registers	AUTDA , AUTDZA on page C6-913
AUTIB	Authenticate PAC for instruction address using APIBKey_EL1 , registers	AUTIB , AUTIB1716 , AUTIBSP , AUTIBZ , AUTIZB on page C6-917
AUTDB	Authenticate PAC for data address using APDBKey_EL1 , registers	AUTDB , AUTDZB on page C6-914
AUTIZA	Authenticate PAC for instruction address using APIAKey_EL1 , register and zero	AUTIA , AUTIA1716 , AUTIASP , AUTIAZ , AUTIZA on page C6-915

Table C3-14 Instructions that authenticate a PAC (continued)

Mnemonic	Instruction	See
AUTDZA	Authenticate PAC for data address using APDAKey_EL1 , register and zero	AUTDA , AUTDZA on page C6-913
AUTIZB	Authenticate PAC for instruction address using APIBKey_EL1 , register and zero	AUTIB , AUTIB1716 , AUTIBSP , AUTIBZ , AUTIZB on page C6-917
AUTDZB	Authenticate PAC for data address using APDBKey_EL1 , register and zero	AUTDB , AUTDZB on page C6-914

[Table C3-15 on page C3-222](#) shows the instructions that strip a PAC from a register, without performing any authentication:

Table C3-15 Instructions that strip a PAC

Mnemonic	Instruction	See
XPACLRI	Strip instruction address PAC from LR	XPACD , XPACI , XPACLRI on page C6-1517
XPACI	Strip instruction address PAC, register	
XPACD	Strip data address PAC, register	

Combined instructions that include pointer authentication

Each of these instructions combines a pointer authentication with another operation that uses the authenticated pointer. [Table C3-16 on page C3-222](#) shows these instructions:

Table C3-16 Combined pointer authentication instructions

Mnemonic	Instruction	See
RETAA	Authenticate PAC for LR using APIAKey_EL1 and SP, and return	RETAA , RETAB on page C6-1283
RETAB	Authenticate PAC for LR using APIBKey_EL1 and SP, and return	
BRAA	Authenticate PAC using APIAKey_EL1 (registers), and branch	BRAA , BRAAZ , BRAB , BRABZ on page C6-939
BRAB	Authenticate PAC using APIBKey_EL1 (registers), and branch

BRAAZ	Authenticate PAC using APIAKey_EL1 (register and zero), and branch	BRAA , BRAAZ , BRAB , BRABZ on page C6-939
BRABZ	Authenticate PAC using APIBKey_EL1 (register and zero), and branch	
BLRAAZ	Authenticate PAC using APIAKey_EL1 (register and zero), and branch with link	BLRAA , BLRAAZ , BLRAB , BLRABZ on page C6-936
BLRABZ	Authenticate PAC using APIBKey_EL1 (register and zero), and branch with link	
ERETAA	Authenticate PAC for ELR using APIAKey_EL1 and SP, and exception return	ERETAA , ERETAB on page C6-1027
ERETAB	Authenticate PAC for ELR using APIBKey_EL1 and SP, and exception return	
LDRAA	Authenticate PAC for data address using APDAKey_EL1 (register and zero) and Load	LDRAA , LDRAB on page C6-1113
LDRAB	Authenticate PAC for data address using APDBKey_EL1 (register and zero) and Load	

C3.2 Loads and stores

This section describes the load/store instructions. It contains the following subsections:

- [Load/store register](#) on page C3-224.
- [Load/store register \(unscaled offset\)](#) on page C3-225.
- [Load/store pair](#) on page C3-226.
- [Load/store non-temporal pair](#) on page C3-227.
- [Load/store unprivileged](#) on page C3-228.
- [Load-Exclusive/Store-Exclusive](#) on page C3-228.
- [Load-Acquire/Store-Release](#) on page C3-229.
- [LoadLOAcquire/StoreLORelease](#) on page C3-231.
- [Load/store scalar SIMD and floating-point](#) on page C3-231.
- [Load/store Vector](#) on page C3-233.
- [Prefetch memory](#) on page C3-235.
- [Atomic instructions](#) on page C3-236.
- [Memory Tagging instructions](#) on page C3-240.

The requirements for the alignment of data memory accesses are strict, for more information see [Alignment of data accesses](#) on page B2-160.

The additional control bits `SCTLR_ELx.SA` and `SCTLR_EL1.SA0` control whether the stack pointer must be quadword aligned when used as a base register. See [SP alignment checking](#) on page D1-2469. Using a misaligned stack pointer generates an SP alignment fault exception.

For information about the encoding structure of the instructions in this instruction group, see [Loads and Stores](#) on page C4-298.

———— Note ————

In some cases, load/store instructions can lead to CONSTRAINED UNPREDICTABLE behavior. See [AArch64 CONSTRAINED UNPREDICTABLE behaviors](#) on page K1-8408.

C3.2.1 Load/store register

The load/store register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset, optionally scaled.
- Base plus a 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

See also [Load/store addressing modes](#) on page C1-202.

If a Load instruction specifies writeback and the register being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs the load using the specified addressing mode and the base register becomes UNKNOWN. In addition, if an exception occurs during the execution of such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store instruction performs a writeback and the register that is stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.

- The instruction is treated as a NOP.
- The instruction performs the store to the designated register using the specified addressing mode, but the value stored is UNKNOWN.

Table C3-17 on page C3-225 shows the load/store register instructions.

Table C3-17 Load/store register instructions

Mnemonic	Instruction	See
LDR	Load register (register offset)	<i>LDR (register)</i> on page C6-1111
	Load register (immediate offset)	<i>LDR (immediate)</i> on page C6-1106
	Load register (PC-relative literal)	<i>LDR (literal)</i> on page C6-1109
LDRB	Load byte (register offset)	<i>LDRB (register)</i> on page C6-1118
	Load byte (immediate offset)	<i>LDRB (immediate)</i> on page C6-1115
LDRSB	Load signed byte (register offset)	<i>LDRSB (register)</i> on page C6-1129
	Load signed byte (immediate offset)	<i>LDRSB (immediate)</i> on page C6-1125
LDRH	Load halfword (register offset)	<i>LDRH (register)</i> on page C6-1123
	Load halfword (immediate offset)	<i>LDRH (immediate)</i> on page C6-1120
LDRSH	Load signed halfword (register offset)	<i>LDRSH (register)</i> on page C6-1135
	Load signed halfword (immediate offset)	<i>LDRSH (immediate)</i> on page C6-1131
LDRSW	Load signed word (register offset)	<i>LDRSW (register)</i> on page C6-1141
	Load signed word (immediate offset)	<i>LDRSW (immediate)</i> on page C6-1137
	Load signed word (PC-relative literal)	<i>LDRSW (literal)</i> on page C6-1140
STR	Store register (register offset)	<i>STR (register)</i> on page C6-1386
	Store register (immediate offset)	<i>STR (immediate)</i> on page C6-1383
STRB	Store byte (register offset)	<i>STRB (register)</i> on page C6-1391
	Store byte (immediate offset)	<i>STRB (immediate)</i> on page C6-1388
STRH	Store halfword (register offset)	<i>STRH (register)</i> on page C6-1396
	Store halfword (immediate offset)	<i>STRH (immediate)</i> on page C6-1393

C3.2.2 Load/store register (unscaled offset)

The load/store register instructions with an unscaled offset support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See [Load/store addressing modes on page C1-202](#).

The load/store register (unscaled offset) instructions are required to disambiguate this instruction class from the load/store register instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset, because that can represent some offset values in the same range.

The ambiguous immediate offsets are byte offsets that are both:

- In the range 0-255, inclusive.
- Naturally aligned to the access size.

Other byte offsets in the range -256 to 255 inclusive are unambiguous. An assembler program translating a load/store instruction, for example LDR, is required to encode an unambiguous offset using the unscaled 9-bit offset form, and to encode an ambiguous offset using the scaled 12-bit offset form. A programmer might force the generation of the unscaled 9-bit form by using one of the mnemonics in [Table C3-18 on page C3-226](#). Arm recommends that a disassembler outputs all unscaled 9-bit offset forms using one of these mnemonics, but unambiguous offsets can be output using a load/store single register mnemonic, for example, LDR.

[Table C3-18 on page C3-226](#) shows the load/store register instructions with an unscaled offset.

Table C3-18 Load/store register (unscaled offset) instructions

Mnemonic	Instruction	See
LDUR	Load register (unscaled offset)	LDUR on page C6-1190
LDURB	Load byte (unscaled offset)	LDURB on page C6-1192
LDURSB	Load signed byte (unscaled offset)	LDURSB on page C6-1194
LDURH	Load halfword (unscaled offset)	LDURH on page C6-1193
LDURSH	Load signed halfword (unscaled offset)	LDURSH on page C6-1196
LDURSW	Load signed word (unscaled offset)	LDURSW on page C6-1198
STUR	Store register (unscaled offset)	STUR on page C6-1434
STURB	Store byte (unscaled offset)	STURB on page C6-1436
STURH	Store halfword (unscaled offset)	STURH on page C6-1437

C3.2.3 Load/store pair

The load/store pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also [Load/store addressing modes on page C1-202](#).

If a Load Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

If a Load Pair instruction specifies writeback and one of the registers being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the base register becomes UNKNOWN. In addition, if an exception occurs during the instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store Pair instruction performs a writeback and one of the registers being stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the stores of the registers indicated by the specified addressing mode, but the value stored for the base register is UNKNOWN.

Table C3-19 on page C3-227 shows the load/store pair instructions.

Table C3-19 Load/store pair instructions

Mnemonic	Instruction	See
LDP	Load Pair	LDP on page C6-1099
LDPSW	Load Pair signed words	LDPSW on page C6-1103
STP	Store Pair	STP on page C6-1380

C3.2.4 Load/store non-temporal pair

The load/store non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See [Load/store addressing modes on page C1-202](#).

The load/store non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a Load Non-temporal Pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, the memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-Temporal Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-20 on page C3-227 shows the load/store non-temporal pair instructions.

Table C3-20 Load/store non-temporal pair instructions

Mnemonic	Instruction	See
LDNP	Load Non-temporal Pair	LDNP on page C6-1097
STNP	Store Non-temporal Pair	STNP on page C6-1378

C3.2.5 Load/store unprivileged

The load/store unprivileged instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See [Load/store addressing modes on page C1-202](#).

The access permissions that apply to accesses made at EL0 apply to the memory accesses made by a load/store unprivileged instruction that is executed either:

- At EL1 when the *Effective value* of `PSTATE.UAO` is 0.
- At EL2 when both the *Effective value* of `HCR_EL2.{E2H, TGE}` is {1, 1} and the *Effective value* of `PSTATE.UAO` is 0.

Otherwise, memory accesses made by a load/store unprivileged instruction are subject to the access permissions that apply to the Exception level at which the instruction is executed. These are the permissions that apply to the corresponding load/store register instruction, see [Load/store register on page C3-224](#).

———— **Note** ————

This means that when the value of `PSTATE.UAO` is 1 the access permissions for a load/store unprivileged instruction are always the same as those for the corresponding load/store register instruction.

[Table C3-21 on page C3-228](#) shows the load/store unprivileged instructions.

Table C3-21 Load-Store unprivileged instructions

Mnemonic	Instruction	See
LDTR	Load unprivileged register	LDTR on page C6-1164
LDTRB	Load unprivileged byte	LDTRB on page C6-1166
LDTRSB	Load unprivileged signed byte	LDTRSB on page C6-1170
LDTRH	Load unprivileged halfword	LDTRH on page C6-1168
LDTRSH	Load unprivileged signed halfword	LDTRSH on page C6-1172
LDTRSW	Load unprivileged signed word	LDTRSW on page C6-1174
STTR	Store unprivileged register	STTR on page C6-1416
STTRB	Store unprivileged byte	STTRB on page C6-1418
STTRH	Store unprivileged halfword	STTRH on page C6-1420

C3.2.6 Load-Exclusive/Store-Exclusive

The Load-Exclusive/Store-Exclusive instructions support only one addressing mode:

- Base register with no offset.

See [Load/store addressing modes on page C1-202](#).

The Load-Exclusive instructions mark the physical address being accessed as an exclusive access. This exclusive access mark is checked by the Store-Exclusive instruction, permitting the construction of atomic read-modify-write operations on shared memory variables, semaphores, mutexes, and spinlocks. See [Synchronization and semaphores on page B2-179](#).

If [FEAT_LSE2](#) is not implemented then:

- The Load-Exclusive/Store-Exclusive instructions other than Load-Exclusive pair and Store-Exclusive pair require natural alignment, and an unaligned address generates an Alignment fault.
- Memory accesses generated by Load-Exclusive pair or Store-Exclusive pair instructions must be aligned to the size of the pair, otherwise the access generates an Alignment fault.

For more information on alignment requirements and behaviors see [Load-Exclusive/ Store-Exclusive and Atomic instructions on page B2-160](#).

When a Store-Exclusive pair succeeds, it causes a single-copy atomic update of the entire memory location being stored to.

[Table C3-22 on page C3-229](#) shows the Load-Exclusive/Store-Exclusive instructions.

Table C3-22 Load-Exclusive/Store-Exclusive instructions

Mnemonic	Instruction	See
LDXR	Load Exclusive register	LDXR on page C6-1201
LDXRB	Load Exclusive byte	LDXRB on page C6-1203
LDXRH	Load Exclusive halfword	LDXRH on page C6-1204
LDXP	Load Exclusive pair	LDXP on page C6-1199

STXRB	Store Exclusive byte	STXRB on page C6-1443
STXRH	Store Exclusive halfword	STXRH on page C6-1445
STXP	Store Exclusive pair	STXP on page C6-1438

C3.2.7 Load-Acquire/Store-Release

The Load-Acquire, Load-AcquirePC, and Store-Release instructions support only one addressing mode:

- Base register with no offset.

See [Load/store addressing modes on page C1-202](#).

The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit [DMB](#) memory barrier instruction. For more information about the ordering of Load-Acquire, Load-AcquirePC, and Store-Release, see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

The Load-Acquire, Load-AcquirePC, and Store-Release instructions other than Load-Acquire pair and Store-Release pair require natural alignment, and an unaligned address generates an Alignment fault. Memory accesses generated by Load-Acquire pair or Store-Release pair instructions must be aligned to the size of the pair, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the Release semantics if the store is successful.

Armv8.1 adds more instructions with load-acquire and store-release mechanisms, see [LoadLOAcquire/StoreLORelease on page C3-231](#).

[FEAT_LRCPC2](#) introduces changes to the alignment requirements of Load-Acquire/Store-Release instructions.

Table C3-23 on page C3-230 shows the Non-exclusive Load-Acquire/Store-Release instructions.

Table C3-23 Non-exclusive Load-Acquire and Store-Release instructions

STLXP	Store-Release Exclusive pair	STLXP on page C6-1368

C3.2.8 LoadLOAcquire/StoreLORelease

The LoadLOAcquire/StoreLORelease instructions support only one addressing mode:

- Base register with no offset.

See [Load/store addressing modes on page C1-202](#).

The LoadLOAcquire/StoreLORelease instructions can remove the requirement to use the explicit **DMB** memory barrier instruction. For more information about the ordering of LoadLOAcquire/StoreLORelease, see [LoadLOAcquire, StoreLORelease on page B2-153](#).

The LoadLOAcquire/StoreLORelease instructions require natural alignment, and an unaligned address generates an Alignment fault.

[Table C3-25 on page C3-231](#) shows the LoadLOAcquire/StoreLORelease instructions.

Table C3-25 LoadLOAcquire and StoreLORelease instructions

STLLRH	StoreLORelease halfword	STLLRH on page C6-1355
STLLR	StoreLORelease register	STLLR on page C6-1356

C3.2.9 Load/store scalar SIMD and floating-point

The load/store scalar SIMD and floating-point instructions operate on scalar values in the SIMD and floating-point register file as described in [SIMD and floating-point scalar register names on page C1-199](#). The memory addressing modes available, described in [Load/store addressing modes on page C1-202](#), are identical to the general-purpose register load/store instructions, and like those instructions permit arbitrary address alignment unless strict alignment checking is enabled. However, unlike the load/store instructions that transfer general-purpose registers, load/store scalar SIMD and floating-point instructions make no guarantee of atomicity, even when the address is naturally aligned to the size of the data.

Load/store scalar SIMD and floating-point register

The load/store scalar SIMD and floating-point register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus unscaled 9-bit signed immediate offset.
- Base plus 64-bit register offset, optionally scaled.
- Base plus 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.

- PC-relative literal for loads of 32 bits or more.

For more information on the addressing modes, see [Load/store addressing modes](#) on page C1-202.

———— **Note** —————

The unscaled 9-bit signed immediate offset address mode requires its own instruction form, see [Load/store scalar SIMD and floating-point register \(unscaled offset\)](#) on page C3-232.

[Table C3-26 on page C3-232](#) shows the load/store instructions for a single SIMD and floating-point register.

Table C3-26 Load/store single SIMD and floating-point register instructions

Mnemonic	Instruction	See
LDR	Load scalar SIMD&FP register (register offset)	LDR (register, SIMD&FP) on page C7-1976
	Load scalar SIMD&FP register (immediate offset)	LDR (immediate, SIMD&FP) on page C7-1970
	Load scalar SIMD&FP register (PC-relative literal)	LDR (literal, SIMD&FP) on page C7-1974
STR	Store scalar SIMD&FP register (register offset)	STR (register, SIMD&FP) on page C7-2294
	Store scalar SIMD&FP register (immediate offset)	STR (immediate, SIMD&FP) on page C7-2290

Load/store scalar SIMD and floating-point register (unscaled offset)

The load /store scalar SIMD and floating-point register instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See also [Load/store addressing modes](#) on page C1-202.

The load/store scalar SIMD and floating-point register (unscaled offset) instructions are required to disambiguate this instruction class from the load/store single SIMD and floating-point instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset. This is similar to the load/store register (unscaled offset) instructions, that disambiguate this instruction class from the load/store register instruction, see [Load/store register \(unscaled offset\)](#) on page C3-225.

[Table C3-27 on page C3-232](#) shows the load/store SIMD and floating-point register instructions with an unscaled offset.

Table C3-27 Load/store SIMD and floating-point register instructions

Mnemonic	Instruction	See
LDUR	Load scalar SIMD&FP register (unscaled offset)	LDUR (SIMD&FP) on page C7-1979
STUR	Store scalar SIMD&FP register (unscaled offset)	STUR (SIMD&FP) on page C7-2297

Load/store SIMD and floating-point register pair

The load/store SIMD and floating-point register pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also [Load/store addressing modes](#) on page C1-202.

If a Load pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode and the register being loaded takes an UNKNOWN value.

Table C3-28 on page C3-233 shows the load/store SIMD and floating-point register pair instructions.

Table C3-28 Load/store SIMD and floating-point register pair instructions

Mnemonic	Instruction	See
LDP	Load pair of scalar SIMD&FP registers	<i>LDP (SIMD&FP)</i> on page C7-1966
STP	Store pair of scalar SIMD&FP registers	<i>STP (SIMD&FP)</i> on page C7-2287

Load/store SIMD and floating-point non-temporal pair

The load/store SIMD and floating-point non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See also *Load/store addressing modes* on page C1-202.

The load/store non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a load non-temporal pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, those memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a load non-temporal pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-29 on page C3-233 shows the load/store SIMD and floating-point Non-temporal pair instructions.

Table C3-29 Load/store SIMD and floating-point non-temporal pair instructions

Mnemonic	Instruction	See
LDNP	Load pair of scalar SIMD&FP registers	<i>LDNP (SIMD&FP)</i> on page C7-1964
STNP	Store pair of scalar SIMD&FP registers	<i>STNP (SIMD&FP)</i> on page C7-2285

C3.2.10 Load/store Vector

The Vector load/store structure instructions support the following addressing modes:

- Base register only.
- Post-indexed by a 64-bit register.

- Post-indexed by an immediate, equal to the number of bytes transferred.

Load/store vector instructions, like other load/store instructions, allow any address alignment, unless strict alignment checking is enabled. If strict alignment checking is enabled, then alignment checking to the size of the element is performed. However, unlike the load/store instructions that transfer general-purpose registers, the load/store vector instructions do not guarantee atomicity, even when the address is naturally aligned to the size of the element.

Load/store structures

Table C3-30 on page C3-234 shows the load/store structure instructions. A post-increment immediate offset, if present, must be 8, 16, 24, 32, 48, or 64, depending on the number of elements transferred.

Table C3-30 Load/store multiple structures instructions

Mnemonic	Instruction	See
LD1	Load single 1-element structure to one lane of one register	<i>LD1 (single structure) on page C7-1927</i>
	Load multiple 1-element structures to one register or to two, three, or four consecutive registers	<i>LD1 (multiple structures) on page C7-1923</i>
LD2	Load single 2-element structure to one lane of two consecutive registers	<i>LD2 (single structure) on page C7-1937</i>
	Load multiple 2-element structures to two consecutive registers	<i>LD2 (multiple structures) on page C7-1934</i>
LD3	Load single 3-element structure to one lane of three consecutive registers	<i>LD3 (single structure) on page C7-1947</i>
	Load multiple 3-element structures to three consecutive registers	<i>LD3 (multiple structures) on page C7-1944</i>
LD4	Load single 4-element structure to one lane of four consecutive registers	<i>LD4 (single structure) on page C7-1957</i>
	Load multiple 4-element structures to four consecutive registers	<i>LD4 (multiple structures) on page C7-1954</i>
ST1	Store single 1-element structure from one lane of one register	<i>ST1 (single structure) on page C7-2260</i>
	Store multiple 1-element structures from one register, or from two, three, or four consecutive registers	<i>ST1 (multiple structures) on page C7-2256</i>
ST2	Store single 2-element structure from one lane of two consecutive registers	<i>ST2 (single structure) on page C7-2267</i>
	Store multiple 2-element structures from two consecutive registers	<i>ST2 (multiple structures) on page C7-2264</i>
ST3	Store single 3-element structure from one lane of three consecutive registers	<i>ST3 (single structure) on page C7-2274</i>
	Store multiple 3-element structures from three consecutive registers	<i>ST3 (multiple structures) on page C7-2271</i>
ST4	Store single 4-element structure from one lane of four consecutive registers	<i>ST4 (single structure) on page C7-2281</i>
	Store multiple 4-element structures from four consecutive registers	<i>ST4 (multiple structures) on page C7-2278</i>

Load single structure and replicate

Table C3-31 on page C3-235 shows the Load single structure and replicate instructions. A post-increment immediate offset, if present, must be 1, 2, 3, 4, 6, 8, 12, 16, 24, or 32, depending on the number of elements transferred.

Table C3-31 Load single structure and replicate instructions

Mnemonic	Instruction	See
LD1R	Load single 1-element structure and replicate to all lanes of one register	LD1R on page C7-1931
LD2R	Load single 2-element structure and replicate to all lanes of two registers	LD2R on page C7-1941
LD3R	Load single 3-element structure and replicate to all lanes of three registers	LD3R on page C7-1951
LD4R	Load single 4-element structure and replicate to all lanes of four registers	LD4R on page C7-1961

C3.2.11 Prefetch memory

The Prefetch memory instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset. This can be optionally scaled by 8-bits, for example LSL#3.
- Base plus a 32-bit extended register offset. This can be optionally scaled by 8-bits.
- PC-relative literal.

The prefetch memory instructions signal to the memory system that memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory access when they do occur, such as preloading the specified address into one or more caches. Because these signals are only hints, it is valid for the PE to treat any or all prefetch instructions as a NOP.

Because they are hints to the memory system, the operation of a PRFM instruction cannot cause a synchronous exception. However, a memory operation performed as a result of one of these memory system hints might in exceptional cases trigger an asynchronous event, and thereby influence the execution of the PE. An example of an asynchronous event that might be triggered is an SError interrupt.

A PRFM instruction can only have an effect on software visible structures, such as caches and translation lookaside buffers associated with memory locations that can be accessed by reads, writes, or execution as defined in the translation regime of the current Exception level.

A PRFM instruction is guaranteed not to access Device memory.

A PRFM instruction using a PLI hint must not result in any access that could not be performed by the PE speculatively fetching an instruction. Therefore, if all associated MMUs are disabled, a PLI hint cannot access any memory location that cannot be accessed by instruction fetches.

The PRFM instructions require an additional <prfop> operand to be specified, which must be one of the following:

PLDL1KEEP, PLDL1STRM, PLDL2KEEP, PLDL2STRM, PLDL3KEEP, PLDL3STRM

PSTL1KEEP, PSTL1STRM, PSTL2KEEP, PSTL2STRM, PSTL3KEEP, PSTL3STRM

PLIL1KEEP, PLIL1STRM, PLIL2KEEP, PLIL2STRM, PLIL3KEEP, PLIL3STRM

<prfop> is defined as <type><target><policy>.

Here:

<type>	Is one of:
	PLD Prefetch for load.
	PST Prefetch for store.
	PLI Preload instructions.

<target>	Is one of:	
	L1	Level 1 cache.
	L2	Level 2 cache.
	L3	Level 3 cache.
<policy>	Is one of:	
	KEEP	Retained or temporal prefetch, allocated in the cache normally.
	STRM	Streaming or non-temporal prefetch, for data that is used only once.

PRFUM explicitly uses the unscaled 9-bit signed immediate offset addressing mode, as described in [Load/store register \(unscaled offset\)](#) on page C3-225.

Table C3-32 on page C3-236 shows the Prefetch memory instructions.

Table C3-32 Prefetch memory instructions

Mnemonic	Instruction	See
PRFM	Prefetch memory (register offset)	PRFM (register) on page C6-1274
	Prefetch memory (immediate offset)	PRFM (immediate) on page C6-1270
	Prefetch memory (PC-relative offset)	PRFM (literal) on page C6-1272
PRFUM	Prefetch memory (unscaled offset)	PRFUM on page C6-1276

C3.2.12 Atomic instructions

The atomic instructions perform atomic read and write operations on a memory location such that the architecture guarantees that no modification of that memory location by another observer can occur between the read and the write defined by that instruction.

This section describes the following operations:

- [Atomic memory operations](#) on page C3-236.
- [Single-copy atomic 64-byte load/store](#) on page C3-238.
- [Swap](#) on page C3-239.
- [Compare and Swap](#) on page C3-239.

Atomic memory operations

The atomic memory operation instructions support only one addressing mode:

- Base register only.

See also [Load/store addressing modes](#) on page C1-202.

For the purpose of permission checking, and for watchpoints, all of the Atomic memory operation instructions are treated as performing both a load and a store.

If [FEAT_LSE2](#) is not implemented then the LD<OP> and ST<OP> instructions require natural alignment, and an unaligned address generates an Alignment fault. For more information on alignment requirements and behaviors see [Load-Exclusive/ Store-Exclusive and Atomic instructions](#) on page B2-160.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the Armv8-A architecture. The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity. These operations map to the acquire and release definitions, and are counted as Load-Acquire and Store-Release operations respectively.

For the LD<OP> instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

The ST<OP> instructions, and LD<OP> instructions where the destination register is WZR or XZR, are not regarded as doing a read for the purpose of a DMB LD barrier.

Table C3-33 Atomic memory operation instructions

Mnemonic	Instruction	See
LDADD	Atomic add	<i>LDADD, LDADDA, LDADDAL, LDADDL</i> on page C6-1045
LDADDB	Atomic add on byte	<i>LDADDB, LDADDAB, LDADDALB, LDADDLB</i> on page C6-1041

STADD	Atomic add, without return	<i>STADD, STADDL</i> on page C6-1334
STADDB	Atomic add on byte, without return	<i>STADDB, STADDLB</i> on page C6-1330
STADDH	Atomic add on halfword, without return	<i>STADDH, STADDLH</i> on page C6-1332
STCLR	Atomic bit clear, without return	<i>STCLR, STCLRL</i> on page C6-1340

Table C3-33 Atomic memory operation instructions (continued)

Mnemonic	Instruction	See
STCLRB	Atomic bit clear on byte, without return	STCLRB , STCLRLB on page C6-1336
STCLRH	Atomic bit clear on halfword, without return	STCLRH , STCLRLH on page C6-1338
STEOR	Atomic exclusive OR, without return	STEOR , STEORL on page C6-1346
STEORB	Atomic exclusive OR on byte, without return	STEORB , STEORLB on page C6-1342
STEORH	Atomic exclusive OR on halfword, without return	STEORH , STEORLH on page C6-1344
STSET	Atomic bit set, without return	STSET , STSETL on page C6-1402
STSETB	Atomic bit set on byte, without return	STSETB , STSETLB on page C6-1398
STSETH	Atomic bit set on halfword, without return	STSETH , STSETLH on page C6-1400
STMAX	Atomic signed maximum, without return	STSMAX , STSMAXL on page C6-1408
STMAXB	Atomic signed maximum on byte, without return	STSMAXB , STSMAXLB on page C6-1404
STMAXH	Atomic signed maximum on halfword, without return	STSMAXH , STSMAXLH on page C6-1406
STMIN	Atomic signed minimum, without return	STSMIN , STSMINL on page C6-1414
STMINB	Atomic signed minimum on byte, without return	STSMINB , STSMINLB on page C6-1410
STMINH	Atomic signed minimum on halfword, without return	STSMINH , STSMINLH on page C6-1412
STUMAX	Atomic unsigned maximum, without return	STUMAX , STUMAXL on page C6-1426
STUMAXB	Atomic unsigned maximum on byte, without return	STUMAXB , STUMAXLB on page C6-1422
STUMAXH	Atomic unsigned maximum on halfword, without return	STUMAXH , STUMAXLH on page C6-1424
STUMIN	Atomic unsigned minimum, without return	STUMIN , STUMINL on page C6-1432
STUMINB	Atomic unsigned minimum on byte, without return	STUMINB , STUMINLB on page C6-1428
STUMINH	Atomic unsigned minimum on halfword, without return	STUMINH , STUMINLH on page C6-1430

Single-copy atomic 64-byte load/store

If [FEAT_LS64](#) is implemented, the following instructions are implemented.

The single-copy atomic 64-byte load/store instructions support one addressing mode:

- Base register only.

See also [Load/store addressing modes](#) on page C1-202.

The memory location accessed by the instructions is required to be aligned on a 64-byte boundary, otherwise an Alignment fault occurs.

When the instructions access a memory type for an enabled translation stage that is not one of the following, a data abort for that translation stage occurs:

- Normal Inner Non-cacheable, Outer Non-cacheable.
- Device-GRE.
- Device-nGRE.
- Device-nGnRE.
- Device-nGnRnE.

Table C3-34 Single-copy atomic 64-byte load/store instructions

Mnemonic	Instruction	See
LD64B	Single-copy atomic 64-byte load	LD64B on page C6-1040
ST64B	Single-copy atomic 64-byte store without return	ST64B on page C6-1325
ST64BV	Single-copy atomic 64-byte store with return	ST64BV on page C6-1326
ST64BV0	Single-copy atomic 64-byte EL0 store with return	ST64BV0 on page C6-1328

Swap

The swap instructions support only one addressing mode:

- Base register only.

See also [Load/store addressing modes on page C1-202](#).

For the purpose of permission checking, and for watchpoints, all of the Swap instructions are treated as performing both a load and a store.

If [FEAT_LSE2](#) is not implemented then the SWP instructions require natural alignment, and an unaligned address generates an Alignment fault. For more information on alignment requirements and behaviors see [Load-Exclusive/Store-Exclusive and Atomic instructions on page B2-160](#).

The instructions are provided with ordering options, which map to the acquire and release definitions used in the Armv8-A architecture. The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity.

For the SWP instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

Table C3-35 Swap instructions

Mnemonic	Instruction	See
SWP	Swap	SWP, SWPA, SWPAL, SWPL on page C6-1475
SWPB	Swap byte	SWPB, SWPAB, SWPALB, SWPLB on page C6-1471
SWPH	Swap halfword	SWPH, SWPAH, SWPALH, SWPLH on page C6-1473

Compare and Swap

The Compare and Swap instructions support only one addressing mode:

- Base register only.

See also [Load/store addressing modes on page C1-202](#).

For the purpose of permission checking, and for watchpoints, all of the Compare and Swap instructions are treated as performing both a load and a store.

If [FEAT_LSE2](#) is not implemented then:

- The CAS instructions require natural alignment.
- The CASP instructions require alignment to the total size of the memory being accessed.
 For more information on alignment requirements and behaviors see [Load-Exclusive/ Store-Exclusive and Atomic instructions on page B2-160](#).

The instructions are provided with ordering options, which map to the acquire and release definitions used in the Armv8-A architecture. If a compare and swap instruction does not perform a store, then the instruction does not have release semantics, regardless of the instruction ordering options.

The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity.

For the CAS and CASP instructions, the architecture permits that a data read clears any Excludes monitors associated with that location, even if the compare subsequently fails. If these instructions generate a synchronous Data Abort, the registers which are compared and loaded are restored to the values held in the registers before the instruction was executed.

Table C3-36 Compare and swap instructions

Mnemonic	Instruction	See
CAS	Compare and swap	CAS, CASA, CASAL, CASL on page C6-951
CASB	Compare and swap byte	CASB, CASAB, CASALB, CASLB on page C6-944
CASH	Compare and swap halfword	CASH, CASAH, CASALH, CASLH on page C6-946
CASP	Compare and swap pair	CASP, CASPA, CASPAL, CASPL on page C6-948

C3.2.13 Memory Tagging instructions

If [FEAT_MTE](#) is implemented, the following instructions are implemented.

[Table C3-37 on page C3-240](#) shows the Memory Tagging Extension Tag generation instructions.

Table C3-37 Tag generation instructions

Mnemonic	Instruction	See
ADDG	Add immediate value to Logical Address Tag	ADDG on page C6-887
GMI	Tag Mask Insert	GMI on page C6-1031
IRG	Random Logical Address Tag generation	IRG on page C6-1037
SUBG	Subtract immediate value to Logical Address Tag	SUBG on page C6-1459

[Table C3-38 on page C3-240](#) shows the Memory Tagging Extension Pointer Arithmetic instructions.

Table C3-38 Pointer Arithmetic

STG	Store Allocation Tag to granule	STG on page C6-1348
STZG	Store Allocation Tag to granule Zeroing	STZG on page C6-1449
ST2G	Store Allocation Tag to two granules	ST2G on page C6-1323
STZ2G	Store Allocation Tag to two granules Zeroing	STZ2G on page C6-1447
STGP	Store Allocation Tag to memory	STGP on page C6-1351

Table C3-40 on page C3-241 shows the Memory Tagging Extension Tag getting instructions.

Table C3-40 Tag getting instructions

Mnemonic	Instruction	See
LDG	Load Allocation Tag	LDG on page C6-1090

If [FEAT_MTE2](#) is implemented, all of the [FEAT_MTE](#) instructions are implemented, plus the following instructions.

Table C3-41 on page C3-241 shows the Memory Tagging Extension Bulk Allocation Tag access instructions.

Table C3-41 Bulk Allocation Tag access

Mnemonic	Instruction	See
LDGM	Load an IMPLEMENTATION DEFINED number of Allocation Tags	LDGM on page C6-1091
STGM	Store an IMPLEMENTATION DEFINED number of Allocation Tags	STGM on page C6-1350
STZGM	Store Allocation Tag to granule Zeroing Multiple	STZGM on page C6-1451

C3.3 Data processing - immediate

This section describes the instruction groups for data processing with immediate operands. It contains the following subsections:

- [Arithmetic \(immediate\)](#) on page C3-242.
- [Logical \(immediate\)](#) on page C3-242.
- [Move \(wide immediate\)](#) on page C3-243.
- [Move \(immediate\)](#) on page C3-243.
- [PC-relative address calculation](#) on page C3-244.
- [Bitfield move](#) on page C3-244.
- [Bitfield insert and extract](#) on page C3-245
- [Extract register](#) on page C3-245.
- [Shift \(immediate\)](#) on page C3-245.
- [Sign-extend and Zero-extend](#) on page C3-246.

For information about the encoding structure of the instructions in this instruction group, see [Data Processing -- Immediate](#) on page C4-284.

C3.3.1 Arithmetic (immediate)

The Arithmetic (immediate) instructions accept a 12-bit unsigned immediate value, optionally shifted left by 12 bits.

The Arithmetic (immediate) instructions that do not set Condition flags can read from and write to the current stack pointer. The flag setting instructions can read from the stack pointer, but they cannot write to it.

[Table C3-42](#) on page C3-242 shows the Arithmetic instructions with an immediate offset.

Table C3-42 Arithmetic instructions with an immediate

Mnemonic	Instruction	See
ADD	Add	ADD (immediate) on page C6-883
ADDS	Add and set flags	ADDS (immediate) on page C6-891
SUB	Subtract	SUB (immediate) on page C6-1455
SUBS	Subtract and set flags	SUBS (immediate) on page C6-1466
CMP	Compare	CMP (immediate) on page C6-982
CMN	Compare negative	CMN (immediate) on page C6-976

C3.3.2 Logical (immediate)

The Logical (immediate) instructions accept a bitmask immediate value that is a 32-bit pattern or a 64-bit pattern viewed as a vector of identical elements of size $e = 2, 4, 8, 16, 32$ or, 64 bits. Each element contains the same sub-pattern, that is a single run of 1 to $(e - 1)$ nonzero bits from bit 0 followed by zero bits, then rotated by 0 to $(e - 1)$ bits. This mechanism can generate 5 334 unique 64-bit patterns as 2 667 pairs of pattern and their bitwise inverse.

———— **Note** ————

Values that consist of only zeros or only ones cannot be described in this way.

The Logical (immediate) instructions that do not set the Condition flags can write to the current stack pointer, for example to align the stack pointer in a function prologue.

Note

Apart from ANDS, and its TST alias, Logical (immediate) instructions do not set the Condition flags. However, the final results of a bitwise operation can be tested by a CBZ, CBNZ, TBZ, or TBNZ conditional branch.

Table C3-43 on page C3-243 shows the Logical immediate instructions.

Table C3-43 Logical immediate instructions

Mnemonic	Instruction	See
AND	Bitwise AND	AND (immediate) on page C6-897
ANDS	Bitwise AND and set flags	ANDS (immediate) on page C6-901
EOR	Bitwise exclusive OR	EOR (immediate) on page C6-1022
ORR	Bitwise inclusive OR	ORR (immediate) on page C6-1257
TST	Test bits	TST (immediate) on page C6-1491

C3.3.3 Move (wide immediate)

The Move (wide immediate) instructions insert a 16-bit immediate, or inverted immediate, into a 16-bit aligned position in the destination register. The value of the other bits in the destination register depends on the variant used. The optional shift amount can be any multiple of 16 that is smaller than the register size.

Table C3-44 on page C3-243 shows the Move (wide immediate) instructions.

Table C3-44 Move (wide immediate) instructions

Mnemonic	Instruction	See
MOVZ	Move wide with zero	MOVZ on page C6-1234
MOVN	Move wide with NOT	MOVN on page C6-1232
MOVK	Move wide with keep	MOVK on page C6-1230

C3.3.4 Move (immediate)

The Move (immediate) instructions are aliases for a single MOVZ, MOVN, or ORR (immediate with zero register), instruction to load an immediate value into the destination register. An assembler must permit a signed or unsigned immediate, as long as its binary representation can be generated using one of these instructions, and an assembler error results if the immediate cannot be generated in this way. On disassembly, it is unspecified whether the immediate is output as a signed or an unsigned value.

If there is a choice between the MOVZ, MOVN, and ORR instruction to encode the immediate, then an assembler must prefer MOVZ to MOVN, and MOVZ or MOVN to ORR, to ensure reversability. A disassembler must output ORR (immediate with zero register) MOVZ, and MOVN, as a MOV mnemonic except that the underlying instruction must be used when:

- ORR has an immediate that can be generated by a MOVZ or MOVN instruction.
- A MOVN instruction has an immediate that can be encoded by MOVZ.
- MOVZ #0 or MOVN #0 have a shift amount other than LSL #0.

Table C3-45 on page C3-244 shows the Move (immediate) instructions.

Table C3-45 Move (immediate) instructions

Mnemonic	Instruction	See
MOV	Move (inverted wide immediate)	<i>MOV (inverted wide immediate)</i> on page C6-1222
	Move (wide immediate)	<i>MOV (wide immediate)</i> on page C6-1224
	Move (bitmask immediate)	<i>MOV (bitmask immediate)</i> on page C6-1226

C3.3.5 PC-relative address calculation

The ADR instruction adds a signed, 21-bit immediate to the value of the program counter that fetched this instruction, and then writes the result to a general-purpose register. This permits the calculation of any byte address within $\pm 1\text{MB}$ of the current PC.

The ADRP instruction shifts a signed, 21-bit immediate left by 12 bits, adds it to the value of the program counter with the bottom 12 bits cleared to zero, and then writes the result to a general-purpose register. This permits the calculation of the address at a 4KB aligned memory region. In conjunction with an ADD (immediate) instruction, or a load/store instruction with a 12-bit immediate offset, this allows for the calculation of, or access to, any address within $\pm 4\text{GB}$ of the current PC.

———— **Note** ————

The term *page* used in the ADRP description is short-hand for the 4KB memory region, and is not related to the virtual memory translation granule size.

Table C3-46 on page C3-244 shows the instructions used for PC-relative address calculations are as follows:

Table C3-46 PC-relative address calculation instructions

Mnemonic	Instruction	See
ADRP	Compute address of 4KB page at a PC-relative offset	<i>ADRP</i> on page C6-896
ADR	Compute address of label at a PC-relative offset.	<i>ADR</i> on page C6-895

C3.3.6 Bitfield move

The Bitfield move instructions copy a field of constant width from bit 0 in the source register to a constant bit position in the destination register, or from a constant bit position in the source register to bit 0 in the destination register. The remaining bits in the destination register are set as follows:

- For BFM, the remaining bits are unchanged.
- For UBFM the lower bits, if any, and upper bits, if any, are set to zero.
- For SBFM, the lower bits, if any, are set to zero, and the upper bits, if any, are set to a copy of the most-significant bit in the copied field.

Table C3-47 on page C3-245 shows the Bitfield move instructions.

Table C3-47 Bitfield move instructions

Mnemonic	Instruction	See
BFM	Bitfield move	BFM on page C6-926
SBFM	Signed bitfield move	SBFM on page C6-1305
UBFM	Unsigned bitfield move (32-bit)	UBFM on page C6-1496

C3.3.7 Bitfield insert and extract

The Bitfield insert and extract instructions are implemented as aliases of the Bitfield move instructions. Table C3-48 on page C3-245 shows the Bitfield insert and extract aliases.

Table C3-48 Bitfield insert and extract instructions

Mnemonic	Instruction	See
BFC	Bitfield insert clear	BFC on page C6-922
BFI	Bitfield insert	BFI on page C6-924
BFXIL	Bitfield extract and insert low	BFXIL on page C6-928
SBFIZ	Signed bitfield insert in zero	SBFIZ on page C6-1303
SBFX	Signed bitfield extract	SBFX on page C6-1308
UBFIZ	Unsigned bitfield insert in zero	UBFIZ on page C6-1494
UBFX	Unsigned bitfield extract	UBFX on page C6-1499

C3.3.8 Extract register

Depending on the register width of the operands, the Extract register instruction copies a 32-bit or 64-bit field from a constant bit position within a double-width value formed by the concatenation of a pair of source registers to a destination register.

Table C3-49 on page C3-245 shows the Extract (immediate) instructions.

Table C3-49 Extract register instructions

Mnemonic	Instruction	See
EXTR	Extract register from pair	EXTR on page C6-1029

C3.3.9 Shift (immediate)

Shifts and rotates by a constant amount are implemented as aliases of the Bitfield move or Extract register instructions. The shift or rotate amount must be in the range 0 to one less than the register width of the instruction, inclusive.

Table C3-50 on page C3-246 shows the aliases that can be used as immediate shift and rotate instructions.

Table C3-50 Aliases for immediate shift and rotate instructions

Mnemonic	Instruction	See
ASR	Arithmetic shift right	ASR (immediate) on page C6-907
LSL	Logical shift left	LSL (immediate) on page C6-1207
LSR	Logical shift right	LSR (immediate) on page C6-1213
ROR	Rotate right	ROR (immediate) on page C6-1292

C3.3.10 Sign-extend and Zero-extend

The Sign-extend and Zero-extend instructions are implemented as aliases of the Bitfield move instructions.

Table C3-51 on page C3-246 shows the aliases that can be used as zero-extend and sign-extend instructions.

Table C3-51 Zero-extend and sign-extend instructions

Mnemonic	Instruction	See
SXTB	Sign-extend byte	SXTB on page C6-1477
SXTH	Sign-extend halfword	SXTH on page C6-1479
SXTW	Sign-extend word	SXTW on page C6-1481
UXTB	Unsigned extend byte	UXTB on page C6-1510
UXTH	Unsigned extend halfword	UXTH on page C6-1511

C3.4 Data processing - register

This section describes the instruction groups for data processing with all register operands. It contains the following subsections:

- *Arithmetic (shifted register)* on page C3-247.
- *Arithmetic (extended register)* on page C3-248.
- *Arithmetic with carry* on page C3-249.
- *Flag manipulation instructions* on page C3-249.
- *Logical (shifted register)* on page C3-249.
- *Move (register)* on page C3-250.
- *Shift (register)* on page C3-250.
- *Multiply and divide* on page C3-251.
- *CRC32* on page C3-252.
- *Bit operation* on page C3-253.
- *Conditional select* on page C3-253.
- *Conditional comparison* on page C3-254.

For information about the encoding structure of the instructions in this instruction group, see *Data Processing -- Register* on page C4-332.

C3.4.1 Arithmetic (shifted register)

The Arithmetic (shifted register) instructions apply an optional shift operator to the second source register value before performing the arithmetic operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators LSL, ASR, and LSR accept an immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator implies LSL #0, which means that there is no shift. A disassembler must not output LSL #0. However, a disassembler must output all other shifts by zero.

The current stack pointer, SP or WSP, cannot be used with this class of instructions. See *Arithmetic (extended register)* on page C3-248 for arithmetic instructions that can operate on the current stack pointer.

Table C3-52 on page C3-247 shows the Arithmetic (shifted register) instructions.

Table C3-52 Arithmetic (shifted register) instructions

Mnemonic	Instruction	See
ADD	Add	<i>ADD (shifted register)</i> on page C6-885
ADDS	Add and set flags	<i>ADDS (shifted register)</i> on page C6-893
SUB	Subtract	<i>SUB (shifted register)</i> on page C6-1457
SUBS	Subtract and set flags	<i>SUBS (shifted register)</i> on page C6-1468
CMN	Compare negative	<i>CMN (shifted register)</i> on page C6-978
CMP	Compare	<i>CMP (shifted register)</i> on page C6-984
NEG	Negate	<i>NEG (shifted register)</i> on page C6-1246
NEGS	Negate and set flags	<i>NEGS</i> on page C6-1248

C3.4.2 Arithmetic (extended register)

The extended register instructions provide an optional sign-extension or zero-extension of a portion of the second source register value, followed by an optional left shift by a constant amount of 1-4, inclusive.

The extended shift is described by the mandatory extend operator SXTB, SXTH, SXTW, UXTB, UXTH, or UXTW. This is followed by an optional left shift amount. If the shift amount is not specified, the default shift amount is zero. A disassembler must not output a shift amount of zero.

For 64-bit instruction forms, the additional operators UXTX and SXTX use all 64 bits of the second source register with an optional shift. In that case, Arm recommends UXTX as the operator. If and only if at least one register is SP, Arm recommends use of the LSL operator name, rather than UXTX, and when the shift amount is also zero then both the operator and the shift amount can be omitted. UXTW and SXTW both use all 32 bits of the second source register with an optional shift. In that case Arm recommends UXTW as the operator. If and only if at least one register is WSP, Arm recommends use of the LSL operator name, rather than UXTW, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

For 32-bit instruction forms, the operators UXTW and SXTW both use all 32 bits of the second source register with an optional shift. In that case, Arm recommends UXTW as the operator. If and only if at least one register is WSP, Arm recommends use of the LSL operator name, rather than UXTW, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

The non-flag setting variants of the extended register instruction permit the use of the current stack pointer as either the destination register and the first source register. The flag setting variants only permit the stack pointer to be used as the first source register.

In the 64-bit form of these instructions, the final register operand is written as *Wm* for all except the UXTX/LSL and SXTX extend operators. For example:

```
CMP X4, W5, SXTW
ADD X1, X2, W3, UXTB #2
SUB SP, SP, X1           // SUB SP, SP, X1, UXTX #0
```

Table C3-53 on page C3-248 shows the Arithmetic (extended register) instructions.

Table C3-53 Arithmetic (extended register) instructions

Mnemonic	Instruction	See
ADD	Add	<i>ADD (extended register)</i> on page C6-880
ADDS	Add and set flags	<i>ADDS (extended register)</i> on page C6-888
SUB	Subtract	<i>SUB (extended register)</i> on page C6-1452
SUBS	Subtract and set flags	<i>SUBS (extended register)</i> on page C6-1463
CMN	Compare negative	<i>CMN (extended register)</i> on page C6-974
CMP	Compare	<i>CMP (extended register)</i> on page C6-980

C3.4.3 Arithmetic with carry

The Arithmetic with carry instructions accept two source registers, with the carry flag as an additional input to the calculation. They do not support shifting of the second source register.

Table C3-54 on page C3-249 shows the Arithmetic with carry instructions

Table C3-54 Arithmetic with carry instructions

Mnemonic	Instruction	See
ADC	Add with carry	ADC on page C6-876
ADCS	Add with carry and set flags	ADCS on page C6-878
SBC	Subtract with carry	SBC on page C6-1299
SBCS	Subtract with carry and set flags	SBCS on page C6-1301
NGC	Negate with carry	NGC on page C6-1250
NGCS	Negate with carry and set flags	NGCS on page C6-1252

C3.4.4 Flag manipulation instructions

The Flag manipulation instructions set the value of the NZCV condition flags directly.

The instructions SETF8 and SETF16 accept one source register and set the NZV condition flags based on the value of the input register. The instruction RMIF accepts one source register and two immediate values, rotating the first source register using the first immediate value and setting the NZCV condition flags masked by the second immediate value.

The instructions XAFLAG and AXFLAG convert PSTATE condition flags between the FCMP instruction format and an alternative format. See [Table C6-1 on page C6-874](#) for more information.

Table C3-55 on page C3-249 shows the Flag manipulation instructions.

Table C3-55 Flag manipulation instructions

Mnemonic	Instruction	See
AXFLAG	Convert from FCMP comparison format to the alternative format	AXFLAG on page C6-919
CFINV	Invert value of the PSTATE.C bit	CFINV on page C6-964
RMIF	Rotate, mask insert flags	RMIF on page C6-1291
SETF8	Evaluation of 8-bit flags	SETF8, SETF16 on page C6-1311
SETF16	Evaluation of 16-bit flags	SETF8, SETF16 on page C6-1311
XAFLAG	Convert from alternative format to FCMP comparison format	XAFLAG on page C6-1516

C3.4.5 Logical (shifted register)

The Logical (shifted register) instructions apply an optional shift operator to the second source register value before performing the main operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators LSL, ASR, LSR, and ROR accept a constant immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator and amount implies LSL #0, which means that there is no shift. A disassembler must not output LSL #0. However, a disassembler must output all other shifts by zero.

Note

Apart from ANDS, TST, and BICS the logical instructions do not set the Condition flags, but the final result of a bit operation can usually directly control a CBZ, CBNZ, TBZ, or TBNZ conditional branch.

Table C3-56 on page C3-250 shows the Logical (shifted register) instructions.

Table C3-56 Logical (shifted register) instructions

Mnemonic	Instruction	See
AND	Bitwise AND	<i>AND (shifted register)</i> on page C6-899
ANDS	Bitwise AND and set flags	<i>ANDS (shifted register)</i> on page C6-903
BIC	Bitwise bit clear	<i>BIC (shifted register)</i> on page C6-930
BICS	Bitwise bit clear and set flags	<i>BICS (shifted register)</i> on page C6-932
EON	Bitwise exclusive OR NOT	<i>EON (shifted register)</i> on page C6-1020
EOR	Bitwise exclusive OR	<i>EOR (shifted register)</i> on page C6-1024
ORR	Bitwise inclusive OR	<i>ORR (shifted register)</i> on page C6-1259
MVN	Bitwise NOT	<i>MVN</i> on page C6-1244
ORN	Bitwise inclusive OR NOT	<i>ORN (shifted register)</i> on page C6-1255
TST	Test bits	<i>TST (shifted register)</i> on page C6-1492

C3.4.6 Move (register)

The Move (register) instructions are aliases for other data processing instructions. They copy a value from a general-purpose register to another general-purpose register or the current stack pointer, or from the current stack pointer to a general-purpose register.

Table C3-57 MOV register instructions

Mnemonic	Instruction	See
MOV	Move register	<i>MOV (register)</i> on page C6-1228
	Move register to SP or move SP to register	<i>MOV (to/from SP)</i> on page C6-1221

C3.4.7 Shift (register)

In the Shift (register) instructions, the shift amount is the positive value in the second source register modulo the register size. The register width of the instruction controls whether the new bits are fed into the result on a right shift or rotate at bit[63] or bit[31].

Table C3-58 on page C3-250 shows the Shift (register) instructions.

Table C3-58 Shift (register) instructions

Mnemonic	Instruction	See
ASRV	Arithmetic shift right variable	<i>ASRV</i> on page C6-909

Table C3-58 Shift (register) instructions (continued)

Mnemonic	Instruction	See
LSLV	Logical shift left variable	LSLV on page C6-1209
LSRV	Logical shift right variable	LSRV on page C6-1215
RORV	Rotate right variable	RORV on page C6-1296

However, the Shift (register) instructions have a preferred set of aliases that match the shift immediate aliases described in [Shift \(immediate\) on page C3-245](#).

[Table C3-59 on page C3-251](#) shows the aliases for Shift (register) instructions.

Table C3-59 Aliases for Variable shift instructions

Mnemonic	Instruction	See
ASR	Arithmetic shift right	ASR (register) on page C6-905
LSL	Logical shift left	LSL (register) on page C6-1205
LSR	Logical shift right	LSR (register) on page C6-1211
ROR	Rotate right	ROR (register) on page C6-1294

C3.4.8 Multiply and divide

This section describes the instructions used for integer multiplication and division. It contains the following subsections:

- [Multiply on page C3-251](#).
- [Divide on page C3-252](#).

Multiply

The Multiply instructions write to a single 32-bit or 64-bit destination register, and are built around the fundamental four operand multiply-add and multiply-subtract operation, together with 32-bit to 64-bit widening variants. A 64-bit to 128-bit widening multiple can be constructed with two instructions, using SMULH or UMULH to generate the upper 64 bits. [Table C3-60 on page C3-251](#) shows the Multiply instructions.

Table C3-60 Multiply integer instructions

Mnemonic	Instruction	See
MADD	Multiply-add	MADD on page C6-1217
MSUB	Multiply-subtract	MSUB on page C6-1241
MNEG	Multiply-negate	MNEG on page C6-1219
MUL	Multiply	MUL on page C6-1243
SMADDL	Signed multiply-add long	SMADDL on page C6-1314
SMSUBL	Signed multiply-subtract long	SMSUBL on page C6-1318
SMNEGL	Signed multiply-negate long	SMNEGL on page C6-1317
SMULL	Signed multiply long	SMULL on page C6-1321
SMULH	Signed multiply high	SMULH on page C6-1320

Table C3-60 Multiply integer instructions (continued)

Mnemonic	Instruction	See
UMADDL	Unsigned multiply-add long	UMADDL on page C6-1503
UMSUBL	Unsigned multiply-subtract long	UMSUBL on page C6-1506
UMNEGL	Unsigned multiply-negate long	UMNEGL on page C6-1505
UMULL	Unsigned multiply long	UMULL on page C6-1509
UMULH	Unsigned multiply high	UMULH on page C6-1508

Divide

The Divide instructions compute the quotient of a division, rounded towards zero. The remainder can then be computed as (numerator - (quotient × denominator)), using the MSUB instruction.

If a signed integer division ($INT_MIN / -1$) is performed where INT_MIN is the most negative integer value representable in the selected register size, then the result overflows the signed integer range. No indication of this overflow is produced and the result that is written to the destination register is INT_MIN .

A division by zero results in a zero being written to the destination register, without any indication that the division by zero occurred.

[Table C3-61 on page C3-252](#) shows the Divide instructions.

Table C3-61 Divide instructions

Mnemonic	Instruction	See
SDIV	Signed divide	SDIV on page C6-1310
UDIV	Unsigned divide	UDIV on page C6-1502

C3.4.9 CRC32

The CRC32 instructions operate on the general-purpose register file to update a 32-bit CRC value from an input value comprising 1, 2, 4, or 8 bytes. There are two different classes of CRC instructions, CRC32, and CRC32C, that support two commonly used 32-bit polynomials, known as CRC-32 and CRC-32C.

To fit with common usage, the bit order of the values is reversed as part of the operation.

When bits[19:16] of `ID_AA64ISAR0_EL1` are set to `0b0001`, the CRC instructions are implemented.

These instructions are OPTIONAL in an Armv8.0 implementation.

All implementations of Armv8.1 architecture and later are required to implement the CRC32 instructions.

[Table C3-62 on page C3-252](#) shows the CRC instructions.

Table C3-62 CRC32 instructions

Mnemonic	Instruction	See
CRC32B	CRC-32 sum from byte	CRC32B, CRC32H, CRC32W, CRC32X on page C6-990

CRC32W	CRC-32 sum from word	CRC32B, CRC32H, CRC32W, CRC32X on page C6-990
CRC32X	CRC-32 sum from doubleword	CRC32B, CRC32H, CRC32W, CRC32X on page C6-990

Table C3-62 CRC32 instructions (continued)

Mnemonic	Instruction	See
CRC32CB	CRC-32C sum from byte	CRC32CB , CRC32CH , CRC32CW , CRC32CX on page C6-992
CRC32CH	CRC-32C sum from halfword	CRC32CB , CRC32CH , CRC32CW , CRC32CX on page C6-992
CRC32CW	CRC-32C sum from word	CRC32CB , CRC32CH , CRC32CW , CRC32CX on page C6-992
CRC32CX	CRC-32C sum from doubleword	CRC32CB , CRC32CH , CRC32CW , CRC32CX on page C6-992

C3.4.10 Bit operation

[Table C3-63 on page C3-253](#) shows the Bit operation instructions.

Table C3-63 Bit operation instructions

Mnemonic	Instruction	See
CLS	Count leading sign bits	CLS on page C6-971
CLZ	Count leading zero bits	CLZ on page C6-973
RBIT	Reverse bit order	RBIT on page C6-1280
REV	Reverse bytes in register	REV on page C6-1284
REV16	Reverse bytes in halfwords	REV16 on page C6-1286
REV32	Reverse bytes in words	REV32 on page C6-1288
REV64	Reverse bytes in register	REV64 on page C6-1290

C3.4.11 Conditional select

The Conditional select instructions select between the first or second source register, depending on the current state of the Condition flags. When the named condition is true, the first source register is selected and its value is copied without modification to the destination register. When the condition is false the second source register is selected and its value might be optionally inverted, negated, or incremented by one, before writing to the destination register.

Other useful conditional set and conditional unary operations are implemented as aliases of the four Conditional select instructions.

[Table C3-64 on page C3-253](#) shows the Conditional select instructions.

Table C3-64 Conditional select instructions

Mnemonic	Instruction	See
CSEL	Conditional select	CSEL on page C6-995
CSINC	Conditional select increment	CSINC on page C6-1001
CSINV	Conditional select inversion	CSINV on page C6-1003
CSNEG	Conditional select negation	CSNEG on page C6-1005
CSET	Conditional set	CSET on page C6-997
CSETM	Conditional set mask	CSETM on page C6-999

Table C3-64 Conditional select instructions (continued)

Mnemonic	Instruction	See
CINC	Conditional increment	CINC on page C6-966
CINV	Conditional invert	CINV on page C6-968
CNEG	Conditional negate	CNEG on page C6-987

C3.4.12 Conditional comparison

The Conditional comparison instructions provide a conditional select for the NZCV Condition flags, setting the flags to the result of an arithmetic comparison of its two source register values if the named input condition is true, or to an immediate value if the input condition is false. There are register and immediate forms. The immediate form compares the source register to a small 5-bit unsigned value.

[Table C3-65 on page C3-254](#) shows the Conditional comparison instructions.

Table C3-65 Conditional comparison instructions

Mnemonic	Instruction	See
CCMN	Conditional compare negative (register)	CCMN (register) on page C6-958
CCMN	Conditional compare negative (immediate)	CCMN (immediate) on page C6-956
CCMP	Conditional compare (register)	CCMP (register) on page C6-962
CCMP	Conditional compare (immediate)	CCMP (immediate) on page C6-960

C3.5 Data processing - SIMD and floating-point

This section describes the instruction groups for data processing with SIMD and floating-point register operands.

[Common features of SIMD instructions on page C3-255](#) gives general information about SIMD instructions.

The following subsections describe the scalar floating-point data processing instructions:

- [Floating-point move \(register\) on page C3-256.](#)
- [Floating-point move \(immediate\) on page C3-256.](#)
- [Floating-point conversion on page C3-257.](#)
- [Floating-point round to integral value on page C3-258.](#)
- [Floating-point multiply-add on page C3-260.](#)
- [Floating-point arithmetic \(one source\) on page C3-260.](#)
- [Floating-point arithmetic \(two sources\) on page C3-260.](#)
- [Floating-point minimum and maximum on page C3-260.](#)
- [Floating-point comparison on page C3-261.](#)
- [Floating-point conditional select on page C3-262.](#)
- [BFloat16 floating-point instructions on page C3-262.](#)

The following subsections describe the SIMD data processing instructions:

- [SIMD move on page C3-262](#)
- [SIMD arithmetic on page C3-262.](#)
- [SIMD compare on page C3-266.](#)
- [SIMD widening and narrowing arithmetic on page C3-267.](#)
- [SIMD table lookup on page C3-276.](#)
- [SIMD by element arithmetic on page C3-270.](#)
- [SIMD permute on page C3-271.](#)
- [SIMD immediate on page C3-271.](#)
- [SIMD shift \(immediate\) on page C3-272.](#)
- [SIMD floating-point and integer conversion on page C3-273.](#)
- [SIMD reduce \(across vector lanes\) on page C3-274.](#)
- [SIMD pairwise arithmetic on page C3-275.](#)
- [SIMD dot product on page C3-275.](#)
- [SIMD table lookup on page C3-276.](#)
- [SIMD complex number arithmetic on page C3-276.](#)
- [SIMD BFloat16 on page C3-276.](#)
- [SIMD matrix multiplication on page C3-277.](#)
- [The Cryptographic Extension on page C3-278.](#)

For information about the encoding structure of the instructions in this instruction group, see [Data Processing -- Scalar Floating-Point and Advanced SIMD on page C4-342](#).

For information about the floating-point exceptions, see [Floating-point exceptions and exception traps on page D1-2495](#).

C3.5.1 Common features of SIMD instructions

A number of SIMD instructions come in three forms:

Wide	Indicated by the suffix <i>W</i> . The element width of the destination register and the first source operand is double that of the second source operand.
Long	Indicated by the suffix <i>L</i> . The element width of the destination register is double that of both source operands.
Narrow	Indicated by the suffix <i>N</i> . The element width of the destination register is half that of both source operands.

In addition, each vector form of the instruction is part of a pair, with a second and upper half suffix of 2, to identify the variant of the instruction:

- Where a SIMD operation widens or lengthens a 64-bit vector to a 128-bit vector, the instruction provides a second part operation that can extract the source from the upper 64 bits of the source registers.
- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the instruction provides a second-part operation that can pack the result of a second operation into the upper part of the same destination register.

———— **Note** ————

This is referred to as a *lane set specifier*.

C3.5.2 Floating-point move (register)

The Floating-point move (register) instructions copy a scalar floating-point value from one register to another register without performing any conversion.

Some of the Floating-point move (register) instructions overlap with the functionality provided by the Advanced SIMD instructions DUP, INS, and UMOV. However, Arm recommends using the FMOV instructions when operating on scalar floating-point data to avoid the creation of scalar floating-point code that depends on the availability of the Advanced SIMD instruction set.

[Table C3-66 on page C3-256](#) shows the Floating-point move (register) instructions.

Table C3-66 Floating-point move (register) instructions

Mnemonic	Instruction	See
FMOV	Floating-point move register without conversion	<i>FMOV (register)</i> on page C7-1819
	Floating-point move to or from general-purpose register without conversion	<i>FMOV (general)</i> on page C7-1821

C3.5.3 Floating-point move (immediate)

The Floating-point move (immediate) instructions convert a small constant immediate floating-point value into a half-precision, single-precision, or double-precision scalar floating-point value in a SIMD and floating-point register.

The floating-point constant can be specified either in decimal notation, such as 12.0 or -1.2e1, or as a string beginning with 0x followed by a hexadecimal representation of the IEEE 754 half-precision, single-precision, or double-precision encoding. Arm recommends that a disassembler uses the decimal notation, provided that this displays the value precisely.

———— **Note** ————

When [FEAT_FP16](#) is not implemented, the only half-precision instructions that are supported are floating-point conversions between half-precision, single-precision, and double-precision.

The floating-point value must be expressible as $(\pm n/16 \times 2^r)$, where n is an integer in the range $16 \leq n \leq 31$ and r is an integer in the range $-3 \leq r \leq 4$, that is a normalized binary floating-point encoding with one sign bit, four bits of fraction, and a 3-bit exponent.

[Table C3-67 on page C3-256](#) shows the Floating-point move (immediate) instruction:

Table C3-67 Floating-point move (immediate) instruction

Mnemonic	Instruction	See
FMOV	Floating-point move immediate	<i>FMOV (scalar, immediate)</i> on page C7-1824

C3.5.4 Floating-point conversion

The following subsections describe the conversion of floating-point values:

- [Convert floating-point precision on page C3-257.](#)
- [Convert between floating-point and integer or fixed-point on page C3-257.](#)

Convert floating-point precision

These instructions convert a floating-point scalar with one precision to a floating-point scalar with a different precision, using the current rounding mode as specified by `FPCR.RMode`.

[Table C3-68 on page C3-257](#) shows the Floating-point precision conversion instruction.

Table C3-68 Floating-point precision conversion instruction

Mnemonic	Instruction	See
FCVT	Floating-point convert precision (scalar)	FCVT on page C7-1681

Convert between floating-point and integer or fixed-point

These instructions convert a floating-point scalar in a SIMD and floating-point register to or from a signed or unsigned integer or fixed-point value in a general-purpose register. For a fixed-point value, a final immediate operand indicates that the general-purpose register holds a fixed-point number and `fbits` indicates the number of bits after the binary point. `fbits` is in the range 1- 32 inclusive for a 32-bit general-purpose register name, and 1-64 inclusive for a 64-bit general-purpose register name.

These instructions can cause the following floating-point exceptions:

Invalid Operation

Occurs if the floating-point input is a NaN, infinity, or a numerical value that cannot be represented in the destination register. An out of range integer or fixed-point result is saturated to the size of the destination register.

Inexact Occurs if the numeric result that differs from the input value.

Input Denormal

Can occur when zero replaces a double-precision or single-precision denormal input, see [Flushing denormalized numbers to zero on page A1-54](#) and [Input Denormal exceptions on page D1-2495](#).

[Table C3-69 on page C3-257](#) shows the Floating-point and fixed-point conversion instructions.

Table C3-69 Floating-point and integer or fixed-point conversion instructions

Mnemonic	Instruction	See
FCVTAS	Floating-point scalar convert to signed integer, rounding to nearest with ties to away (scalar form)	FCVTAS (scalar) on page C7-1686

	Unsigned fixed-point convert to floating-point, using the current rounding mode (scalar form)	UCVTF (scalar, fixed-point) on page C7-2341

C3.5.5 Floating-point round to integral value

The following subsections describe instructions which round a floating-point number to an integral valued floating-point number in the same format:

- [Floating-point round to an integer of the same size as the register on page C3-258](#)
- [Floating-point round to 32-bit or 64-bit integer on page C3-259](#)

Floating-point round to an integer of the same size as the register

The following instructions round a floating-point value to an integer floating-point value of the same size.

For these instructions:

- A zero input gives a zero result with the same sign.
- An infinite input gives an infinite result with the same sign.
- A NaN is propagated as in normal floating-point arithmetic.

These instructions can cause the following floating-point exceptions:

Invalid Operation

Occurs in response to a floating-point input of a signaling NaN.

Inexact, FRINTX instruction only

Occurs if the result is numeric and does not have the same numerical value as the input.

Input Denormal

Can occur when zero replaces a double-precision or single-precision denormal input, see [Flushing denormalized numbers to zero on page A1-54](#) and [Input Denormal exceptions on page D1-2495](#).

[Table C3-70 on page C3-259](#) shows the Floating-point round to integer instructions.

Table C3-70 Floating-point round to integer instructions

Mnemonic	Instruction	See
FRINTA	Floating-point round to integer, to nearest with ties to away	FRINTA (scalar) on page C7-1879
FRINTI	Floating-point round to integer, using current rounding mode	FRINTI (scalar) on page C7-1883

FRINTN	Floating-point round to integer, to nearest with ties to even	FRINTN (scalar) on page C7-1891
FRINTP	Floating-point round to integer, toward positive infinity	FRINTP (scalar) on page C7-1895
FRINTX	Floating-point round to integer exact, using current rounding mode	FRINTX (scalar) on page C7-1899
FRINTZ	Floating-point round to integer, toward zero	FRINTZ (scalar) on page C7-1903

Floating-point round to 32-bit or 64-bit integer

The following instructions are present if [FEAT_FRINTTS](#) is implemented, The instructions round to a value that fits in a 32-bit integer or a 64-bit integer size, and use either round towards zero or the ambient rounding model.

Invalid Operation

Forced to be the most negative integer representable in the target size, and occurs in response to a floating-point input of a signaling NaN, an infinite input, or an out of range input.

Inexact

Occurs if the result is numeric and does not have the same numerical value as the input.

Input Denormal

Can occur when zero replaces a double-precision or single-precision denormal input, see [Flushing denormalized numbers to zero on page A1-54](#) and [Input Denormal exceptions on page D1-2495](#).

[Table C3-71 on page C3-259](#) shows the Floating-point round to 32-bit or 64-bit integer instructions.

Table C3-71 Floating-point round to integer instructions

Mnemonic	Instruction	See
FRINT32X	Floating-point round to 32-bit integer, using current rounding model	FRINT32X (scalar) on page C7-1863
FRINT32Z	Floating-point round to 32-bit integer, toward zero	FRINT32Z (scalar) on page C7-1867
FRINT64X	Floating point round to 64-bit integer using current rounding model	FRINT64X (scalar) on page C7-1871
FRINT64Z	Floating point round to 64-bit integer, toward zero	FRINT64Z (scalar) on page C7-1875

C3.5.6 Floating-point multiply-add

Table C3-72 on page C3-260 shows the Floating-point multiply-add instructions that require three source register operands.

Table C3-72 Floating-point multiply-add instructions

Mnemonic	Instruction	See
FMADD	Floating-point scalar fused multiply-add	FMADD on page C7-1755
FMSUB	Floating-point scalar fused multiply-subtract	FMSUB on page C7-1826
FNMADD	Floating-point scalar negated fused multiply-add	FNMADD on page C7-1847
FNMSUB	Floating-point scalar negated fused multiply-subtract	FNMSUB on page C7-1849

C3.5.7 Floating-point arithmetic (one source)

Table C3-73 on page C3-260 shows the Floating-point arithmetic instructions that require a single source register operand.

Table C3-73 Floating-point arithmetic instructions with one source register

Mnemonic	Instructions	See
FABS	Floating-point scalar absolute value	FABS (scalar) on page C7-1618
FNEG	Floating-point scalar negate	FNEG (scalar) on page C7-1845

C3.5.8 Floating-point arithmetic (two sources)

Table C3-74 on page C3-260 shows the Floating-point arithmetic instructions that require two source register operands.

Table C3-74 Floating-point arithmetic instructions with two source registers

Mnemonic	Instruction	See
FADD	Floating-point scalar add	FADD (scalar) on page C7-1630
FDIV	Floating-point scalar divide	FDIV (scalar) on page C7-1752
FMUL	Floating-point scalar multiply	FMUL (scalar) on page C7-1834
FNMUL	Floating-point scalar multiply-negate	FNMUL (scalar) on page C7-1851
FSUB	Floating-point scalar subtract	FSUB (scalar) on page C7-1917

C3.5.9 Floating-point minimum and maximum

The $\min(x, y)$ and $\max(x, y)$ operations return a quiet NaN when either x or y is NaN.

As described in [Flushing denormalized numbers to zero on page A1-54](#), if flushing denormalized inputs to zero is enabled, denormal operands are flushed to zero before comparison, and if the result of the comparison is the flushed value, then a zero value is returned. Where both x and y are zero, or denormal values flushed to zero, with different signs, then +0.0 is returned by $\max()$ and -0.0 by $\min()$.

The `minNum(x,y)` and `maxNum(x,y)` operations follow the IEEE 754-2008 standard and return the numerical operand when one operand is numerical and the other a quiet NaN. Apart from this additional handling of a single quiet NaN the result is then identical to `min(x,y)` and `max(x,y)`.

Table C3-75 on page C3-261 shows the Floating-point instructions that can perform floating-point minimum and maximum operations.

Table C3-75 Floating-point minimum and maximum instructions

Mnemonic	Instruction	See
FMAX	Floating-point scalar maximum	<i>FMAX (scalar)</i> on page C7-1759
FMAXNM	Floating-point scalar maximum number	<i>FMAXNM (scalar)</i> on page C7-1763
FMIN	Floating-point scalar minimum	<i>FMIN (scalar)</i> on page C7-1779
FMINNM	Floating-point scalar minimum number	<i>FMINNM (scalar)</i> on page C7-1783

C3.5.10 Floating-point comparison

These instructions set the NZCV Condition flags in PSTATE, based on the result of a comparison of two operands. If the floating-point comparisons are *unordered*, where one or both operands are a form of NaN, the C and V bits are set to 1 and the N and Z bits are cleared to 0.

———— **Note** ————

The NZCV flags in the [FPSR](#) are associated with AArch32 state. The A64 floating-point comparison instructions do not change the Condition flags in the [FPSR](#).

For the conditional Floating-point comparison instructions, if the condition is TRUE, the flags are updated to the result of the comparison, otherwise the flags are updated to the immediate value that is defined in the instruction encoding.

The quiet compare instructions generate an Invalid Operation floating-point exception if either of the source operands is a signaling NaN. The signaling compare instructions generate an Invalid Operation floating-point exception if either of the source operands is any type of NaN.

———— **Note** ————

If [FEAT_FlagM2](#) is implemented, instructions [AXFLAG](#) and [XAFLAG](#) convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format. See [FEAT_FlagM](#) on page A2-91 for more information.

Table C3-76 on page C3-261 shows the Floating-point comparison instructions.

Table C3-76 Floating-point comparison instructions

Mnemonic	Instruction	See
FCMP	Floating-point quiet compare	<i>FCMP</i> on page C7-1675
FCMPE	Floating-point signaling compare	<i>FCMPE</i> on page C7-1677
FCCMP	Floating-point conditional quiet compare	<i>FCCMP</i> on page C7-1638
FCCMPE	Floating-point conditional signaling compare	<i>FCCMPE</i> on page C7-1640

C3.5.11 Floating-point conditional select

Table C3-77 on page C3-262 shows the Floating-point conditional select instructions.

Table C3-77 Floating-point conditional select instructions

Mnemonic	Instruction	See
FCSEL	Floating-point scalar conditional select	FCSEL on page C7-1679

C3.5.12 BFloat16 floating-point instructions

The BFloat16 floating-point instructions are provided by [FEAT_BF16](#). The instructions to convert single-precision floating-point values to BF16 format give a more accurate conversion than a simple truncation of F32 to BF16 by removing the least significant 16 bits of the fraction. They also honor the settings of [FPCR](#).

Table C3-78 on page C3-262 shows these instructions.

Table C3-78 BFloat16 floating-point instructions

Mnemonic	Instruction	See
BFCVT	BFloat16 floating-point convert from single-precision to BFloat16 format (scalar)	BFCVT on page C7-1545

C3.5.13 SIMD move

The functionality of some data movement instructions overlaps with that provided by the scalar floating-point FMOV instructions described in [Floating-point move \(register\)](#) on page C3-256.

Table C3-79 on page C3-262 shows the SIMD move instructions.

Table C3-79 SIMD move instructions

Mnemonic	Instruction	See
DUP	Duplicate vector element to vector or scalar	DUP (element) on page C7-1603
DUP	Duplicate general-purpose register to vector	DUP (general) on page C7-1606
INS ^a	Insert vector element from another vector element	INS (element) on page C7-1919
	Insert vector element from general-purpose register	INS (general) on page C7-1921
MOV	Move vector element to vector element	MOV (element) on page C7-1991
	Move general-purpose register to vector element	MOV (from general) on page C7-1993
	Move vector element to scalar	MOV (scalar) on page C7-1989
	Move vector element to general-purpose register	MOV (to general) on page C7-1996
UMOV	Unsigned move vector element to general-purpose register	UMOV on page C7-2376
SMOV	Signed move vector element to general-purpose register	SMOV on page C7-2143

a. Disassembles as MOV.

C3.5.14 SIMD arithmetic

Table C3-80 on page C3-263 shows the SIMD arithmetic instructions.

Table C3-80 SIMD arithmetic instructions

Mnemonic	Instruction	See
ADD	Add (vector and scalar form)	<i>ADD (vector)</i> on page C7-1527
AND	Bitwise AND (vector form)	<i>AND (vector)</i> on page C7-1541
BIC	Bitwise bit clear (register) (vector form)	<i>BIC (vector, register)</i> on page C7-1559
BIF	Bitwise insert if false (vector form)	<i>BIF</i> on page C7-1561
BIT	Bitwise insert if true (vector form)	<i>BIT</i> on page C7-1563
BSL	Bitwise select (vector form)	<i>BSL</i> on page C7-1565
EOR	Bitwise exclusive OR (vector form)	<i>EOR (vector)</i> on page C7-1608
FABD	Floating-point absolute difference (vector and scalar form)	<i>FABD</i> on page C7-1613
FADD	Floating-point add (vector form)	<i>FADD (vector)</i> on page C7-1628
FDIV	Floating-point divide (vector form)	<i>FDIV (vector)</i> on page C7-1750
FMAX	Floating-point maximum (vector form)	<i>FMAXP (vector)</i> on page C7-1773
FMAXNM	Floating-point maximum number (vector form)	<i>FMAXNM (vector)</i> on page C7-1761
FMIN	Floating-point minimum (vector form)	<i>FMIN (vector)</i> on page C7-1777
FMINNM	Floating-point minimum number (vector form)	<i>FMINNM (vector)</i> on page C7-1781
FMLA	Floating-point fused multiply-add (vector form)	<i>FMLA (vector)</i> on page C7-1801
FMLAL, FMLAL2	Floating-point fused multiply-add long (vector form)	<i>FMLAL, FMLAL2 (vector)</i> on page C7-1805
FMLS	Floating-point fused multiply-subtract (vector form)	<i>FMLS (vector)</i> on page C7-1811
FMLS, FMLS2	Floating-point fused multiply-subtract long (vector form)	<i>FMLS, FMLS2 (vector)</i> on page C7-1815
FMUL	Floating-point multiply (vector form)	<i>FMUL (vector)</i> on page C7-1832
FMULX	Floating-point multiply extended (vector and scalar form)	<i>FMULX</i> on page C7-1840
FRECPS	Floating-point reciprocal step (vector and scalar form)	<i>FRECPS</i> on page C7-1856
FRSQRTS	Floating-point reciprocal square root step (vector and scalar form)	<i>FRSQRTS</i> on page C7-1908
FSUB	Floating-point subtract (vector form)	<i>FSUB (vector)</i> on page C7-1915
MLA	Multiply-add (vector form)	<i>MLA (vector)</i> on page C7-1983
MLS	Multiply-subtract (vector form)	<i>MLS (vector)</i> on page C7-1987
MUL	Multiply (vector form)	<i>MUL (vector)</i> on page C7-2003
MOV	Move vector register (vector form)	<i>MOV (vector)</i> on page C7-1995
ORN	Bitwise inclusive OR NOT (vector form)	<i>ORN (vector)</i> on page C7-2013
ORR	Bitwise inclusive OR (register) (vector form)	<i>ORR (vector, register)</i> on page C7-2017
PMUL	Polynomial multiply (vector form)	<i>PMUL</i> on page C7-2019

Table C3-80 SIMD arithmetic instructions (continued)

Mnemonic	Instruction	See
SABA	Signed absolute difference and accumulate (vector form)	SABA on page C7-2038
SABD	Signed absolute difference (vector form)	SABD on page C7-2042
SHADD	Signed halving add (vector form)	SHADD on page C7-2088
SHSUB	Signed halving subtract (vector form)	SHSUB on page C7-2097
SMAX	Signed maximum (vector form)	SMAX on page C7-2120
SMIN	Signed minimum (vector form)	SMIN on page C7-2126
SQADD	Signed saturating add (vector and scalar form)	SQADD on page C7-2152
SQDMULH	Signed saturating doubling multiply returning high half (vector and scalar form)	SQDMULH (vector) on page C7-2171
SQRSHL	Signed saturating rounding shift left (register) (vector and scalar form)	SQRSHL on page C7-2198
SQRDMLAH	Signed saturating rounding doubling multiply accumulate returning high half	SQRDMLAH (vector) on page C7-2184
SQRDMLSH	Signed saturating rounding doubling multiply subtract returning high half	SQRDMLSH (vector) on page C7-2190
SQRDMULH	Signed saturating rounding doubling multiply returning high half (vector and scalar form)	SQRDMULH (vector) on page C7-2196
SQSHL	Signed saturating shift left (register) (vector and scalar form)	SQSHL (register) on page C7-2209
SQSUB	Signed saturating subtract (vector and scalar form)	SQSUB on page C7-2220
SRHADD	Signed rounding halving add (vector form)	SRHADD on page C7-2228
SRSHL	Signed rounding shift left (register) (vector and scalar form)	SRSHL on page C7-2233
SSHL	Signed shift left (register) (vector and scalar form)	SSHL on page C7-2241
SUB	Subtract (vector and scalar form)	SUB (vector) on page C7-2299
UABA	Unsigned absolute difference and accumulate (vector form)	UABA on page C7-2317
UABD	Unsigned absolute difference (vector form)	UABD on page C7-2321
UHADD	Unsigned halving add (vector form)	UHADD on page C7-2349
UHSUB	Unsigned halving subtract (vector form)	UHSUB on page C7-2351
UMAX	Unsigned maximum (vector form)	UMAX on page C7-2353
UMIN	Unsigned minimum (vector form)	UMIN on page C7-2359
UQADD	Unsigned saturating add (vector and scalar form)	UQADD on page C7-2383
UQRSHL	Unsigned saturating rounding shift left (register) (vector and scalar form)	UQRSHL on page C7-2385
UQSHL	Unsigned saturating shift left (register) (vector and scalar form)	UQSHL (register) on page C7-2393
UQSUB	Unsigned saturating subtract (vector and scalar form)	UQSUB on page C7-2398

Table C3-80 SIMD arithmetic instructions (continued)

Mnemonic	Instruction	See
URHADD	Unsigned rounding halving add (vector form)	URHADD on page C7-2404
URSHL	Unsigned rounding shift left (register) (vector and scalar form)	URSHL on page C7-2406
USHL	Unsigned shift left (register) (vector and scalar form)	USHL on page C7-2419

C3.5.15 SIMD compare

The SIMD compare instructions compare vector or scalar elements according to the specified condition and set the destination vector element to all ones if the condition holds, or to zero if the condition does not hold.

———— **Note** ————

Some of the comparisons, such as LS, LE, LO, and LT, can be made by reversing the operands and using the opposite comparison, HS, GE, HI, or GT.

Table C3-81 on page C3-266 shows that SIMD compare instructions.

Table C3-81 SIMD compare instructions

Mnemonic	Instruction	See
CMEQ	Compare bitwise equal (vector and scalar form)	<i>CMEQ (register)</i> on page C7-1571
	Compare bitwise equal to zero (vector and scalar form)	<i>CMEQ (zero)</i> on page C7-1573
CMHS	Compare unsigned higher or same (vector and scalar form)	<i>CMHS (register)</i> on page C7-1591
CMGE	Compare signed greater than or equal (vector and scalar form)	<i>CMGE (register)</i> on page C7-1576
	Compare signed greater than or equal to zero (vector and scalar form)	<i>CMGE (zero)</i> on page C7-1579
CMHI	Compare unsigned higher (vector and scalar form)	<i>CMHI (register)</i> on page C7-1588
CMGT	Compare signed greater than (vector and scalar form)	<i>CMGT (register)</i> on page C7-1582
	Compare signed greater than zero (vector and scalar form)	<i>CMGT (zero)</i> on page C7-1585
CMLE	Compare signed less than or equal to zero (vector and scalar form)	<i>CMLE (zero)</i> on page C7-1594
CMLT	Compare signed less than zero (vector and scalar form)	<i>CMLT (zero)</i> on page C7-1597
CMTST	Compare bitwise test bits nonzero (vector and scalar form)	<i>CMTST</i> on page C7-1599
FCMEQ	Floating-point compare equal (vector and scalar form)	<i>FCMEQ (register)</i> on page C7-1642
	Floating-point compare equal to zero (vector and scalar form)	<i>FCMEQ (zero)</i> on page C7-1646
FCMGE	Floating-point compare greater than or equal (vector and scalar form)	<i>FCMGE (register)</i> on page C7-1649
	Floating-point compare greater than or equal to zero (vector and scalar form)	<i>FCMGE (zero)</i> on page C7-1653
FCMGT	Floating-point compare greater than (vector and scalar form)	<i>FCMGT (register)</i> on page C7-1656
	Floating-point compare greater than zero (vector and scalar form)	<i>FCMGT (zero)</i> on page C7-1660
FCMLE	Floating-point compare less than or equal to zero (vector and scalar form)	<i>FCMLE (zero)</i> on page C7-1669
FCMLT	Floating-point compare less than zero (vector and scalar form)	<i>FCMLT (zero)</i> on page C7-1672
FACGE	Floating-point absolute compare greater than or equal (vector and scalar form)	<i>FACGE</i> on page C7-1620
FACGT	Floating-point absolute compare greater than (vector and scalar form)	<i>FACGT</i> on page C7-1624

C3.5.16 SIMD widening and narrowing arithmetic

For information about the variants of these instructions, see [Common features of SIMD instructions](#) on page C3-255.

[Table C3-82 on page C3-267](#) shows the SIMD widening and narrowing arithmetic instructions.

Table C3-82 SIMD widening and narrowing arithmetic instructions

Mnemonic	Instruction	See
ADDHN, ADDHN2	Add returning high, narrow (vector form)	ADDHN, ADDHN2 on page C7-1529
PMULL, PMULL2	Polynomial multiply long (vector form)	PMULL, PMULL2 on page C7-2021 See also The Cryptographic Extension on page C3-278
RADDHN, RADDHN2	Rounding add returning high, narrow (vector form)	RADDHN, RADDHN2 on page C7-2023
RSUBHN, RSUBHN2	Rounding subtract returning high, narrow (vector form)	RSUBHN, RSUBHN2 on page C7-2036
SABAL, SABAL2	Signed absolute difference and accumulate long (vector form)	SABAL, SABAL2 on page C7-2040
SABDL, SABDL2	Signed absolute difference long (vector form)	SABDL, SABDL2 on page C7-2044
SADDL, SADDL2	Signed add long (vector form)	SADDL, SADDL2 on page C7-2048
SADDW, SADDW2	Signed add wide (vector form)	SADDW, SADDW2 on page C7-2054
SMLAL, SMLAL2	Signed multiply-add long (vector form)	SMLAL, SMLAL2 (vector) on page C7-2135
SMLSL, SMLSL2	Signed multiply-subtract long (vector form)	SMLSL, SMLSL2 (vector) on page C7-2140
SMULL, SMULL2	Signed multiply long (vector form)	SMULL, SMULL2 (vector) on page C7-2148
SQDMLAL, SQDMLAL2	Signed saturating doubling multiply-add long (vector and scalar form)	SQDMLAL, SQDMLAL2 (vector) on page C7-2158
SQDMLSL, SQDMLSL2	Signed saturating doubling multiply-subtract long (vector and scalar form)	SQDMLSL, SQDMLSL2 (vector) on page C7-2165
SQDMULL, SQDMULL2	Signed saturating doubling multiply long (vector and scalar form)	SQDMULL, SQDMULL2 (vector) on page C7-2176
SSUBL, SSUBL2	Signed subtract long (vector form)	SSUBL, SSUBL2 on page C7-2252
SSUBW, SSUBW2	Signed subtract wide (vector form)	SSUBW, SSUBW2 on page C7-2254
SUBHN, SUBHN2	Subtract returning high, narrow (vector form)	SUBHN, SUBHN2 on page C7-2301
UABAL, UABAL2	Unsigned absolute difference and accumulate long (vector form)	UABAL, UABAL2 on page C7-2319
UABDL, UABDL2	Unsigned absolute difference long (vector form)	UABDL, UABDL2 on page C7-2323
UADDL, UADDL2	Unsigned add long (vector form)	UADDL, UADDL2 on page C7-2327
UADDW, UADDW2	Unsigned add wide (vector form)	UADDW, UADDW2 on page C7-2333
UMLAL, UMLAL2	Unsigned multiply-add long (vector form)	UMLAL, UMLAL2 (vector) on page C7-2368
UMLSL, UMLSL2	Unsigned multiply-subtract long (vector form)	UMLSL, UMLSL2 (vector) on page C7-2373
UMULL, UMULL2	Unsigned multiply long (vector form)	UMULL, UMULL2 (vector) on page C7-2381
USUBL, USUBL2	Unsigned subtract long (vector form)	USUBL, USUBL2 on page C7-2433
USUBW, USUBW2	Unsigned subtract wide (vector form)	USUBW, USUBW2 on page C7-2435

C3.5.17 SIMD unary arithmetic

For information about the variants of these instructions, see [Common features of SIMD instructions](#) on page C3-255.

[Table C3-83 on page C3-268](#) shows the SIMD unary arithmetic instructions.

Table C3-83 SIMD unary arithmetic instructions

Mnemonic	Instruction	See
ABS	Absolute value (vector and scalar form)	ABS on page C7-1525
CLS	Count leading sign bits (vector form)	CLS (vector) on page C7-1567
CLZ	Count leading zero bits (vector form)	CLZ (vector) on page C7-1569
CNT	Population count per byte (vector form)	CNT on page C7-1601
FABS	Floating-point absolute (vector form)	FABS (vector) on page C7-1616
FCVTL, FCVTL2	Floating-point convert to higher precision long (vector form)	FCVTL, FCVTL2 on page C7-1693
FCVTN, FCVTN2	Floating-point convert to lower precision narrow (vector form)	FCVTN, FCVTN2 on page C7-1705
FCVTXN, FCVTXN2	Floating-point convert to lower precision narrow, rounding to odd (vector and scalar form)	FCVTXN, FCVTXN2 on page C7-1727
FNEG	Floating-point negate (vector form)	FNEG (vector) on page C7-1843
FRECPE	Floating-point reciprocal estimate (vector and scalar form)	FRECPE on page C7-1853
FRECPX	Floating-point reciprocal exponent (scalar form)	FRECPX on page C7-1859
FRINT32X	Floating-point round to 32-bit integer, using current rounding mode (vector form)	FRINT32X (vector) on page C7-1861
FRINT32Z	Floating-point round to 32-bit integer, toward zero (vector form)	FRINT32Z (vector) on page C7-1865
FRINT64X	Floating-point round to 64-bit integer, using current rounding mode (vector form)	FRINT64X (vector) on page C7-1869
FRINT64Z	Floating-point round to 64-bit integer, toward zero (vector form)	FRINT64Z (vector) on page C7-1873
FRINTA	Floating-point round to integer, to nearest with ties to away (vector form)	FRINTA (vector) on page C7-1877
FRINTI	Floating-point round to integer, using current rounding mode (vector form)	FRINTI (vector) on page C7-1881
FRINTM	Floating-point round to integer, toward minus infinity (vector form)	FRINTM (vector) on page C7-1885
FRINTN	Floating-point round to integer, to nearest with ties to even (vector form)	FRINTN (vector) on page C7-1889
FRINTP	Floating-point round to integer, toward positive infinity (vector form)	FRINTP (vector) on page C7-1893
FRINTX	Floating-point round to integer exact, using current rounding mode (vector form)	FRINTX (vector) on page C7-1897
FRINTZ	Floating-point round to integer, toward zero (vector form)	FRINTZ (vector) on page C7-1901
FRSQRTE	Floating-point reciprocal square root estimate (vector and scalar form)	FRSQRTE on page C7-1905

Table C3-83 SIMD unary arithmetic instructions (continued)

Mnemonic	Instruction	See
FSQRT	Floating-point square root (vector form)	<i>FSQRT (vector)</i> on page C7-1911
MVN	Bitwise NOT (vector form)	<i>MVN</i> on page C7-2005
NEG	Negate (vector and scalar form)	<i>NEG (vector)</i> on page C7-2009
NOT	Bitwise NOT (vector form)	<i>NOT</i> on page C7-2011
RBIT	Bitwise reverse (vector form)	<i>RBIT (vector)</i> on page C7-2026
REV16	Reverse elements in 16-bit halfwords (vector form)	<i>REV16 (vector)</i> on page C7-2028
REV32	Reverse elements in 32-bit words (vector form)	<i>REV32 (vector)</i> on page C7-2030
REV64	Reverse elements in 64-bit doublewords (vector form)	<i>REV64</i> on page C7-2032
SADALP	Signed add and accumulate long pairwise (vector form)	<i>SADALP</i> on page C7-2046
SADDLP	Signed add long pairwise (vector form)	<i>SADDLP</i> on page C7-2050
SQABS	Signed saturating absolute value (vector and scalar form)	<i>SQABS</i> on page C7-2150
SQNEG	Signed saturating negate (vector and scalar form)	<i>SQNEG</i> on page C7-2179
SQXTN, SQXTN2	Signed saturating extract narrow (vector form)	<i>SQXTN, SQXTN2</i> on page C7-2222
SQXTUN, SQXTUN2	Signed saturating extract unsigned narrow (vector and scalar form)	<i>SQXTUN, SQXTUN2</i> on page C7-2225
SUQADD	Signed saturating accumulate of unsigned value (vector and scalar form)	<i>SUQADD</i> on page C7-2305
SXTL, SXTL2	Signed extend long	<i>SXTL, SXTL2</i> on page C7-2307
UADALP	Unsigned add and accumulate long pairwise (vector form)	<i>UADALP</i> on page C7-2325
UADDLP	Unsigned add long pairwise (vector form)	<i>UADDLP</i> on page C7-2329
UQXTN, UQXTN2	Unsigned saturating extract narrow (vector form)	<i>UQXTN, UQXTN2</i> on page C7-2400
URECPE	Unsigned reciprocal estimate (vector form)	<i>URECPE</i> on page C7-2403
URSQRTE	Unsigned reciprocal square root estimate (vector form)	<i>URSQRTE</i> on page C7-2411
USQADD	Unsigned saturating accumulate of signed value (vector and scalar form)	<i>USQADD</i> on page C7-2428
UXTL, UXTL2	Unsigned extend long	<i>UXTL, UXTL2</i> on page C7-2437
XTN, XTN2	Extract narrow (vector form)	<i>XTN, XTN2</i> on page C7-2444

C3.5.18 SIMD by element arithmetic

For information about the variants of these instructions, see [Common features of SIMD instructions](#) on page C3-255.

[Table C3-84 on page C3-270](#) shows the SIMD by element arithmetic instructions.

Table C3-84 SIMD by element arithmetic instructions

Mnemonic	Instruction	See
FMLA	Floating-point fused multiply-add (vector and scalar form)	FMLA (by element) on page C7-1797
FMLAL, FMLAL2	Floating-point fused multiply-add long (vector form)	FMLAL, FMLAL2 (by element) on page C7-1803
FMLS	Floating-point fused multiply-subtract (vector and scalar form)	FMLS (by element) on page C7-1807.
FMLS, FMLSL2	Floating-point fused multiply-subtract long (vector form)	FMLS, FMLSL2 (by element) on page C7-1813
FMUL	Floating-point multiply (vector and scalar form)	FMUL (by element) on page C7-1828
FMULX	Floating-point multiply extended (vector and scalar form)	FMULX (by element) on page C7-1836
MLA	Multiply-add (vector form)	MLA (by element) on page C7-1981
MLS	Multiply-subtract (vector form)	MLS (by element) on page C7-1985
MUL	Multiply (vector form)	MUL (by element) on page C7-2001
SMLAL, SMLAL2	Signed multiply-add long (vector form)	SMLAL, SMLAL2 (by element) on page C7-2132
SMLS, SMLS2	Signed multiply-subtract long (vector form)	SMLS, SMLS2 (by element) on page C7-2137
SMULL, SMULL2	Signed multiply long (vector form)	SMULL, SMULL2 (by element) on page C7-2145
SQDMLAL, SQDMLAL2	Signed saturating doubling multiply-add long (vector and scalar form)	SQDMLAL, SQDMLAL2 (by element) on page C7-2154
SQDMLS, SQDMLS2	Signed saturating doubling multiply-subtract long (vector form)	SQDMLS, SQDMLS2 (by element) on page C7-2161
SQDMULH	Signed saturating doubling multiply returning high half (vector and scalar form)	SQDMULH (by element) on page C7-2168
SQDMULL, SQDMULL2	Signed saturating doubling multiply long (vector and scalar form)	SQDMULL, SQDMULL2 (by element) on page C7-2173
SQRDMLAH	Signed saturating rounding doubling multiply accumulate returning high half	SQRDMLSH (by element) on page C7-2187
SQRDMLSH	Signed saturating rounding doubling multiply subtract returning high half	SQRDMLSH (vector) on page C7-2190
SQRDMULH	Signed saturating rounding doubling multiply returning high half (vector and scalar form)	SQRDMULH (by element) on page C7-2193

Table C3-84 SIMD by element arithmetic instructions (continued)

Mnemonic	Instruction	See
UMLAL, UMLAL2	Unsigned multiply-add long (vector form)	UMLAL, UMLAL2 (by element) on page C7-2365
UMLSL, UMLSL2	Unsigned multiply-subtract long (vector form)	UMLSL, UMLSL2 (by element) on page C7-2370
UMULL, UMULL2	Unsigned multiply long (vector form)	UMULL, UMULL2 (by element) on page C7-2378

C3.5.19 SIMD permute

[Table C3-85 on page C3-271](#) shows the SIMD permute instructions.

Table C3-85 SIMD permute instructions

Mnemonic	Instruction	See
EXT	Extract vector from a pair of vectors	EXT on page C7-1611
TRN1	Transpose vectors (primary)	TRN1 on page C7-2313
TRN2	Transpose vectors (secondary)	TRN2 on page C7-2315
UZP1	Unzip vectors (primary)	UZP1 on page C7-2439
UZP2	Unzip vectors (secondary)	UZP2 on page C7-2441
ZIP1	Zip vectors (primary)	ZIP1 on page C7-2446
ZIP2	Zip vectors (secondary)	ZIP2 on page C7-2448

C3.5.20 SIMD immediate

[Table C3-86 on page C3-271](#) shows the SIMD immediate instructions.

Table C3-86 SIMD immediate instructions

Mnemonic	Instruction	See
BIC	Bitwise bit clear immediate	BIC (vector, immediate) on page C7-1557
FMOV	Floating-point move immediate	FMOV (vector, immediate) on page C7-1817
MOVI	Move immediate	MOVI on page C7-1998
MVNI	Move inverted immediate	MVNI on page C7-2006
ORR	Bitwise inclusive OR immediate	ORR (vector, immediate) on page C7-2015

C3.5.21 SIMD shift (immediate)

For information about the variants of these instructions, see [Common features of SIMD instructions on page C3-255](#).

Table C3-87 on page C3-272 shows the SIMD shift immediate instructions.

Table C3-87 SIMD shift (immediate) instructions

Mnemonic	Instruction	See
RSHRN, RSHRN2	Rounding shift right narrow immediate (vector form)	<i>RSHRN, RSHRN2</i> on page C7-2034
SHL	Shift left immediate (vector and scalar form)	<i>SHL</i> on page C7-2090
SHLL, SHLL2	Shift left long (by element size) (vector form)	<i>SHLL, SHLL2</i> on page C7-2093
SHRN, SHRN2	Shift right narrow immediate (vector form)	<i>SHRN, SHRN2</i> on page C7-2095
SLI	Shift left and insert immediate (vector and scalar form)	<i>SLI</i> on page C7-2099
SQRSHRN, SQRSHRN2	Signed saturating rounded shift right narrow immediate (vector and scalar form)	<i>SQRSHRN, SQRSHRN2</i> on page C7-2200
SQRSHRUN, SQRSHRUN2	Signed saturating shift right unsigned narrow immediate (vector and scalar form)	<i>SQRSHRUN, SQRSHRUN2</i> on page C7-2203
SQSHL	Signed saturating shift left immediate (vector and scalar form)	<i>SQSHL (immediate)</i> on page C7-2206
SQSHLU	Signed saturating shift left unsigned immediate (vector and scalar form)	<i>SQSHLU</i> on page C7-2211
SQSHRN, SQSHRN2	Signed saturating shift right narrow immediate (vector and scalar form)	<i>SQSHRN, SQSHRN2</i> on page C7-2214
SQSHRUN, SQSHRUN2	Signed saturating shift right unsigned narrow immediate (vector and scalar form)	<i>SQSHRUN, SQSHRUN2</i> on page C7-2217
SRI	Shift right and insert immediate (vector and scalar form)	<i>SRI</i> on page C7-2230
SRSRHR	Signed rounding shift right immediate (vector and scalar form)	<i>SRSRHR</i> on page C7-2235
SRSRA	Signed rounding shift right and accumulate immediate (vector and scalar form)	<i>SRSRA</i> on page C7-2238.
SSHLL, SSHLL2	Signed shift left long immediate (vector form)	<i>SSHLL, SSHLL2</i> on page C7-2244
SSHR	Signed shift right immediate (vector and scalar form)	<i>SSHR</i> on page C7-2246
SSRA	Signed integer shift right and accumulate immediate (vector and scalar form)	<i>SSRA</i> on page C7-2249
SXTL, SXTL2	Signed integer extend (vector only)	<i>SXTL, SXTL2</i> on page C7-2307
UQRSHRN, UQRSHRN2	Unsigned saturating rounded shift right narrow immediate (vector and scalar form)	<i>UQRSHRN, UQRSHRN2</i> on page C7-2387
UQSHL	Unsigned saturating shift left immediate (vector and scalar form)	<i>UQSHL (immediate)</i> on page C7-2390

UXTL, UXTL2	Unsigned integer extend (vector only)	UXTL, UXTL2 on page C7-2437

C3.5.22 SIMD floating-point and integer conversion

The SIMD floating-point and integer conversion instructions generate the Invalid Operation floating-point exception in response to a floating-point input of NaN, infinity, or a numerical value that cannot be represented within the destination register. An out of range integer or a fixed-point result is saturated to the size of the destination register. A numeric result that differs from the input raises the Inexact floating-point exception.

[Table C3-88 on page C3-273](#) shows the SIMD floating-point and integer conversion instructions.

Table C3-88 SIMD floating-point and integer conversion instructions

Mnemonic	Instruction	See
FCVTAS	Floating-point convert to signed integer, rounding to nearest with ties to away (vector and scalar form)	FCVTAS (vector) on page C7-1683

	Unsigned fixed-point convert to floating-point (vector and scalar form)	UCVTF (vector, fixed-point) on page C7-2335

C3.5.23 SIMD reduce (across vector lanes)

The SIMD reduce (across vector lanes) instructions perform arithmetic operations horizontally, that is across all lanes of the input vector. They deliver a single scalar result.

[Table C3-89 on page C3-274](#) shows the SIMD reduce (across vector lanes) instructions.

Table C3-89 SIMD reduce (across vector lanes) instructions

Mnemonic	Instruction	See

UMAXP	Unsigned maximum pairwise	UMAXP on page C7-2355
UMINP	Unsigned minimum pairwise	UMINP on page C7-2361

C3.5.25 SIMD dot product

[FEAT_DotProd](#) provides SIMD instructions that perform the dot product of the four 8-bit subelements of the 32-bit elements of one vector with the four 8-bit subelements of a second vector. It provides two forms of the instructions, each with signed and unsigned versions:

Vector form The dot product is calculated for each element of the first vector with the corresponding element of the second vector.

Indexed form The dot product is calculated for each element of the first vector with the element of the second vector that is indicated by the index argument to the instruction.

———— **Note** ————

That is, a single element from the second vector is used, and the dot product is calculated between each element of the first vector and this single element from the second vector.

Table C3-91 on page C3-276 shows the SIMD dot product instructions.

Table C3-91 SIMD dot product

Mnemonic	Instruction	See
SDOT	Signed dot product (vector form)	<i>SDOT (vector)</i> on page C7-2068
UDOT	Unsigned dot product (vector form)	<i>UDOT (vector)</i> on page C7-2347
SDOT	Signed dot product (indexed form)	<i>SDOT (by element)</i> on page C7-2066
UDOT	Unsigned dot product (indexed form)	<i>UDOT (by element)</i> on page C7-2345
USDOT	Mixed sign integer dot product (vector form) ^a	<i>USDOT (vector)</i> on page C7-2415
	Mixed sign integer dot product by indexed quaduplet ^a	<i>USDOT (by element)</i> on page C7-2417
SUDOT	Mixed sign integer dot product by indexed quaduplet ^a	<i>SUDOT (by element)</i> on page C7-2303

a. This instruction is supported when [FEAT_I8MM](#) is implemented.

C3.5.26 SIMD table lookup

Table C3-92 on page C3-276 shows the SIMD table lookup instructions.

Table C3-92 SIMD table lookup instructions

Mnemonic	Instruction	See
TBL	Table vector lookup	<i>TBL</i> on page C7-2309
TBX	Table vector lookup extension	<i>TBX</i> on page C7-2311

C3.5.27 SIMD complex number arithmetic

[FEAT_FCMA](#) provides SIMD instructions that perform arithmetic on complex numbers held in element pairs in vector registers, where the less significant element of the pair contains the real component and the more significant element contains the imaginary component.

These instructions provide double-precision and single-precision versions. If [FEAT_FP16](#) is implemented they also provide half-precision versions, otherwise the half-precision encodings are UNDEFINED.

Table C3-93 on page C3-276 shows the [FEAT_FCMA](#) SIMD instructions.

Table C3-93 SIMD complex number arithmetic

Mnemonic	Instruction	See
FCADD	Floating-point complex add	<i>FCADD</i> on page C7-1636
FCMLA	Floating-point complex multiply accumulate (vector form)	<i>FCMLA</i> on page C7-1666
FCMLA	Floating-point complex multiply accumulate (indexed form)	<i>FCMLA (by element)</i> on page C7-1663

A pair of FCMLA instructions can be used to perform a complex number multiplication. This is demonstrated in [Complex multiplication on page K10-8512](#).

C3.5.28 SIMD BFloat16

The SIMD BFloat16 instructions are provided by [FEAT_BF16](#).

These instructions perform an implicit conversion of vectors of BF16 input values to IEEE 754 single-precision floating-point format, combined with an N-way dot product calculation that accumulates the products into a vector of single-precision accumulators.

All of these instructions perform arithmetic with fixed behaviors, irrespective of the values of **FPCR**. These behaviors are:

- Exceptional floating-point conditions produce the expected IEEE 754 default result, but do not modify the cumulative floating-point exception flags in **FPSR**, and cannot cause a trapped floating-point exception.
- Multiplication and addition operations are always chained and never fused. Multiplication that overflows cannot be brought back into range by a fused addition.

———— **Note** —————

The fractional part of the product of two BF16 inputs can be exactly represented in single-precision format, see *BFloating16 floating-point format* on page A1-48.

Table C3-94 on page C3-277 shows these instructions.

Table C3-94 BFloat16 SIMD instructions

Mnemonic	Instruction	See
BFDOT	BFloat16 floating-point dot product (vector and indexed forms)	<i>BFDOT (vector)</i> on page C7-1550 <i>BFDOT (by element)</i> on page C7-1548

BFMLALT	BFloat16 floating-point widening multiply-add long top (vector and index forms)	<i>BFMLALB, BFMLALT (vector)</i> on page C7-1554 <i>BFMLALB, BFMLALT (by element)</i> on page C7-1552
BFCVTN, BFCVTN2	Floating-point convert from single-precision to BFloat16 format (vector form)	<i>BFCVTN, BFCVTN2</i> on page C7-1546

C3.5.29 SIMD matrix multiplication

These instructions are provided by **FEAT_I8MM**, and include integer matrix multiply-accumulate instructions.

The matrix multiply-accumulate instructions delimit source and destination vectors into segments. Within each segment:

- The first source vector matrix is organized in row-by-row order.
- The second source vector matrix is organized in a column-by-column order.
- The destination vector matrix is organized in row-by-row order.

One matrix multiplication is performed per segment.

Table C3-95 on page C3-278 shows these instructions.

Table C3-95 Matrix multiply SIMD instructions

Mnemonic	Instruction	See
SMMLA	Widening 8-bit signed integer matrix multiply-accumulate into 2x2 matrix	SMMLA (vector) on page C7-2142
UMMLA	Widening 8-bit unsigned integer matrix multiply-accumulate into 2x2 matrix	UMMLA (vector) on page C7-2375
USMMLA	Widening 8-bit mixed sign integer matrix multiply-accumulate into 2x2 matrix	USMMLA (vector) on page C7-2427

C3.5.30 The Cryptographic Extension

The instructions provided by the OPTIONAL Armv8.0 Cryptographic Extension use the SIMD and floating-point register file. For more information about the functions they provide see:

- [Announcing the Advanced Encryption Standard.](#)
- [The Galois/Counter Mode of Operation.](#)
- [Announcing the Secure Hash Standard.](#)

Table C3-96 on page C3-278 shows the Armv8.0 Cryptographic Extension instructions.

SHA256SU0	SHA256 schedule update 0	SHA256SU0 on page C7-2078
SHA256SU1	SHA256 schedule update 1	SHA256SU1 on page C7-2079

a. The Cryptographic Extension adds the variant of the instruction that operates on two 64-bit polynomials.

See [The Armv8 Cryptographic Extension on page A2-72](#) for information about the permitted implementation options for the Cryptographic Extension.

Armv8.2 extensions to the Cryptographic Extension

Armv8.2 supports the following OPTIONAL extensions to the Cryptographic Extension:

- [FEAT_SHA512, SHA2-512 functionality on page C3-279.](#)
- [FEAT_SHA3, SHA3 functionality on page C3-279.](#)
- [FEAT_SM3, SM3 functionality on page C3-280.](#)
- [FEAT_SM4, SM4 functionality on page C3-281.](#)

FEAT_SHA512, SHA2-512 functionality

[FEAT_SHA512](#) provides instructions to accelerate the SHA-2 hash algorithm using a digest that is larger than 256 bits. The relevant standards are SHA-384, SHA-512, SHA-512|224 and SHA-512|256. These are all based on the SHA-512 computation, and therefore this set of instructions is described as the *SHA512 instructions*.

Implementation of [FEAT_SHA512](#) requires the implementation of the SHA1 and SHA2-256 instructions from the Armv8.0 Cryptographic Extension.

———— Note ————

Implementation of [FEAT_SHA512](#) does not require the implementation of the AES instructions, and the 64-bit polynomial variants of the PMULL instructions, from the Armv8.0 Cryptographic Extension.

When [FEAT_SHA512](#) is implemented, the value of `ID_AA64ISAR0_EL1.SHA2` is `0b0010`, indicating support for the SHA512 instructions.

[Table C3-97 on page C3-279](#) shows the [FEAT_SHA512](#) instructions:

Table C3-97 FEAT_SHA512 instructions

Mnemonic	Instruction	See
SHA512H	SHA512 Hash update part 1	SHA512H on page C7-2081
SHA512H2	SHA512 Hash update part 2	SHA512H2 on page C7-2083
SHA512SU0	SHA512 Schedule Update 0	SHA512SU0 on page C7-2085
SHA512SU1	SHA512 Schedule Update 1	SHA512SU1 on page C7-2086

[Use of the SHA512 instructions on page K10-8514](#) shows an example of the use of these instructions to calculate a SHA512 hash iteration. This example code is not part of the architectural definition of these instructions.

FEAT_SHA3, SHA3 functionality

[FEAT_SHA3](#) provides instructions to accelerate the SHA-3 hash algorithm. This set of instructions is described as the *SHA3 instructions*.

———— Note ————

Implementation of [FEAT_SHA3](#) does not require the implementation of the AES instructions, and the 64-bit polynomial variants of the PMULL instructions, from the Armv8.0 Cryptographic Extension.

When [FEAT_SHA3](#) is implemented, the value of `ID_AA64ISAR0_EL1.SHA3` is `0b0001`, indicating support for the SHA3 instructions.

[Table C3-98 on page C3-280](#) shows the [FEAT_SHA3](#) instructions. The SHA-3 hash algorithm is based on a running digest of 1600 bytes, arranged as a five by five array of 64-bit registers. The Arm acceleration of these instructions is based on mapping the 25 64-bit values into 25 vector registers, with each 64-bit value occupying the same 64-bit element in each vector. A series of transformations is performed on these registers as part of a round of the SHA-3 hash calculation.

The SIMD nature of the vector registers means the acceleration can compute two parallel SHA3 hash calculations, where one calculation is performed using the zeroth 64-bit element of each vector, and the other calculation is performed using the first 64-bit element of each vector.

To provide acceleration where the SIMD calculation is not required, the instructions provide variants that operate only on the zeroth 64-bit elements. These are provided as a power optimization.

Table C3-98 FEAT_SHA3 instructions

Mnemonic	Instruction	See
EOR3	Three-way Exclusive OR	EOR3 on page C7-1610
RAX1	Rotate and Exclusive OR	RAX1 on page C7-2025
XAR	Exclusive OR and Rotate	XAR on page C7-2443
BCAX	Bit Clear and Exclusive OR	BCAX on page C7-1543

[Use of the SHA3 instructions on page K10-8515](#) shows an example of the use of these instructions to calculate the combined theta, phi, rho and chi operations of a SHA3 iteration. This example code is not part of the architectural definition of these instructions.

FEAT_SM3, SM3 functionality

[FEAT_SM3](#) provides instructions to accelerate the SM3 hash algorithm, the standard Chinese hash algorithm. These are described as the *SM3 instructions*.

[FEAT_SM3](#) can be implemented independently of any part of the Armv8.0 Cryptographic Extension, and independently of [FEAT_SHA512](#).

———— **Note** —————

This means that Armv8.2 permits an implementation of the Cryptographic Extension that provides only the [FEAT_SM3](#) functionality.

When [FEAT_SM3](#) is implemented, the value of [ID_AA64ISAR0_EL1.SM3](#) is 0b0001, indicating support for the SM3 instructions.

[Table C3-99 on page C3-280](#) shows the [FEAT_SM3](#) instructions. The SM3 algorithm computes a digest of 256 bits, that can be held in two vector registers. The SM3 instructions include instructions to accelerate the computation of the hash and the schedule update.

———— **Note** —————

The SM3 instruction names refer to intermediate variables defined as part of the *SM3 Cryptographic Hash Algorithm* specification.

Table C3-99 FEAT_SM3 instructions

Mnemonic	Instruction	See
SM3SS1	SM3 SS1 calculation	SM3SS1 on page C7-2106
SM3TT1A	SM3 TT1 calculation, part A	SM3TT1A on page C7-2108

Mnemonic	Instruction	See
SM3TT2B	SM3 TT2 calculation, part B	SM3TT2B on page C7-2114
SM3PARTW1	SM3 PARTW calculation, part 1	SM3PARTW1 on page C7-2102
SM3PARTW2	SM3 PARTW calculation, part 1	SM3PARTW2 on page C7-2104

[Use of the SM3 instructions on page K10-8516](#) shows an example of the use of these instructions to generate an SM3 hash. This example code is not part of the architectural definition of these instructions.

FEAT_SM4, SM4 functionality

[FEAT_SM4](#) provides instruction to accelerate the SM4 encryption algorithm, the standard Chinese encryption algorithm. This set of instructions is described as the *SM4 instructions*.

[FEAT_SM4](#) can be implemented independently of any part of the Armv8.0 Cryptographic Extension, and independently of [FEAT_SHA3](#).

———— **Note** ————

This means that Armv8.2 permits an implementation of the Cryptographic Extension that provides only the [FEAT_SM4](#) functionality.

When [FEAT_SM4](#) is implemented, the value of [ID_AA64ISAR0_EL1.SM4](#) is 0b0001, indicating support for the SM4 instructions.

[Table C3-100 on page C3-281](#) shows the [FEAT_SM4](#) instructions. The SM4 algorithm is 128-bit wide block cipher. The SM4E instruction accelerates a single round of encryption or decryption, and the SM4EKEY instruction accelerates a single round of key generation:

Table C3-100 FEAT_SM4 instructions

Mnemonic	Instruction	See
SM4E	SM4 Encrypt	SM4E on page C7-2116
SM4EKEY	SM4 Key	SM4EKEY on page C7-2118

[Use of the SM4 instructions on page K10-8518](#) shows an example of the use of these instructions to perform SM4 encryption and decryption. This example code is not part of the architectural definition of these instructions.

Chapter C4

A64 Instruction Set Encoding

This chapter describes the encoding of the A64 instruction set. It contains the following section:

- [A64 instruction set encoding on page C4-284.](#)

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.

C4.1 A64 instruction set encoding

The A64 instruction encoding is:

Table C4-1 Main encoding table for the A64 instruction set

Decode fields		Decode group or instruction page
op0		
0000		<i>Reserved on page C4-284.</i>
0001		Unallocated.
0010		SVE instructions. See <i>The Scalable Vector Extension (SVE)</i> on page A2-110.
0011		Unallocated.
100x		<i>Data Processing -- Immediate on page C4-284.</i>
101x		<i>Branches, Exception Generating and System instructions on page C4-289.</i>
x1x0		<i>Loads and Stores on page C4-298.</i>
x101		<i>Data Processing -- Register on page C4-332.</i>
x111		<i>Data Processing -- Scalar Floating-Point and Advanced SIMD on page C4-342.</i>

C4.1.1 Reserved

This section describes the encoding of the Reserved group. The encodings in this section are decoded from *A64 instruction set encoding on page C4-284*.

Table C4-2 Encoding table for the Reserved group

Decode fields			Decode group or instruction page
op0	op1		
000	000000000		UDF
000	0001xxxxx		Unallocated.
!= 000	-		Unallocated.

C4.1.2 Data Processing -- Immediate

This section describes the encoding of the Data Processing -- Immediate group. The encodings in this section are decoded from *A64 instruction set encoding on page C4-284*.

Decode fields			Instruction page
sf	op	S	
0	0	0	ADD (immediate) - 32-bit variant
0	0	1	ADDS (immediate) - 32-bit variant
0	1	0	SUB (immediate) - 32-bit variant
0	1	1	SUBS (immediate) - 32-bit variant
1	0	0	ADD (immediate) - 64-bit variant
1	0	1	ADDS (immediate) - 64-bit variant
1	1	0	SUB (immediate) - 64-bit variant
1	1	1	SUBS (immediate) - 64-bit variant

Add/subtract (immediate, with tags)

This section describes the encoding of the Add/subtract (immediate, with tags) instruction class. The encodings in this section are decoded from [Data Processing -- Immediate on page C4-284](#).

Decode fields				Instruction page	Feature
sf	op	S	o2		
-	-	-	1	Unallocated.	-
0	-	-	0	Unallocated.	-
1	-	1	0	Unallocated.	-
1	0	0	0	ADDG	FEAT_MTE
1	1	0	0	SUBG	FEAT_MTE

Logical (immediate)

This section describes the encoding of the Logical (immediate) instruction class. The encodings in this section are decoded from [Data Processing -- Immediate on page C4-284](#).

31	30	29	28	27	26	25	24	23	22	21	16	15	10	9	5	4	0

Load/store register (register offset)

This section describes the encoding of the Load/store register (register offset) instruction class. The encodings in this section are decoded from *Loads and Stores* on page C4-298.

Conversion between floating-point and integer

This section describes the encoding of the Conversion between floating-point and integer instruction class. The encodings in this section are decoded from *Data Processing -- Scalar Floating-Point and Advanced SIMD* on page C4-342.

Chapter C5

The A64 System Instruction Class

This chapter describes the A64 System instruction class, and the System instruction class encoding space, that is a subset of the System registers encoding space. It contains the following sections:

- [The System instruction class encoding space on page C5-394.](#)
- [Special-purpose registers on page C5-408.](#)
- [A64 System instructions for cache maintenance on page C5-506.](#)
- [A64 System instructions for address translation on page C5-567.](#)
- [A64 System instructions for TLB maintenance on page C5-592.](#)
- [A64 System instructions for prediction restriction on page C5-860.](#)

See [General information about the A64 instruction descriptions on page C2-211](#) for information about entries used in the instruction encoding descriptions.

C5.1 The System instruction class encoding space

Part of the A64 instruction encoding space is assigned to instructions that access the System register encoding space. These instructions provide:

- Access to *System registers*, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as [SPSR_ELx](#), [ELR_ELx](#), and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the CLREX instruction.
- Architectural hint instructions.

This section describes the general model for accessing this functionality.

———— Note ————

- See [Fixed values in AArch64 instruction and System register descriptions on page C2-211](#) for information about abbreviations used in the System instruction descriptions.
- In AArch32 state much of this functionality is provided through the System register interface described in [The AArch32 System register interface on page G1-6109](#). In AArch64 state, the parameters used to characterize the System register encoding space are {op0, op1, CRn, CRm, op2}. These are based on the parameters that characterize the AArch32 System register encoding space, which reflect the original implementation of these registers, as described in [Background to the System register interface on page G1-6110](#). In Armv8, there is no particular significance to the naming of these parameters, and no functional distinction between the opn parameters and the CRx parameters.

[Principles of the System instruction class encoding on page C5-394](#) describes some general properties of these encodings. [System instruction class encoding overview on page C5-395](#) then describes the top-level encoding of these instructions, and the following sections then describe the next level of the encoding hierarchy of System instructions and Special-purpose registers:

- [op0==0b00, architectural hints, barriers and CLREX, and PSTATE access on page C5-396](#).
- [op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-399](#).
- [op0==0b11, Moves to and from Special-purpose registers on page C5-405](#).

For the description of the next level of encoding hierarchy of System registers, see:

- [op0==0b10, Moves to and from debug and trace System registers on page D12-3021](#).
- [op0==0b11, Moves to and from non-debug System registers, Special-purpose registers on page D12-3023](#).
- [Reserved encodings for IMPLEMENTATION DEFINED registers on page D12-3038](#).

C5.1.1 Principles of the System instruction class encoding

In Armv8, an encoding in the System instruction space is identified by a set of arguments, {op0, op1, CRn, CRm, op2}. These form an encoding hierarchy, where:

- op0 Defines the top-level division of the encoding space, see [System instruction class encoding overview on page C5-395](#).
- op1 Identifies the lowest Exception level at which the encoding is accessible, as follows:
 - Accessible at EL0** op1 has the value 3.
 - Accessible at EL1** op1 has the value 0, 1, or 2. The value is the same as the op1 value used to access the equivalent AArch32 register.
 - Accessible at Secure EL1** op1 has the value 7.

- Accessible at EL2** op1 has the value 4 or 5. The value 5 is used for the EL12 encodings that access EL1 System registers used when [FEAT_VHE](#) is implemented and [HCR_EL2.E2H](#) is 1.
- Accessible at EL3** op1 has the value 6.

Arm strongly recommends that implementers adopt this use of op1 when using the IMPLEMENTATION DEFINED regions of the encoding space described in [Reserved encodings for IMPLEMENTATION DEFINED registers](#) on page D12-3038.

C5.1.2 System instruction class encoding overview

The encoding of the System instruction class describes each instruction as being either:

- A transfer to a System register. This is a System instruction with the semantics of a write.
- A transfer from a System register. This is a System instruction with the semantics of a read.

A System instruction that initiates an operation operates as if it was making a transfer to a register.

In the AArch64 instruction set, the decode structure for the System instruction class is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0
1	1	0	1	0	1	0	1	0	0	L	op0	op1	CRn	CRm	op2	Rt						

The value of L indicates the transfer direction:

- 0** Transfer to System register.
1 Transfer from System register.

The op0 field is the top level encoding of the System instruction type. Its possible values are:

0b00 These encodings provide:

- Instructions with an immediate field for accessing [PSTATE](#), the current PE state.
- The architectural hint instructions.
- Barriers and the [CLREX](#) instruction.

For more information about these encodings, see [op0==0b00, architectural hints, barriers and CLREX, and PSTATE access](#) on page C5-396.

0b01 These encodings provide the cache maintenance, TLB maintenance, and address translation instructions.

———— **Note** —————

These are equivalent to operations in the AArch32 (coproc==0b1111) encoding space.

For more information, see [op0==0b01, cache maintenance, TLB maintenance, and address translation instructions](#) on page C5-399.

0b10 These encodings provide moves to and from:

- Legacy AArch32 System registers for execution environments, to provide access to these registers from higher Exception levels that are using AArch64.
- Debug and trace registers.

———— **Note** —————

These are equivalent to the registers in the AArch32 (coproc==0b1110) encoding space.

For more information, see [op0==0b10, Moves to and from debug and trace System registers](#) on page D12-3021.

0b11 These encodings provide:

- Moves to and from Non-debug System registers. The accessed registers provide system control, and system status information.

————— **Note** —————

The accessed registers are equivalent to the registers in the AArch32 (coproc==0b1111) encoding space.

- Access to Special-purpose registers.

For more information, see [Instructions for accessing Special-purpose registers on page C5-405](#) and [Instructions for accessing non-debug System registers on page D12-3023](#).

UNDEFINED behaviors

In the System register instruction encoding space, the following principles apply:

- All unallocated encodings are treated as UNDEFINED.
- All encodings with L==1 and op0==0b0x are undefined, except for encodings in the area reserved for implementation defined use, see [Reserved encoding space for IMPLEMENTATION DEFINED instructions on page C5-404](#).

For registers and operations that are accessible from a particular Exception level, any attempt to access those registers from a lower Exception level is UNDEFINED.

If a particular Exception level:

- Defines a register to be RO, then any attempt to write to that register, at that Exception level, is UNDEFINED. This means that any access to that register with L==0 is UNDEFINED.
- Defines a register to be WO, then any attempt to read from that register, at that Exception level, is UNDEFINED. This means that any access to that register with L==1 is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED, but see the recommendation in [Principles of the System instruction class encoding on page C5-394](#).

C5.1.3 op0==0b00, architectural hints, barriers and CLREX, and PSTATE access

The different groups of System register instructions with op0==0b00:

- Are identified by the value of CRn.
- Are always encoded with a value of 0b11111 in the Rt field.

The encoding of these instructions is:

The encoding of the CRn field is as follows:

- 0b0010** See [Architectural hint instructions on page C5-396](#).
- 0b0011** See [Barriers and CLREX on page C5-397](#).
- 0b0100** See [Instructions for accessing the PSTATE fields on page C5-398](#).

Architectural hint instructions

Within the op0==0b00 encodings, the architectural hint instructions are identified by CRn having the value 0b0010. The encoding of these instructions is:

The value of op<6:0>, formed by concatenating the CRm and op2 fields, determines the hint instruction as follows:
 0b00000000 NOP instruction.

0b0000001	YIELD instruction.
0b0000010	WFE instruction.
0b0000011	WFI instruction.
0b0000100	SEV instruction.
0b0000101	SEVL instruction.
0b0000110	DGH instruction.
0b0000111	XPACD, XPACI, XPAQLRI instruction.
0b0001000	PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA instruction, PACIA1716 variant.
0b0001010	PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB instruction, PACIB1716 variant.
0b0001100	AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA instruction, AUTIA1716 variant.
0b0001110	AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB instruction, AUTIB1716 variant.
0b0010000	ESB instruction.
0b0010001	PSB CSYNC instruction.
0b0010010	TSB CSYNC instruction.
0b0010100	CSDB instruction.
0b0011000	PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA instruction, PACIAZ variant.
0b0011001	PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA instruction, PACIASP variant.
0b0011010	PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB instruction, PACIBZ variant.
0b0011011	PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB instruction, PACIBSP variant.
0b0011100	AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA instruction, AUTIAZ variant.
0b0011101	AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA instruction, AUTIASP variant.
0b0011110	AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB instruction, AUTIBZ variant.
0b0011111	AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB instruction, AUTIBSP variant.
0b010xx0	BTI instruction.

These instructions are described in [Chapter C6 A64 Base Instruction Descriptions](#).

———— **Note** —————

- Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.
- The operation of the A64 instructions for architectural hints are identical to the corresponding A32 and T32 instructions.

For more information about:

- The WFE, WFI, SEV, and SEVL instructions, see [Mechanisms for entering a low-power state on page D1-2536](#).
- The YIELD instruction, see [Software control features and EL0 on page B1-122](#).

Barriers and CLREX

Within the op0==0b00 encodings, the barriers and CLREX instructions are identified by CRn having the value 0b0011. The encoding of these instructions is:

The value of op2 determines the instruction, as follows.

0b001	DSB instruction, Memory nXS barrier variant.
0b010	CLREX instruction.
0b100	DSB instruction, Memory barrier variant.
0b101	DMB instruction.

0b110 ISB instruction.

0b000, 0b011, 0b111 UNDEFINED.

These instructions are described in [Chapter C6 A64 Base Instruction Descriptions](#).

Note

- Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.
- The operation of the A64 instructions for barriers and CLREX are identical to the corresponding A32 and T32 instructions.

For more information about:

- The barrier instructions, see [Memory barriers on page B2-146](#).
- The CLREX instruction, see [Synchronization and semaphores on page B2-179](#).

Instructions for accessing the PSTATE fields

Within the `op0==0b000` encodings, the instructions that can be used to modify [PSTATE](#) fields directly are identified by CRn having the value 0b0100. The encoding of these instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0	
1	1	0	1	0	1	0	1	0	0	0	0	0	op1	0	1	0	0	Imm4	op2	1	1	1	1
												op0		CRn			CRm			Rt			

These instructions are:

- CFINV ; Inverts the value of PSTATE.C
- MSR DAIFSet, #Imm4 ; Used to set any or all of DAIF to 1
- MSR DAIFClr, #Imm4 ; Used to clear any or all of DAIF to 0
- MSR SPSEL, #Imm4 ; Used to select the Stack Pointer, between SP_EL0 and SP_ELx
- MSR UAO, #Imm4 ; Used to set the value of PSTATE.UAO
- MSR PAN, #Imm4 ; Used to set the value of PSTATE.PAN
- MSR DIT, #Imm4 ; Used to set the value of PSTATE.DIT
- MSR SSBS, #Imm4 ; Used to set the value of PSTATE.SSBS
- MSR TCO, #Imm4 ; Used to set the value of PSTATE.TCO

The value of `op2` selects the instruction form, which defines the constraints on the values of the `op1` and `Imm4` arguments, as follows:

- `op2==0b000` Selects the CFINV instruction.
- `op2==0b011` Selects the MSR UAO instruction.
- `op2==0b100` Selects the MSR PAN instruction.
- `op2==0b101` Selects the MSR SPSEL instruction.
- `op2==0b001` Selects the MSR SSBS instruction.
- `op2==0b010` Selects the MSR DIT instruction.
- `op2==0b100` Selects the MSR TCO instruction.
- `op2==0b110` Selects the MSR DAIFSet instruction, that sets the specified [PSTATE](#).{D, A, I, F} bits to 1.
- `op2==0b111` Selects the MSR DAIFClr instruction, that clears the specified [PSTATE](#).{D, A, I, F} bits to 0.

All other combinations of `op1` and `op2` are reserved, and the corresponding instructions are UNDEFINED.

Note

For [PSTATE](#) updates, instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.

Writes to [PSTATE](#) occur in program order without the need for additional synchronization. Changing [PSTATE.SPSEL](#) to use [SP_EL0](#) synchronizes any updates to [SP_EL0](#) that have been written by an MSR to [SP_EL0](#), without the need for additional synchronization.

C5.1.4 $op0=0b01$, cache maintenance, TLB maintenance, and address translation instructions

The System instructions are encoded with $op0=0b01$. The different groups of System instructions are identified by the values of CRn and CRm, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0
1	1	0	1	0	1	0	1	0	0	0	0	1	op1	CRn	CRm	op2	Xt					

op0

The grouping of these instructions depending on the CRn and CRm fields is as follows:

- CRn==7 The instruction group is determined by the value of CRm, as follows:
- CRm=={1, 5} Instruction cache maintenance instructions.
See [Cache maintenance instructions, and data cache zero operation on page C5-399](#).
 - CRm==3 Prediction restriction instructions.
See [Prediction restriction instructions on page C5-400](#).
 - CRm==4 Data cache zero operation.
See [Cache maintenance instructions, and data cache zero operation on page C5-399](#).
 - CRm=={6, 10, 11, 12, 14} Data cache maintenance instructions.
See [Cache maintenance instructions, and data cache zero operation on page C5-399](#).
 - CRm==8 See [Address translation instructions on page C5-401](#).
- CRn=={8, 9} See [TLB maintenance instructions on page C5-401](#).
- CRn=={11, 15} See [Reserved encoding space for IMPLEMENTATION DEFINED instructions on page C5-404](#).

Cache maintenance instructions, and data cache zero operation

Table C5-1 on page C5-399 lists the Cache maintenance instructions and their encodings. Instructions that take an argument include Xt in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as 0b11111. For these instructions, if the Xt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Xt field is set to 0b11111.

Table C5-1 Cache maintenance instructions and data cache zero operation

Instruction	Access instruction encoding					Notes
	op0	op1	CRn	CRm	op2	
IC IALLUIS	1	0	7	1	0	Accessible from EL1 or higher.
IC IALLU				5	0	
IC IVAU, Xt		3	7	5	1	When SCTLR_ELI.UCI==1, accessible from EL0 or higher. Otherwise, accessible from EL1 or higher.

Table C5-1 Cache maintenance instructions and data cache zero operation (continued)

Instruction	Access instruction encoding					Notes
	op0	op1	CRn	CRm	op2	
DC IVAC, Xt	1	0	7	6	1	Accessible from EL1 or higher.
DC ISW, Xt					2	
DC CSW, Xt				10	2	
DC CISW, Xt				14	2	
DC CVAC, Xt		3	7	10	1	When <code>SCTLR_EL1.UCI == 1</code> , accessible from EL0 or higher. Otherwise, accessible from EL1 or higher.
DC CVAU, Xt				11	1	
DC CVAP, Xt				12	1	
DC CIVAC, Xt				14	1	
DC ZVA, Xt	1	3	7	4	1	When <code>SCTLR_EL1.DZE == 1</code> , accessible from EL0 or higher. Otherwise, accessible from EL1 or higher.

For more information about these instructions, see [About cache maintenance in AArch64 state on page D4-2644](#) and [A64 Cache maintenance instructions on page D4-2648](#).

Prediction restriction instructions

[Table C5-2 on page C5-400](#) lists the Prediction restriction instructions and their encodings. Instructions that take an argument include Xt in the instruction syntax.

Table C5-2 Prediction restriction instructions

Instruction	Prediction restriction encoding					Notes
	op0	op1	CRn	CRm	op2	
CFP RCTX, Xt	1	3	7	3	4	When <code>FEAT_SPECRES</code> is implemented, accessible from EL0 or higher.
CPP RCTX, Xt					5	
DVP RCTX, Xt					7	

For more information about these instructions, see [Execution and data prediction restriction System instructions on page D4-2663](#).

Address translation instructions

Table C5-3 on page C5-401 lists the Address translation instructions and their encodings. The syntax of the instructions includes Xt, that provides the address to be translated.

Table C5-3 Address translation instructions

Instruction	Access instruction encoding					Notes
	op0	op1	CRn	CRm	op2	
AT S1E1R , Xt	1	0	7	8	0	Accessible from EL1 or higher.
AT S1E1W , Xt					1	
AT S1E0R , Xt					2	
AT S1E0W , Xt					3	
AT S1E1RP , Xt				9	0	
AT S1E1WP , Xt					1	
AT S1E2R , Xt		4	7	8	0	Accessible from EL2 or higher.
AT S1E2W , Xt					1	
AT S12E1R , Xt					4	
AT S12E1W , Xt					5	
AT S12E0R , Xt					6	
AT S12E0W , Xt					7	
AT S1E3R , Xt		6	7	8	0	Accessible only from EL3.
AT S1E3W , Xt					1	

For more information about these instructions, see [Address translation instructions on page D5-2735](#).

TLB maintenance instructions

Table C5-4 on page C5-402 lists the TLB maintenance instructions and their encodings. Instructions that take an argument include Xt in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as 0b11111. For these instructions, if the Xt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Xt field is set to 0b11111.

a. When FEAT_XS is implemented, applies to the nXS variant of the TLB maintenance instruction.

For more information about these instructions, see [TLB maintenance instructions on page D5-2819](#).

Reserved encoding space for IMPLEMENTATION DEFINED instructions

The A64 instruction set reserves the following encoding space for IMPLEMENTATION DEFINED instructions:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0	
1	1	0	1	0	1	0	1	0	0	L	0	1	op1	1	x	1	1	CRm	op2			Rt	
												op0						CRn					

The value of L defines the use of Rt as follows:

- 0** Rt is an argument supplied to the instruction.
- 1** Rt is a result returned by the instruction.

Table C5-5 on page C5-406 lists the encodings for op1, CRn, and op2 fields for accesses to the Special-purpose registers in AArch64.

Table C5-5 Special-purpose register accesses

Register	Access instruction encoding					Notes
	op0	op1	CRn	CRm	op2	
SPSR_EL1	3	0	4	0	0	Accessible from EL1 or higher
ELR_EL1					1	
SP_EL0				1	0	Accessible from EL1 or higher. If SP_EL0 is the current stack pointer then the access is UNDEFINED.
SPSel				2	0	Accessible from EL1 or higher.
CurrentEL					2	RO. Accessible from EL1 or higher.
PAN					3	Accessible from EL1 or higher.
UAO					4	
NZCV		3	4	2	0	Accessible from EL0 or higher.
DAIF					1	Configurable whether accesses at EL0 are permitted.
DIT					5	Accessible from EL0 or higher.
SSBS					6	
TCO					7	
FPCR				4	0	Accessible from EL0 or higher.
FPSR					1	
DSPSR_EL0				5	0	Accessible only in Debug state, from EL0 or higher.
DLR_EL0					1	
SPSR_EL2		4	4	0	0	Accessible from EL2 or higher.
ELR_EL2					1	
SP_EL1				1	0	
SPSR_irq				3	0	
SPSR_abt					1	
SPSR_und					2	
SPSR_fiq					3	
*_EL12		5	4	{0-15}	{0-7}	Reserved for EL2 aliases of EL1 Special-purpose registers, see Table D5-49 on page D5-2792.
SPSR_EL3	3	6	4	0	0	Accessible from EL3 or higher.
ELR_EL3					1	
SP_EL2				1	0	

All direct and indirect reads and writes to Special-purpose registers appear to occur in program order relative to other instructions.

C5.2 Special-purpose registers

This section describes the following Special-purpose registers:

- **CurrentEL**, that holds **PSTATE.EL**, and that software can read to determine the current Exception level.
- **DAIF**, that holds the current **PSTATE**. {D, A, I, F} interrupt mask bits.
- **DIT**, that holds the **PSTATE.DIT** bit.
- **ELR_EL1**, that holds the address to return to for an exception return from EL1.
- **ELR_EL2**, that holds the address to return to for an exception return from EL2.
- **ELR_EL3**, that holds the address to return to for an exception return from EL3.
- **FPCR**, that provides control of floating-point operation.
- **FPSR**, that provides floating-point status information.
- **NZCV**, that holds the **PSTATE**. {N, Z, C, V} condition flags.
- **PAN**, that holds the **PSTATE.PAN** state bit.
- **SP_EL0**, that holds the stack pointer for EL0.
- **SP_EL1**, that holds the stack pointer for EL1.
- **SP_EL2**, that holds the stack pointer for EL2.
- **SP_EL3**, that holds the stack pointer for EL3.
- **SPSel**, that holds **PSTATE.SP**, that at EL1 or higher selects the current SP.
- **SPSR_abt**, that holds process state on taking an exception to AArch32 Abort mode.
- **SPSR_EL1**, that holds process state on taking an exception to AArch64 EL1.
- **SPSR_EL2**, that holds process state on taking an exception to AArch64 EL2.
- **SPSR_EL3**, that holds process state on taking an exception to AArch64 EL3.
- **SPSR_fiq**, that holds process state on taking an exception to AArch32 FIQ mode.
- **SPSR_irq**, that holds process state on taking an exception to AArch32 IRQ mode.
- **SPSR_und**, that holds process state on taking an exception to AArch32 Undefined mode.
- **SSBS**, that holds the **PSTATE.SSBS** bit.
- **TCO**, that holds the **PSTATE.TCO** bit.
- **UAO**, that holds the **PSTATE.UAO** bit.

The following registers are also Special-purpose registers:

- **DLR_EL0**, that holds the address to return to for a return from Debug state.
- **DSPSR_EL0**, that holds process state on entry to Debug state.

C5.2.1 CurrentEL, Current Exception Level

The CurrentEL characteristics are:

Purpose

Holds the current Exception level.

Configurations

There are no configuration notes.

Attributes

CurrentEL is a 64-bit register.

Field descriptions

Bits [63:4]

Reserved, RES0.

EL, bits [3:2]

Current Exception level. Possible values of this field are:

0b00 EL0.
0b01 EL1.
0b10 EL2.
0b11 EL3.

When the [HCR_EL2.NV](#) bit is 1, EL1 read accesses to the CurrentEL register return the value of 0b10 in this field.

The reset behavior of this field is:

- This field resets to the highest implemented Exception level.

Bits [1:0]

Reserved, RES0.

Accessing CurrentEL

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CurrentEL

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0010	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
```

```
        return Zeros(60):'10':Zeros(2);  
    else  
        return Zeros(60):PSTATE.EL:Zeros(2);  
    elsif PSTATE.EL == EL2 then  
        return Zeros(60):PSTATE.EL:Zeros(2);  
    elsif PSTATE.EL == EL3 then  
        return Zeros(60):PSTATE.EL:Zeros(2);
```

C5.2.2 DAIF, Interrupt Mask Bits

The DAIF characteristics are:

Purpose

Allows access to the interrupt mask bits.

Configurations

There are no configuration notes.

Attributes

DAIF is a 64-bit register.

Field descriptions

Bits [63:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

- 0b0 Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.
- 0b1 Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to 1.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

- 0b0 Exception not masked.
- 0b1 Exception masked.

The reset behavior of this field is:

- On a Warm reset, this field resets to 1.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0b0 Exception not masked.
- 0b1 Exception masked.

The reset behavior of this field is:

- On a Warm reset, this field resets to 1.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0b0 Exception not masked.

0b1 Exception masked.

The reset behavior of this field is:

- On a Warm reset, this field resets to 1.

Bits [5:0]

Reserved, RES0.

Accessing DAIF

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DAIF

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0010	0b001

```

C5.2.3 DIT, Data Independent Timing

The DIT characteristics are:

Purpose

Allows access to the Data Independent Timing bit.

Configurations

This register is present only when FEAT_DIT is implemented. Otherwise, direct accesses to DIT are UNDEFINED.

Attributes

DIT is a 64-bit register.

Field descriptions

Bits [63:25]

Reserved, RES0.

DIT, bit [24]

Data Independent Timing.

0b0 The architecture makes no statement about the timing properties of any instructions.

0b1 The architecture requires that:

- The timing of every load and store instruction is insensitive to the value of the data being loaded or stored.
- For certain data processing instructions, the instruction takes a time which is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- For certain data processing instructions, the response of the instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

The data processing instructions affected by this bit are:

- All cryptographic instructions. These instructions are:
 - AESD, AESE, AESIMC, AESMC, SHA1C, SHA1H, SHA1M, SHA1P, SHA1SU0, SHA1SU1, SHA256H, SHA256H2, SHA256SU0, SHA256SU1, SHA512H, SHA512H2, SHA512SU0, SHA512SU1, EOR3, RAX1, XAR, BCAX, SM3SS1, SM3TT1A, SM3TT1B, SM3TT2A, SM3TT2B, SM3PARTW1, SM3PARTW2, SM4E, and SM4EKEY.
- A subset of those instructions which use the general-purpose register file. These instructions are:
 - ADC, ADCS, ADD, ADDS, AND, ANDS, ASR, ASRV, BFC, BFI, BFM, BFXIL, BIC, BICS, CCMN, CCMP, CFINV, CINC, CINV, CLS, CLZ, CMN, CMP, CNEG, CSEL, CSET, CSETM, CSINC, CSINV, CSNEG, EON, EOR, EXTR, LSL, LSLV, LSR, LSRV, MADD, MNEG, MOV, MOVK, MOVN, MOVZ, MSUB, MUL, MVN, NEG, NEGS, NGC, NGCS,

NOP, ORN, ORR, RBIT, RET, REV, REV16, REV32, REV64, RMIF, ROR, RORV, SBC, SBCS, SBFIZ, SBFM, SBFX, SETF8, SETF16, SMADDL, SMNEGL, SMSUBL, SMULH, SMULL, SUB, SUBS, SXTB, SXTH, SXTW, TST, UBFIZ, UBFM, UBFX, UMADDL, UMNEGL, UMSUBL, UMULH, UMULL, UXTB, and UXTH.

— If FEAT_CRC32 is implemented, CRC32B, CRC32H, CRC32W, CRC32X, CRC32CB, CRC32CH, CRC32CW, and CRC32CX.

• A subset of those instructions which use the SIMD&FP register file. These instructions are:

— ABS, ADD, ADDHN, ADDHN2, ADDP, ADDV, AND, BIC, BIF, BIT, BSL, CLS, CLZ, CMEQ, CMGE, CMGT, CMHI, CMHS, CMLE, CMLT, CMTST, CNT, DUP, EOR, EXT, FCSEL, INS, MLA, MLS, MOV, MOVI, MUL, MVN, MVNI, NEG, NOT, ORN, ORR, PMUL, PMULL, PMULL2, RADDHN, RADDHN2, RBIT, REV16, REV32, RSHRN, RSHRN2, RSUBHN, RSUBHN2, SABA, SABD, SABAL, SABAL2, SABDL, SABDL2, SADALP, SADDL, SADDL2, SADDLP, SADDLV, SADDW, SADDW2, SHADD, SHL, SHLL, SHLL2, SHRN, SHRN2, SHSUB, SLI, SMAX, SMAXP, SMAXV, SMIN, SMINP, SMINV, SMLAL, SMLAL2, SMLSL, SMLSL2, SMOV, SMULL, SMULL2, SRI, SSSL, SSSL2, SSSL2, SSSL2, SSRA, SSUBL, SSUBL2, SSUBW, SSUBW2, SUB, SUBHN, SUBHN2, SXTL, SXTL2, TBL, TBX, TRN1, TRN2, UABA, UABAL, UABAL2, UABD, UABDL, UABDL2, UADALP, UADDL, UADDL2, UADDLP, UADDLV, UADDW, UADDW2, UHADD, UHSUB, UMAX, UMAXP, UMAXV, UMIN, UMINP, UMINV, UMLAL, UMLAL2, UMLSL, UMOV, UMLSL2, UMULL, UMULL2, USHL, USHL2, USHL2, USHR, USRA, USUBL, USUBL2, USUBW, USUBW2, UXTL, UXTL2, UZP1, UZP2, XTN, XTN2, ZIP1, and ZIP2.

Note

The architecture makes no statement about the timing properties when the PSTATE.DIT bit is not set. However, it is likely that many of these instructions have timing that is invariant of the data in many situations.

In particular, Arm strongly recommends that the Armv8.3 pointer authentication instructions do not have their timing dependent on the key value used in the pointer authentication in all cases, regardless of the PSTATE.DIT bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

Bits [23:0]

Reserved, RES0.

Accessing DIT

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DIT

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0010	0b101

```

if PSTATE.EL == EL0 then

elsif PSTATE.EL == EL1 then
    PSTATE.DIT = X[t]<24>;
elsif PSTATE.EL == EL2 then
    PSTATE.DIT = X[t]<24>;
elsif PSTATE.EL == EL3 then
    PSTATE.DIT = X[t]<24>;
```

MSR DIT, #<imm>

op0	op1	CRn	op2
0b00	0b011	0b0100	0b010

C5.2.4 ELR_EL1, Exception Link Register (EL1)

The ELR_EL1 characteristics are:

Purpose

When taking an exception to EL1, holds the address to return to.

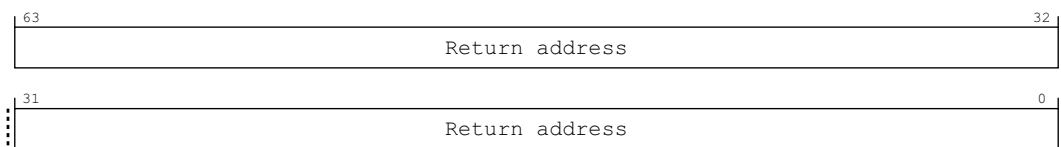

Configurations

There are no configuration notes.

Attributes

ELR_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Return address.

An exception return from EL1 using AArch64 makes ELR_EL1 become UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ELR_EL1

When [HCR_EL2.E2H](#) is 1, without explicit synchronization, access from EL3 using the mnemonic [ELR_EL1](#) or [ELR_EL12](#) are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ELR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0000	0b001

```

C5.2.5 ELR_EL2, Exception Link Register (EL2)

The ELR_EL2 characteristics are:

Purpose

When taking an exception to EL2, holds the address to return to.

Configurations

AArch64 System register ELR_EL2 bits [31:0] are architecturally mapped to AArch32 System register [ELR_hyp](#)[31:0].

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

ELR_EL2 is a 64-bit register.

Field descriptions

Bits [63:0]

Return address.

An exception return from EL2 using AArch64 makes ELR_EL2 become UNKNOWN.

When EL2 is in AArch32 Execution state and an exception is taken from EL0, EL1, or EL2 to EL3 and AArch64 execution, the upper 32-bits of ELR_EL2 are either set to 0 or hold the same value that they did before AArch32 execution. Which option is adopted is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ELR_EL2

When [HCR_EL2.E2H](#) is 1, without explicit synchronization, access from EL2 using the mnemonic ELR_EL2 or ELR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ELR_EL2

```

C5.2.6 ELR_EL3, Exception Link Register (EL3)

The ELR_EL3 characteristics are:

Purpose

When taking an exception to EL3, holds the address to return to.

Configurations

This register is present only when EL3 is implemented. Otherwise, direct accesses to ELR_EL3 are UNDEFINED.

Attributes

ELR_EL3 is a 64-bit register.

Field descriptions

Bits [63:0]

Return address.

An exception return from EL3 using AArch64 makes ELR_EL3 become UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ELR_EL3

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ELR_EL3

op0	op1	CRn	CRm	op2
0b11	0b110	0b0100	0b0000	0b001

```

if PSTATE.EL == EL0 then

elsif PSTATE.EL == EL3 then
    ELR_EL3 = X[t];
```

C5.2.7 FPCR, Floating-point Control Register

The FPCR characteristics are:

Purpose

Controls floating-point behavior.

Configurations

AArch64 System register FPCR bits [26:15] are architecturally mapped to AArch32 System register [FPSCR](#)[26:15].

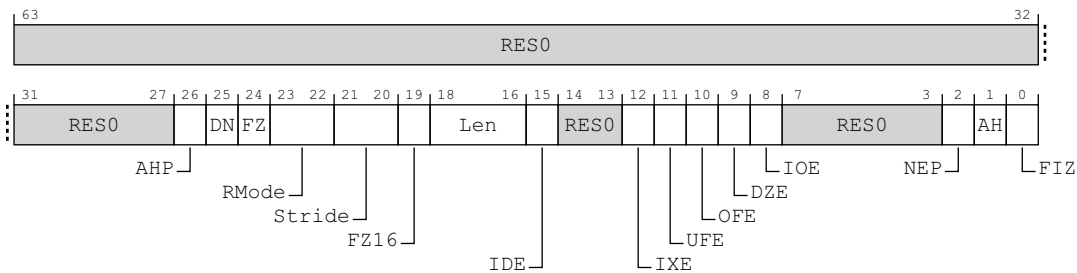

AArch64 System register FPCR bits [12:8] are architecturally mapped to AArch32 System register [FPSCR](#)[12:8].

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

Attributes

FPCR is a 64-bit register.

Field descriptions

Bits [63:27]

Reserved, RES0.

AHP, bit [26]

Alternative half-precision control bit.

0b0 IEEE half-precision format selected.

0b1 Alternative half-precision format selected.

This bit is used only for conversions between half-precision floating-point and other floating-point formats.

The data-processing instructions added as part of the [FEAT_FP16](#) extension always use the IEEE half-precision format, and ignore the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DN, bit [25]

Default NaN use for NaN propagation.

0b0 NaN operands propagate through to the output of a floating-point operation.

0b1 Any operation involving one or more NaNs returns the Default NaN.

This bit has no effect on the output of FABS, FMAX*, FMIN*, and FNEG instructions, and a default NaN is never returned as a result of these instructions.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FZ, bit [24]

Flushing denormalized numbers to zero control bit.

0b0 If FPCR.AH is 0, the flushing to zero of single-precision and double-precision denormalized inputs to, and outputs of, floating-point instructions not enabled by this control, but other factors might cause the input denormalized numbers to be flushed to zero.

If FPCR.AH is 1, the flushing to zero of single-precision and double-precision denormalized outputs of floating-point instructions not enabled by this control, but other factors might cause the input denormalized numbers to be flushed to zero.

0b1 If FPCR.AH is 0, denormalized single-precision and double-precision inputs to, and outputs from, floating-point instructions are flushed to zero.

If FPCR.AH is 1, denormalized single-precision and double-precision outputs from floating-point instructions are flushed to zero.

For more information, see 'Flushing denormalized numbers to zero' and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

RMode, bits [23:22]

Rounding Mode control field.

0b00 Round to Nearest (RN) mode.

0b01 Round towards Plus Infinity (RP) mode.

0b10 Round towards Minus Infinity (RM) mode.

0b11 Round towards Zero (RZ) mode.

The specified rounding mode is used by both scalar and Advanced SIMD floating-point instructions.

If FPCR.AH is 1, then the following instructions use Round to Nearest mode regardless of the value of this bit:

- The FRECPPE, FRECPX, FRSQRTE, and FRSQRTS instructions.
- The BFCVT, BFCVTN, BFCVTN2, BFCVTNT, BFMLALB, and BFMLALT instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Stride, bits [21:20]

This field has no function in AArch64 state, and non-zero values are ignored during execution in AArch64 state.

This field is included only for context saving and restoration of the AArch32 [FPSCR.Stride](#) field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FZ16, bit [19]

When FEAT_FP16 is implemented:

FZ16

Flushing denormalized numbers to zero control bit on half-precision data-processing instructions.

0b0 For some instructions, this bit disables flushing to zero of inputs and outputs that are half-precision denormalized numbers.

0b1 Flushing denormalized numbers to zero enabled.

For some instructions that do not convert a half-precision input to a higher precision output, this bit enables flushing to zero of inputs and outputs that are half-precision denormalized numbers.

The value of this bit applies to both scalar and Advanced SIMD floating-point half-precision calculations.

For more information, see 'Flushing denormalized numbers to zero' and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Len, bits [18:16]

This field has no function in AArch64 state, and non-zero values are ignored during execution in AArch64 state.

This field is included only for context saving and restoration of the AArch32 [FPSCR.Len](#) field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDE, bit [15]

Input Denormal floating-point exception trap enable.

0b0 Untrapped exception handling selected. If the floating-point exception occurs, the [FPSR.IDC](#) bit is set to 1.

0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the [FPSR.IDC](#) bit.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [14:13]

Reserved, RES0.

IXE, bit [12]

Inexact floating-point exception trap enable.

0b0 Untrapped exception handling selected. If the floating-point exception occurs, the [FPSR.IXC](#) bit is set to 1.

0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the [FPSR.IXC](#) bit.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFE, bit [11]

Underflow floating-point exception trap enable.

0b0 Untrapped exception handling selected. If the floating-point exception occurs, the [FPSR.UFC](#) bit is set to 1.

0b1 Trapped exception handling selected. If the floating-point exception occurs and Flush-to-zero is not enabled, the PE does not update the `FPSR.UFC` bit.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFE, bit [10]

Overflow floating-point exception trap enable.

0b0 Untrapped exception handling selected. If the floating-point exception occurs, the `FPSR.OFC` bit is set to 1.

0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the `FPSR.OFC` bit.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZE, bit [9]

Divide by Zero floating-point exception trap enable.

0b0 Untrapped exception handling selected. If the floating-point exception occurs, the `FPSR.DZC` bit is set to 1.

0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the `FPSR.DZC` bit.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOE, bit [8]

Invalid Operation floating-point exception trap enable.

0b0 Untrapped exception handling selected. If the floating-point exception occurs, the `FPSR.IOC` bit is set to 1.

0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the `FPSR.IOC` bit.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [7:3]

Reserved, RES0.

NEP, bit [2]

When FEAT_AFP is implemented:

NEP

Controls how the output elements other than the lowest element of the vector are determined for Advanced SIMD scalar instructions.

0b0 Does not affect how the output elements other than the lowest are determined for Advanced SIMD scalar instructions.

- 0b1 The output elements other than the lowest are taken from the following registers:
- For 3-input scalar versions of the FMLA (by element) and FMLS (by element) instructions, the <Hd>, <Sd>, or <Dd> register.
 - For 3-input versions of the FMADD, FMSUB, FNMADD, and FNMSUB instructions, the <Ha>, <Sa>, or <Da> register.
 - For 2-input scalar versions of the FACGE, FACGT, FCMEQ (register), FCMGE (register), and FCMGT (register) instructions, the <Hm>, <Sm>, or <Dm> register.
 - For 2-input scalar versions of the FABD, FADD (scalar), FDIV (scalar), FMAX (scalar), FMAXNM (scalar), FMIN (scalar), FMINNM (scalar), FMUL (by element), FMUL (scalar), FMULX (by element), FMULX (scalar), FNMUL (scalar), FRECPs, FRSQRTs, and FSUB (scalar) instructions, the <Hn>, <Sn>, or <Dn> register.
 - For 1-input scalar versions of the following instructions, the <Hd>, <Sd>, or <Dd> register:
 - The (vector) versions of the FCVTAS, FCVTAU, FCVTMS, FCVTMU, FCVTNS, FCVTNU, FCVTPS, and FCVTPU instructions.
 - The (vector, fixed-point) and (vector, integer) versions of the FCVTZS, FCVTZU, SCVTF, and UCVTF instructions.
 - The (scalar) versions of the FABS, FNEG, FRINT32X, FRINT32Z, FRINT64X, FRINT64Z, FRINTA, FRINTI, FRINTM, FRINTN, FRINTP, FRINTX, FRINTZ, and FSQRT instructions.
 - The (scalar, fixed-point) and (scalar, integer) versions of the SCVTF and UCVTF instructions.
 - The BFCVT, FCVT, FCVTXN, FRECPe, FRECPX, and FRSQRTE instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AH, bit [1]

When FEAT_AFP is implemented:

AH

Alternate Handling. Controls alternate handling of floating-point numbers.

The Arm architecture supports two models for handling some of the corner cases of the floating-point behaviors, such as the nature of flushing of denormalized numbers, the detection of tininess and other exceptions and a range of other behaviors. The value of the FPCR.AH bit selects between these models.

For more information on the FPCR.AH bit, see 'Flushing denormalized numbers to zero', 'Floating-point exceptions and exception traps' and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FIZ, bit [0]

When FEAT_AFP is implemented:

FIZ

Flush Inputs to Zero. Controls whether single-precision, double-precision and BFloat16 input operands that are denormalized numbers are flushed to zero.

- 0b0 The flushing to zero of single-precision and double-precision denormalized inputs to floating-point instructions not enabled by this control, but other factors might cause the input denormalized numbers to be flushed to zero.
- 0b1 Denormalized single-precision and double-precision inputs to most floating-point instructions flushed to zero.

For more information, see 'Flushing denormalized numbers to zero' and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

C5.2.8 FPSR, Floating-point Status Register

The FPSR characteristics are:

Purpose

Provides floating-point system status information.

Configurations

AArch64 System register FPSR bits [31:27] are architecturally mapped to AArch32 System register [FPSCR](#)[31:27].

AArch64 System register FPSR bit [7] is architecturally mapped to AArch32 System register [FPSCR](#)[7].

AArch64 System register FPSR bits [4:0] are architecturally mapped to AArch32 System register [FPSCR](#)[4:0].

Attributes

FPSR is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

N, bit [31]

When AArch32 is supported at EL0 and AArch32 floating-point is implemented:

N

Negative condition flag for AArch32 floating-point comparison operations.

———— Note ————

AArch64 floating-point comparisons set the PSTATE.N flag instead.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Z, bit [30]

When AArch32 is supported at EL0 and AArch32 floating-point is implemented:

Z

Zero condition flag for AArch32 floating-point comparison operations.

———— **Note** —————

AArch64 floating-point comparisons set the PSTATE.Z flag instead.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

C, bit [29]

When AArch32 is supported at EL0 and AArch32 floating-point is implemented:

C

Carry condition flag for AArch32 floating-point comparison operations.

———— **Note** —————

AArch64 floating-point comparisons set the PSTATE.C flag instead.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

V, bit [28]

When AArch32 is supported at EL0 and AArch32 floating-point is implemented:

V

Overflow condition flag for AArch32 floating-point comparison operations.

———— **Note** —————

AArch64 floating-point comparisons set the PSTATE.V flag instead.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

QC, bit [27]

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [26:8]

Reserved, RES0.

IDC, bit [7]

Input Denormal cumulative floating-point exception bit. This bit is set to 1 to indicate that the Input Denormal floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the **FPCR.IDE** bit. This bit is set to 1 to indicate a floating-point exception only if **FPCR.IDE** is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXC, bit [4]

Inexact cumulative floating-point exception bit. This bit is set to 1 to indicate that the Inexact floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the [FPCR.IXE](#) bit. This bit is set to 1 to indicate a floating-point exception only if [FPCR.IXE](#) is 0.

The criteria for the Inexact floating-point exception to occur are affected by whether denormalized numbers are flushed to zero and by the value of the [FPCR.AH](#) bit. For more information, see [Floating-point exceptions and exception traps on page D1-2495](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFC, bit [3]

Underflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Underflow floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the [FPCR.UFE](#) bit. This bit is set to 1 to indicate a floating-point exception only if [FPCR.UFE](#) is 0 or if flushing denormalized numbers to zero is enabled.

The criteria for the Underflow floating-point exception to occur are affected by whether denormalized numbers are flushed to zero and by the value of the [FPCR.AH](#) bit. For more information, see [Floating-point exceptions and exception traps on page D1-2495](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFC, bit [2]

Overflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Overflow floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the [FPCR.OFE](#) bit. This bit is set to 1 to indicate a floating-point exception only if [FPCR.OFE](#) is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZC, bit [1]

Divide by Zero cumulative floating-point exception bit. This bit is set to 1 to indicate that the Divide by Zero floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the [FPCR.DZE](#) bit. This bit is set to 1 to indicate a floating-point exception only if [FPCR.DZE](#) is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOC, bit [0]

Invalid Operation cumulative floating-point exception bit. This bit is set to 1 to indicate that the Invalid Operation floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the [FPCR.IOE](#) bit. This bit is set to 1 to indicate a floating-point exception only if [FPCR.IOE](#) is 0.

The criteria for the Invalid Operation floating-point exception to occur are affected by the value of the [FPCR.AH](#) bit. For more information, see [Floating-point exceptions and exception traps on page D1-2495](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C5.2.9 NZCV, Condition Flags

The NZCV characteristics are:

Purpose

Allows access to the condition flags.

Configurations

There are no configuration notes.

Attributes

NZCV is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative condition flag. Set to 1 if the result of the last flag-setting instruction was negative.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Bits [27:0]

Reserved, RES0.

Accessing NZCV

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, NZCV

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0010	0b000

```
if PSTATE.EL == EL0 then
    return Zeros(32):PSTATE.<N,Z,C,V>:Zeros(28);
```

```

elseif PSTATE.EL == EL1 then
    return Zeros(32):PSTATE.<N,Z,C,V>:Zeros(28);
elseif PSTATE.EL == EL2 then
    return Zeros(32):PSTATE.<N,Z,C,V>:Zeros(28);
elseif PSTATE.EL == EL3 then
    return Zeros(32):PSTATE.<N,Z,C,V>:Zeros(28);

```

MSR NZCV, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0010	0b000

```

if PSTATE.EL == EL0 then
    PSTATE.<N,Z,C,V> = X[t]<31:28>;
elseif PSTATE.EL == EL1 then
    PSTATE.<N,Z,C,V> = X[t]<31:28>;
elseif PSTATE.EL == EL2 then
    PSTATE.<N,Z,C,V> = X[t]<31:28>;
elseif PSTATE.EL == EL3 then
    PSTATE.<N,Z,C,V> = X[t]<31:28>;

```

C5.2.10 PAN, Privileged Access Never

The PAN characteristics are:

Purpose

Allows access to the Privileged Access Never bit.

Configurations

This register is present only when FEAT_PAN is implemented. Otherwise, direct accesses to PAN are UNDEFINED.

Attributes

PAN is a 64-bit register.

Field descriptions

Bits [63:23]

Reserved, RES0.

PAN, bit [22]

Privileged Access Never.

0b0 Privileged reads and write are not disabled by this mechanism.

0b1 Disables privileged read and write accesses to addresses accessible at EL0 for an enabled stage 1 translation regime that defines the EL0 permissions.

The value of this bit is usually preserved on taking an exception, except in the following situations:

- When the target of the exception is EL1, and the value of the [SCTLR_EL1.SPAN](#) bit is 0, this bit is set to 1.
- When the target of the exception is EL2, [HCR_EL2](#).{E2H, TGE} is {1, 1}, and the value of the [SCTLR_EL2.SPAN](#) bit is 0, this bit is set to 1.

Bits [21:0]

Reserved, RES0.

Accessing PAN

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PAN

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0010	0b011

```
if PSTATE.EL == EL0 then

elseif PSTATE.EL == EL3 then
    PSTATE.PAN = X[t]<22>;

```

MSR PAN, #<imm>

op0	op1	CRn	op2
0b00	0b000	0b0100	0b100

C5.2.11 SP_EL0, Stack Pointer (EL0)

The SP_EL0 characteristics are:

Purpose

Holds the stack pointer associated with EL0. At higher Exception levels, this is used as the current stack pointer when the value of SPSel.SP is 0.

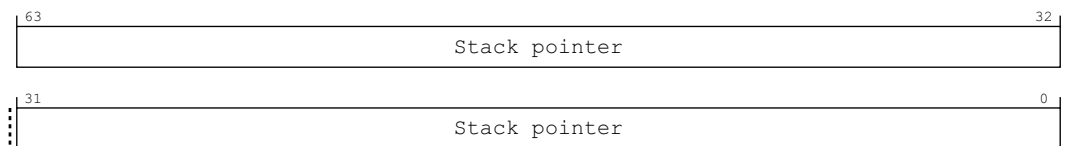

Configurations

There are no configuration notes.

Attributes

SP_EL0 is a 64-bit register.

Field descriptions

Bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SP_EL0

When the value of PSTATE.SP is 0, this register is accessible at all Exception levels as the current stack pointer.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SP_EL0

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0001	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if PSTATE.SP == '0' then
        UNDEFINED;
    else
        return SP_EL0;
elseif PSTATE.EL == EL2 then
    if PSTATE.SP == '0' then
        UNDEFINED;
    else
        return SP_EL0;
elseif PSTATE.EL == EL3 then
    if PSTATE.SP == '0' then
        UNDEFINED;
  
```

```
else
  return SP_EL0;
```

MSR SP_EL0, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0001	0b000

```
if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  if PSTATE.SP == '0' then
    UNDEFINED;
  else
    SP_EL0 = X[t];
elsif PSTATE.EL == EL2 then
  if PSTATE.SP == '0' then
    UNDEFINED;
  else
    SP_EL0 = X[t];
elsif PSTATE.EL == EL3 then
  if PSTATE.SP == '0' then
    UNDEFINED;
  else
    SP_EL0 = X[t];
```

C5.2.12 SP_EL1, Stack Pointer (EL1)

The SP_EL1 characteristics are:

Purpose

Holds the stack pointer associated with EL1. When executing at EL1, the value of `SPSel.SP` determines the current stack pointer:

SPSel.SP	Current stack pointer
0b0	SP_EL0
0b1	SP_EL1

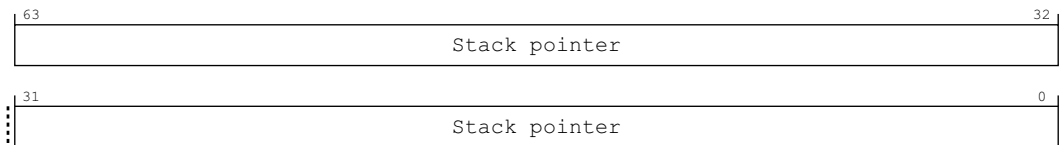

Configurations

There are no configuration notes.

Attributes

SP_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SP_EL1

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of `SPSel.SP` is 1, this register is also accessible at EL1 as the current stack pointer.

————— Note —————

When the value of `SPSel.SP` is 0, `SP_EL0` is used as the current stack pointer at all Exception levels.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SP_EL1

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0001	0b000

```
if PSTATE.EL == EL0 then
  UNDEFINED;
elseif PSTATE.EL == EL1 then
```

```

if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
    return NVMem[0x240];
elseif EL2Enabled() && HCR_EL2.NV == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
else
    UNDEFINED;
elseif PSTATE.EL == EL2 then
    return SP_EL1;
elseif PSTATE.EL == EL3 then
    return SP_EL1;

```

MSR SP_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0001	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
        NVMem[0x240] = X[t];
    elseif EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    SP_EL1 = X[t];
elseif PSTATE.EL == EL3 then
    SP_EL1 = X[t];

```

C5.2.13 SP_EL2, Stack Pointer (EL2)

The SP_EL2 characteristics are:

Purpose

Holds the stack pointer associated with EL2. When executing at EL2, the value of `SPSel.SP` determines the current stack pointer:

SPSel.SP	Current stack pointer
0b0	SP_EL0
0b1	SP_EL2

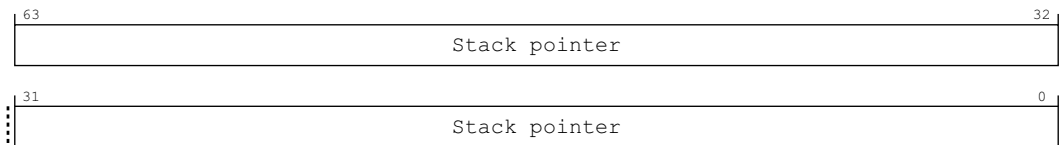

Configurations

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

SP_EL2 is a 64-bit register.

Field descriptions

Bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SP_EL2

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of `SPSel.SP` is 1, this register is also accessible at EL2 as the current stack pointer.

Note

When the value of `SPSel.SP` is 0, `SP_EL0` is used as the current stack pointer at all Exception levels.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SP_EL2

op0	op1	CRn	CRm	op2
0b11	0b110	0b0100	0b0001	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
```

```

    UNDEFINED;
elseif PSTATE.EL == EL2 then
    UNDEFINED;
elseif PSTATE.EL == EL3 then
    return SP_EL2;

```

MSR SP_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b110	0b0100	0b0001	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    UNDEFINED;
elseif PSTATE.EL == EL2 then
    UNDEFINED;
elseif PSTATE.EL == EL3 then
    SP_EL2 = X[t];

```

C5.2.14 SP_EL3, Stack Pointer (EL3)

The SP_EL3 characteristics are:

Purpose

Holds the stack pointer associated with EL3. When executing at EL3, the value of [SPSel.SP](#) determines the current stack pointer:

SPSel.SP	Current stack pointer
0b0	SP_EL0
0b1	SP_EL3

Configurations

This register is present only when EL3 is implemented. Otherwise, direct accesses to SP_EL3 are UNDEFINED.

Attributes

SP_EL3 is a 64-bit register.

Field descriptions

Bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C5.2.15 SPSel, Stack Pointer Select

The SPSel characteristics are:

Purpose

Allows the Stack Pointer to be selected between SP_EL0 and SP_ELx.

Configurations

There are no configuration notes.

Attributes

SPSel is a 64-bit register.

Field descriptions

Bits [63:1]

Reserved, RES0.

SP, bit [0]

Stack pointer to use. Possible values of this bit are:

- 0b0 Use SP_EL0 at all Exception levels.
- 0b1 Use SP_ELx for Exception level ELx.

The reset behavior of this field is:

- On a Warm reset, this field resets to 1.

Accessing SPSel

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SPSel

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0010	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    return Zeros(63):PSTATE.SP;
elseif PSTATE.EL == EL2 then
    return Zeros(63):PSTATE.SP;
elseif PSTATE.EL == EL3 then
    return Zeros(63):PSTATE.SP;

```

MSR SPSel, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0010	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    PSTATE.SP = X[t]<0>;
elsif PSTATE.EL == EL2 then
    PSTATE.SP = X[t]<0>;
elsif PSTATE.EL == EL3 then
    PSTATE.SP = X[t]<0>;
```

MSR SPSel, #<imm>

op0	op1	CRn	op2
0b00	0b000	0b0100	0b101

C5.2.16 SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

Purpose

Holds the saved process state when an exception is taken to Abort mode.

Configurations

AArch64 System register SPSR_abt bits [31:0] are architecturally mapped to AArch32 System register `SPSR_abt[31:0]`.

If EL1 only supports execution in AArch64 state, this register is RES0 from EL2 and EL3.

Attributes

SPSR_abt is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Abort mode, and copied to PSTATE.N on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Abort mode, and copied to PSTATE.Z on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Abort mode, and copied to PSTATE.C on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Abort mode, and copied to PSTATE.V on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Abort mode, and copied to PSTATE.Q on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to Abort mode, and copied to PSTATE.IT on executing an exception return operation in Abort mode.

SPSR_abt.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

- IT[1:0] is SPSR_abt[26:25].
- IT[7:2] is SPSR_abt[15:10].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state.

Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:

SSBS

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Abort mode, and copied to PSTATE.SSBS on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

PAN

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Abort mode, and copied to PSTATE.PAN on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:

DIT

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Abort mode, and copied to PSTATE.DIT on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Abort mode, and copied to PSTATE.IL on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Abort mode, and copied to PSTATE.GE on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to Abort mode, and copied to PSTATE.E on executing an exception return operation in Abort mode.

If the implementation does not support big-endian operation, SPSR_abt.E is RES0. If the implementation does not support little-endian operation, SPSR_abt.E is RES1. On executing an exception return operation in Abort mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_abt.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_abt.E is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SERror interrupt mask. Set to the value of PSTATE.A on taking an exception to Abort mode, and copied to PSTATE.A on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Abort mode, and copied to PSTATE.I on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Abort mode, and copied to PSTATE.F on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Abort mode, and copied to PSTATE.T on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Abort mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Abort mode.

0b10000	User.
0b10001	FIQ.
0b10010	IRQ.
0b10011	Supervisor.
0b10111	Abort.
0b11011	Undefined.
0b11111	System.

Other values are reserved. If SPSR_abt.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Abort mode is an illegal return event, as described in *Illegal return events from AArch32 state on page G1-6066*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_abt

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SPSR_abt

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0011	0b001

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    return SPSR_abt;
elseif PSTATE.EL == EL3 then
    return SPSR_abt;

```

MSR SPSR_abt, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0011	0b001

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else

```

```
        UNDEFINED;  
elseif PSTATE.EL == EL2 then  
    SPSR_abt = X[t];  
elseif PSTATE.EL == EL3 then  
    SPSR_abt = X[t];
```

C5.2.17 SPSR_EL1, Saved Program Status Register (EL1)

The SPSR_EL1 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL1.

Configurations

AArch64 System register SPSR_EL1 bits [31:0] are architecturally mapped to AArch32 System register `SPSR_svc`[31:0].

Attributes

SPSR_EL1 is a 64-bit register.

Field descriptions

When AArch32 is supported at EL0 and exception taken from AArch32 state:

An exception return from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL1, and copied to PSTATE.N on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL1, and copied to PSTATE.Z on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL1, and copied to PSTATE.C on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL1, and copied to PSTATE.V on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to EL1, and copied to PSTATE.Q on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to EL1, and copied to PSTATE.IT on executing an exception return operation in EL1.

SPSR_EL1.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

- IT[1:0] is SPSR_EL1[26:25].
- IT[7:2] is SPSR_EL1[15:10].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DIT, bit [24]

When FEAT_DIT is implemented:

DIT

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL1, and copied to PSTATE.DIT on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSBS, bit [23]

When FEAT_SSBS is implemented:

SSBS

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL1, and copied to PSTATE.SSBS on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

PAN

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL1, and copied to PSTATE.PAN on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL1, and conditionally copied to PSTATE.SS on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL1, and copied to PSTATE.IL on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to EL1, and copied to PSTATE.GE on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to EL1, and copied to PSTATE.E on executing an exception return operation in EL1.

If the implementation does not support big-endian operation, SPSR_EL1.E is RES0. If the implementation does not support little-endian operation, SPSR_EL1.E is RES1. On executing an exception return operation in EL1, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_EL1.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_EL1.E is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL1, and copied to PSTATE.A on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL1, and copied to PSTATE.I on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL1, and copied to PSTATE.F on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to EL1, and copied to PSTATE.T on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4], bit [4]

Execution state. Set to 0b1, the value of PSTATE.nRW, on taking an exception to EL1 from AArch32 state, and copied to PSTATE.nRW on executing an exception return operation in EL1.

0b1 AArch32 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch32 Mode. Set to the value of PSTATE.M[3:0] on taking an exception to EL1, and copied to PSTATE.M[3:0] on executing an exception return operation in EL1.

0b0000 User.

0b0001 FIQ.

0b0010 IRQ.

0b0011 Supervisor.

0b0111 Abort.

0b1011 Undefined.

0b1111 System.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL1 is an illegal return event, as described in *Illegal return events from AArch64 state* on page D1-2486.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When exception taken from AArch64 state:

An exception return from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL1, and copied to PSTATE.N on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL1, and copied to PSTATE.Z on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL1, and copied to PSTATE.C on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL1, and copied to PSTATE.V on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:26]

Reserved, RES0.

TCO, bit [25]

When FEAT_MTE is implemented:

TCO

Tag Check Override. Set to the value of PSTATE.TCO on taking an exception to EL1, and copied to PSTATE.TCO on executing an exception return operation in EL1.

When [FEAT_MTE](#) is not implemented, it is CONstrained UNPREDICTABLE whether this field is RES0 or behaves as if [FEAT_MTE](#) is implemented.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [24]

When FEAT_DIT is implemented:

DIT

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL1, and copied to PSTATE.DIT on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UAO, bit [23]

When FEAT_UAO is implemented:

UAO

User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL1, and copied to PSTATE.UAO on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

PAN

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL1, and copied to PSTATE.PAN on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL1, and conditionally copied to PSTATE.SS on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL1, and copied to PSTATE.IL on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:13]

Reserved, RES0.

SSBS, bit [12]

When FEAT_SSBS is implemented:

SSBS

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL1, and copied to PSTATE.SSBS on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BTYPE, bits [11:10]

When FEAT_BTI is implemented:

BTYPE

Branch Type Indicator. Set to the value of PSTATE.BTYPE on taking an exception to EL1, and copied to PSTATE.BTYPE on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL1, and copied to PSTATE.D on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL1, and copied to PSTATE.A on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL1, and copied to PSTATE.I on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL1, and copied to PSTATE.F on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to 0b0, the value of PSTATE.nRW, on taking an exception to EL1 from AArch64 state, and copied to PSTATE.nRW on executing an exception return operation in EL1.

0b0 AArch64 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

0b0000 EL0t.

0b0100 EL1t.

0b0101 EL1h.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL1 is an illegal return event, as described in [Illegal return events from AArch64 state on page D1-2486](#).

The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on taking an exception to EL1 and copied to PSTATE.EL on executing an exception return operation in EL1.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on taking an exception to EL1 and copied to PSTATE.SP on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_EL1

When `HCR_EL2.E2H` is 1, without explicit synchronization, access from EL3 using the mnemonic `SPSR_EL1` or `SPSR_EL12` are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, *SPSR_EL1*

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0000	0b000

```

if PSTATE.EL == EL0 then

```

C5.2.18 SPSR_EL2, Saved Program Status Register (EL2)

The SPSR_EL2 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL2.

Configurations

AArch64 System register SPSR_EL2 bits [31:0] are architecturally mapped to AArch32 System register `SPSR_hyp`[31:0].

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

SPSR_EL2 is a 64-bit register.

Field descriptions

When AArch32 is supported at EL0 and exception taken from AArch32 state:

An exception return from EL2 using AArch64 makes SPSR_EL2 become UNKNOWN.

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL2, and copied to PSTATE.N on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL2, and copied to PSTATE.Z on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL2, and copied to PSTATE.C on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL2, and copied to PSTATE.V on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to EL2, and copied to PSTATE.Q on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to EL2, and copied to PSTATE.IT on executing an exception return operation in EL2.

SPSR_EL2.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

- IT[1:0] is SPSR_EL2[26:25].
- IT[7:2] is SPSR_EL2[15:10].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DIT, bit [24]

When FEAT_DIT is implemented:

DIT

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL2, and copied to PSTATE.DIT on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSBS, bit [23]

When FEAT_SSBS is implemented:

SSBS

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL2, and copied to PSTATE.SSBS on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

PAN

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL2, and copied to PSTATE.PAN on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL2, and conditionally copied to PSTATE.SS on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL2, and copied to PSTATE.IL on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to EL2, and copied to PSTATE.GE on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to EL2, and copied to PSTATE.E on executing an exception return operation in EL2.

If the implementation does not support big-endian operation, SPSR_EL2.E is RES0. If the implementation does not support little-endian operation, SPSR_EL2.E is RES1. On executing an exception return operation in EL2, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_EL2.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_EL2.E is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SERror interrupt mask. Set to the value of PSTATE.A on taking an exception to EL2, and copied to PSTATE.A on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL2, and copied to PSTATE.I on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL2, and copied to PSTATE.F on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to EL2, and copied to PSTATE.T on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4], bit [4]

Execution state. Set to 0b1, the value of PSTATE.nRW, on taking an exception to EL2 from AArch32 state, and copied to PSTATE.nRW on executing an exception return operation in EL2.

0b1 AArch32 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch32 Mode. Set to the value of PSTATE.M[3:0] on taking an exception to EL2, and copied to PSTATE.M[3:0] on executing an exception return operation in EL2.

0b0000 User.

0b0001 FIQ.

0b0010 IRQ.

0b0011 Supervisor.

0b0111 Abort.

0b1010 Hyp.

0b1011 Undefined.

0b1111 System.

Other values are reserved. If SPSR_EL2.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL2 is an illegal return event, as described in *Illegal return events from AArch64 state* on page D1-2486.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When exception taken from AArch64 state:

An exception return from EL2 using AArch64 makes SPSR_EL2 become UNKNOWN.

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL2, and copied to PSTATE.N on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL2, and copied to PSTATE.Z on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL2, and copied to PSTATE.C on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL2, and copied to PSTATE.V on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:26]

Reserved, RES0.

TCO, bit [25]

When FEAT_MTE is implemented:

TCO

Tag Check Override. Set to the value of PSTATE.TCO on taking an exception to EL2, and copied to PSTATE.TCO on executing an exception return operation in EL2.

When [FEAT_MTE](#) is not implemented, it is CONSTRAINED UNPREDICTABLE whether this field is RES0 or behaves as if [FEAT_MTE](#) is implemented.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [24]

When FEAT_DIT is implemented:

DIT

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL2, and copied to PSTATE.DIT on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UAO, bit [23]

When FEAT_UAO is implemented:

UAO

User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL2, and copied to PSTATE.UAO on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

PAN

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL2, and copied to PSTATE.PAN on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL2, and conditionally copied to PSTATE.SS on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL2, and copied to PSTATE.IL on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:13]

Reserved, RES0.

SSBS, bit [12]

When FEAT_SSBS is implemented:

SSBS

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL2, and copied to PSTATE.SSBS on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BTYPE, bits [11:10]

When FEAT_BTI is implemented:

BTYPE

Branch Type Indicator. Set to the value of PSTATE.BTYPE on taking an exception to EL2, and copied to PSTATE.BTYPE on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL2, and copied to PSTATE.D on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL2, and copied to PSTATE.A on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL2, and copied to PSTATE.I on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL2, and copied to PSTATE.F on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to 0b0, the value of PSTATE.nRW, on taking an exception to EL2 from AArch64 state, and copied to PSTATE.nRW on executing an exception return operation in EL2.

0b0 AArch64 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

0b0000 EL0t.

0b0100 EL1t.

0b0101 EL1h.

0b1000 EL2t.

0b1001 EL2h.

Other values are reserved. If SPSR_EL2.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL2 is an illegal return event, as described in *Illegal return events from AArch64 state* on page D1-2486.

The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on taking an exception to EL2 and copied to PSTATE.EL on executing an exception return operation in EL2.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on taking an exception to EL2 and copied to PSTATE.SP on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_EL2

When [HCR_EL2.E2H](#) is 1, without explicit synchronization, access from EL2 using the mnemonic `SPSR_EL2` or `SPSR_EL1` are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

```

C5.2.19 SPSR_EL3, Saved Program Status Register (EL3)

The SPSR_EL3 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL3.

Configurations

AArch64 System register SPSR_EL3 bits [31:0] can be mapped to AArch32 System register [SPSR_mon](#)[31:0], but this is not architecturally mandated.

This register is present only when EL3 is implemented. Otherwise, direct accesses to SPSR_EL3 are UNDEFINED.

Attributes

SPSR_EL3 is a 64-bit register.

Field descriptions

When AArch32 is supported at EL0 and exception taken from AArch32 state:

An exception return from EL3 using AArch64 makes SPSR_EL1 become UNKNOWN.

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL3, and copied to PSTATE.N on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL3, and copied to PSTATE.Z on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL3, and copied to PSTATE.C on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL3, and copied to PSTATE.V on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to EL3, and copied to PSTATE.Q on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to EL3, and copied to PSTATE.IT on executing an exception return operation in EL3.

SPSR_EL1.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

- IT[1:0] is SPSR_EL3[26:25].
- IT[7:2] is SPSR_EL3[15:10].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DIT, bit [24]

When FEAT_DIT is implemented:

DIT

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL3, and copied to PSTATE.DIT on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSBS, bit [23]

When FEAT_SSBS is implemented:

SSBS

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL3, and copied to PSTATE.SSBS on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

PAN

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL3, and copied to PSTATE.PAN on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL3, and conditionally copied to PSTATE.SS on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL3, and copied to PSTATE.IL on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to EL3, and copied to PSTATE.GE on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to EL3, and copied to PSTATE.E on executing an exception return operation in EL3.

If the implementation does not support big-endian operation, SPSR_EL1.E is RES0. If the implementation does not support little-endian operation, SPSR_EL1.E is RES1. On executing an exception return operation in EL3, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_EL1.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_EL1.E is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SERror interrupt mask. Set to the value of PSTATE.A on taking an exception to EL3, and copied to PSTATE.A on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL3, and copied to PSTATE.I on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL3, and copied to PSTATE.F on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to EL3, and copied to PSTATE.T on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4], bit [4]

Execution state. Set to 0b1, the value of PSTATE.nRW, on taking an exception to EL3 from AArch32 state, and copied to PSTATE.nRW on executing an exception return operation in EL3.

0b1 AArch32 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch32 Mode. Set to the value of PSTATE.M[3:0] on taking an exception to EL3, and copied to PSTATE.M[3:0] on executing an exception return operation in EL3.

- 0b0000 User.
- 0b0001 FIQ.
- 0b0010 IRQ.
- 0b0011 Supervisor.
- 0b0110 Monitor.
- 0b0111 Abort.
- 0b1010 Hyp.
- 0b1011 Undefined.
- 0b1111 System.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL3 is an illegal return event, as described in *Illegal return events from AArch64 state on page D1-2486*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When exception taken from AArch64 state:

An exception return from EL3 using AArch64 makes SPSR_EL1 become UNKNOWN.

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL3, and copied to PSTATE.N on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL3, and copied to PSTATE.Z on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL3, and copied to PSTATE.C on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL3, and copied to PSTATE.V on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:26]

Reserved, RES0.

TCO, bit [25]

When FEAT_MTE is implemented:

TCO

Tag Check Override. Set to the value of PSTATE.TCO on taking an exception to EL3, and copied to PSTATE.TCO on executing an exception return operation in EL3.

When [FEAT_MTE](#) is not implemented, it is CONstrained UNPREDICTABLE whether this field is RES0 or behaves as if [FEAT_MTE](#) is implemented.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [24]

When FEAT_DIT is implemented:

DIT

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL3, and copied to PSTATE.DIT on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UAO, bit [23]

When FEAT_UAO is implemented:

UAO

User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL3, and copied to PSTATE.UAO on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

PAN

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL3, and copied to PSTATE.PAN on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL3, and conditionally copied to PSTATE.SS on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL3, and copied to PSTATE.IL on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:13]

Reserved, RES0.

SSBS, bit [12]

When FEAT_SSBS is implemented:

SSBS

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL3, and copied to PSTATE.SSBS on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BTYPE, bits [11:10]

When FEAT_BTI is implemented:

BTYP

Branch Type Indicator. Set to the value of PSTATE.BTYP on taking an exception to EL3, and copied to PSTATE.BTYP on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL3, and copied to PSTATE.D on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SERror interrupt mask. Set to the value of PSTATE.A on taking an exception to EL3, and copied to PSTATE.A on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL3, and copied to PSTATE.I on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL3, and copied to PSTATE.F on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to 0b0, the value of PSTATE.nRW, on taking an exception to EL3 from AArch64 state, and copied to PSTATE.nRW on executing an exception return operation in EL3.

0b0 AArch64 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

0b0000 EL0t.

0b0100 EL1t.

0b0101 EL1h.

0b1000 EL2t.
0b1001 EL2h.
0b1100 EL3t.
0b1101 EL3h.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL3 is an illegal return event, as described in *Illegal return events from AArch64 state on page D1-2486*.

The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on taking an exception to EL3 and copied to PSTATE.EL on executing an exception return operation in EL3.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on taking an exception to EL3 and copied to PSTATE.SP on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_EL3

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SPSR_EL3

op0	op1	CRn	CRm	op2
0b11	0b110	0b0100	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    return SPSR_EL3;
```

MSR SPSR_EL3, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b110	0b0100	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    SPSR_EL3 = X[t];
```

C5.2.20 SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

Purpose

Holds the saved process state when an exception is taken to FIQ mode.

Configurations

AArch64 System register SPSR_fiq bits [31:0] are architecturally mapped to AArch32 System register SPSR_fiq[31:0].

If EL1 only supports execution in AArch64 state, this register is RES0 from EL2 and EL3.

Attributes

SPSR_fiq is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to FIQ mode, and copied to PSTATE.N on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to FIQ mode, and copied to PSTATE.Z on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to FIQ mode, and copied to PSTATE.C on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to FIQ mode, and copied to PSTATE.V on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to FIQ mode, and copied to PSTATE.Q on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to FIQ mode, and copied to PSTATE.IT on executing an exception return operation in FIQ mode.

SPSR_fiq.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

- IT[1:0] is SPSR_fiq[26:25].
- IT[7:2] is SPSR_fiq[15:10].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state.

Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:

SSBS

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to FIQ mode, and copied to PSTATE.SSBS on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

PAN

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to FIQ mode, and copied to PSTATE.PAN on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:

DIT

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to FIQ mode, and copied to PSTATE.DIT on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to FIQ mode, and copied to PSTATE.IL on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to FIQ mode, and copied to PSTATE.GE on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to FIQ mode, and copied to PSTATE.E on executing an exception return operation in FIQ mode.

If the implementation does not support big-endian operation, SPSR_fiq.E is RES0. If the implementation does not support little-endian operation, SPSR_fiq.E is RES1. On executing an exception return operation in FIQ mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_fiq.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_fiq.E is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SERror interrupt mask. Set to the value of PSTATE.A on taking an exception to FIQ mode, and copied to PSTATE.A on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to FIQ mode, and copied to PSTATE.I on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to FIQ mode, and copied to PSTATE.F on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to FIQ mode, and copied to PSTATE.T on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to FIQ mode, and copied to PSTATE.M[4:0] on executing an exception return operation in FIQ mode.

0b10000	User.
0b10001	FIQ.
0b10010	IRQ.
0b10011	Supervisor.
0b10111	Abort.
0b11011	Undefined.
0b11111	System.

Other values are reserved. If SPSR_fiq.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in FIQ mode is an illegal return event, as described in *Illegal return events from AArch32 state on page G1-6066*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_fiq

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SPSR_fiq

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0011	0b011

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    return SPSR_fiq;
elseif PSTATE.EL == EL3 then
    return SPSR_fiq;

```

MSR SPSR_fiq, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0011	0b011

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else

```

```
        UNDEFINED;  
elseif PSTATE.EL == EL2 then  
    SPSR_fiq = X[t];  
elseif PSTATE.EL == EL3 then  
    SPSR_fiq = X[t];
```

C5.2.21 SPSR_irq, Saved Program Status Register (IRQ mode)

The SPSR_irq characteristics are:

Purpose

Holds the saved process state when an exception is taken to IRQ mode.

Configurations

AArch64 System register SPSR_irq bits [31:0] are architecturally mapped to AArch32 System register SPSR_irq[31:0].

If EL1 only supports execution in AArch64 state, this register is RES0 from EL2 and EL3.

Attributes

SPSR_irq is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to IRQ mode, and copied to PSTATE.N on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to IRQ mode, and copied to PSTATE.Z on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to IRQ mode, and copied to PSTATE.C on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to IRQ mode, and copied to PSTATE.V on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to IRQ mode, and copied to PSTATE.Q on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to IRQ mode, and copied to PSTATE.IT on executing an exception return operation in IRQ mode.

SPSR_irq.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

- IT[1:0] is SPSR_irq[26:25].
- IT[7:2] is SPSR_irq[15:10].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state.

Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:

SSBS

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to IRQ mode, and copied to PSTATE.SSBS on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

PAN

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to IRQ mode, and copied to PSTATE.PAN on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:

DIT

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to IRQ mode, and copied to PSTATE.DIT on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to IRQ mode, and copied to PSTATE.IL on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to IRQ mode, and copied to PSTATE.GE on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to IRQ mode, and copied to PSTATE.E on executing an exception return operation in IRQ mode.

If the implementation does not support big-endian operation, SPSR_irq.E is RES0. If the implementation does not support little-endian operation, SPSR_irq.E is RES1. On executing an exception return operation in IRQ mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_irq.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_irq.E is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to IRQ mode, and copied to PSTATE.A on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to IRQ mode, and copied to PSTATE.I on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to IRQ mode, and copied to PSTATE.F on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to IRQ mode, and copied to PSTATE.T on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to IRQ mode, and copied to PSTATE.M[4:0] on executing an exception return operation in IRQ mode.

0b10000	User.
0b10001	FIQ.
0b10010	IRQ.
0b10011	Supervisor.
0b10111	Abort.
0b11011	Undefined.
0b11111	System.

Other values are reserved. If SPSR_irq.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in IRQ mode is an illegal return event, as described in *Illegal return events from AArch32 state on page G1-6066*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_irq

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SPSR_irq

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0011	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    return SPSR_irq;
elseif PSTATE.EL == EL3 then
    return SPSR_irq;

```

MSR SPSR_irq, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0011	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else

```

```
        UNDEFINED;  
    elif PSTATE.EL == EL2 then  
        SPSR_irq = X[t];  
    elif PSTATE.EL == EL3 then  
        SPSR_irq = X[t];
```

C5.2.22 SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

Purpose

Holds the saved process state when an exception is taken to Undefined mode.

Configurations

AArch64 System register SPSR_und bits [31:0] are architecturally mapped to AArch32 System register [SPSR_und](#)[31:0].

If EL1 only supports execution in AArch64 state, this register is RES0 from EL2 and EL3.

Attributes

SPSR_und is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Undefined mode, and copied to PSTATE.N on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Undefined mode, and copied to PSTATE.Z on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Undefined mode, and copied to PSTATE.C on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Undefined mode, and copied to PSTATE.V on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Undefined mode, and copied to PSTATE.Q on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to Undefined mode, and copied to PSTATE.IT on executing an exception return operation in Undefined mode.

SPSR_und.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

- IT[1:0] is SPSR_und[26:25].
- IT[7:2] is SPSR_und[15:10].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state.

Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:

SSBS

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Undefined mode, and copied to PSTATE.SSBS on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

PAN

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Undefined mode, and copied to PSTATE.PAN on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:

DIT

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Undefined mode, and copied to PSTATE.DIT on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Undefined mode, and copied to PSTATE.IL on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Undefined mode, and copied to PSTATE.GE on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to Undefined mode, and copied to PSTATE.E on executing an exception return operation in Undefined mode.

If the implementation does not support big-endian operation, SPSR_und.E is RES0. If the implementation does not support little-endian operation, SPSR_und.E is RES1. On executing an exception return operation in Undefined mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_und.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_und.E is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SERror interrupt mask. Set to the value of PSTATE.A on taking an exception to Undefined mode, and copied to PSTATE.A on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Undefined mode, and copied to PSTATE.I on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Undefined mode, and copied to PSTATE.F on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Undefined mode, and copied to PSTATE.T on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Undefined mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Undefined mode.

0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11011 Undefined.
0b11111 System.

Other values are reserved. If SPSR_und.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Undefined mode is an illegal return event, as described in *Illegal return events from AArch32 state on page G1-6066*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_und

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SPSR_und

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0011	0b010

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    return SPSR_und;
elseif PSTATE.EL == EL3 then
    return SPSR_und;

```

0b11	0b100	0b0100	0b0011	0b010

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else

```

```
        UNDEFINED;  
elseif PSTATE.EL == EL2 then  
    SPSR_und = X[t];  
elseif PSTATE.EL == EL3 then  
    SPSR_und = X[t];
```

C5.2.23 SSBS, Speculative Store Bypass Safe

The SSBS characteristics are:

Purpose

Allows access to the Speculative Store Bypass Safe bit.

Configurations

This register is present only when FEAT_SSBS is implemented. Otherwise, direct accesses to SSBS are UNDEFINED.

Attributes

SSBS is a 64-bit register.

Field descriptions

Bits [63:13]

Reserved, RES0.

SSBS, bit [12]

Speculative Store Bypass Safe.

Prohibits speculative loads or stores which might practically allow a cache timing side channel.

A cache timing side channel might be exploited where a load or store uses an address that is derived from a register that is being loaded from memory using a load instruction speculatively read from a memory location. If PSTATE.SSBS is enabled, the address derived from the load instruction might be from earlier in the coherence order than the latest store to that memory location with the same virtual address.

- 0b0 Hardware is not permitted to load or store speculatively, in a manner that could practically give rise to a cache timing side channel, using an address derived from a register value that has been loaded from memory using a load instruction (L) that speculatively reads an entry from earlier in the coherence order from that location being loaded from than the entry generated by the latest store (S) to that location using the same virtual address as L.
- 0b1 Hardware is permitted to load or store speculatively, in a manner that could practically give rise to a cache timing side channel, using an address derived from a register value that has been loaded from memory using a load instruction (L) that speculatively reads an entry from earlier in the coherence order from that location being loaded from than the entry generated by the latest store (S) to that location using the same virtual address as L.

The value of this bit is set to the value in the SCTLR_ELx.DSSBS field on taking an exception to ELx.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

Bits [11:0]

Reserved, RES0.

Accessing SSBS

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SSBS

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0010	0b110

```

if PSTATE.EL == EL0 then
    return Zeros(51):PSTATE.SSBS:Zeros(12);
elsif PSTATE.EL == EL1 then
    return Zeros(51):PSTATE.SSBS:Zeros(12);
elsif PSTATE.EL == EL2 then
    return Zeros(51):PSTATE.SSBS:Zeros(12);
elsif PSTATE.EL == EL3 then
    return Zeros(51):PSTATE.SSBS:Zeros(12);

```

MSR SSBS, <Xt>

op0	op1	CRn	CRm	op2

    PSTATE.SSBS = X[t]<12>;
elsif PSTATE.EL == EL1 then
    PSTATE.SSBS = X[t]<12>;
elsif PSTATE.EL == EL2 then
    PSTATE.SSBS = X[t]<12>;
elsif PSTATE.EL == EL3 then
    PSTATE.SSBS = X[t]<12>;

```

MSR SSBS, #<imm>

op0	op1	CRn	op2
0b00	0b011	0b0100	0b001

C5.2.24 TCO, Tag Check Override

The TCO characteristics are:

Purpose

When [FEAT_MTE](#) is implemented, this register allows tag checks to be disabled globally.

When [FEAT_MTE](#) is not implemented, it is CONSTRAINED UNPREDICTABLE whether this register is RES0 or behaves as if [FEAT_MTE](#) is implemented.

Configurations

This register is present only when [FEAT_MTE](#) is implemented. Otherwise, direct accesses to TCO are UNDEFINED.

Attributes

TCO is a 64-bit register.

Field descriptions

Bits [63:26]

Reserved, RES0.

TCO, bit [25]

Allows memory tag checks to be globally disabled.

- 0b0 Loads and Stores are not affected by this control.
- 0b1 Loads and Stores are unchecked.

Bits [24:0]

Reserved, RES0.

Accessing TCO

For information about the operation of the MSR (immediate) accessor, see [MSR \(immediate\)](#).

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TCO

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0010	0b111

```

if PSTATE.EL == EL0 then
    return Zeros(38):PSTATE.TCO:Zeros(25);
elseif PSTATE.EL == EL1 then
    return Zeros(38):PSTATE.TCO:Zeros(25);
elseif PSTATE.EL == EL2 then
    return Zeros(38):PSTATE.TCO:Zeros(25);

```

```
elseif PSTATE.EL == EL3 then
  return Zeros(38):PSTATE.TCO:Zeros(25);
```

MSR TCO, <Xt>

C5.2.25 UAO, User Access Override

The UAO characteristics are:

Purpose

Allows access to the User Access Override bit.

Configurations

This register is present only when FEAT_UAO is implemented. Otherwise, direct accesses to UAO are UNDEFINED.

Attributes

UAO is a 64-bit register.

Field descriptions

Bits [63:24]

Reserved, RES0.

UAO, bit [23]

User Access Override.

0b0 The behavior of LDTR* and STTR* instructions is as defined in the base Armv8 architecture.

0b1 When executed at EL1, or at EL2 with [HCR_EL2](#).{E2H, TGE} = {1, 1}, LDTR* and STTR* instructions behave as the equivalent LDR* and STR* instructions.

When executed at EL3, or at EL2 with [HCR_EL2](#).E2H = 0 or [HCR_EL2](#).TGE = 0, the LDTR* and STTR* instructions behave as the equivalent LDR* and STR* instructions, regardless of the setting of the PSTATE.UAO bit.

Bits [22:0]

Reserved, RES0.

Accessing UAO

For more information about the operation of the MSR (immediate) accessor, see [MSR \(immediate\)](#).

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, UAO

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0010	0b100

```
if PSTATE.EL == EL0 then

0b00	0b000	0b0100	0b011

C5.3 A64 System instructions for cache maintenance

This section lists the A64 System instructions for cache maintenance.

C5.3.1 DC CGDSW, Clean of Data and Allocation Tags by Set/Way

The DC CGDSW characteristics are:

Purpose

Clean data and Allocation Tags in data cache by set/way.

Configurations

This instruction is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to DC CGDSW are UNDEFINED.

Attributes

DC CGDSW is a 64-bit System instruction.

Field descriptions

Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing DC CGDSW instruction

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC CGDSW, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1010	0b110

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TSW == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.DCCSW == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        AArch64.DC(X[t], CacheType_Data_Tag, CacheOp_Clean, CacheOpScope_SetWay);
elsif PSTATE.EL == EL2 then
    AArch64.DC(X[t], CacheType_Data_Tag, CacheOp_Clean, CacheOpScope_SetWay);
elsif PSTATE.EL == EL3 then
    AArch64.DC(X[t], CacheType_Data_Tag, CacheOp_Clean, CacheOpScope_SetWay);
```

C5.3.2 DC CGDVAC, Clean of Data and Allocation Tags by VA to PoC

The DC CGDVAC characteristics are:

Purpose

Clean data and Allocation Tags in data cache by address to Point of Coherency.

Configurations

This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC CGDVAC are UNDEFINED.

Attributes

DC CGDVAC is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC CGDVAC instruction

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault, subject to the constraints described in [Permission fault on page D5-2801](#).

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see [The data cache maintenance instruction \(DC\) on page D4-2650](#).

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC CGDVAC, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b1010	0b101

```

if PSTATE.EL == EL0 then
    if !(EL2Enabled() && HCR_EL2.<E2H,TGE> == '11') && SCTLR_EL1.UCI == '0' then
        if EL2Enabled() && HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    elsif EL2Enabled() && HCR_EL2.<E2H,TGE> != '11' && HCR_EL2.TPCP == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && HCR_EL2.<E2H,TGE> != '11' && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') &&
HFGITR_EL2.DCCVAC == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && HCR_EL2.<E2H,TGE> == '11' && SCTLR_EL2.UCI == '0' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        AArch64.DC(X[t], CacheType_Data_Tag, CacheOp_Clean, CacheOpScope_PoC);
elseif PSTATE.EL == EL1 then

```

```
if EL2Enabled() && HCR_EL2.TPCP == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
elsif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.DCCVAC == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
else
    AArch64.DC(X[t], CacheType_Data_Tag, CacheOp_Clean, CacheOpScope_PoC);
elsif PSTATE.EL == EL2 then
    AArch64.DC(X[t], CacheType_Data_Tag, CacheOp_Clean, CacheOpScope_PoC);
elsif PSTATE.EL == EL3 then
    AArch64.DC(X[t], CacheType_Data_Tag, CacheOp_Clean, CacheOpScope_PoC);
```

C5.3.3 DC CGDVADP, Clean of Data and Allocation Tags by VA to PoDP

The DC CGDVADP characteristics are:

Purpose

Clean Allocation Tags and data in data cache by address to Point of Deep Persistence.

If the memory system does not identify a Point of Deep Persistence, then this instruction behaves as a [DC CGDVAP](#).

Configurations

This instruction is present only when FEAT_DPB2 is implemented and FEAT_MTE is implemented. Otherwise, direct accesses to DC CGDVADP are UNDEFINED.

Attributes

DC CGDVADP is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC CGDVADP instruction

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault, see [Permission fault on page D5-2801](#).

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see [The data cache maintenance instruction \(DC\) on page D4-2650](#).

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC CGDVADP, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b1101	0b101

```

```

C5.3.4 DC CGDVAP, Clean of Data and Allocation Tags by VA to PoP

The DC CGDVAP characteristics are:

Purpose

Clean data and Allocation Tags in data cache by address to Point of Persistence.

If the memory system does not identify a Point of Persistence, then this instruction behaves as a [DC CGDVAC](#).

Configurations

This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC CGDVAP are UNDEFINED.

Attributes

DC CGDVAP is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC CGDVAP instruction

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault, see [Permission fault on page D5-2801](#).

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see [The data cache maintenance instruction \(DC\) on page D4-2650](#).

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC CGDVAP, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b1100	0b101

```

if PSTATE.EL == EL0 then

    AArch64.DC(X[t], CacheType_Data_Tag, CacheOp_Clean, CacheOpScope_PoP);
```

C5.3.5 DC CGSW, Clean of Allocation Tags by Set/Way

The DC CGSW characteristics are:

Purpose

Clean Allocation Tags in data cache by set/way.

Configurations

This instruction is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to DC CGSW are UNDEFINED.

Attributes

DC CGSW is a 64-bit System instruction.

Field descriptions

Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing DC CGSW instruction

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC CGSW, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1010	0b100

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TSW == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.DCCSW == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        AArch64.DC(X[t], CacheType_Tag, CacheOp_Clean, CacheOpScope_SetWay);
elsif PSTATE.EL == EL2 then
    AArch64.DC(X[t], CacheType_Tag, CacheOp_Clean, CacheOpScope_SetWay);
elsif PSTATE.EL == EL3 then
    AArch64.DC(X[t], CacheType_Tag, CacheOp_Clean, CacheOpScope_SetWay);
```

C5.3.6 DC CGVAC, Clean of Allocation Tags by VA to PoC

The DC CGVAC characteristics are:

Purpose

Clean Allocation Tags in data cache by address to Point of Coherency.

Configurations

This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC CGVAC are UNDEFINED.

Attributes

DC CGVAC is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC CGVAC instruction

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault, subject to the constraints described in [Permission fault on page D5-2801](#).

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see [The data cache maintenance instruction \(DC\) on page D4-2650](#).

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC CGVAC, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b1010	0b011

```

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing DC CIGSW instruction

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC CIGSW, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1110	0b100

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TSW == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.DCCISW == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        AArch64.DC(X[t], CacheType_Tag, CacheOp_CleanInvalidate, CacheOpScope_SetWay);
    endif PSTATE.EL == EL2 then
        AArch64.DC(X[t], CacheType_Tag, CacheOp_CleanInvalidate, CacheOpScope_SetWay);
    elsif PSTATE.EL == EL3 then
        AArch64.DC(X[t], CacheType_Tag, CacheOp_CleanInvalidate, CacheOpScope_SetWay);
  
```

C5.3.12 DC CIGVAC, Clean and Invalidate of Allocation Tags by VA to PoC

The DC CIGVAC characteristics are:

Purpose

Clean and Invalidate Allocation Tags in data cache by address to Point of Coherency.

Configurations

This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC CIGVAC are UNDEFINED.

Attributes

DC CIGVAC is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC CIGVAC instruction

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see [The data cache maintenance instruction \(DC\) on page D4-2650](#).

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault, subject to the constraints described in [Permission fault on page D5-2801](#).

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC CIGVAC, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b1110	0b011

```

if PSTATE.EL == EL0 then

```

C5.3.13 DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way

The DC CISW characteristics are:

Purpose

Clean and Invalidate data cache by set/way.

When [FEAT_MTE](#) is implemented, this instruction might clean and invalidate Allocation Tags from caches.

Configurations

AArch64 System register DC CISW performs the same function as AArch32 System register [DCCISW](#).

Attributes

DC CISW is a 64-bit System instruction.

Field descriptions

Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

C5.3.20 DC GVA, Data Cache set Allocation Tag by VA

The DC GVA characteristics are:

Purpose

Write a value to the Allocation Tags of a naturally aligned block of N bytes, where the size of N is identified in [DCZID_EL0](#). The Allocation Tag used is determined by the input address.

Configurations

This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC GVA are UNDEFINED.

Attributes

DC GVA is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.

Executing DC GVA instruction

When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is not set.

If the memory region being modified is any type of Device memory, this instruction can give an alignment fault that is prioritized in the same way as other alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of stores to each Allocation Tag within the block being accessed, and so it:

- Generates a Permission fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC GVA, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b0100	0b011

C5.3.21 DC GZVA, Data Cache set Allocation Tags and Zero by VA

The DC GZVA characteristics are:

Purpose

Zero data and write a value to the Allocation Tags of a naturally aligned block of N bytes, where the size of N is identified in `DCZID_ELO`. The Allocation Tag used is determined by the input address.

Configurations

This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC GZVA are UNDEFINED.

Attributes

DC GZVA is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.

Executing DC GZVA instruction

When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is not set.

If the memory region being zeroed is any type of Device memory, this instruction can give an alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of Stores to each byte and Allocation tag within the block being accessed, and so it:

- Generates a Permission fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```

C5.3.22 DC IGDSW, Invalidate of Data and Allocation Tags by Set/Way

The DC IGDSW characteristics are:

Purpose

Invalidate data and Allocation Tags in data cache by set/way.

Configurations

This instruction is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to DC IGDSW are UNDEFINED.

Attributes

DC IGDSW is a 64-bit System instruction.

Field descriptions

Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing DC IGDSW instruction

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC IGDSW, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b0110	0b110

```

if PSTATE.EL == EL0 then

elseif PSTATE.EL == EL3 then
    AArch64.DC(X[t], CacheType_Data_Tag, CacheOp_Invalidate, CacheOpScope_SetWay);

```

C5.3.23 DC IGDVAC, Invalidate of Data and Allocation Tags by VA to PoC

The DC IGDVAC characteristics are:

Purpose

Invalidate data and Allocation Tags in data cache by address to Point of Coherency.

Configurations

This instruction is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to DC IGDVAC are UNDEFINED.

Attributes

DC IGDVAC is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC IGDVAC instruction

When the instruction is executed, it can generate a watchpoint, which is prioritized in the same way as other watchpoints. If a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 1.

This instruction requires write access permission to the VA, otherwise it generates a Permission fault, subject to the constraints described in [Permission fault on page D5-2801](#).

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see [The data cache maintenance instruction \(DC\) on page D4-2650](#).

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC IGDVAC, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b0110	0b101

    AArch64.DC(X[t], CacheType_Tag, CacheOp_Invalidate, CacheOpScope_PoC);
```

C5.3.26 DC ISW, Data or unified Cache line Invalidate by Set/Way

The DC ISW characteristics are:

Purpose

Invalidate data cache by set/way.

When [FEAT_MTE](#) is implemented, this instruction might invalidate Allocation Tags from caches. When it invalidates Allocation Tags from caches, it also cleans them.

Configurations

AArch64 System register DC ISW performs the same function as AArch32 System register [DCISW](#).

Attributes

DC ISW is a 64-bit System instruction.

Field descriptions

Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

    AArch64.DC(X[t], CacheType_Data, CacheOp_Invalidate, CacheOpScope_PoC);

```

```
elseif PSTATE.EL == EL3 then  
    AArch64.DC(X[t], CacheType_Data, CacheOp_Invalidate, CacheOpScope_PoC);
```

C5.3.28 DC ZVA, Data Cache Zero by VA

The DC ZVA characteristics are:

Purpose

Zero data cache by address. Zeroes a naturally aligned block of N bytes, where the size of N is identified in [DCZID_EL0](#).

Configurations

There are no configuration notes.

Attributes

DC ZVA is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.

Executing DC ZVA instruction

When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 0.

If the memory region being zeroed is any type of Device memory, this instruction can give an Alignment fault which is prioritized in the same way as other Alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of Stores to each byte within the block being accessed, and so it:

- Generates a Permission fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

Accesses to this instruction use the following encodings in the System instruction encoding space:

DC ZVA, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b0100	0b001

```

if PSTATE.EL == EL0 then
    if !(EL2Enabled() && HCR_EL2.<E2H,TGE> == '11') && SCTLR_EL1.DZE == '0' then
        if EL2Enabled() && HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else

```

```
        AArch64.SystemAccessTrap(EL1, 0x18);

```

C5.3.29 IC IALLU, Instruction Cache Invalidate All to PoU

The IC IALLU characteristics are:

Purpose

Invalidate all instruction caches of the PE executing the instruction to the Point of Unification.

Configurations

AArch64 System register IC IALLU performs the same function as AArch32 System register [ICIALLU](#).

Attributes

IC IALLU is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing IC IALLU instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

IC IALLU{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b0101	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TPU == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && HCR_EL2.TOCU == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.ICIALLU == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && HCR_EL2.FB == '1' then
        AArch64.IC(CacheOpScope_ALLUIS);
    else
        AArch64.IC(CacheOpScope_ALLU);
elseif PSTATE.EL == EL2 then
    AArch64.IC(CacheOpScope_ALLU);
elseif PSTATE.EL == EL3 then
    AArch64.IC(CacheOpScope_ALLU);

```

C5.3.30 IC IALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The IC IALLUIS characteristics are:

Purpose

Invalidate all instruction caches in the Inner Shareable domain of the PE executing the instruction to the Point of Unification.

Configurations

AArch64 System register IC IALLUIS performs the same function as AArch32 System register [ICIALLUIS](#).

Attributes

IC IALLUIS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing IC IALLUIS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

IC IALLUIS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b0001	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TPU == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && HCR_EL2.TICAB == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elseif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.ICIALLUIS == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        AArch64.IC(CacheOpScope_ALLUIS);
elseif PSTATE.EL == EL2 then
    AArch64.IC(CacheOpScope_ALLUIS);
elseif PSTATE.EL == EL3 then
    AArch64.IC(CacheOpScope_ALLUIS);
```

C5.3.31 IC IVAU, Instruction Cache line Invalidate by VA to PoU

The IC IVAU characteristics are:

Purpose

Invalidate instruction cache by address to Point of Unification.

Configurations

AArch64 System register IC IVAU performs the same function as AArch32 System register [ICIMVAU](#).

Attributes

IC IVAU is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing IC IVAU instruction

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see [The instruction cache maintenance instruction \(IC\)](#) on page D4-2650.

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it is IMPLEMENTATION DEFINED whether it generates a Permission fault, see [Permission fault on page D5-2801](#).

Accesses to this instruction use the following encodings in the System instruction encoding space:

IC IVAU{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b0101	0b001

```

```

C5.4 A64 System instructions for address translation

This section lists the A64 System instructions for address translation.

C5.4.1 AT S12E0R, Address Translate Stages 1 and 2 EL0 Read

The AT S12E0R characteristics are:

Purpose

Performs stage 1 and 2 address translations from EL0, with permissions as if reading from the given virtual address from EL0, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of `SCR_EL3.NS`:
 - If `HCR_EL2.{E2H, TGE}` is not {1, 1}, the EL1&0 translation regime.
 - If `HCR_EL2.{E2H, TGE}` is {1, 1}, the EL2&0 translation regime.
- Otherwise, the EL1&0 translation regime.

Configurations

There are no configuration notes.

Attributes

AT S12E0R is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the `PAR_EL1`.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then `VA[63:32]` is `RES0`.

Executing AT S12E0R instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

AT S12E0R, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b110

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    if HCR_EL2.<E2H,TGE> == '11' || HCR_EL2.<DC,VM> == '00' then
        AT_S1E0R(X[t]);
    else
        AT_S12E0R(X[t]);
  
```

```
elseif PSTATE.EL == EL3 then
    if !EL2Enabled() then
        AT_S1E0R(X[t]);
    elseif EL2Enabled() && (HCR_EL2.<E2H,TGE> == '11' || HCR_EL2.<DC,VM> == '00') then
        AT_S1E0R(X[t]);
    else
        AT_S12E0R(X[t]);
```

C5.4.2 AT S12E0W, Address Translate Stages 1 and 2 EL0 Write

The AT S12E0W characteristics are:

Purpose

Performs stage 1 and 2 address translations from EL0, with permissions as if writing to the given virtual address from EL0, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of `SCR_EL3.NS`:
 - If `HCR_EL2.{E2H, TGE}` is not {1, 1}, the EL1&0 translation regime.
 - If `HCR_EL2.{E2H, TGE}` is {1, 1}, the EL2&0 translation regime.
- Otherwise, the EL1&0 translation regime.

Configurations

There are no configuration notes.

Attributes

AT S12E0W is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the `PAR_EL1`.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then `VA[63:32]` is RES0.

Executing AT S12E0W instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

AT S12E0W, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b111

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    if HCR_EL2.<E2H,TGE> == '11' || HCR_EL2.<DC,VM> == '00' then
        AT_S1E0W(X[t]);
    else
        AT_S12E0W(X[t]);
    
```

```
elseif PSTATE.EL == EL3 then
    if !EL2Enabled() then
        AT_S1E0W(X[t]);
    elseif EL2Enabled() && (HCR_EL2.<E2H,TGE> == '11' || HCR_EL2.<DC,VM> == '00') then
        AT_S1E0W(X[t]);
    else
        AT_S12E0W(X[t]);
```

C5.4.3 AT S12E1R, Address Translate Stages 1 and 2 EL1 Read

The AT S12E1R characteristics are:

Purpose

Performs stage 1 and 2 address translation, with permissions as if reading from the given virtual address from EL1, or from EL2 if the Effective value of [HCR_EL2](#).{E2H, TGE} is {1, 1}, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of [SCR_EL3](#).NS:
 - If [HCR_EL2](#).{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
 - If [HCR_EL2](#).{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.
- Otherwise, the EL1&0 translation regime, accessed from EL1.

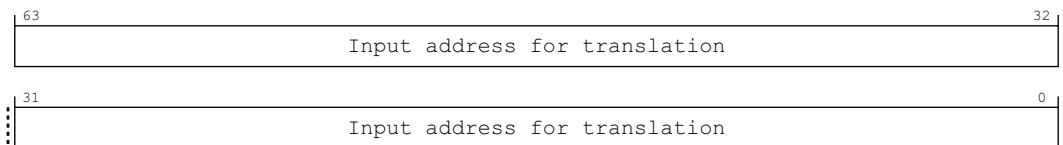

Configurations

There are no configuration notes.

Attributes

AT S12E1R is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the [PAR_EL1](#).

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing AT S12E1R instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

AT S12E1R, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b100

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elsif PSTATE.EL == EL2 then
    if HCR_EL2.<E2H,TGE> == '11' || HCR_EL2.<DC,VM> == '00' then
    
```

```
        AT_S1E1R(X[t]);
    else
        AT_S12E1R(X[t]);
elseif PSTATE.EL == EL3 then
    if !EL2Enabled() then
        AT_S1E1R(X[t]);
    elseif EL2Enabled() && (HCR_EL2.<E2H,TGE> == '11' || HCR_EL2.<DC,VM> == '00') then
        AT_S1E1R(X[t]);
    else
        AT_S12E1R(X[t]);
```

C5.4.4 AT S12E1W, Address Translate Stages 1 and 2 EL1 Write

The AT S12E1W characteristics are:

Purpose

Performs stage 1 and 2 address translation, with permissions as if writing to the given virtual address from EL1, or from EL2 if the Effective value of [HCR_EL2](#).{E2H, TGE} is {1, 1}, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of [SCR_EL3.NS](#):
 - If [HCR_EL2](#).{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
 - If [HCR_EL2](#).{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.
- Otherwise, the EL1&0 translation regime, accessed from EL1.

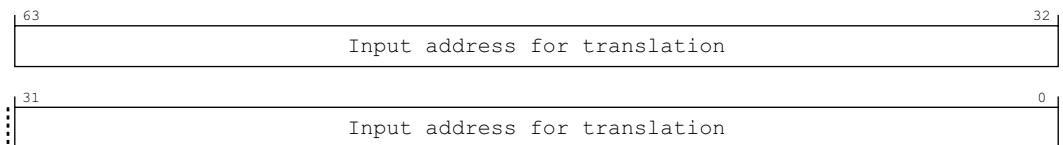

Configurations

There are no configuration notes.

Attributes

AT S12E1W is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the [PAR_EL1](#).

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing AT S12E1W instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

AT S12E1W, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b101

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;

    if HCR_EL2.<E2H,TGE> == '11' || HCR_EL2.<DC,VM> == '00' then
    
```

```
        AT_S1E1W(X[t]);
    else
        AT_S12E1W(X[t]);
elseif PSTATE.EL == EL3 then
    if !EL2Enabled() then
        AT_S1E1W(X[t]);
    elseif EL2Enabled() && (HCR_EL2.<E2H,TGE> == '11' || HCR_EL2.<DC,VM> == '00') then
        AT_S1E1W(X[t]);
    else
        AT_S12E1W(X[t]);
```

C5.4.5 AT S1E0R, Address Translate Stage 1 EL0 Read

The AT S1E0R characteristics are:

Purpose

Performs stage 1 address translation from EL0, with permissions as if reading from the given virtual address from EL0, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of `SCR_EL3.NS`:
 - If `HCR_EL2.{E2H, TGE}` is not {1, 1}, the EL1&0 translation regime.
 - If `HCR_EL2.{E2H, TGE}` is {1, 1}, the EL2&0 translation regime.
- Otherwise, the EL1&0 translation regime.

Configurations

There are no configuration notes.

Attributes

AT S1E0R is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the `PAR_EL1`.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then `VA[63:32]` is `RES0`.

Executing AT S1E0R instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

AT S1E0R, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1000	0b010

```

if PSTATE.EL == EL0 then
    UNDEFINED;

elseif PSTATE.EL == EL3 then
    AT_S1E1R(X[t]);
```

C5.4.8 AT S1E1RP, Address Translate Stage 1 EL1 Read PAN

The AT S1E1RP characteristics are:

Purpose

Performs a stage 1 address translation, where the value of PSTATE.PAN determines if a read from a location will generate a Permission fault for a privileged access, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
 - If HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
 - If HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.
- Otherwise, the EL1&0 translation regime, accessed from EL1.

Configurations

This instruction is present only when FEAT_PAN2 is implemented. Otherwise, direct accesses to AT S1E1RP are UNDEFINED.

Attributes

AT S1E1RP is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing AT S1E1RP instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

AT S1E1RP, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1001	0b000

```

if PSTATE.EL == EL0 then
  UNDEFINED;
elseif PSTATE.EL == EL1 then
  if EL2Enabled() && HCR_EL2.AT == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  elseif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.ATS1E1RP == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  else

```

```
        AT_S1E1RP(X[t]);  
elseif PSTATE.EL == EL2 then  
        AT_S1E1RP(X[t]);  
elseif PSTATE.EL == EL3 then  
        AT_S1E1RP(X[t]);
```

C5.4.9 AT S1E1W, Address Translate Stage 1 EL1 Write

The AT S1E1W characteristics are:

Purpose

Performs stage 1 address translation, with permissions as if writing to the given virtual address from EL1, or from EL2 if the Effective value of [HCR_EL2](#).{E2H, TGE} is {1, 1}, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of [SCR_EL3](#).NS:
 - If [HCR_EL2](#).{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
 - If [HCR_EL2](#).{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.
- Otherwise, the EL1&0 translation regime, accessed from EL1.

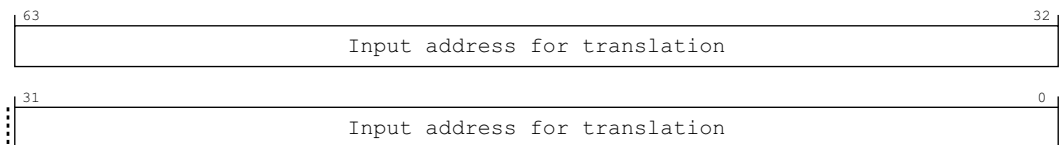

Configurations

There are no configuration notes.

Attributes

AT S1E1W is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the [PAR_EL1](#).

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing AT S1E1W instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

AT S1E1W, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1000	0b001

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.AT == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.ATS1E1W == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        AT_S1E1W(X[t]);
    
```

```
elseif PSTATE.EL == EL2 then

elseif PSTATE.EL == EL3 then
    AT_S1E1W(X[t]);
```

C5.4.10 AT S1E1WP, Address Translate Stage 1 EL1 Write PAN

The AT S1E1WP characteristics are:

Purpose

Performs a stage 1 address translation, where the value of PSTATE.PAN determines if a write to a location will generate a Permission fault for a privileged access, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
 - If HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
 - If HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.
- Otherwise, the EL1&0 translation regime, accessed from EL1.

Configurations

This instruction is present only when FEAT_PAN2 is implemented. Otherwise, direct accesses to AT S1E1WP are UNDEFINED.

Attributes

AT S1E1WP is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing AT S1E1WP instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

AT S1E1WP, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1001	0b001

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then

    elseif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.ATS1E1WP == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else

```

```
        AT_S1E1WP(X[t]);  
elseif PSTATE.EL == EL2 then  
        AT_S1E1WP(X[t]);  
elseif PSTATE.EL == EL3 then  
        AT_S1E1WP(X[t]);
```

C5.4.11 AT S1E2R, Address Translate Stage 1 EL2 Read

The AT S1E2R characteristics are:

Purpose

Performs stage 1 address translation as defined for EL2, with permissions as if reading from the given virtual address.

Configurations

There are no configuration notes.

Attributes

AT S1E2R is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the [PAR_EL1](#).

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing AT S1E2R instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

AT S1E2R, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b000

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    AT_S1E2R(X[t]);
elseif PSTATE.EL == EL3 then

        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    AT_S1E2W(X[t]);
elseif PSTATE.EL == EL3 then
    if !EL2Enabled() then
        UNDEFINED;
    else
        AT_S1E2W(X[t]);

```

C5.4.13 AT S1E3R, Address Translate Stage 1 EL3 Read

The AT S1E3R characteristics are:

Purpose

Performs stage 1 address translation as defined for EL3, with permissions as if reading from the given virtual address.

Configurations

There are no configuration notes.

Attributes

AT S1E3R is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the [PAR_EL1](#).

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing AT S1E3R instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

AT S1E3R, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b110	0b0111	0b1000	0b000

    AT_S1E3R(X[t]);
```

C5.4.14 AT S1E3W, Address Translate Stage 1 EL3 Write

The AT S1E3W characteristics are:

Purpose

Performs stage 1 address translation as defined for EL3, with permissions as if writing to the given virtual address.

Configurations

There are no configuration notes.

Attributes

AT S1E3W is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Input address for translation. The resulting address can be read from the [PAR_EL1](#).

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing AT S1E3W instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

```

C5.5 A64 System instructions for TLB maintenance

This section lists the A64 System instructions for TLB maintenance.

For more information about these instructions see [TLB maintenance instructions on page D5-2819](#). In particular, for the full description of the scope of each instruction see [Scope of the A64 TLB maintenance instructions on page D5-2824](#).

C5.5.1 TLBI ALLE1, TLBI ALLE1NXS, TLB Invalidate All, EL1

The TLBI ALLE1 and TLBI ALLE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation only applies to the PE that executes this System instruction.

———— Note —————

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE1, TLBI ALLE1NXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE1, TLBI ALLE1NXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI ALLE1{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0111	0b100

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL1), Regime_EL10, Shareability_NSH, TLBI_AllAttr);
elseif PSTATE.EL == EL3 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL1), Regime_EL10, Shareability_NSH, TLBI_AllAttr);
  
```

TLBI ALLE1NXS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b100	0b1001	0b0111	0b100

```

if !IsFeatureImplemented(FEAT_XS) then
    UNDEFINED;
elseif PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL1), Regime_EL10, Shareability_NSH, TLBI_ExcludeXS);
elseif PSTATE.EL == EL3 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL1), Regime_EL10, Shareability_NSH, TLBI_ExcludeXS);
  
```

C5.5.2 TLBI ALLE1IS, TLBI ALLE1ISNXS, TLB Invalidate All, EL1, Inner Shareable

The TLBI ALLE1IS and TLBI ALLE1ISNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE1IS, TLBI ALLE1ISNXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE1IS, TLBI ALLE1ISNXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI ALLE1IS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0011	0b100

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then

elseif PSTATE.EL == EL3 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL1), Regime_EL10, Shareability_ISH, TLBI_AllAttr);
  
```

TLBI ALLE1ISNXS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b100	0b1001	0b0011	0b100

```

if !IsFeatureImplemented(FEAT_XS) then
    UNDEFINED;
elseif PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL1), Regime_EL10, Shareability_ISH, TLBI_ExcludeXS);
elseif PSTATE.EL == EL3 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL1), Regime_EL10, Shareability_ISH, TLBI_ExcludeXS);
  
```

C5.5.3 TLBI ALLE1OS, TLBI ALLE1OSNXS, TLB Invalidate All, EL1, Outer Shareable

The TLBI ALLE1OS and TLBI ALLE1OSNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- One of the following applies:
 - [SCR_EL3.NS](#) is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
 - [SCR_EL3.NS](#) is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when [FEAT_TLBIOS](#) is implemented. Otherwise, direct accesses to TLBI ALLE1OS, TLBI ALLE1OSNXS are UNDEFINED.

Attributes

TLBI ALLE1OS, TLBI ALLE1OSNXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE1OS, TLBI ALLE1OSNXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI ALLE1OS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0001	0b100

    AArch64.TLBI_ALL(SecurityStateAtEL(EL1), Regime_EL10, Shareability_OSH, TLBI_ExcludeXS);
  
```

C5.5.4 TLBI ALLE2, TLBI ALLE2NXS, TLB Invalidate All, EL2

The TLBI ALLE2 and TLBI ALLE2NXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE2, TLBI ALLE2NXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE2, TLBI ALLE2NXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```

C5.5.5 TLBI ALLE2IS, TLBI ALLE2ISNXS, TLB Invalidate All, EL2, Inner Shareable

The TLBI ALLE2IS and TLBI ALLE2ISNXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE2IS, TLBI ALLE2ISNXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by `<Xt>` is ignored.

Executing TLBI ALLE2IS, TLBI ALLE2ISNXS instruction

The `Rt` field should be set to `0b11111`. If the `Rt` field is not set to `0b11111`, it is CONstrained UNpredictable whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the `Rt` field is set to `0b11111`.

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI ALLE2IS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0011	0b000

    else
        AArch64.TLBI_ALL(SecurityStateAtEL(EL2), Regime_EL2, Shareability_ISH, TLBI_ExcludeXS);

```

C5.5.6 TLBI ALLE2OS, TLBI ALLE2OSNXS, TLB Invalidate All, EL2, Outer Shareable

The TLBI ALLE2OS and TLBI ALLE2OSNXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI ALLE2OS, TLBI ALLE2OSNXS are UNDEFINED.

Attributes

TLBI ALLE2OS, TLBI ALLE2OSNXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by `<Xt>` is ignored.

Executing TLBI ALLE2OS, TLBI ALLE2OSNXS instruction

The `Rt` field should be set to `0b11111`. If the `Rt` field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the `Rt` field is set to `0b11111`.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```

C5.5.7 TLBI ALLE3, TLBI ALLE3NXS, TLB Invalidate All, EL3

The TLBI ALLE3 and TLBI ALLE3NXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL3 translation regime.

The invalidation applies to the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE3, TLBI ALLE3NXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by `<Xt>` is ignored.

Executing TLBI ALLE3, TLBI ALLE3NXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```

C5.5.9 TLBI ALLE3OS, TLBI ALLE3OSNXS, TLB Invalidate All, EL3, Outer Shareable

The TLBI ALLE3OS and TLBI ALLE3OSNXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL3 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI ALLE3OS, TLBI ALLE3OSNXS are UNDEFINED.

Attributes

TLBI ALLE3OS, TLBI ALLE3OSNXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE3OS, TLBI ALLE3OSNXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI ALLE3OS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1000	0b0001	0b000

```

C5.5.10 TLBI ASIDE1, TLBI ASIDE1NXS, TLB Invalidate by ASID, EL1

The TLBI ASIDE1 and TLBI ASIDE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
 - Is from a level of lookup above the final level.
 - Is a non-global entry from the final level of lookup.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not {1, 1}, the entry would be used with the current VMID and would be required to translate an address using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is {1, 1}, the entry would be required to translate an address using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate an address using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI ASIDE1, TLBI ASIDE1NXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this System instruction.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Bits [47:0]

Reserved, RES0.

Executing TLBI ASIDE1, TLBI ASIDE1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI ASIDE1{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0111	0b010

C5.5.11 TLBI ASIDE1IS, TLBI ASIDE1ISNXS, TLB Invalidate by ASID, EL1, Inner Shareable

The TLBI ASIDE1IS and TLBI ASIDE1ISNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
 - Is from a level of lookup above the final level.
 - Is a non-global entry from the final level of lookup.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not {1, 1}, the entry would be used with the current VMID and would be required to translate an address using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is {1, 1}, the entry would be required to translate an address using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate an address using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI ASIDE1IS, TLBI ASIDE1ISNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this System instruction.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Bits [47:0]

Reserved, RES0.

Executing TLBI ASIDE1IS, TLBI ASIDE1ISNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI ASIDE1IS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0011	0b010

```

C5.5.12 TLBI ASIDE1OS, TLBI ASIDE1OSNXS, TLB Invalidate by ASID, EL1, Outer Shareable

The TLBI ASIDE1OS and TLBI ASIDE1OSNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
 - Is from a level of lookup above the final level.
 - Is a non-global entry from the final level of lookup.
- When EL2 is implemented and enabled in the current Security state:
 - If [HCR_EL2](#).{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate an address using the EL1&0 translation regime for the Security state.
 - If [HCR_EL2](#).{E2H, TGE} is {1, 1}, the entry would be required to translate an address using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate an address using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of [SCR_EL3](#).NS.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when [FEAT_TLBIOS](#) is implemented. Otherwise, direct accesses to TLBI ASIDE1OS, TLBI ASIDE1OSNXS are UNDEFINED.

Attributes

TLBI ASIDE1OS, TLBI ASIDE1OSNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this System instruction.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Bits [47:0]

Reserved, RES0.

```

C5.5.13 TLBI IPAS2E1, TLBI IPAS2E1NXS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI IPAS2E1 and TLBI IPAS2E1NXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI IPAS2E1, TLBI IPAS2E1NXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_SEL2 is implemented:

NS

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When [FEAT_SEL2](#) is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3. |
| 0b11xx | The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

Bits [43:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

When FEAT_LPA is implemented:

IPA[51:48]

Extension to IPA[47:12]. For more information, see IPA[47:12].

Otherwise:

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

When **FEAT_LPA** is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

Executing TLBI IPAS2E1, TLBI IPAS2E1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI IPAS2E1{, <Xt>}

        TLBI_ExcludeXS, X[t]);

```

C5.5.14 TLBI IPAS2E1IS, TLBI IPAS2E1ISNXS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable

The TLBI IPAS2E1IS and TLBI IPAS2E1ISNXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI IPAS2E1IS, TLBI IPAS2E1ISNXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_SEL2 is implemented:

NS

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When [FEAT_SEL2](#) is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

```

C5.5.15 TLBI IPAS2E1OS, TLBI IPAS2E1OSNXS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Outer Shareable

The TLBI IPAS2E1OS and TLBI IPAS2E1OSNXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI IPAS2E1OS, TLBI IPAS2E1OSNXS are UNDEFINED.

Attributes

TLBI IPAS2E1OS, TLBI IPAS2E1OSNXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_SEL2 is implemented:

NS

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When **FEAT_SEL2** is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|---|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3. |
| 0b11xx | The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

Bits [43:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

Extension to IPA[47:12]. For more information, see IPA[47:12].

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

When **FEAT_LPA** is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

Executing TLBI IPAS2E1OS, TLBI IPAS2E1OSNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.5.19 TLBI RIPAS2E1, TLBI RIPAS2E1NXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI RIPAS2E1 and TLBI RIPAS2E1NXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to 000000000000000000.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to 000000000.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to 00000000000.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to 00000000000000000000000000000000.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to 0000000000000000.

For more information about the architectural requirements for this System instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIRANGE` is implemented. Otherwise, direct accesses to TLBI RIPAS2E1, TLBI RIPAS2E1NXS are UNDEFINED.

Attributes

TLBI RIPAS2E1, TLBI RIPAS2E1NXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_SEL2 is implemented:

NS

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.

0b01 4K translation granule.

0b10 16K translation granule.

0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00 The entries in the range can be using any level for the translation table entries.

0b01 All entries to invalidate are Level 1 translation table entries.

If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.

0b10 All entries to invalidate are Level 2 translation table entries.

0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RIPAS2E1, TLBI RIPAS2E1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RIPAS2E1{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0100	0b010

```

C5.5.20 TLBI RIPAS2E1IS, TLBI RIPAS2E1ISNXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable

The TLBI RIPAS2E1IS and TLBI RIPAS2E1ISNXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula $[BaseADDR \leq VA < BaseADDR + ((NUM + 1) * 2^{(5 * SCALE + 1)} * Translation_Granule_Size)]$.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to 000000000000000000.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to 000000000.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to 00000000000.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to 00000000000000000000000000000000.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to 00000000000000000000000000000000.

For more information about the architectural requirements for this System instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIRANGE` is implemented. Otherwise, direct accesses to TLBI RIPAS2E1IS, TLBI RIPAS2E1ISNXS are UNDEFINED.

Attributes

TLBI RIPAS2E1IS, TLBI RIPAS2E1ISNXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_SEL2 is implemented:

NS

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When [FEAT_SEL2](#) is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.

0b01 4K translation granule.

0b10 16K translation granule.

0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00 The entries in the range can be using any level for the translation table entries.

0b01 All entries to invalidate are Level 1 translation table entries.

If [FEAT_LPA2](#) is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.

0b10 All entries to invalidate are Level 2 translation table entries.

0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RIPAS2E1IS, TLBI RIPAS2E1ISNXS instruction

```

C5.5.21 TLBI RIPAS2E1OS, TLBI RIPAS2E1OSNXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1, Outer Shareable

The TLBI RIPAS2E1OS and TLBI RIPAS2E1OSNXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to 000000000000000000.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to 000000000.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to 00000000000.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to 00000000000000000000000000000000.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to 0000000000000000.

For more information about the architectural requirements for this System instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIRANGE` is implemented and `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI RIPAS2E1OS, TLBI RIPAS2E1OSNXS are UNDEFINED.

Attributes

TLBI RIPAS2E1OS, TLBI RIPAS2E1OSNXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_SEL2 is implemented:

NS

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.

0b01 4K translation granule.

0b10 16K translation granule.

0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00 The entries in the range can be using any level for the translation table entries.

0b01 All entries to invalidate are Level 1 translation table entries.

If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.

0b10 All entries to invalidate are Level 2 translation table entries.

0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RIPAS2E1OS, TLBI RIPAS2E1OSNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

```

C5.5.22 TLBI RIPAS2LE1, TLBI RIPAS2LE1NXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1

The TLBI RIPAS2LE1 and TLBI RIPAS2LE1NXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- One of the following applies:
 - [SCR_EL3.NS](#) is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
 - [SCR_EL3.NS](#) is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If $\text{TTL} == 01$ and $\text{BaseADDR}[29:12]$ is not equal to 000000000000000000.
 - If $\text{TTL} == 10$ and $\text{BaseADDR}[20:12]$ is not equal to 000000000.
- For the 16K translation granule:
 - If $\text{TTL} == 10$ and $\text{BaseADDR}[24:14]$ is not equal to 00000000000.
- For the 64K translation granule:
 - If $\text{TTL} == 01$ and $\text{BaseADDR}[41:16]$ is not equal to 00000000000000000000000000000000.
 - If $\text{TTL} == 10$ and $\text{BaseADDR}[28:16]$ is not equal to 0000000000000000.

For more information about the architectural requirements for this System instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when [FEAT_TLBIRANGE](#) is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1, TLBI RIPAS2LE1NXS are UNDEFINED.

Attributes

TLBI RIPAS2LE1, TLBI RIPAS2LE1NXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_SEL2 is implemented:

NS

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When [FEAT_SEL2](#) is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.

0b01 4K translation granule.

0b10 16K translation granule.

0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00 The entries in the range can be using any level for the translation table entries.

0b01 All entries to invalidate are Level 1 translation table entries.

If [FEAT_LPA2](#) is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.

0b10 All entries to invalidate are Level 2 translation table entries.

0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RIPAS2LE1, TLBI RIPAS2LE1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RIPAS2LE1{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0100	0b110

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    AArch64.TLBI_RIPAS2(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Shareability_NSH, TLBILevel_Last,
    TLBI_A11Attr, X[t]);
elseif PSTATE.EL == EL3 then
    if !EL2Enabled() then
        //no operation
    else
        AArch64.TLBI_RIPAS2(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Shareability_NSH,
    TLBILevel_Last, TLBI_A11Attr, X[t]);

```

TLBI RIPAS2LE1NXS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b100	0b1001	0b0100	0b110

```

if !IsFeatureImplemented(FEAT_XS) then
    UNDEFINED;
elseif PSTATE.EL == EL0 then
    UNDEFINED;

```

```
elseif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elseif PSTATE.EL == EL2 then
    AArch64.TLBI_RIPAS2(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Shareability_NSH, TLBILevel_Last,
    TLBI_ExcludeXS, X[t]);
elseif PSTATE.EL == EL3 then
    if !EL2Enabled() then
        //no operation
    else
        AArch64.TLBI_RIPAS2(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Shareability_NSH,
    TLBILevel_Last, TLBI_ExcludeXS, X[t]);
```

C5.5.23 TLBI RIPAS2LE1IS, TLBI RIPAS2LE1ISNXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable

The TLBI RIPAS2LE1IS and TLBI RIPAS2LE1ISNXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula $[BaseADDR \leq VA < BaseADDR + ((NUM + 1) * 2^{(5 * SCALE + 1)} * Translation_Granule_Size)]$.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to 000000000000000000.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to 000000000.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to 00000000000.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to 00000000000000000000000000000000.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to 0000000000000000.

For more information about the architectural requirements for this System instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

If `FEAT_XS` is implemented, the `nXS` variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the `nXS` qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the `nXS` qualifier is considered complete when the subset of these memory accesses with `XS` attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIRANGE` is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1IS, TLBI RIPAS2LE1ISNXS are UNDEFINED.

Attributes

TLBI RIPAS2LE1IS, TLBI RIPAS2LE1ISNXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_SEL2 is implemented:

NS

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When [FEAT_SEL2](#) is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.

0b01 4K translation granule.

0b10 16K translation granule.

0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00 The entries in the range can be using any level for the translation table entries.

0b01 All entries to invalidate are Level 1 translation table entries.

If [FEAT_LPA2](#) is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.

0b10 All entries to invalidate are Level 2 translation table entries.

0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RIPAS2LE1IS, TLBI RIPAS2LE1ISNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RIPAS2LE1IS{, <Xt>}

op0	op1	CRn	CRm	op2

```

C5.5.24 TLBI RIPAS2LE1OS, TLBI RIPAS2LE1OSNXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Outer Shareable

The TLBI RIPAS2LE1OS and TLBI RIPAS2LE1OSNXS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- One of the following applies:
 - `SCR_EL3.NS` is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
 - `SCR_EL3.NS` is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to 000000000000000000.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to 000000000.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to 000000000000.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to 00000000000000000000000000000000.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to 0000000000000000.

For more information about the architectural requirements for this System instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1OS, TLBI RIPAS2LE1OSNXS are UNDEFINED.

Attributes

TLBI RIPAS2LE1OS, TLBI RIPAS2LE1OSNXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_SEL2 is implemented:

NS

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

```

C5.5.25 TLBI RVAAE1, TLBI RVAAE1NXS, TLB Range Invalidate by VA, All ASID, EL1

The TLBI RVAAE1 and TLBI RVAAE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$.
- When EL2 is implemented and enabled in the current Security state:
 - If [HCR_EL2](#).{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If [HCR_EL2](#).{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of [SCR_EL3](#).NS.

The invalidation applies to the PE that executes this System instruction.

Note

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If $\text{TTL} == 01$ and $\text{BaseADDR}[29:12]$ is not equal to 000000000000000000.
 - If $\text{TTL} == 10$ and $\text{BaseADDR}[20:12]$ is not equal to 000000000.
- For the 16K translation granule:
 - If $\text{TTL} == 10$ and $\text{BaseADDR}[24:14]$ is not equal to 00000000000.
- For the 64K translation granule:
 - If $\text{TTL} == 01$ and $\text{BaseADDR}[41:16]$ is not equal to 00000000000000000000000000000000.
 - If $\text{TTL} == 10$ and $\text{BaseADDR}[28:16]$ is not equal to 0000000000000000.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when [FEAT_TLBIRANGE](#) is implemented. Otherwise, direct accesses to TLBI RVAAE1, TLBI RVAAE1NXS are UNDEFINED.

Attributes

TLBI RVAAE1, TLBI RVAAE1NXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
 If **FEAT_LPA2** is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVAAE1, TLBI RVAAE1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RVAAE1{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0110	0b011

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TTLB == '1' then

```

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAAE1IS, TLBI RVAAE1ISNXS are UNDEFINED.

Attributes

TLBI RVAAE1IS, TLBI RVAAE1ISNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
 If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

```

C5.5.28 TLBI RVAALE1, TLBI RVAALE1NXS, TLB Range Invalidate by VA, All ASID, Last level, EL1

The TLBI RVAALE1 and TLBI RVAALE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$.
- When EL2 is implemented and enabled in the current Security state:
 - If [HCR_EL2](#).{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If [HCR_EL2](#).{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of [SCR_EL3](#).NS.

The invalidation applies to the PE that executes this System instruction.

Note

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If $\text{TTL} == 01$ and $\text{BaseADDR}[29:12]$ is not equal to 0000000000000000.
 - If $\text{TTL} == 10$ and $\text{BaseADDR}[20:12]$ is not equal to 000000000.
- For the 16K translation granule:
 - If $\text{TTL} == 10$ and $\text{BaseADDR}[24:14]$ is not equal to 00000000000.
- For the 64K translation granule:
 - If $\text{TTL} == 01$ and $\text{BaseADDR}[41:16]$ is not equal to 00000000000000000000000000000000.
 - If $\text{TTL} == 10$ and $\text{BaseADDR}[28:16]$ is not equal to 0000000000000000.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when [FEAT_TLBRANGE](#) is implemented. Otherwise, direct accesses to TLBI RVAALE1, TLBI RVAALE1NXS are UNDEFINED.

Attributes

TLBI RVAALE1, TLBI RVAALE1NXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
 If [FEAT_LPA2](#) is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVAALE1, TLBI RVAALE1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RVAALE1{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0110	0b111

```

```

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAALE1IS, TLBI RVAALE1ISNXS are UNDEFINED.

Attributes

TLBI RVAALE1IS, TLBI RVAALE1ISNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
 If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

```

C5.5.31 TLBI RVAE1, TLBI RVAE1NXS, TLB Range Invalidate by VA, EL1

The TLBI RVAE1 and TLBI RVAE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is from a level of lookup above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula $[BaseADDR \leq VA < BaseADDR + ((NUM + 1) * 2^{(5 * SCALE + 1)} * Translation_Granule_Size)]$.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2`.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2`.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to 00000000000000000000.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to 000000000.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to 000000000000.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to 00.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to 00.

Configurations

This instruction is present only when `FEAT_TLBIRANGE` is implemented. Otherwise, direct accesses to TLBI RVAE1, TLBI RVAE1NXS are UNDEFINED.

Attributes

TLBI RVAE1, TLBI RVAE1NXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
 If **FEAT_LPA2** is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVAE1, TLBI RVAE1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RVAE1{, <Xt>}

op0	op1	CRn	CRm	op2

```

C5.5.32 TLBI RVAE1IS, TLBI RVAE1ISNXS, TLB Range Invalidate by VA, EL1, Inner Shareable

The TLBI RVAE1IS and TLBI RVAE1ISNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is from a level of lookup above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula $[BaseADDR \leq VA < BaseADDR + ((NUM + 1) * 2^{(5 * SCALE + 1)} * Translation_Granule_Size)]$.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

———— Note —————

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `00000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `0000000000000000`.

Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAE1IS, TLBI RVAE1ISNXS are UNDEFINED.

Attributes

TLBI RVAE1IS, TLBI RVAE1ISNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
 If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

```

C5.5.33 TLBI RVAE1OS, TLBI RVAE1OSNXS, TLB Range Invalidate by VA, EL1, Outer Shareable

The TLBI RVAE1OS and TLBI RVAE1OSNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is from a level of lookup above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula $[BaseADDR \leq VA < BaseADDR + ((NUM + 1) * 2^{(5 * SCALE + 1)} * Translation_Granule_Size)]$.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

———— Note —————

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `0000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `000000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `0000000000000000`.

Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVAE1OS, TLBI RVAE1OSNXS are UNDEFINED.

Attributes

TLBI RVAE1OS, TLBI RVAE1OSNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
 If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

```

C5.5.34 TLBI RVAE2, TLBI RVAE2NXS, TLB Range Invalidate by VA, EL2

The TLBI RVAE2 and TLBI RVAE2NXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$ using the EL2 or EL2&0 translation regime for the Security state.
- If `HCR_EL2.E2H == 0`, the entry is from any level of the translation table walk.
- If `HCR_EL2.E2H == 1`, one of the following applies:
 - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `0000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `000000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `0000000000000000`.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIRANGE` is implemented. Otherwise, direct accesses to TLBI RVAE2, TLBI RVAE2NXS are UNDEFINED.

Attributes

TLBI RVAE2, TLBI RVAE2NXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

When HCR_EL2.E2H == 1:

ASID

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Otherwise:

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
 If [FEAT_LPA2](#) is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL2.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVAE2, TLBI RVAE2NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RVAE2{, <Xt>}

```

C5.5.35 TLBI RVAE2IS, TLBI RVAE2ISNXS, TLB Range Invalidate by VA, EL2, Inner Shareable

The TLBI RVAE2IS and TLBI RVAE2ISNXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$ using the EL2 or EL2&0 translation regime for the Security state.
- If `HCR_EL2.E2H == 0`, the entry is from any level of the translation table walk.
- If `HCR_EL2.E2H == 1`, one of the following applies:
 - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `0000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `000000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `0000000000000000`.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

C5.5.36 TLBI RVAE2OS, TLBI RVAE2OSNXS, TLB Range Invalidate by VA, EL2, Outer Shareable

The TLBI RVAE2OS and TLBI RVAE2OSNXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$ using the EL2 or EL2&0 translation regime for the Security state.
- If `HCR_EL2.E2H == 0`, the entry is from any level of the translation table walk.
- If `HCR_EL2.E2H == 1`, one of the following applies:
 - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `0000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `000000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `0000000000000000`.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIRANGE` is implemented and `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI RVAE2OS, TLBI RVAE2OSNXS are UNDEFINED.

Attributes

TLBI RVAE2OS, TLBI RVAE2OSNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

When HCR_EL2.E2H == 1:

ASID

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Otherwise:

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
 If [FEAT_LPA2](#) is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL2.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVAE2OS, TLBI RVAE2OSNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RVAE2OS{, <Xt>}

    TLBI_ExcludeXS, X[t]);

```

C5.5.37 TLBI RVAE3, TLBI RVAE3NXS, TLB Range Invalidate by VA, EL3

The TLBI RVAE3 and TLBI RVAE3NXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.
- The entry is within the address range determined by the formula $[BaseADDR \leq VA < BaseADDR + ((NUM + 1) * 2^{(5 * SCALE + 1)} * Translation_Granule_Size)]$.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If $TTL == 01$ and $BaseADDR[29:12]$ is not equal to 000000000000000000 .
 - If $TTL == 10$ and $BaseADDR[20:12]$ is not equal to 0000000000 .
- For the 16K translation granule:
 - If $TTL == 10$ and $BaseADDR[24:14]$ is not equal to 000000000000 .
- For the 64K translation granule:
 - If $TTL == 01$ and $BaseADDR[41:16]$ is not equal to $00000000000000000000000000000000$.
 - If $TTL == 10$ and $BaseADDR[28:16]$ is not equal to 0000000000000000 .

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when [FEAT_TLBIRANGE](#) is implemented. Otherwise, direct accesses to TLBI RVAE3, TLBI RVAE3NXS are UNDEFINED.

Attributes

TLBI RVAE3, TLBI RVAE3NXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.

- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
 If **FEAT_LPA2** is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL3.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVAE3, TLBI RVAE3NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RVAE3{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1000	0b0110	0b001

```

if PSTATE.EL == EL0 then
  UNDEFINED;
elseif PSTATE.EL == EL1 then
  UNDEFINED;

```

```

elseif PSTATE.EL == EL2 then
    UNDEFINED;
elseif PSTATE.EL == EL3 then
    AArch64.TLBI_RVA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_NSH, TLBILevel_Any,
    TLBI_AllAttr, X[t]);
    
```

TLBI RVAE3NXS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1001	0b0110	0b001

```

if !IsFeatureImplemented(FEAT_XS) then
    UNDEFINED;
elseif PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    UNDEFINED;
elseif PSTATE.EL == EL2 then
    UNDEFINED;
elseif PSTATE.EL == EL3 then
    AArch64.TLBI_RVA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_NSH, TLBILevel_Any,
    TLBI_ExcludeXS, X[t]);
    
```

C5.5.38 TLBI RVAE3IS, TLBI RVAE3ISNXS, TLB Range Invalidate by VA, EL3, Inner Shareable

The TLBI RVAE3IS and TLBI RVAE3ISNXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.
- The entry is within the address range determined by the formula $[BaseADDR \leq VA < BaseADDR + ((NUM + 1) * 2^{(5 * SCALE + 1)} * Translation_Granule_Size)]$.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If $TTL == 01$ and $BaseADDR[29:12]$ is not equal to 000000000000000000 .
 - If $TTL == 10$ and $BaseADDR[20:12]$ is not equal to 0000000000 .
- For the 16K translation granule:
 - If $TTL == 10$ and $BaseADDR[24:14]$ is not equal to 000000000000 .
- For the 64K translation granule:
 - If $TTL == 01$ and $BaseADDR[41:16]$ is not equal to $00000000000000000000000000000000$.
 - If $TTL == 10$ and $BaseADDR[28:16]$ is not equal to 0000000000000000 .

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when [FEAT_TLBIRANGE](#) is implemented. Otherwise, direct accesses to TLBI RVAE3IS, TLBI RVAE3ISNXS are UNDEFINED.

Attributes

TLBI RVAE3IS, TLBI RVAE3ISNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.

    TLBI_ExcludeXS, X[t]);
  
```

C5.5.40 TLBI RVALE1, TLBI RVALE1NXS, TLB Range Invalidate by VA, Last level, EL1

The TLBI RVALE1 and TLBI RVALE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `000000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `00000000000000`.

For more information about the architectural requirements for this System instruction, see [Invalidation of TLB entries from stage 2 translations on page D5-2829](#).

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIRANGE` is implemented. Otherwise, direct accesses to TLBI RVALE1, TLBI RVALE1NXS are UNDEFINED.

Attributes

TLBI RVALE1, TLBI RVALE1NXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
If **FEAT_LPA2** is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVALE1, TLBI RVALE1NXS instruction

```

C5.5.41 TLBI RVALE1IS, TLBI RVALE1ISNXS, TLB Range Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI RVALE1IS and TLBI RVALE1ISNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

———— Note —————

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `0000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `000000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `00000000000000`.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVALE1IS, TLBI RVALE1ISNXS are UNDEFINED.

Attributes

TLBI RVALE1IS, TLBI RVALE1ISNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.

If **FEAT_LPA2** is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as **0b00**.

- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as **0b0000**.

When using a 16KB translation granule, BaseADDR[15:14] is treated as **0b00**.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVALE1IS, TLBI RVALE1ISNXS instruction

C5.5.42 TLBI RVALE1OS, TLBI RVALE1OSNXS, TLB Range Invalidate by VA, Last level, EL1, Outer Shareable

The TLBI RVALE1OS and TLBI RVALE1OSNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

———— Note —————

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `0000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `000000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `00000000000000`.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBI RANGE is implemented and FEAT_TLBI OS is implemented. Otherwise, direct accesses to TLBI RVALE1OS, TLBI RVALE1OSNXS are UNDEFINED.

Attributes

TLBI RVALE1OS, TLBI RVALE1OSNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.

If **FEAT_LPA2** is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as **0b00**.

- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as **0b0000**.

When using a 16KB translation granule, BaseADDR[15:14] is treated as **0b00**.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.43 TLBI RVALE2, TLBI RVALE2NXS, TLB Range Invalidate by VA, Last level, EL2

The TLBI RVALE2 and TLBI RVALE2NXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$ using the EL2 or EL2&0 translation regime for the Security state.
- If `HCR_EL2.E2H == 0`, the entry is from the final level of the translation table walk.
- If `HCR_EL2.E2H == 1`, one of the following applies:
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `00000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `0000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `000000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `0000000000000000`.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIRANGE` is implemented. Otherwise, direct accesses to TLBI RVALE2, TLBI RVALE2NXS are UNDEFINED.

Attributes

TLBI RVALE2, TLBI RVALE2NXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

When HCR_EL2.E2H == 1:

ASID

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Otherwise:

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
If [FEAT_LPA2](#) is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL2.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVALE2, TLBI RVALE2NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RVALE2{, <Xt>}

op0	op1	CRn	CRm	op2

```

C5.5.44 TLBI RVALE2IS, TLBI RVALE2ISNXS, TLB Range Invalidate by VA, Last level, EL2, Inner Shareable

The TLBI RVALE2IS and TLBI RVALE2ISNXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$ using the EL2 or EL2&0 translation regime for the Security state.
- If `HCR_EL2.E2H == 0`, the entry is from the final level of the translation table walk.
- If `HCR_EL2.E2H == 1`, one of the following applies:
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `0000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `000000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `0000000000000000`.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBRANGE` is implemented. Otherwise, direct accesses to TLBI RVALE2IS, TLBI RVALE2ISNXS are UNDEFINED.

Attributes

TLBI RVALE2IS, TLBI RVALE2ISNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

When HCR_EL2.E2H == 1:

C5.5.45 TLBI RVALE2OS, TLBI RVALE2OSNXS, TLB Range Invalidate by VA, Last level, EL2, Outer Shareable

The TLBI RVALE2OS and TLBI RVALE2OSNXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 * \text{SCALE} + 1)} * \text{Translation_Granule_Size})]$ using the EL2 or EL2&0 translation regime for the Security state.
- If `HCR_EL2.E2H == 0`, the entry is from the final level of the translation table walk.
- If `HCR_EL2.E2H == 1`, one of the following applies:
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If `TTL==01` and `BaseADDR[29:12]` is not equal to `000000000000000000`.
 - If `TTL==10` and `BaseADDR[20:12]` is not equal to `0000000000`.
- For the 16K translation granule:
 - If `TTL==10` and `BaseADDR[24:14]` is not equal to `000000000000`.
- For the 64K translation granule:
 - If `TTL==01` and `BaseADDR[41:16]` is not equal to `00000000000000000000000000000000`.
 - If `TTL==10` and `BaseADDR[28:16]` is not equal to `0000000000000000`.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBI RANGE` is implemented and `FEAT_TLBI OS` is implemented. Otherwise, direct accesses to TLBI RVALE2OS, TLBI RVALE2OSNXS are UNDEFINED.

Attributes

TLBI RVALE2OS, TLBI RVALE2OSNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

When HCR_EL2.E2H == 1:

ASID

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Otherwise:

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
If [FEAT_LPA2](#) is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL2.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVALE2OS, TLBI RVALE2OSNXS instruction

C5.5.46 TLBI RVALE3, TLBI RVALE3NXS, TLB Range Invalidate by VA, Last level, EL3

The TLBI RVALE3 and TLBI RVALE3NXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.
- The entry is within the address range determined by the formula $[BaseADDR \leq VA < BaseADDR + ((NUM + 1) * 2^{(5 * SCALE + 1)} * Translation_Granule_Size)]$.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If $TTL == 01$ and $BaseADDR[29:12]$ is not equal to 000000000000000000 .
 - If $TTL == 10$ and $BaseADDR[20:12]$ is not equal to 0000000000 .
- For the 16K translation granule:
 - If $TTL == 10$ and $BaseADDR[24:14]$ is not equal to 000000000000 .
- For the 64K translation granule:
 - If $TTL == 01$ and $BaseADDR[41:16]$ is not equal to $00000000000000000000000000000000$.
 - If $TTL == 10$ and $BaseADDR[28:16]$ is not equal to 0000000000000000 .

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when [FEAT_TLBIRANGE](#) is implemented. Otherwise, direct accesses to TLBI RVALE3, TLBI RVALE3NXS are UNDEFINED.

Attributes

TLBI RVALE3, TLBI RVALE3NXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.

- 0b01 4K translation granule.
- 0b10 16K translation granule.
- 0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00 The entries in the range can be using any level for the translation table entries.
- 0b01 All entries to invalidate are Level 1 translation table entries.
If [FEAT_LPA2](#) is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10 All entries to invalidate are Level 2 translation table entries.
- 0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL3.DS == 1:

BaseADDR

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.

When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

BaseADDR

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVALE3, TLBI RVALE3NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI RVALE3{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1000	0b0110	0b101

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    UNDEFINED;

```

```
elseif PSTATE.EL == EL2 then
    UNDEFINED;
elseif PSTATE.EL == EL3 then
    AArch64.TLBI_RVA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_NSH, TLBILevel_Last,
    TLBI_AllAttr, X[t]);
```

TLBI RVALE3NXS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1001	0b0110	0b101

```
if !IsFeatureImplemented(FEAT_XS) then
    UNDEFINED;
elseif PSTATE.EL == EL0 then
    UNDEFINED;
elseif PSTATE.EL == EL1 then
    UNDEFINED;
elseif PSTATE.EL == EL2 then
    UNDEFINED;
elseif PSTATE.EL == EL3 then
    AArch64.TLBI_RVA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_NSH, TLBILevel_Last,
    TLBI_ExcludeXS, X[t]);
```

C5.5.47 TLBI RVALE3IS, TLBI RVALE3ISNXS, TLB Range Invalidate by VA, Last level, EL3, Inner Shareable

The TLBI RVALE3IS and TLBI RVALE3ISNXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.
- The entry is within the address range determined by the formula $[BaseADDR \leq VA < BaseADDR + ((NUM + 1) * 2^{(5 * SCALE + 1)} * Translation_Granule_Size)]$.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
 - If $TTL == 01$ and $BaseADDR[29:12]$ is not equal to 000000000000000000 .
 - If $TTL == 10$ and $BaseADDR[20:12]$ is not equal to 0000000000 .
- For the 16K translation granule:
 - If $TTL == 10$ and $BaseADDR[24:14]$ is not equal to 000000000000 .
- For the 64K translation granule:
 - If $TTL == 01$ and $BaseADDR[41:16]$ is not equal to $00000000000000000000000000000000$.
 - If $TTL == 10$ and $BaseADDR[28:16]$ is not equal to 0000000000000000 .

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when [FEAT_TLBIRANGE](#) is implemented. Otherwise, direct accesses to TLBI RVALE3IS, TLBI RVALE3ISNXS are UNDEFINED.

Attributes

TLBI RVALE3IS, TLBI RVALE3ISNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

elseif PSTATE.EL == EL3 then
    AArch64.TLBI_RVA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_OSH, TLBILevel_Last,
    TLBI_ExcludeXS, X[t]);
  
```

C5.5.49 TLBI VAAE1, TLBI VAAE1NXS, TLB Invalidate by VA, All ASID, EL1

The TLBI VAAE1 and TLBI VAAE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

———— Note ————

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VAAE1, TLBI VAAE1NXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAAE1, TLBI VAAE1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VAAE1{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0111	0b011

```

```

C5.5.50 TLBI VAAE1IS, TLBI VAAE1ISNXS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI VAAE1IS and TLBI VAAE1ISNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VAAE1IS, TLBI VAAE1ISNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- 0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- 0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 - 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
 - 0b01 : Level 1.
 - 0b10 : Level 2.
 - 0b11 : Level 3.
- 0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 - 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
 - 0b10 : Level 2.
 - 0b11 : Level 3.
- 0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 - 0b01 : Level 1.
 - 0b10 : Level 2.
 - 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAAE1IS, TLBI VAAE1ISNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VAAE1IS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0011	0b011

```

C5.5.51 TLBI VAAE1OS, TLBI VAAE1OSNXS, TLB Invalidate by VA, All ASID, EL1, Outer Shareable

The TLBI VAAE1OS and TLBI VAAE1OSNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI VAAE1OS, TLBI VAAE1OSNXS are UNDEFINED.

Attributes

TLBI VAAE1OS, TLBI VAAE1OSNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3. |
| 0b11xx | The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

```

C5.5.52 TLBI VAALE1, TLBI VAALE1NXS, TLB Invalidate by VA, All ASID, Last level, EL1

The TLBI VAALE1 and TLBI VAALE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

———— Note ————

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VAALE1, TLBI VAALE1NXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAALE1, TLBI VAALE1NXS instruction

```

C5.5.53 TLBI VAALE1IS, TLBI VAALE1ISNXS, TLB Invalidate by VA, All ASID, Last Level, EL1, Inner Shareable

The TLBI VAALE1IS and TLBI VAALE1ISNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VAALE1IS, TLBI VAALE1ISNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3. |
| 0b11xx | The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAALE1IS, TLBI VAALE1ISNXS instruction

```

C5.5.54 TLBI VAALE1OS, TLBI VAALE1OSNXS, TLB Invalidate by VA, All ASID, Last Level, EL1, Outer Shareable

The TLBI VAALE1OS and TLBI VAALE1OSNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

———— Note ————

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

———— Note ————

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI VAALE1OS, TLBI VAALE1OSNXS are UNDEFINED.

Attributes

TLBI VAALE1OS, TLBI VAALE1OSNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3. |
| 0b11xx | The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAALE1OS, TLBI VAALE1OSNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VAALE1OS{, <Xt>}

```

C5.5.55 TLBI VAE1, TLBI VAE1NXS, TLB Invalidate by VA, EL1

The TLBI VAE1 and TLBI VAE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is from a level of lookup above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
 - If [HCR_EL2](#).{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If [HCR_EL2](#).{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of [SCR_EL3](#).NS.

The invalidation applies to the PE that executes this System instruction.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VAE1, TLBI VAE1NXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE1, TLBI VAE1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VAE1{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0111	0b001

```

```

C5.5.56 TLBI VAE1IS, TLBI VAE1ISNXS, TLB Invalidate by VA, EL1, Inner Shareable

The TLBI VAE1IS and TLBI VAE1ISNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is from a level of lookup above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
 - If [HCR_EL2](#).{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If [HCR_EL2](#).{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of [SCR_EL3](#).NS.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if [SCR_EL3](#).EEL2==1, then:

- A PE with [SCR_EL3](#).EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with [SCR_EL3](#).EEL2==0.
- A PE with [SCR_EL3](#).EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with [SCR_EL3](#).EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VAE1IS, TLBI VAE1ISNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- 0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- 0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 - 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
 - 0b01 : Level 1.
 - 0b10 : Level 2.
 - 0b11 : Level 3.
- 0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 - 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
 - 0b10 : Level 2.
 - 0b11 : Level 3.
- 0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 - 0b01 : Level 1.
 - 0b10 : Level 2.
 - 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

```

C5.5.57 TLBI VAE1OS, TLBI VAE1OSNXXS, TLB Invalidate by VA, EL1, Outer Shareable

The TLBI VAE1OS and TLBI VAE1OSNXXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is from a level of lookup above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

————— Note —————

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI VAE1OS, TLBI VAE1OSNXXS are UNDEFINED.

Attributes

TLBI VAE1OS, TLBI VAE1OSNXXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3. |
| 0b11xx | The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE1OS, TLBI VAE1OSNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VAE1OS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0001	0b001

```

if PSTATE.EL == EL0 then
    UNDEFINED;

C5.5.58 TLBI VAE2, TLBI VAE2NXS, TLB Invalidate by VA, EL2

The TLBI VAE2 and TLBI VAE2NXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be required to translate the specified VA using the EL2 or EL2&0 translation regime for the Security state.
- If `HCR_EL2.E2H == 0`, the entry is from any level of the translation table walk.
- If `HCR_EL2.E2H == 1`, one of the following applies:
 - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VAE2, TLBI VAE2NXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE2, TLBI VAE2NXS instruction

C5.5.59 TLBI VAE2IS, TLBI VAE2ISNXS, TLB Invalidate by VA, EL2, Inner Shareable

The TLBI VAE2IS and TLBI VAE2ISNXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be required to translate the specified VA using the EL2 or EL2&0 translation regime for the Security state.
- If `HCR_EL2.E2H == 0`, the entry is from any level of the translation table walk.
- If `HCR_EL2.E2H == 1`, one of the following applies:
 - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VAE2IS, TLBI VAE2ISNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE2IS, TLBI VAE2ISNXS instruction

C5.5.60 TLBI VAE2OS, TLBI VAE2OSNXS, TLB Invalidate by VA, EL2, Outer Shareable

The TLBI VAE2OS and TLBI VAE2OSNXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be required to translate the specified VA using the EL2 or EL2&0 translation regime for the Security state.
- If $HCR_EL2.E2H == 0$, the entry is from any level of the translation table walk.
- If $HCR_EL2.E2H == 1$, one of the following applies:
 - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of $SCR_EL3.NS$.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If $FEAT_XS$ is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when $FEAT_TLBIOS$ is implemented. Otherwise, direct accesses to TLBI VAE2OS, TLBI VAE2OSNXS are UNDEFINED.

Attributes

TLBI VAE2OS, TLBI VAE2OSNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

When $HCR_EL2.E2H == 1$:

ASID

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Otherwise:

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE2OS, TLBI VAE2OSNXS instruction

C5.5.61 TLBI VAE3, TLBI VAE3NXS, TLB Invalidate by VA, EL3

The TLBI VAE3 and TLBI VAE3NXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to the PE that executes this System instruction.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VAE3, TLBI VAE3NXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : If [FEAT_LPA2](#) is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
 0b01 : Level 1.
 0b10 : Level 2.
 0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 0b01 : If [FEAT_LPA2](#) is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.

0b10 : Level 2.
 0b11 : Level 3.
 0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 0b01 : Level 1.
 0b10 : Level 2.
 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE3, TLBI VAE3NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VAE3{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1000	0b0111	0b001

```

    TLBI_Attr, X[t]);
  
```

TLBI VAE3NXS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1001	0b0111	0b001

```
if !IsFeatureImplemented(FEAT_XS) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    AArch64.TLBI_VA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_NSH, TLBILevel_Any,
    TLBI_ExcludeXS, X[t]);
```

C5.5.62 TLBI VAE3IS, TLBI VAE3ISNXS, TLB Invalidate by VA, EL3, Inner Shareable

The TLBI VAE3IS and TLBI VAE3ISNXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VAE3IS, TLBI VAE3ISNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00. |

0b01 : If [FEAT_LPA2](#) is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
 0b10 : Level 2.
 0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 0b01 : Level 1.
 0b10 : Level 2.
 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE3IS, TLBI VAE3ISNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VAE3IS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1000	0b0011	0b001

```

if PSTATE.EL == EL0 then

    AArch64.TLBI_VA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_ISH, TLBILevel_Any,
    TLBI_ExcludeXS, X[t]);
```

C5.5.63 TLBI VAE3OS, TLBI VAE3OSNXS, TLB Invalidate by VA, EL3, Outer Shareable

The TLBI VAE3OS and TLBI VAE3OSNXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VAE3OS, TLBI VAE3OSNXS are UNDEFINED.

Attributes

TLBI VAE3OS, TLBI VAE3OSNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00. |

0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
 0b10 : Level 2.
 0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 0b01 : Level 1.
 0b10 : Level 2.
 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE3OS, TLBI VAE3OSNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VAE3OS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1000	0b0001	0b001

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    AArch64.TLBI_VA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_OSH, TLBIlevel_Any,
    TLBI_Attr, X[t]);
    
```

TLBI VAE3OSNXS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1001	0b0001	0b001

```
if !IsFeatureImplemented(FEAT_XS) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;

    AArch64.TLBI_VA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_OSH, TLBILevel_Any,
    TLBI_ExcludeXS, X[t]);
```

C5.5.64 TLBI VALE1, TLBI VALE1NXS, TLB Invalidate by VA, Last level, EL1

The TLBI VALE1 and TLBI VALE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VALE1, TLBI VALE1NXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE1, TLBI VALE1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VALE1{, <Xt>}

    else
        AArch64.TLBI_VA(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Shareability_NSH, TLBILevel_Last,
TLBI_ExcludeXS, X[t]);
```

C5.5.65 TLBI VALE1IS, TLBI VALE1ISNXS, TLB Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI VALE1IS and TLBI VALE1ISNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

———— Note —————

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VALE1IS, TLBI VALE1ISNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3. |
| 0b11xx | The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE1IS, TLBI VALE1ISNXS instruction

```

C5.5.66 TLBI VALE1OS, TLBI VALE1OSNXS, TLB Invalidate by VA, Last level, EL1, Outer Shareable

The TLBI VALE1OS and TLBI VALE1OSNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

———— Note —————

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI VALE1OS, TLBI VALE1OSNXS are UNDEFINED.

Attributes

TLBI VALE1OS, TLBI VALE1OSNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3. |
| 0b11xx | The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE1OS, TLBI VALE1OSNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VALE1OS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0001	0b101

```

C5.5.67 TLBI VALE2, TLBI VALE2NXS, TLB Invalidate by VA, Last level, EL2

The TLBI VALE2 and TLBI VALE2NXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA using the EL2 or EL2&0 translation regime for the Security state.
- If $HCR_EL2.E2H = 0$, the entry is from the final level of the translation table walk.
- If $HCR_EL2.E2H = 1$, one of the following applies:
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VALE2, TLBI VALE2NXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

When $HCR_EL2.E2H = 1$:

ASID

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Otherwise:

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE2, TLBI VALE2NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VALE2{, <Xt>}

```

C5.5.68 TLBI VALE2IS, TLBI VALE2ISNXS, TLB Invalidate by VA, Last level, EL2, Inner Shareable

The TLBI VALE2IS and TLBI VALE2ISNXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA using the EL2 or EL2&0 translation regime for the Security state.
- If $HCR_EL2.E2H == 0$, the entry is from the final level of the translation table walk.
- If $HCR_EL2.E2H == 1$, one of the following applies:
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VALE2IS, TLBI VALE2ISNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE2IS, TLBI VALE2ISNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VALE2IS{, <Xt>}

C5.5.69 TLBI VALE2OS, TLBI VALE2OSNXS, TLB Invalidate by VA, Last level, EL2, Outer Shareable

The TLBI VALE2OS and TLBI VALE2OSNXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA using the EL2 or EL2&0 translation regime for the Security state.
- If $HCR_EL2.E2H = 0$, the entry is from the final level of the translation table walk.
- If $HCR_EL2.E2H = 1$, one of the following applies:
 - The entry is a global entry from the final level of the translation table walk.
 - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI VALE2OS, TLBI VALE2OSNXS are UNDEFINED.

Attributes

TLBI VALE2OS, TLBI VALE2OSNXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

When $HCR_EL2.E2H = 1$:

ASID

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Otherwise:

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE2OS, TLBI VALE2OSNXS instruction

```

C5.5.70 TLBI VALE3, TLBI VALE3NXS, TLB Invalidate by VA, Last level, EL3

The TLBI VALE3 and TLBI VALE3NXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to the PE that executes this System instruction.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VALE3, TLBI VALE3NXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : If [FEAT_LPA2](#) is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
 0b01 : Level 1.
 0b10 : Level 2.
 0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 0b01 : If [FEAT_LPA2](#) is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.

0b10 : Level 2.
0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE3, TLBI VALE3NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VALE3{, <Xt>}

```

C5.5.71 TLBI VALE3IS, TLBI VALE3ISNXS, TLB Invalidate by VA, Last level, EL3, Inner Shareable

The TLBI VALE3IS and TLBI VALE3ISNXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VALE3IS, TLBI VALE3ISNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : If [FEAT_LPA2](#) is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
 0b01 : Level 1.
 0b10 : Level 2.
 0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.

0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
 0b10 : Level 2.
 0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 0b01 : Level 1.
 0b10 : Level 2.
 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE3IS, TLBI VALE3ISNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VALE3IS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1000	0b0011	0b101

```

    AArch64.TLBI_VA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_ISH, TLBIlevel_Last,
    TLBI_AllAttr, X[t]);
  
```

TLBI VALE3ISNXS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1001	0b0011	0b101

```
if !IsFeatureImplemented(FEAT_XS) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    AArch64.TLBI_VA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_ISH, TLBILevel_Last,
    TLBI_ExcludeXS, X[t]);
```

C5.5.72 TLBI VALE3OS, TLBI VALE3OSNXS, TLB Invalidate by VA, Last level, EL3, Outer Shareable

The TLBI VALE3OS and TLBI VALE3OSNXS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If [FEAT_XS](#) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VALE3OS, TLBI VALE3OSNXS are UNDEFINED.

Attributes

TLBI VALE3OS, TLBI VALE3OSNXS is a 64-bit System instruction.

Field descriptions

Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

TTL

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- | | |
|--------|--|
| 0b00xx | No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0. |
| 0b01xx | The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3. |
| 0b10xx | The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00. |

0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
 0b10 : Level 2.
 0b11 : Level 3.
 0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
 0b01 : Level 1.
 0b10 : Level 2.
 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE3OS, TLBI VALE3OSNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VALE3OS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1000	0b0001	0b101

```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    AArch64.TLBI_VA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_OSH, TLBIlevel_Last,
    TLBI_Attr, X[t]);
    
```

TLBI VALE3OSNXS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b110	0b1001	0b0001	0b101

```
if !IsFeatureImplemented(FEAT_XS) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    AArch64.TLBI_VA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_0SH, TLBILevel_Last,
    TLBI_ExcludeXS, X[t]);
```

C5.5.73 TLBI VMALLE1, TLBI VMALLE1NXS, TLB Invalidate by VMID, All at stage 1, EL1

The TLBI VMALLE1 and TLBI VMALLE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to the PE that executes this System instruction.

———— Note —————

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLE1, TLBI VMALLE1NXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by `<Xt>` is ignored.

Executing TLBI VMALLE1, TLBI VMALLE1NXS instruction

The `Rt` field should be set to `0b11111`. If the `Rt` field is not set to `0b11111`, it is CONstrained UNpredictable whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the `Rt` field is set to `0b11111`.

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VMALLE1{, <Xt>}

op0	op1	CRn	CRm	op2

        AArch64.TLBI_VMALL(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Shareability_NSH,  
TLBI_ExcludeXS);
```

C5.5.74 TLBI VMALLE1IS, TLBI VMALLE1ISNXS, TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable

The TLBI VMALLE1IS and TLBI VMALLE1ISNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

C5.5.75 TLBI VMALLE1OS, TLBI VMALLE1OSNXS, TLB Invalidate by VMID, All at stage 1, EL1, Outer Shareable

The TLBI VMALLE1OS and TLBI VMALLE1OSNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
 - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
 - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of `SCR_EL3.NS`.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

———— Note ————

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

———— Note ————

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI VMALLE1OS, TLBI VMALLE1OSNXS are UNDEFINED.

Attributes

TLBI VMALLE1OS, TLBI VMALLE1OSNXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI VMALLE1OS, TLBI VMALLE1OSNXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

TLBI VMALLE1OS{, <Xt>}

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0001	0b000

```

```

C5.5.76 TLBI VMALLS12E1, TLBI VMALLS12E1NXS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1

The TLBI VMALLS12E1 and TLBI VMALLS12E1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- One of the following applies:
 - If `SCR_EL3.NS` is 0, then:
 - The entry would be required to translate an address using the Secure EL1&0 translation regime.
 - If `FEAT_SEL2` is implemented and enabled, the entry would be used with the current VMID.
 - If `SCR_EL3.NS` is 1, then:
 - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
 - If Non-secure EL2 is implemented, the entry would be used with the current VMID.

The invalidation applies to the PE that executes this System instruction.

———— Note —————

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLS12E1, TLBI VMALLS12E1NXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI VMALLS12E1, TLBI VMALLS12E1NXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```

C5.5.77 TLBI VMALLS12E1IS, TLBI VMALLS12E1ISNXS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Inner Shareable

The TLBI VMALLS12E1IS and TLBI VMALLS12E1ISNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- One of the following applies:
 - If `SCR_EL3.NS` is 0, then:
 - The entry would be required to translate an address using the Secure EL1&0 translation regime.
 - If `FEAT_SEL2` is implemented and enabled, the entry would be used with the current VMID.
 - If `SCR_EL3.NS` is 1, then:
 - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
 - If Non-secure EL2 is implemented, the entry would be used with the current VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

————— Note —————

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

————— Note —————

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLS12E1IS, TLBI VMALLS12E1ISNXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI VMALLS12E1IS, TLBI VMALLS12E1ISNXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.

```

C5.5.78 TLBI VMALLS12E1OS, TLBI VMALLS12E1OSNXS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Outer Shareable

The TLBI VMALLS12E1OS and TLBI VMALLS12E1OSNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- One of the following applies:
 - If `SCR_EL3.NS` is 0, then:
 - The entry would be required to translate an address using the Secure EL1&0 translation regime.
 - If `FEAT_SEL2` is implemented and enabled, the entry would be used with the current VMID.
 - If `SCR_EL3.NS` is 1, then:
 - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
 - If Non-secure EL2 is implemented, the entry would be used with the current VMID.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

————— Note —————

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if `SCR_EL3.EEL2==1`, then:

- A PE with `SCR_EL3.EEL2==1` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==0`.
- A PE with `SCR_EL3.EEL2==0` is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with `SCR_EL3.EEL2==1`.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

————— Note —————

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If `FEAT_XS` is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when `FEAT_TLBIOS` is implemented. Otherwise, direct accesses to TLBI VMALLS12E1OS, TLBI VMALLS12E1OSNXS are UNDEFINED.

Attributes

TLBI VMALLS12E1OS, TLBI VMALLS12E1OSNXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI VMALLS12E1OS, TLBI VMALLS12E1OSNXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

```

C5.6 A64 System instructions for prediction restriction

This section lists the A64 System instructions for prediction restriction.

C5.6.1 CFP RCTX, Control Flow Prediction Restriction by Context

The CFP RCTX characteristics are:

Purpose

Control Flow Prediction Restriction by Context applies to all Control Flow Prediction Resources that predict execution based on information gathered within the target execution context or contexts.

Control flow predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control speculative execution occurring after the instruction is complete and synchronized.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

———— Note ————

This instruction does not require the invalidation of prediction structures so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

Configurations

This instruction is present only when FEAT_SPECREC is implemented. Otherwise, direct accesses to CFP RCTX are UNDEFINED.

Attributes

CFP RCTX is a 64-bit System instruction.

Field descriptions

Bits [63:49]

Reserved, RES0.

GVMID, bit [48]

Execution of this instruction applies to all VMIDs or a specified VMID.

0b0 Applies to specified VMID for an EL0 or EL1 target execution context.

0b1 Applies to all VMIDs for an EL0 or EL1 target execution context.

For target execution contexts other than EL0 or EL1, this field is RES0.

If the instruction is executed at EL0 or EL1, this field has an Effective value of 0.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

VMID, bits [47:32]

Only applies when bit[48] is 0 and the target execution context is either:

- EL1.
- EL0 when (`HCR_EL2.E2H==0` or `HCR_EL2.TGE==0`).

Otherwise this field is RES0.

When the instruction is executed at EL1, this field is treated as the current VMID.

When the instruction is executed at EL0 and (`HCR_EL2.E2H==0` or `HCR_EL2.TGE==0`), this field is treated as the current VMID.

When the instruction is executed at EL0 and (`HCR_EL2.E2H==1` and `HCR_EL2.TGE==1`), this field is ignored.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

If the implementation supports 16 bits of VMID, then the upper 8 bits of the VMID must be written to 0 by software when the context being affected only uses 8 bits.

Bits [31:27]

Reserved, RES0.

NS, bit [26]

Security State. Defined values are:

- | | |
|-----|-------------------|
| 0b0 | Secure state. |
| 0b1 | Non-secure state. |

When executed in Non-secure state, the *Effective value* of NS is 1.

EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.

- | | |
|------|------|
| 0b00 | EL0. |
| 0b01 | EL1. |
| 0b10 | EL2. |
| 0b11 | EL3. |

If the instruction is executed at an Exception level lower than the specified level, this instruction is treated as a NOP.

Bits [23:17]

Reserved, RES0.

GASID, bit [16]

Execution of this instruction applies to all ASIDs or a specified ASID.

- | | |
|-----|--|
| 0b0 | Applies to specified ASID for an EL0 target execution context. |
| 0b1 | Applies to all ASID for an EL0 target execution context. |

For target execution contexts other than EL0, this field is RES0.

If the instruction is executed at EL0, this field has an Effective value of 0.

ASID, bits [15:0]

Only applies for an EL0 target execution context and when bit[16] is 0.

Otherwise, this field is RES0.

When the instruction is executed at EL0, this field is treated as the current ASID.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being affected only uses 8 bits.

Executing CFP RCTX instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

CFP RCTX, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b0011	0b100

```

if PSTATE.EL == EL0 then
  if !(EL2Enabled() && HCR_EL2.<E2H,TGE> == '11') && SCTLR_EL1.EnRCTX == '0' then
    if EL2Enabled() && HCR_EL2.TGE == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    else
      AArch64.SystemAccessTrap(EL1, 0x18);
    elsif EL2Enabled() && HCR_EL2.<E2H,TGE> != '11' && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') &&
HFGITR_EL2.CFPRCTX == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && HCR_EL2.<E2H,TGE> == '11' && SCTLR_EL2.EnRCTX == '0' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    else
      CFP_RCTX(X[t]);
  elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.CFPRCTX == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    else
      CFP_RCTX(X[t]);
  elsif PSTATE.EL == EL2 then
    CFP_RCTX(X[t]);
  elsif PSTATE.EL == EL3 then
    CFP_RCTX(X[t]);

```

C5.6.2 CPP RCTX, Cache Prefetch Prediction Restriction by Context

The CPP RCTX characteristics are:

Purpose

Cache Prefetch Prediction Restriction by Context applies to all Cache Allocation Resources that predict cache allocations based on information gathered within the target execution context or contexts.

Cache prefetch predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control speculative execution occurring after the instruction is complete and synchronized.

This instruction applies to all:

- Instruction caches.
- Data caches.
- TLB prefetching hardware used by the executing PE that applies to the supplied context or contexts.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

———— Note ————

This instruction does not require the invalidation of Cache Allocation Resources so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

Configurations

This instruction is present only when FEAT_SPECRES is implemented. Otherwise, direct accesses to CPP RCTX are UNDEFINED.

Attributes

CPP RCTX is a 64-bit System instruction.

Field descriptions

Bits [63:49]

Reserved, RES0.

GVMID, bit [48]

Execution of this instruction applies to all VMIDs or a specified VMID.

0b0 Applies to specified VMID for an EL0 or EL1 target execution context.

0b1 Applies to all VMIDs for an EL0 or EL1 target execution context.

For target execution contexts other than EL0 and EL1, this field is RES0.

If the instruction is executed at EL0 or EL1, this field has an Effective value of 0.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

VMID, bits [47:32]

Only applies when bit[48] is 0 and the target execution context is either:

- EL1.
- EL0 when (`HCR_EL2.E2H==0` or `HCR_EL2.TGE==0`).

Otherwise this field is RES0.

When the instruction is executed at EL1, this field is treated as the current VMID.

When the instruction is executed at EL0 and (`HCR_EL2.E2H==0` or `HCR_EL2.TGE==0`), this field is treated as the current VMID.

When the instruction is executed at EL0 and (`HCR_EL2.E2H==1` and `HCR_EL2.TGE==1`), this field is ignored.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

If the implementation supports 16 bits of VMID, then the upper 8 bits of the VMID must be written to 0 by software when the context being affected only uses 8 bits.

Bits [31:27]

Reserved, RES0.

NS, bit [26]

Security State. Defined values are:

0b0 Secure state.

0b1 Non-secure state.

When executed in Non-secure state, the *Effective value* of NS is 1.

EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.

0b00 EL0.

0b01 EL1.

0b10 EL2.

0b11 EL3.

If the instruction is executed at an Exception level lower than the specified level, this instruction is treated as a NOP.

Bits [23:17]

Reserved, RES0.

GASID, bit [16]

Execution of this instruction applies to all ASIDs or a specified ASID.

0b0 Applies to specified ASID for an EL0 target execution context.

0b1 Applies to all ASID for an EL0 target execution context.

For target execution contexts other than EL0, this field is RES0.

If the instruction is executed at EL0, this field has an Effective value of 0.

ASID, bits [15:0]

Only applies for an EL0 target execution context and when bit[16] is 0.

Otherwise, this field is RES0.

When the instruction is executed at EL0, this field is treated as the current ASID.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being affected only uses 8 bits.

Executing CPP RCTX instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

CPP RCTX, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b011	0b01111	0b0011	0b111

```

if PSTATE.EL == EL0 then
  if !(EL2Enabled() && HCR_EL2.<E2H,TGE> == '11') && SCTLR_EL1.EnRCTX == '0' then
    if EL2Enabled() && HCR_EL2.TGE == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    else
      AArch64.SystemAccessTrap(EL1, 0x18);
    elsif EL2Enabled() && HCR_EL2.<E2H,TGE> != '11' && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') &&
HFGITR_EL2.CPPRCTX == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && HCR_EL2.<E2H,TGE> == '11' && SCTLR_EL2.EnRCTX == '0' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    else
      CPP_RCTX(X[t]);
  elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HFGITR_EL2.CPPRCTX == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    else
      CPP_RCTX(X[t]);
  elsif PSTATE.EL == EL2 then
    CPP_RCTX(X[t]);
  elsif PSTATE.EL == EL3 then
    CPP_RCTX(X[t]);
  
```

C5.6.3 DVP RCTX, Data Value Prediction Restriction by Context

The DVP RCTX characteristics are:

Purpose

Data Value Prediction Restriction by Context applies to all Data Value Prediction Resources that predict execution based on information gathered within the target execution context or contexts.

Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control speculative execution occurring after the instruction is complete and synchronized.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

———— Note ————

This instruction does not require the invalidation of prediction structures so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

Configurations

This instruction is present only when FEAT_SPECRECRES is implemented. Otherwise, direct accesses to DVP RCTX are UNDEFINED.

Attributes

DVP RCTX is a 64-bit System instruction.

Field descriptions

Bits [63:49]

Reserved, RES0.

GVMID, bit [48]

Execution of this instruction applies to all VMIDs or a specified VMID.

0b0 Applies to specified VMID for an EL0 or EL1 target execution context.

0b1 Applies to all VMIDs for an EL0 or EL1 target execution context.

For target execution contexts other than EL0 or EL1, this field is RES0.

If the instruction is executed at EL0 or EL1, then this field has an Effective value of 0.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

VMID, bits [47:32]

Only applies when bit[48] is 0 and the target execution context is either:

- EL1.
- EL0 when (`HCR_EL2.E2H==0` or `HCR_EL2.TGE==0`).

Otherwise this field is RES0.

When the instruction is executed at EL1, this field is treated as the current VMID.

When the instruction is executed at EL0 and (`HCR_EL2.E2H==0` or `HCR_EL2.TGE==0`), this field is treated as the current VMID.

When the instruction is executed at EL0 and (`HCR_EL2.E2H==1` and `HCR_EL2.TGE==1`), this field is ignored.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

If the implementation supports 16 bits of VMID, then the upper 8 bits of the VMID must be written to 0 by software when the context being affected only uses 8 bits.

Bits [31:27]

Reserved, RES0.

NS, bit [26]

Security State. Defined values are:

- | | |
|-----|-------------------|
| 0b0 | Secure state. |
| 0b1 | Non-secure state. |

When executed in Non-secure state, the *Effective value* of NS is 1.

EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.

- | | |
|------|------|
| 0b00 | EL0. |
| 0b01 | EL1. |
| 0b10 | EL2. |
| 0b11 | EL3. |

If the instruction is executed at an Exception level lower than the specified level, this instruction is treated as a NOP.

Bits [23:17]

Reserved, RES0.

GASID, bit [16]

Execution of this instruction applies to all ASIDs or a specified ASID.

- | | |
|-----|--|
| 0b0 | Applies to specified ASID for an EL0 target execution context. |
| 0b1 | Applies to all ASID for an EL0 target execution context. |

For target execution contexts other than EL0, this field is RES0.

If the instruction is executed at EL0, this field has an Effective value of 0.

ASID, bits [15:0]

Only applies for an EL0 target execution context and when bit[16] is 0.

Otherwise this field is RES0.

When the instruction is executed at EL0, this field is treated as the current ASID.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being affected only uses 8 bits.

Executing DVP RCTX instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

DVP RCTX, <Xt>

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b0011	0b101

```

if PSTATE.EL == EL0 then
  if !(EL2Enabled() && HCR_EL2.<E2H,TGE> == '11') && SCTLR_EL1.EnRCTX == '0' then
    if EL2Enabled() && HCR_EL2.TGE == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    else
      AArch64.SystemAccessTrap(EL1, 0x18);
    elsif EL2Enabled() && HCR_EL2.<E2H,TGE> != '11' && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') &&
HFGITR_EL2.DVPRCTX == '1' then
      AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && HCR_EL2.<E2H,TGE> == '11' && SCTLR_EL2.EnRCTX == '0' then

    DVP_RCTX(X[t]);
  elsif PSTATE.EL == EL3 then
    DVP_RCTX(X[t]);

```

Chapter C6

A64 Base Instruction Descriptions

This chapter describes the A64 base instructions.

It contains the following sections:

- [About the A64 base instructions on page C6-872.](#)
- [Alphabetical list of A64 base instructions on page C6-875.](#)

C6.1 About the A64 base instructions

[Alphabetical list of A64 base instructions on page C6-875](#) gives full descriptions of the A64 instructions that are in the following instruction groups:

- Branch, Exception generation, and System instructions.
- Loads and stores associated with the general-purpose registers.
- Data processing (immediate).
- Data processing (register).

[A64 instruction set encoding on page C4-284](#) provides an overview of the instruction encodings as well as of the instruction classes within their functional groups.

The rest of this section is general description of the base instructions. It contains the following subsections:

- [Register size on page C6-872](#).
- [Use of the PC on page C6-872](#).
- [Use of the stack pointer on page C6-873](#).
- [Condition flags and related instructions on page C6-873](#).

C6.1.1 Register size

Most data processing, comparison, and conversion instructions that use the general-purpose registers as the source or destination operand have two instruction variants that operate on either a 32-bit or a 64-bit value.

Where a 32-bit instruction form is selected, the following holds:

- The upper 32 bits of the source registers are ignored.
- The upper 32 bits of the destination register are set to zero.
- Right shifts and right rotates inject at bit[31], not at bit[63].
- The Condition flags, where set by the instruction, are computed from the lower 32 bits.

This distinction applies even when the results of a 32-bit instruction form are indistinguishable from the lower 32 bits computed by the equivalent 64-bit instruction form. For example, a 32-bit bitwise ORR could be performed using a 64-bit ORR and simply ignoring the top 32 bits of the result. However, the A64 instruction set includes separate 32-bit and 64-bit forms of the ORR instruction.

As well as distinct sign-extend or zero-extend instructions, the A64 instruction set also provides the ability to extend and shift the final source register of an ADD, SUB, ADDS, or SUBS instruction and the index register of a load/store instruction. This enables array index calculations involving a 64-bit array pointer and a 32-bit array index to be implemented efficiently.

The assembly language notation enables the distinct identification of registers holding 32-bit values and registers holding 64-bit values. See [Register names on page C1-198](#) and [Register indexed addressing on page C1-202](#).

C6.1.2 Use of the PC

A64 instructions have limited access to the PC. The only instructions that can read the PC are those that generate a PC relative address:

- [ADR](#) and [ADRP](#).
- The Load register (literal) instruction class.
- Direct branches that use an immediate offset.
- The unconditional branch with link instructions, [BL](#) and [BLR](#), that use the PC to create the return link address.

Only explicit control flow instructions can modify the PC:

- Conditional and unconditional branch and return instructions.
- Exception generation and exception return instructions.

For more details of instructions that can modify the PC, see [Branches, Exception generating, and System instructions on page C3-216](#).

C6.1.3 Use of the stack pointer

A64 instructions can use the stack pointer only in a limited number of cases:

- Load/store instructions use the current stack pointer as the base address:
 - When stack alignment checking is enabled by system software and the base register is SP, the current stack pointer must be initially quadword aligned. That is, it must be aligned to 16 bytes. Misalignment generates an SP alignment fault. See [SP alignment checking on page D1-2469](#) for more information.
- Add and subtract data processing instructions in their immediate and extended register forms, use the current stack pointer as a source register or the destination register or both.
- Logical data processing instructions in their immediate form use the current stack pointer as the destination register.

C6.1.4 Condition flags and related instructions

The A64 base instructions that use the Condition flags as an input are:

- Conditional branch. The conditional branch instruction is B.cond.
- Add or subtract with carry. These instruction types include instructions to perform multi-precision arithmetic and calculate checksums. The add or subtract with carry instructions are ADC, ADCS, SBC, and SBCS, or an architectural alias for these instructions.
- Conditional select with increment, negate, or invert. This instruction type conditionally selects between one source register and a second, incremented, negated, inverted, or unmodified source register. The conditional select with increment, negate, or invert instructions are CSINC, CSINV, and CSNEG.

These instructions also implement:

- Conditional select or move. The Condition flags select one of two source registers as the destination register. Short conditional sequences can be replaced by unconditional instructions followed by a conditional select, CSEL.
- Conditional set. Conditionally selects between 0 and 1, or 0 and -1. This can be used to convert the Condition flags to a Boolean value or mask in a general-purpose register, for example. These instructions include CSET and CSETM.
- Conditional compare. This instruction type sets the Condition flags to the result of a comparison if the original condition is true, otherwise it sets the Condition flags to an immediate value. It permits the flattening of nested conditional expressions without using conditional branches or performing Boolean arithmetic within the general-purpose registers. The conditional compare instructions are CCMP and CCMN.

The A64 base instructions that update the Condition flags as an output are:

- Flag-setting data processing instructions, such as ADCS, ADDS, ANDS, BICS, RMIF, SBCS, SETF8, SETF16, and SUBS, and the aliases CMN, CMP, and TST.
- Conditional compare instructions such as CCMN, CCMP.
- The random number generation instructions MRS RNDR and MRS RNDRRS, see [Effect of random number generation instructions on Condition flags on page C6-874](#).

The A64 base instructions that manipulate the Condition flags are:

- The flag manipulation instruction CFINV, which inverts the value of the Carry flag.
- If FEAT_FlagM2 is implemented, the base instructions AXFLAG and XAFLAG. These instructions convert between the Arm floating point comparison PSTATE condition flag format and an alternative format shown in Table C6-1 on page C6-874.

Table C6-1 Relationship between ARM format and alternative format PSTATE condition flags

Result	ARM format				Alternative format			
	N	Z	C	V	N	Z	C	V
Greater than	0	0	1	0	0	0	1	0
Less than	1	0	0	0	0	0	0	0
Equal	0	1	1	0	0	1	1	0
Unordered	0	0	1	1	0	1	0	0

The flags can be directly accessed for a read/write using the *NZCV*, [Condition Flags](#) on page C5-440.

The A64 base instructions also include conditional branch instructions that do not use the Condition flags as an input:

- Compare and branch if a register is zero or nonzero, CBZ and CBNZ.
- Test a single bit in a register and branch if the bit is zero or nonzero, TBZ and TBNZ.

Effect of random number generation instructions on Condition flags

If FEAT_RNG is implemented, then:

- When a valid random number is returned, the PSTATE.NZCV flags are set to 0b0000.
- If the random number hardware is not capable of returning a random number in a reasonable period of time, the PSTATE.NZCV flags are set to 0b0100, and the random number generation instructions return the value 0.

———— **Note** ————

The definition of “reasonable period of time” is IMPLEMENTATION DEFINED. The expectation is that software might use this as an opportunity to reschedule or run a different routine, perhaps after a small number of retries have failed to return a valid value.

C6.2 Alphabetical list of A64 base instructions

This section lists every instruction in the base category of the A64 instruction set. For details of the format used, see [Understanding the A64 instruction descriptions on page C2-208](#).

C6.2.1 ADC

Add with Carry adds two register values and the Carry flag value, and writes the result to the destination register.

32-bit variant

Applies when sf == 0.

ADC <Wd>, <Wn>, <Wm>

64-bit variant

Applies when sf == 1.

ADC <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

(result, -) = AddWithCarry(operand1, operand2, PSTATE.C);

X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.2 ADCS

Add with Carry, setting flags, adds two register values and the Carry flag value, and writes the result to the destination register. It updates the condition flags based on the result.

32-bit variant

Applies when sf == 0.

ADCS <Wd>, <Wn>, <Wm>

64-bit variant

Applies when sf == 1.

ADCS <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcvc;

(result, nzcvc) = AddWithCarry(operand1, operand2, PSTATE.C);

PSTATE.<N,Z,C,V> = nzcvc;

X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.3 ADD (extended register)

Add (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

32-bit variant

Applies when sf == 0.

ADD <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

64-bit variant

Applies when sf == 1.

ADD <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;
```

Assembler symbols

- <Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- <Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- <Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- <R> Is a width specifier, encoded in the "option" field. It can have the following values:
 - W when option = 00x
 - W when option = 010
 - X when option = x11
 - W when option = 10x
 - W when option = 110
- <m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB	when option = 000
UXTH	when option = 001
LSL UXTW	when option = 010
UXTX	when option = 011
SXTB	when option = 100
SXTH	when option = 101
SXTW	when option = 110
SXTX	when option = 111

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB	when option = 000
UXTH	when option = 001
UXTW	when option = 010
LSL UXTX	when option = 011
SXTB	when option = 100
SXTH	when option = 101
SXTW	when option = 110
SXTX	when option = 111

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);

(result, -) = AddWithCarry(operand1, operand2, '0');

if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.4 ADD (immediate)

Add (immediate) adds a register value and an optionally-shifted immediate value, and writes the result to the destination register.

This instruction is used by the alias [MOV \(to/from SP\)](#). See [Alias conditions on page C6-883](#) for details of when each alias is preferred.

32-bit variant

Applies when `sf == 0`.

ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}

64-bit variant

Applies when `sf == 1`.

ADD <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

case sh of
  when '0' imm = ZeroExtend(imm12, datasize);
  when '1' imm = ZeroExtend(imm12:Zeros(12), datasize);
```

Alias conditions

Alias	is preferred when
MOV (to/from SP)	<code>sh == '0' && imm12 == '000000000000' && (Rd == '11111' Rn == '11111')</code>

Assembler symbols

<Wd WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Wn WSP>	Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xd SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn SP>	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<imm>	Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

LSL #0	when sh = 0
LSL #12	when sh = 1

Operation

```
bits(datasize) result;  
bits(datasize) operand1 = if n == 31 then SP[] else X[n];  
  
(result, -) = AddWithCarry(operand1, imm, '0');  
  
if d == 31 then  
    SP[] = result;  
else  
    X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

```
bits(datasize) result;  
bits(datasize) operand1 = X[n];  
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);  
  
(result, -) = AddWithCarry(operand1, operand2, '0');  
  
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.6 ADDG

Add with Tag adds an immediate value scaled by the Tag granule to the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

Integer

(FEAT_MTE)

Encoding

ADDG <Xd|SP>, <Xn|SP>, #<uimm6>, #<uimm4>

Decode for this encoding

```
if !HaveMTEExt() then UNDEFINED;
integer d = UInt(Xd);
integer n = UInt(Xn);
bits(64) offset = LSL(ZeroExtend(uimm6, 64), LOG2_TAG_GRANULE);
```

Assembler symbols

- <Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Xd" field.
- <Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Xn" field.
- <uimm6> Is an unsigned immediate, a multiple of 16 in the range 0 to 1008, encoded in the "uimm6" field.
- <uimm4> Is an unsigned immediate, in the range 0 to 15, encoded in the "uimm4" field.

Operation

```
bits(64) operand1 = if n == 31 then SP[] else X[n];
bits(4) start_tag = AArch64.AllocationTagFromAddress(operand1);
bits(16) exclude = GCR_EL1.Exclude;
bits(64) result;
bits(4) rtag;

if AArch64.AllocationTagAccessIsEnabled(AccType_NORMAL) then
    rtag = AArch64.ChooseNonExcludedTag(start_tag, uimm4, exclude);
else
    rtag = '0000';

(result, -) = AddWithCarry(operand1, offset, '0');
result = AArch64.AddressWithAllocationTag(result, AccType_NORMAL, rtag);

if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

C6.2.7 ADDS (extended register)

Add (extended register), setting flags, adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias [CMN \(extended register\)](#). See [Alias conditions](#) for details of when each alias is preferred.

32-bit variant

Applies when sf == 0.

ADDS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

64-bit variant

Applies when sf == 1.

ADDS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;
```

Alias conditions

Alias	is preferred when
CMN (extended register)	Rd == '11111'

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn WSP>	Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn SP>	Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<R>	Is a width specifier, encoded in the "option" field. It can have the following values: W when option = 00x

- W when option = 010
 X when option = x11
 W when option = 10x
 W when option = 110
- <m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
- <extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:
 UXTB when option = 000
 UXTH when option = 001
 LSL|UXTW when option = 010
 UXTX when option = 011
 SXTB when option = 100
 SXTH when option = 101
 SXTW when option = 110
 SXTX when option = 111
 If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.
 For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:
 UXTB when option = 000
 UXTH when option = 001
 UXTW when option = 010
 LSL|UXTX when option = 011
 SXTB when option = 100
 SXTH when option = 101
 SXTW when option = 110
 SXTX when option = 111
 If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.
- <amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcvc;

(result, nzcvc) = AddWithCarry(operand1, operand2, '0');

PSTATE.<N,Z,C,V> = nzcvc;

X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.8 ADDS (immediate)

Add (immediate), setting flags, adds a register value and an optionally-shifted immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias [CMN \(immediate\)](#). See [Alias conditions on page C6-891](#) for details of when each alias is preferred.

32-bit variant

Applies when sf == 0.

ADDS <Wd>, <Wn|WSP>, #<imm>{, <shift>}

64-bit variant

Applies when sf == 1.

ADDS <Xd>, <Xn|SP>, #<imm>{, <shift>}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

case sh of
  when '0' imm = ZeroExtend(imm12, datasize);
  when '1' imm = ZeroExtend(imm12:Zeros(12), datasize);
```

Alias conditions

Alias	is preferred when
CMN (immediate)	Rd == '11111'

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn WSP>	Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn SP>	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<imm>	Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
<shift>	Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:
LSL #0	when sh = 0
LSL #12	when sh = 1

Operation

```
bits(datasize) result;  
bits(datasize) operand1 = if n == 31 then SP[] else X[n];  
bits(4) nzcvc;  
  
(result, nzcvc) = AddWithCarry(operand1, imm, '0');  
  
PSTATE.<N,Z,C,V> = nzcvc;  
  
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.9 ADDS (shifted register)

Add (shifted register), setting flags, adds a register value and an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias [CMN \(shifted register\)](#). See [Alias conditions on page C6-893](#) for details of when each alias is preferred.

32-bit variant

Applies when `sf == 0`.

ADDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit variant

Applies when `sf == 1`.

ADDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

```
if shift == '11' then UNDEFINED;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
```

```
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
CMN (shifted register)	Rd == '11111'

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

LSL	when shift = 00
LSR	when shift = 01
ASR	when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

```
bits(datasize) result;  
bits(datasize) operand1 = X[n];  
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);  
bits(4) nzcvc;  
  
(result, nzcvc) = AddWithCarry(operand1, operand2, '0');  
  
PSTATE.<N,Z,C,V> = nzcvc;  
  
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.10 ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

Encoding

ADR <Xd>, <label>

Decode for this encoding

```
integer d = UInt(Rd);
bits(64) imm;

imm = SignExtend(immhi:immlo, 64);
```

Assembler symbols

- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <label> Is the program label whose address is to be calculated. Its offset from the address of this instruction, in the range +/-1MB, is encoded in "immhi:immlo".

Operation

```
bits(64) base = PC[];

X[d] = base + imm;
```

C6.2.11 ADRP

Form PC-relative address to 4KB page adds an immediate value that is shifted left by 12 bits, to the PC value to form a PC-relative address, with the bottom 12 bits masked out, and writes the result to the destination register.

Encoding

ADRP <Xd>, <label>

Decode for this encoding

```
integer d = UInt(Rd);
bits(64) imm;

imm = SignExtend(immhi:immlo:Zeros(12), 64);
```

Assembler symbols

- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <label> Is the program label whose 4KB page address is to be calculated. Its offset from the page address of this instruction, in the range +/-4GB, is encoded as "immhi:immlo" times 4096.

Operation

```
bits(64) base = PC[];
base<11:0> = Zeros(12);
X[d] = base + imm;
```

C6.2.12 AND (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

32-bit variant

Applies when `sf == 0` && `N == 0`.

AND <Wd|WSP>, <Wn>, #<imm>

64-bit variant

Applies when `sf == 1`.

AND <Xd|SP>, <Xn>, #<imm>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;
if sf == '0' && N != '0' then UNDEFINED;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Assembler symbols

<Wd WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm>	For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr". For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];

result = operand1 AND imm;
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.13 AND (shifted register)

Bitwise AND (shifted register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when `sf == 0`.

AND <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit variant

Applies when `sf == 1`.

AND <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
```

```
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
 - LSL when shift = 00
 - LSR when shift = 01
 - ASR when shift = 10
 - ROR when shift = 11
- <amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

```
bits(datasize) operand1 = X[n];  
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);  
  
result = operand1 AND operand2;  
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.14 ANDS (immediate)

Bitwise AND (immediate), setting flags, performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias [TST \(immediate\)](#). See *Alias conditions on page C6-901* for details of when each alias is preferred.

32-bit variant

Applies when `sf == 0 && N == 0`.

ANDS <Wd>, <Wn>, #<imm>

64-bit variant

Applies when `sf == 1`.

ANDS <Xd>, <Xn>, #<imm>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

bits(datasize) imm;
if sf == '0' && N != '0' then UNDEFINED;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Alias conditions

Alias	is preferred when
TST (immediate)	Rd == '11111'

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm>	For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr". For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Operation

```
bits(datasize) result;  
bits(datasize) operand1 = X[n];  
  
result = operand1 AND imm;  
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';  
  
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.15 ANDS (shifted register)

Bitwise AND (shifted register), setting flags, performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias [TST \(shifted register\)](#). See [Alias conditions on page C6-903](#) for details of when each alias is preferred.

32-bit variant

Applies when sf == 0.

ANDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit variant

Applies when sf == 1.

ANDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
TST (shifted register)	Rd == '11111'

Assembler symbols

<code><Wd></code>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<code><Wn></code>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<code><Wm></code>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<code><Xd></code>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<code><Xn></code>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<code><Xm></code>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

LSL	when shift = 00
LSR	when shift = 01
ASR	when shift = 10
ROR	when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

result = operand1 AND operand2;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.16 ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the [ASRV](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [ASRV](#).
- The description of [ASRV](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when `sf == 0`.

ASR <Wd>, <Wn>, <Wm>

is equivalent to

ASRV <Wd>, <Wn>, <Wm>

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

ASR <Xd>, <Xn>, <Xm>

is equivalent to

ASRV <Xd>, <Xn>, <Xm>

and is always the preferred disassembly.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of [ASRV](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.17 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of the sign bit in the upper bits and zeros in the lower bits, and writes the result to the destination register.

This instruction is an alias of the [SBFM](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [SBFM](#).
- The description of [SBFM](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf == 0 \ \&\& \ N == 0 \ \&\& \ imms == 011111$.

ASR <Wd>, <Wn>, #<shift>

is equivalent to

SBFM <Wd>, <Wn>, #<shift>, #31

and is always the preferred disassembly.

64-bit variant

Applies when $sf == 1 \ \&\& \ N == 1 \ \&\& \ imms == 111111$.

ASR <Xd>, <Xn>, #<shift>

is equivalent to

SBFM <Xd>, <Xn>, #<shift>, #63

and is always the preferred disassembly.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<shift> For the 32-bit variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.

Operation

The description of [SBFM](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.18 ASRV

Arithmetic Shift Right Variable shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias [ASR \(register\)](#). The alias is always the preferred disassembly.

32-bit variant

Applies when `sf == 0`.

ASRV <Wd>, <Wn>, <Wm>

64-bit variant

Applies when `sf == 1`.

ASRV <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand2 = X[m];

result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.19 AT

Address Translate. For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-399.

This instruction is an alias of the **SYS** instruction. This means that:

- The encodings in this description are named to match the encodings of **SYS**.
- The description of **SYS** gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0		
1	1	0	1	0	1	0	1	0	0	0	0	0	1	op1	0	1	1	1	1	0	0	x	op2	Rt
L											CRn				CRm									

Encoding

AT <at_op>, <Xt>

is equivalent to

SYS #<op1>, C7, <Cm>, #<op2>, <Xt>

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_AT`.

Assembler symbols

<at_op> Is an AT instruction name, as listed for the AT system instruction group, encoded in the "op1:CRm<0>:op2" field. It can have the following values:

S1E1R	when op1 = 000, CRm<0> = 0, op2 = 000
S1E1W	when op1 = 000, CRm<0> = 0, op2 = 001
S1E0R	when op1 = 000, CRm<0> = 0, op2 = 010
S1E0W	when op1 = 000, CRm<0> = 0, op2 = 011
S1E2R	when op1 = 100, CRm<0> = 0, op2 = 000
S1E2W	when op1 = 100, CRm<0> = 0, op2 = 001
S12E1R	when op1 = 100, CRm<0> = 0, op2 = 100
S12E1W	when op1 = 100, CRm<0> = 0, op2 = 101
S12E0R	when op1 = 100, CRm<0> = 0, op2 = 110
S12E0W	when op1 = 100, CRm<0> = 0, op2 = 111
S1E3R	when op1 = 110, CRm<0> = 0, op2 = 000
S1E3W	when op1 = 110, CRm<0> = 0, op2 = 001

When FEAT_PAN2 is implemented, the following values are also valid:

S1E1RP	when op1 = 000, CRm<0> = 1, op2 = 000
S1E1WP	when op1 = 000, CRm<0> = 1, op2 = 001

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of [SYS](#) gives the operational pseudocode for this instruction.

C6.2.20 AUTDA, AUTDZA

Authenticate Data address, using key A. This instruction authenticates a data address, using a modifier and key A.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDA.
- The value zero, for AUTDZA.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

Integer

(FEAT_PAuth)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9				5	4				0
1	1	0	1	1	0	1	0	1	1	0	0	0	0	0	1	0	0	Z	1	1	0					Rn					Rd

AUTDA variant

Applies when Z == 0.

AUTDA <Xd>, <Xn|SP>

AUTDZA variant

Applies when Z == 1 && Rn == 11111.

AUTDZA <Xd>

Decode for all variants of this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UNDEFINED;

if Z == '0' then // AUTDA
    if n == 31 then source_is_sp = TRUE;
else // AUTDZA
    if n != 31 then UNDEFINED;
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if HavePACExt() then
    if source_is_sp then
        X[d] = AuthDA(X[d], SP[], FALSE);
    else
        X[d] = AuthDA(X[d], X[n], FALSE);
```

C6.2.21 AUTDB, AUTDZB

Authenticate Data address, using key B. This instruction authenticates a data address, using a modifier and key B.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDB.
- The value zero, for AUTDZB.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

Integer

(FEAT_PAuth)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9				5	4				0
1	1	0	1	1	0	1	0	1	1	0	0	0	0	0	1	0	0	Z	1	1	1					Rn					Rd

AUTDB variant

Applies when Z == 0.

AUTDB <Xd>, <Xn|SP>

AUTDZB variant

Applies when Z == 1 && Rn == 11111.

AUTDZB <Xd>

Decode for all variants of this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UNDEFINED;

if Z == '0' then // AUTDB
    if n == 31 then source_is_sp = TRUE;
else // AUTDZB
    if n != 31 then UNDEFINED;
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if HavePACExt() then
    if source_is_sp then
        X[d] = AuthDB(X[d], SP[], FALSE);
    else
        X[d] = AuthDB(X[d], X[n], FALSE);
```

C6.2.22 AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA

Authenticate Instruction address, using key A. This instruction authenticates an instruction address, using a modifier and key A.

The address is:

- In the general-purpose register that is specified by <Xd> for AUTIA and AUTIZA.
- In X17, for AUTIA1716.
- In X30, for AUTIASP and AUTIAZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIA.
- The value zero, for AUTIZA and AUTIAZ.
- In X16, for AUTIA1716.
- In SP, for AUTIASP.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

Integer

(FEAT_PAuth)

  otherwise SEE "HINT";
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation for all encodings

```
if HavePACExt() then
  if source_is_sp then
    X[d] = AuthIA(X[d], SP[], FALSE);
  else
    X[d] = AuthIA(X[d], X[n], FALSE);
```

C6.2.23 AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB

Authenticate Instruction address, using key B. This instruction authenticates an instruction address, using a modifier and key B.

The address is:

- In the general-purpose register that is specified by <Xd> for AUTIB and AUTIZB.
- In X17, for AUTIB1716.
- In X30, for AUTIBSP and AUTIBZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIB.
- The value zero, for AUTIZB and AUTIBZ.
- In X16, for AUTIB1716.
- In SP, for AUTIBSP.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

Integer

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation for all encodings

```
if HavePACExt() then
  if source_is_sp then
    X[d] = AuthIB(X[d], SP[], FALSE);
  else
    X[d] = AuthIB(X[d], X[n], FALSE);
```

C6.2.24 AXFLAG

Convert floating-point condition flags from Arm to external format. This instruction converts the state of the PSTATE.{N,Z,C,V} flags from a form representing the result of an Arm floating-point scalar compare instruction to an alternative representation required by some software.

System

(FEAT_FlagM2)

Encoding

AXFLAG

Decode for this encoding

if !HaveFlagFormatExt() then UNDEFINED;

Operation

bit Z = PSTATE.Z OR PSTATE.V;
 bit C = PSTATE.C AND NOT(PSTATE.V);

PSTATE.N = '0';
 PSTATE.Z = Z;
 PSTATE.C = C;
 PSTATE.V = '0';

C6.2.25 B.cond

Branch conditionally to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.

31	30	29	28	27	26	25	24	23													5	4	3		0
0	1	0	1	0	1	0	0	0	imm19													0	cond		

Encoding

B.<cond> <label>

Decode for this encoding

bits(64) offset = [SignExtend](#)(imm19:'00', 64);

Assembler symbols

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
if ConditionHolds(cond) then  
    BranchTo(PC[] + offset, BranchType\_DIR, TRUE);
```

C6.2.26 B

Branch causes an unconditional branch to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.

Encoding

B <label>

Decode for this encoding

bits(64) offset = [SignExtend](#)(imm26:'00', 64);

Assembler symbols

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

Operation

[BranchTo](#)(PC[] + offset, [BranchType_DIR](#), FALSE);

C6.2.27 BFC

Bitfield Clear sets a bitfield of <width> bits at bit position <lsb> of the destination register to zero, leaving the other destination bits unchanged.

This instruction is an alias of the [BFM](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [BFM](#).
- The description of [BFM](#) gives the operational pseudocode for this instruction.

Leaving other bits unchanged

(FEAT_ASMv8p2)

31	30	29	28	27	26	25	24	23	22	21	16	15	10	9	5	4	0		
sf	0	1	1	0	0	1	1	0	N	immr		imms		1	1	1	1	1	Rd
opc										Rn									

32-bit variant

Applies when $sf == 0 \ \&\& \ N == 0$.

BFC <wd>, #<lsb>, #<width>

is equivalent to

BFM <wd>, WZR, #(-<lsb> MOD 32), #(<width>-1)

and is the preferred disassembly when $UInt(imms) < UInt(immr)$.

64-bit variant

Applies when $sf == 1 \ \&\& \ N == 1$.

BFC <Xd>, #<lsb>, #<width>

is equivalent to

BFM <Xd>, XZR, #(-<lsb> MOD 64), #(<width>-1)

and is the preferred disassembly when $UInt(imms) < UInt(immr)$.

Assembler symbols

<wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<lsb> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
 For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
 For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of [BFM](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.28 BFI

Bitfield Insert copies a bitfield of $\langle\text{width}\rangle$ bits from the least significant bits of the source register to bit position $\langle\text{lsb}\rangle$ of the destination register, leaving the other destination bits unchanged.

This instruction is an alias of the [BFM](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [BFM](#).
- The description of [BFM](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when $\text{sf} == 0 \ \&\& \ N == 0$.

BFI $\langle\text{Wd}\rangle, \langle\text{Wn}\rangle, \#\langle\text{lsb}\rangle, \#\langle\text{width}\rangle$

is equivalent to

BFM $\langle\text{Wd}\rangle, \langle\text{Wn}\rangle, \#(-\langle\text{lsb}\rangle \text{ MOD } 32), \#(\langle\text{width}\rangle-1)$

and is the preferred disassembly when $\text{UInt}(\text{imms}) < \text{UInt}(\text{immr})$.

64-bit variant

Applies when $\text{sf} == 1 \ \&\& \ N == 1$.

BFI $\langle\text{Xd}\rangle, \langle\text{Xn}\rangle, \#\langle\text{lsb}\rangle, \#\langle\text{width}\rangle$

is equivalent to

BFM $\langle\text{Xd}\rangle, \langle\text{Xn}\rangle, \#(-\langle\text{lsb}\rangle \text{ MOD } 64), \#(\langle\text{width}\rangle-1)$

and is the preferred disassembly when $\text{UInt}(\text{imms}) < \text{UInt}(\text{immr})$.

Assembler symbols

$\langle\text{Wd}\rangle$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

$\langle\text{Wn}\rangle$ Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

$\langle\text{Xd}\rangle$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

$\langle\text{Xn}\rangle$ Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

$\langle\text{lsb}\rangle$ For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
 For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

$\langle\text{width}\rangle$ For the 32-bit variant: is the width of the bitfield, in the range 1 to $32-\langle\text{lsb}\rangle$.
 For the 64-bit variant: is the width of the bitfield, in the range 1 to $64-\langle\text{lsb}\rangle$.

Operation

The description of [BFM](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.29 BFM

Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.

If $\langle imms \rangle$ is greater than or equal to $\langle immr \rangle$, this copies a bitfield of $(\langle imms \rangle - \langle immr \rangle + 1)$ bits starting from bit position $\langle immr \rangle$ in the source register to the least significant bits of the destination register.

If $\langle imms \rangle$ is less than $\langle immr \rangle$, this copies a bitfield of $(\langle imms \rangle + 1)$ bits from the least significant bits of the source register to bit position $(regsize - \langle immr \rangle)$ of the destination register, where $regsize$ is the destination register size of 32 or 64 bits.

In both cases the other bits of the destination register remain unchanged.

This instruction is used by the aliases [BFC](#), [BFI](#), and [BFXIL](#). See *Alias conditions* on page C6-927 for details of when each alias is preferred.

32-bit variant

Applies when $sf == 0 \ \&\& \ N == 0$.

BFM $\langle wd \rangle$, $\langle wn \rangle$, $\# \langle immr \rangle$, $\# \langle imms \rangle$

64-bit variant

Applies when $sf == 1 \ \&\& \ N == 1$.

BFM $\langle xd \rangle$, $\langle xn \rangle$, $\# \langle immr \rangle$, $\# \langle imms \rangle$

Decode for all variants of this encoding

```

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

integer R;
bits(datasize) wmask;
bits(datasize) tmask;

if sf == '1' && N != '1' then UNDEFINED;
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then UNDEFINED;

R = UInt(immr);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
  
```

Alias conditions

Alias	is preferred when
BFC	$Rn == '11111' \ \&\& \ \text{UInt}(imms) < \text{UInt}(immr)$
BFI	$Rn != '11111' \ \&\& \ \text{UInt}(imms) < \text{UInt}(immr)$
BFXIL	$\text{UInt}(imms) \geq \text{UInt}(immr)$

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<immr>	For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.
<imms>	For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

Operation

```
bits(datasize) dst = X[d];
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = (dst AND NOT(wmask)) OR (ROR(src, R) AND wmask);

// combine extension bits and result bits
X[d] = (dst AND NOT(tmask)) OR (bot AND tmask);
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.30 BFXIL

Bitfield Extract and Insert Low copies a bitfield of $\langle width \rangle$ bits starting from bit position $\langle lsb \rangle$ in the source register to the least significant bits of the destination register, leaving the other destination bits unchanged.

This instruction is an alias of the [BFM](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [BFM](#).
- The description of [BFM](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf == 0 \ \&\& \ N == 0$.

BFXIL $\langle Wd \rangle$, $\langle Wn \rangle$, $\# \langle lsb \rangle$, $\# \langle width \rangle$

is equivalent to

BFM $\langle Wd \rangle$, $\langle Wn \rangle$, $\# \langle lsb \rangle$, $\# (\langle lsb \rangle + \langle width \rangle - 1)$

and is the preferred disassembly when $UInt(imms) \geq UInt(immr)$.

64-bit variant

Applies when $sf == 1 \ \&\& \ N == 1$.

BFXIL $\langle Xd \rangle$, $\langle Xn \rangle$, $\# \langle lsb \rangle$, $\# \langle width \rangle$

is equivalent to

BFM $\langle Xd \rangle$, $\langle Xn \rangle$, $\# \langle lsb \rangle$, $\# (\langle lsb \rangle + \langle width \rangle - 1)$

and is the preferred disassembly when $UInt(imms) \geq UInt(immr)$.

Assembler symbols

- $\langle Wd \rangle$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $\langle Wn \rangle$ Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- $\langle Xd \rangle$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $\langle Xn \rangle$ Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- $\langle lsb \rangle$ For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- $\langle width \rangle$ For the 32-bit variant: is the width of the bitfield, in the range 1 to $32 - \langle lsb \rangle$.
For the 64-bit variant: is the width of the bitfield, in the range 1 to $64 - \langle lsb \rangle$.

Operation

The description of [BFM](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.31 BIC (shifted register)

Bitwise Bit Clear (shifted register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when `sf == 0`.

BIC <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit variant

Applies when `sf == 1`.

BIC <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
```

```
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
 - LSL when shift = 00
 - LSR when shift = 01
 - ASR when shift = 10
 - ROR when shift = 11
- <amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
 For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

```
bits(datasize) operand1 = X[n];  
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
```

```
operand2 = NOT(operand2);
```

```
result = operand1 AND operand2;
```

```
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.32 BICS (shifted register)

Bitwise Bit Clear (shifted register), setting flags, performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

32-bit variant

Applies when `sf == 0`.

BICS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit variant

Applies when `sf == 1`.

BICS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
 - LSL when shift = 00
 - LSR when shift = 01
 - ASR when shift = 10
 - ROR when shift = 11
- <amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

operand2 = NOT(operand2);

result = operand1 AND operand2;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.33 BL

Branch with Link branches to a PC-relative offset, setting the register X30 to PC+4. It provides a hint that this is a subroutine call.

Encoding

BL <label>

Decode for this encoding

bits(64) offset = [SignExtend](#)(imm26:'00', 64);

Assembler symbols

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

Operation

$X[30] = PC[] + 4;$

[BranchTo](#)(PC[] + offset, [BranchType_DIRCALL](#), FALSE);

C6.2.34 BLR

Branch with Link to Register calls a subroutine at an address in a register, setting register X30 to PC+4.

Encoding

BLR <Xn>

Decode for this encoding

integer n = UInt(Rn);

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation

bits(64) target = X[n];

X[30] = PC[] + 4;

```
// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '10';
BranchTo(target, BranchType_INDCALL, FALSE);
```

C6.2.35 BLRAA, BLRAAZ, BLRAB, BLRABZ

Branch with Link to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and calls a subroutine at the authenticated address, setting register X30 to PC+4.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xm|SP> for BLRAA and BLRAB.
- The value zero, for BLRAAZ and BLRABZ.

Key A is used for BLRAA and BLRAAZ, and key B is used for BLRAB and BLRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

Integer

(FEAT_PAuth)

Key A, zero modifier variant

Applies when Z == 0 && M == 0 && Rm == 11111.

BLRAAZ <Xn>

Key A, register modifier variant

Applies when Z == 1 && M == 0.

BLRAA <Xn>, <Xm|SP>

Key B, zero modifier variant

Applies when Z == 0 && M == 1 && Rm == 11111.

BLRABZ <Xn>

Key B, register modifier variant

Applies when Z == 1 && M == 1.

BLRAB <Xn>, <Xm|SP>

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean use_key_a = (M == '0');
boolean source_is_sp = ((Z == '1') && (m == 31));

if !HavePACExt() then
    UNDEFINED;

if Z == '0' && m != 31 then
    UNDEFINED;
```

Assembler symbols

- <Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.
- <Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

```
bits(64) target = X[n];  
bits(64) modifier = if source_is_sp then SP[] else X[m];  
  
if use_key_a then  
    target = AuthIA(target, modifier, TRUE);  
else  
    target = AuthIB(target, modifier, TRUE);  
  
X[30] = PC[] + 4;  
  
// Value in BTypeNext will be used to set PSTATE.BTYPE  
BTypeNext = '10';  
BranchTo(target, BranchType_INDCALL, FALSE);
```

C6.2.36 BR

Branch to Register branches unconditionally to an address in a register, with a hint that this is not a subroutine return.

Encoding

BR <Xn>

Decode for this encoding

integer n = UInt(Rn);

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation

```
bits(64) target = X[n];

// Value in BTypeNext will be used to set PSTATE.BTYPE
if InGuardedPage then
    if n == 16 || n == 17 then
        BTypeNext = '01';
    else
        BTypeNext = '11';
else
    BTypeNext = '01';
BranchTo(target, BranchType_INDIR, FALSE);
```

C6.2.37 BRAA, BRAAZ, BRAB, BRABZ

Branch to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and branches to the authenticated address.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xm|SP> for BRAA and BRAB.
- The value zero, for BRAAZ and BRABZ.

Key A is used for BRAA and BRAAZ, and key B is used for BRAB and BRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

Integer

(FEAT_PAuth)

Key A, zero modifier variant

Applies when Z == 0 && M == 0 && Rm == 11111.

BRAAZ <Xn>

Key A, register modifier variant

Applies when Z == 1 && M == 0.

BRAA <Xn>, <Xm|SP>

Key B, zero modifier variant

Applies when Z == 0 && M == 1 && Rm == 11111.

BRABZ <Xn>

Key B, register modifier variant

Applies when Z == 1 && M == 1.

BRAB <Xn>, <Xm|SP>

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean use_key_a = (M == '0');
boolean source_is_sp = ((Z == '1') && (m == 31));

if !HavePACExt() then
  UNDEFINED;

if Z == '0' && m != 31 then
  UNDEFINED;
```

Assembler symbols

- <Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.
- <Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

```
bits(64) target = X[n];  
bits(64) modifier = if source_is_sp then SP[] else X[m];  
  
if use_key_a then  
    target = AuthIA(target, modifier, TRUE);  
else  
    target = AuthIB(target, modifier, TRUE);  
  
// Value in BTypeNext will be used to set PSTATE.BTYPE  
if InGuardedPage then  
    if n == 16 || n == 17 then  
        BTypeNext = '01';  
    else  
        BTypeNext = '11';  
else  
    BTypeNext = '01';  
BranchTo(target, BranchType_INDIR, FALSE);
```

C6.2.38 BRK

Breakpoint instruction. A BRK instruction generates a Breakpoint Instruction exception. The PE records the exception in [ESR_ELx](#), using the EC value 0x3c, and captures the value of the immediate argument in [ESR_ELx.ISS](#).

Encoding

BRK #<imm>

Decode for this encoding

```
if HaveBTIExt() then
    SetBTypeCompatible(TRUE);
```

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
AArch64.SoftwareBreakpoint(imm16);
```

C6.2.39 BTI

Branch Target Identification. A BTI instruction is used to guard against the execution of instructions which are not the intended target of a branch.

Outside of a guarded memory region, a BTI instruction executes as a NOP. Within a guarded memory region while `PSTATE.BTYPE != 0b00`, a BTI instruction compatible with the current value of `PSTATE.BTYPE` will not generate a Branch Target Exception and will allow execution of subsequent instructions within the memory region.

The operand `<targets>` passed to a BTI instruction determines the values of `PSTATE.BTYPE` which the BTI instruction is compatible with.

———— Note ————

Within a guarded memory region, when `PSTATE.BTYPE != 0b00`, all instructions will generate a Branch Target Exception, other than BRK, BTI, HLT, PACIASP, and PACIBSP, which might not. See the individual instructions for more information.

System

(FEAT_BTI)

Encoding

BTI {<targets>}

Decode for this encoding

```
SystemHintOp op;

if CRm:op2 == '0100 xx0' then
    op = SystemHintOp_BTI;
    // Check branch target compatibility between BTI instruction and PSTATE.BTYPE
    SetBTypeCompatible(BTypeCompatible_BTI(op2<2:1>));
else
    EndOfInstruction();
```

Assembler symbols

`<targets>` Is the type of indirection, encoded in the "op2<2:1>" field. It can have the following values:

(omitted)	when op2<2:1> = 00
c	when op2<2:1> = 01
j	when op2<2:1> = 10
jc	when op2<2:1> = 11

Operation

```
case op of
    when SystemHintOp_YIELD
        Hint_Yield();

    when SystemHintOp_DGH
        Hint_DGH();

    when SystemHintOp_WFE
```

```
        Hint_WFE(-1, WFXType_WFE);
when SystemHintOp_WFI
    Hint_WFI(-1, WFXType_WFI);

when SystemHintOp_SEV
    SendEvent();

when SystemHintOp_SEVL
    SendEventLocal();

when SystemHintOp_ESB
    SynchronizeErrors();
    AArch64.ESB0peration();
    if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then AArch64.vESB0peration();
    TakeUnmaskedSErrorInterrupts();

when SystemHintOp_PSB
    ProfilingSynchronizationBarrier();

when SystemHintOp_TSB
    TraceSynchronizationBarrier();

when SystemHintOp_CSDB
    ConsumptionOfSpeculativeDataBarrier();

when SystemHintOp_BTI
    SetBTypeNext('00');

otherwise // do nothing
```

C6.2.40 CASB, CASAB, CASALB, CASLB

Compare and Swap byte in memory reads an 8-bit byte from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASAB and CASALB load from memory with acquire semantics.
- CASLB and CASALB store to memory with release semantics.
- CASB has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

No offset

(FEAT_LSE)

CASAB variant

Applies when L == 1 && o0 == 0.

CASAB <Ws>, <Wt>, [<Xn|SP>{,#0}]

CASALB variant

Applies when L == 1 && o0 == 1.

CASALB <Ws>, <Wt>, [<Xn|SP>{,#0}]

CASB variant

Applies when L == 0 && o0 == 0.

CASB <Ws>, <Wt>, [<Xn|SP>{,#0}]

CASLB variant

Applies when L == 0 && o0 == 1.

CASLB <Ws>, <Wt>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

```

if !HaveAtomicExt() then UNDEFINED;

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);

AccType ldacctype = if L == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
```

```
AccType stacctype = if o0 == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;  
boolean tag_checked = n != 31;
```

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register to be compared and loaded, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be conditionally stored, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;  
bits(8) comparevalue;  
bits(8) newvalue;  
bits(8) data;  
  
if HaveMTE2Ext() then  
    SetTagCheckedInstruction(tag_checked);  
  
comparevalue = X[s];  
newvalue = X[t];  
  
if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
data = MemAtomicCompareAndSwap(address, comparevalue, newvalue, 1dacctype, stacctype);  
  
X[s] = ZeroExtend(data, 32);
```

C6.2.41 CASH, CASAH, CASALH, CASLH

Compare and Swap halfword in memory reads a 16-bit halfword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASAH and CASALH load from memory with acquire semantics.
- CASLH and CASALH store to memory with release semantics.
- CAS has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

data = MemAtomicCompareAndSwap(address, comparevalue, newvalue, ldacctype, stacctype);
```

```
X[s] = ZeroExtend(data, regsize);
```

C6.2.44 CBNZ

Compare and Branch on Nonzero compares the value in a register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect the condition flags.

32-bit variant

Applies when sf == 0.

CBNZ <Wt>, <label>

64-bit variant

Applies when sf == 1.

CBNZ <Xt>, <label>

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer datasize = if sf == '1' then 64 else 32;
bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
- <label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
bits(datasize) operand1 = X[t];
if IsZero(operand1) == FALSE then
  BranchTo(PC[] + offset, BranchType_DIR, TRUE);
```

C6.2.45 CBZ

Compare and Branch on Zero compares the value in a register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

32-bit variant

Applies when sf == 0.

CBZ <Wt>, <label>

64-bit variant

Applies when sf == 1.

CBZ <Xt>, <label>

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer datasize = if sf == '1' then 64 else 32;
bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
- <label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
bits(datasize) operand1 = X[t];
if IsZero(operand1) == TRUE then
  BranchTo(PC[] + offset, BranchType_DIR, TRUE);
```

C6.2.46 CCMN (immediate)

Conditional Compare Negative (immediate) sets the value of the condition flags to the result of the comparison of a register value and a negated immediate value if the condition is TRUE, and an immediate value otherwise.

32-bit variant

Applies when sf == 0.

CCMN <Wn>, #<imm>, #<nzcw>, <cond>

64-bit variant

Applies when sf == 1.

CCMN <Xn>, #<imm>, #<nzcw>, <cond>

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcw;
bits(datasize) imm = ZeroExtend(imm5, datasize);
```

Assembler symbols

- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <imm> Is a five bit unsigned (positive) immediate encoded in the "imm5" field.
- <nzcw> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcw" field.
- <cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
if ConditionHolds(cond) then
  bits(datasize) operand1 = X[n];
  (-, flags) = AddWithCarry(operand1, imm, '0');
  PSTATE.<N,Z,C,V> = flags;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.47 CCMN (register)

Conditional Compare Negative (register) sets the value of the condition flags to the result of the comparison of a register value and the inverse of another register value if the condition is TRUE, and an immediate value otherwise.

32-bit variant

Applies when sf == 0.

CCMN <Wn>, <Wm>, #<nzcv>, <cond>

64-bit variant

Applies when sf == 1.

CCMN <Xn>, <Xm>, #<nzcv>, <cond>

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcv;
```

Assembler symbols

- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
- <cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
if ConditionHolds(cond) then
  bits(datasize) operand1 = X[n];
  bits(datasize) operand2 = X[m];
  (-, flags) = AddWithCarry(operand1, operand2, '0');
  PSTATE.<N,Z,C,V> = flags;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.

- The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.48 CCMP (immediate)

Conditional Compare (immediate) sets the value of the condition flags to the result of the comparison of a register value and an immediate value if the condition is TRUE, and an immediate value otherwise.

32-bit variant

Applies when sf == 0.

CCMP <Wn>, #<imm>, #<nzcw>, <cond>

64-bit variant

Applies when sf == 1.

CCMP <Xn>, #<imm>, #<nzcw>, <cond>

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcw;
bits(datasize) imm = ZeroExtend(imm5, datasize);
```

Assembler symbols

- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <imm> Is a five bit unsigned (positive) immediate encoded in the "imm5" field.
- <nzcw> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcw" field.
- <cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
if ConditionHolds(cond) then
  bits(datasize) operand1 = X[n];
  bits(datasize) operand2;
  operand2 = NOT(imm);
  (-, flags) = AddWithCarry(operand1, operand2, '1');
  PSTATE.<N,Z,C,V> = flags;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.49 CCMP (register)

Conditional Compare (register) sets the value of the condition flags to the result of the comparison of two registers if the condition is TRUE, and an immediate value otherwise.

32-bit variant

Applies when sf == 0.

CCMP <Wn>, <Wm>, #<nzcv>, <cond>

64-bit variant

Applies when sf == 1.

CCMP <Xn>, <Xm>, #<nzcv>, <cond>

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcv;
```

Assembler symbols

- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
- <cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
if ConditionHolds(cond) then
  bits(datasize) operand1 = X[n];
  bits(datasize) operand2 = X[m];
  operand2 = NOT(operand2);
  (-, flags) = AddWithCarry(operand1, operand2, '1');
  PSTATE.<N,Z,C,V> = flags;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.

- The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.50 CFINV

Invert Carry Flag. This instruction inverts the value of the PSTATE.C flag.

System

(FEAT_FlagM)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	8	7	6	5	4	3	2	1	0

CRm

Encoding

CFINV

Decode for this encoding

if !HaveFlagManipulateExt() then UNDEFINED;

Operation

PSTATE.C = NOT(PSTATE.C);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.51 CFP

Control Flow Prediction Restriction by Context prevents control flow predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Control flow predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.

For more information, see [CFP RCTX](#).

This instruction is an alias of the [SYS](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [SYS](#).
- The description of [SYS](#) gives the operational pseudocode for this instruction.

System

(FEAT_SPECRES)

Encoding

CFP RCTX, <Xt>

is equivalent to

SYS #3, C7, C3, #4, <Xt>

and is always the preferred disassembly.

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of [SYS](#) gives the operational pseudocode for this instruction.

C6.2.52 CINC

Conditional Increment returns, in the destination register, the value of the source register incremented by 1 if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the [CSINC](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [CSINC](#).
- The description of [CSINC](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when `sf == 0`.

CINC <Wd>, <Wn>, <cond>

is equivalent to

CSINC <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when `Rn == Rm`.

64-bit variant

Applies when `sf == 1`.

CINC <Xd>, <Xn>, <cond>

is equivalent to

CSINC <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when `Rn == Rm`.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of [CSINC](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.53 CINV

Conditional Invert returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the [CSINV](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [CSINV](#).
- The description of [CSINV](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when `sf == 0`.

CINV <Wd>, <Wn>, <cond>

is equivalent to

CSINV <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when `Rn == Rm`.

64-bit variant

Applies when `sf == 1`.

CINV <Xd>, <Xn>, <cond>

is equivalent to

CSINV <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when `Rn == Rm`.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of [CSINV](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.54 CLREX

Clear Exclusive clears the local monitor of the executing PE.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	8	7	6	5	4	3	2	1	0
1	1	0	1	0	1	0	1	0	0	0	0	0	0	1	1	0	0	1	1	CRm	0	1	0	1	1	1	1	1	1

Encoding

CLREX {#<imm>}

Decode for this encoding

// CRm field is ignored

Assembler symbols

<imm> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

Operation

```
ClearExclusiveLocal(ProcessorID());
```

C6.2.55 CLS

Count Leading Sign bits counts the number of leading bits of the source register that have the same value as the most significant bit of the register, and writes the result to the destination register. This count does not include the most significant bit of the source register.

32-bit variant

Applies when sf == 0.

CLS <Wd>, <Wn>

64-bit variant

Applies when sf == 1.

CLS <Xd>, <Xn>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
integer result;
bits(datasize) operand1 = X[n];

result = CountLeadingSignBits(operand1);

X[d] = result<datasize-1:0>;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.

— The values of the NZCV flags.

C6.2.56 CLZ

Count Leading Zeros counts the number of binary zero bits before the first binary one bit in the value of the source register, and writes the result to the destination register.

32-bit variant

Applies when sf == 0.

CLZ <Wd>, <Wn>

64-bit variant

Applies when sf == 1.

CLZ <Xd>, <Xn>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
integer result;
bits(datasize) operand1 = X[n];

result = CountLeadingZeroBits(operand1);
X[d] = result<datasize-1:0>;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.57 CMN (extended register)

Compare Negative (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the [ADDS \(extended register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [ADDS \(extended register\)](#).
- The description of [ADDS \(extended register\)](#) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	13	12	10	9	5	4	0
sf	0	1	0	1	0	1	1	0	0	1	Rm	option	imm3	Rn	1	1	1	1	1	1
op S											Rd									

32-bit variant

Applies when `sf == 0`.

CMN <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

is equivalent to

ADDS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

CMN <Xn|SP>, <R><m>{, <extend> {#<amount>}}

is equivalent to

ADDS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

and is always the preferred disassembly.

Assembler symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in the "option" field. It can have the following values:

W	when option = 00x
W	when option = 010
X	when option = x11
W	when option = 10x
W	when option = 110

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB	when option = 000
UXTH	when option = 001
LSL UXTW	when option = 010
UXTX	when option = 011
SXTB	when option = 100
SXTH	when option = 101
SXTW	when option = 110
SXTX	when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB	when option = 000
UXTH	when option = 001
UXTW	when option = 010
LSL UXTX	when option = 011
SXTB	when option = 100
SXTH	when option = 101
SXTW	when option = 110
SXTX	when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

The description of [ADDS \(extended register\)](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.58 CMN (immediate)

Compare Negative (immediate) adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the [ADDS \(immediate\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [ADDS \(immediate\)](#).
- The description of [ADDS \(immediate\)](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when `sf == 0`.

CMN <Wn|WSP>, #<imm>{, <shift>}

is equivalent to

ADDS WZR, <Wn|WSP>, #<imm> {, <shift>}

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

CMN <Xn|SP>, #<imm>{, <shift>}

is equivalent to

ADDS XZR, <Xn|SP>, #<imm> {, <shift>}

and is always the preferred disassembly.

Assembler symbols

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

LSL #0 when sh = 0

LSL #12 when sh = 1

Operation

The description of [ADDS \(immediate\)](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.59 CMN (shifted register)

Compare Negative (shifted register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the [ADDS \(shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [ADDS \(shifted register\)](#).
- The description of [ADDS \(shifted register\)](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when `sf == 0`.

CMN <Wn>, <Wm>{, <shift> #<amount>}

is equivalent to

ADDS WZR, <Wn>, <Wm> {, <shift> #<amount>}

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

CMN <Xn>, <Xm>{, <shift> #<amount>}

is equivalent to

ADDS XZR, <Xn>, <Xm> {, <shift> #<amount>}

and is always the preferred disassembly.

Assembler symbols

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

LSL when shift = 00

LSR when shift = 01

ASR when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

The description of [ADDS \(shifted register\)](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.60 CMP (extended register)

Compare (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the [SUBS \(extended register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [SUBS \(extended register\)](#).
- The description of [SUBS \(extended register\)](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when sf == 0.

CMP <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

is equivalent to

SUBS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

and is always the preferred disassembly.

64-bit variant

Applies when sf == 1.

CMP <Xn|SP>, <R><m>{, <extend> {#<amount>}}

is equivalent to

SUBS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

and is always the preferred disassembly.

Assembler symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in the "option" field. It can have the following values:

W when option = 00x

W when option = 010

X when option = x11

W when option = 10x

W when option = 110

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

- <extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:
- | | |
|----------|-------------------|
| UXTB | when option = 000 |
| UXTH | when option = 001 |
| LSL UXTW | when option = 010 |
| UXTX | when option = 011 |
| SXTB | when option = 100 |
| SXTH | when option = 101 |
| SXTW | when option = 110 |
| SXTX | when option = 111 |
- If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.
- For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:
- | | |
|----------|-------------------|
| UXTB | when option = 000 |
| UXTH | when option = 001 |
| UXTW | when option = 010 |
| LSL UXTX | when option = 011 |
| SXTB | when option = 100 |
| SXTH | when option = 101 |
| SXTW | when option = 110 |
| SXTX | when option = 111 |
- If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.
- <amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

The description of [SUBS \(extended register\)](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.61 CMP (immediate)

Compare (immediate) subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the [SUBS \(immediate\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [SUBS \(immediate\)](#).
- The description of [SUBS \(immediate\)](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when `sf == 0`.

CMP <Wn|WSP>, #<imm>{, <shift>}

is equivalent to

SUBS WZR, <Wn|WSP>, #<imm> {, <shift>}

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

CMP <Xn|SP>, #<imm>{, <shift>}

is equivalent to

SUBS XZR, <Xn|SP>, #<imm> {, <shift>}

and is always the preferred disassembly.

Assembler symbols

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

LSL #0 when sh = 0

LSL #12 when sh = 1

Operation

The description of [SUBS \(immediate\)](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.62 CMP (shifted register)

Compare (shifted register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the [SUBS \(shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [SUBS \(shifted register\)](#).
- The description of [SUBS \(shifted register\)](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when `sf == 0`.

CMP <Wn>, <Wm>{, <shift> #<amount>}

is equivalent to

SUBS WZR, <Wn>, <Wm> {, <shift> #<amount>}

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

CMP <Xn>, <Xm>{, <shift> #<amount>}

is equivalent to

SUBS XZR, <Xn>, <Xm> {, <shift> #<amount>}

and is always the preferred disassembly.

Assembler symbols

- | | |
|----------|---|
| <Wn> | Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field. |
| <Wm> | Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field. |
| <Xn> | Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field. |
| <Xm> | Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field. |
| <shift> | Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
LSL when shift = 00
LSR when shift = 01
ASR when shift = 10
The encoding shift = 11 is reserved. |
| <amount> | For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field. |

Operation

The description of [SUBS \(shifted register\)](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.63 CMPP

Compare with Tag subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, updates the condition flags based on the result of the subtraction, and discards the result.

This instruction is an alias of the [SUBPS](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [SUBPS](#).
- The description of [SUBPS](#) gives the operational pseudocode for this instruction.

Integer

()

Encoding

CMPP <Xn|SP>, <Xm|SP>

is equivalent to

SUBPS XZR, <Xn|SP>, <Xm|SP>

and is always the preferred disassembly.

Assembler symbols

- <Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.
- <Xm|SP> Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Xm" field.

Operation

The description of [SUBPS](#) gives the operational pseudocode for this instruction.

C6.2.64 CNEG

Conditional Negate returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the [CSNEG](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [CSNEG](#).
- The description of [CSNEG](#) gives the operational pseudocode for this instruction.

31 30 29 28 27 26 25 24 23 22 21 20										16 15		12 11 10 9			5 4		0																				
sf										1		0		1		1		0		1		0		0		Rm		!=111x		0		1		Rn		Rd	
op																										cond		o2									

32-bit variant

Applies when $sf == 0$.

CNEG <Wd>, <Wn>, <cond>

is equivalent to

CSNEG <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when $Rn == Rm$.

64-bit variant

Applies when $sf == 1$.

CNEG <Xd>, <Xn>, <cond>

is equivalent to

CSNEG <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when $Rn == Rm$.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of [CSNEG](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.65 CPP

Cache Prefetch Prediction Restriction by Context prevents cache allocation predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Cache allocation predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.

For more information, see [CPP RCTX](#).

This instruction is an alias of the [SYS](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [SYS](#).
- The description of [SYS](#) gives the operational pseudocode for this instruction.

System

(FEAT_SPECRES)

Encoding

CPP RCTX, <Xt>

is equivalent to

SYS #3, C7, C3, #7, <Xt>

and is always the preferred disassembly.

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of [SYS](#) gives the operational pseudocode for this instruction.

C6.2.66 CRC32B, CRC32H, CRC32W, CRC32X

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

In Armv8-A, this is an OPTIONAL instruction, and in Armv8.1 it is mandatory for all implementations to implement it.

———— **Note** —————

[ID_AA64ISAR0_EL1.CRC32](#) indicates whether this instruction is supported.

CRC32B variant

Applies when `sf == 0` && `sz == 00`.

CRC32B <Wd>, <Wn>, <Wm>

CRC32H variant

Applies when `sf == 0` && `sz == 01`.

CRC32H <Wd>, <Wn>, <Wm>

CRC32W variant

Applies when `sf == 0` && `sz == 10`.

CRC32W <Wd>, <Wn>, <Wm>

CRC32X variant

Applies when `sf == 1` && `sz == 11`.

CRC32X <Wd>, <Wn>, <Xm>

Decode for all variants of this encoding

```

if !HaveCRCExt() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sf == '1' && sz != '11' then UNDEFINED;
if sf == '0' && sz == '11' then UNDEFINED;
integer size = 8 << UInt(sz);
  
```

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.

<Wm> Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

Operation

```
bits(32) acc = X[n]; // accumulator
bits(size) val = X[m]; // input value
bits(32) poly = 0x04C11DB7<31:0>;
```

```
bits(32+size) tempacc = BitReverse(acc):Zeros(size);
bits(size+32) tempval = BitReverse(val):Zeros(32);
```

```
// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.67 CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

In Armv8-A, this is an OPTIONAL instruction, and in Armv8.1 it is mandatory for all implementations to implement it.

———— **Note** —————

[ID_AA64ISAR0_EL1.CRC32](#) indicates whether this instruction is supported.

CRC32CB variant

Applies when `sf == 0` && `sz == 00`.

CRC32CB <Wd>, <Wn>, <Wm>

CRC32CH variant

Applies when `sf == 0` && `sz == 01`.

CRC32CH <Wd>, <Wn>, <Wm>

CRC32CW variant

Applies when `sf == 0` && `sz == 10`.

CRC32CW <Wd>, <Wn>, <Wm>

CRC32CX variant

Applies when `sf == 1` && `sz == 11`.

CRC32CX <Wd>, <Wn>, <Xm>

Decode for all variants of this encoding

```

if !HaveCRCExt() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sf == '1' && sz != '11' then UNDEFINED;
if sf == '0' && sz == '11' then UNDEFINED;
integer size = 8 << UInt(sz);
  
```

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.

<Wm> Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

Operation

```
bits(32) acc = X[n]; // accumulator
bits(size) val = X[m]; // input value
bits(32) poly = 0x1EDC6F41<31:0>;
```

```
bits(32+size) tempacc = BitReverse(acc):Zeros(size);
bits(size+32) tempval = BitReverse(val):Zeros(32);
```

```
// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.68 CSDB

Consumption of Speculative Data Barrier is a memory barrier that controls speculative execution and data value prediction.

No instruction other than branch instructions appearing in program order after the CSDB can be speculatively executed using the results of any:

- Data value predictions of any instructions.
- PSTATE.{N,Z,C,V} predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
- Predictions of SVE predication state for any SVE instructions.

———— **Note** —————

For purposes of the definition of CSDB, PSTATE.{N,Z,C,V} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.{N,Z,C,V} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

Encoding

CSDB

Decode for this encoding

// Empty.

Operation

`ConsumptionOfSpeculativeDataBarrier();`

C6.2.69 CSEL

If the condition is true, Conditional Select writes the value of the first source register to the destination register. If the condition is false, it writes the value of the second source register to the destination register.

32-bit variant

Applies when sf == 0.

CSEL <Wd>, <Wn>, <Wm>, <cond>

64-bit variant

Applies when sf == 1.

CSEL <Xd>, <Xn>, <Xm>, <cond>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
bits(datasize) result;
if ConditionHolds(cond) then
  result = X[n];
else
  result = X[m];
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.70 CSET

Conditional Set sets the destination register to 1 if the condition is TRUE, and otherwise sets it to 0.

This instruction is an alias of the [CSINC](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [CSINC](#).
- The description of [CSINC](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when `sf == 0`.

CSET <Wd>, <cond>

is equivalent to

CSINC <Wd>, WZR, WZR, invert(<cond>)

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

CSET <Xd>, <cond>

is equivalent to

CSINC <Xd>, XZR, XZR, invert(<cond>)

and is always the preferred disassembly.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of [CSINC](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.71 CSETM

Conditional Set Mask sets all bits of the destination register to 1 if the condition is TRUE, and otherwise sets all bits to 0.

This instruction is an alias of the [CSINV](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [CSINV](#).
- The description of [CSINV](#) gives the operational pseudocode for this instruction.

32-bit variant

Applies when `sf == 0`.

CSETM <Wd>, <cond>

is equivalent to

CSINV <Wd>, WZR, WZR, invert(<cond>)

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

CSETM <Xd>, <cond>

is equivalent to

CSINV <Xd>, XZR, XZR, invert(<cond>)

and is always the preferred disassembly.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of [CSINV](#) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.72 CSINC

Conditional Select Increment returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register incremented by 1.

This instruction is used by the aliases [CINC](#) and [CSET](#). See [Alias conditions on page C6-1001](#) for details of when each alias is preferred.

32-bit variant

Applies when sf == 0.

CSINC <Wd>, <Wn>, <Wm>, <cond>

64-bit variant

Applies when sf == 1.

CSINC <Xd>, <Xn>, <Xm>, <cond>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Alias conditions

Alias	is preferred when
CINC	Rm != '11111' && cond != '111x' && Rn != '11111' && Rn == Rm
CSET	Rm == '11111' && cond != '111x' && Rn == '11111'

Assembler symbols

<code><Wd></code>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<code><Wn></code>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<code><Wm></code>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<code><Xd></code>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<code><Xn></code>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<code><Xm></code>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<code><cond></code>	Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
bits(datasize) result;  
if ConditionHolds(cond) then  
    result = X[n];  
else  
    result = X[m];  
    result = result + 1;  
  
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.73 CSINV

Conditional Select Invert returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the bitwise inversion value of the second source register.

This instruction is used by the aliases [CINV](#) and [CSETM](#). See [Alias conditions on page C6-1003](#) for details of when each alias is preferred.

32-bit variant

Applies when sf == 0.

CSINV <Wd>, <Wn>, <Wm>, <cond>

64-bit variant

Applies when sf == 1.

CSINV <Xd>, <Xn>, <Xm>, <cond>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Alias conditions

Alias	is preferred when
CINV	Rm != '11111' && cond != '111x' && Rn != '11111' && Rn == Rm
CSETM	Rm == '11111' && cond != '111x' && Rn == '11111'

Assembler symbols

<code><Wd></code>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<code><Wn></code>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<code><Wm></code>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<code><Xd></code>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<code><Xn></code>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<code><Xm></code>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<code><cond></code>	Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
bits(datasize) result;  
if ConditionHolds(cond) then  
    result = X[n];  
else  
    result = X[m];  
    result = NOT(result);  
  
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.74 CSNEG

Conditional Select Negation returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the negated value of the second source register.

This instruction is used by the alias [CNEG](#). See [Alias conditions on page C6-1005](#) for details of when each alias is preferred.

32-bit variant

Applies when sf == 0.

CSNEG <Wd>, <Wn>, <Wm>, <cond>

64-bit variant

Applies when sf == 1.

CSNEG <Xd>, <Xn>, <Xm>, <cond>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Alias conditions

Alias	is preferred when
CNEG	cond != '111x' && Rn == Rm

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<cond>	Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
bits(datasize) result;
if ConditionHolds(cond) then
    result = X[n];
```

```
else
    result = X[m];
    result = NOT(result);
    result = result + 1;

X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.75 DC

Data Cache operation. For more information, see [op0==0b01, cache maintenance, TLB maintenance, and address translation instructions](#) on page C5-399.

This instruction is an alias of the [SYS](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [SYS](#).
- The description of [SYS](#) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0
1	1	0	1	0	1	0	1	0	0	0	0	1	op1	0	1	1	1	CRm	op2	Rt		
L											CRn											

Encoding

DC <dc_op>, <Xt>

is equivalent to

SYS #<op1>, C7, <Cm>, #<op2>, <Xt>

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_DC`.

Assembler symbols

<dc_op> Is a DC instruction name, as listed for the DC system instruction group, encoded in the "op1:CRm:op2" field. It can have the following values:

IVAC	when op1 = 000, CRm = 0110, op2 = 001
ISW	when op1 = 000, CRm = 0110, op2 = 010
CSW	when op1 = 000, CRm = 1010, op2 = 010
CISW	when op1 = 000, CRm = 1110, op2 = 010
ZVA	when op1 = 011, CRm = 0100, op2 = 001
CVAC	when op1 = 011, CRm = 1010, op2 = 001
CVAU	when op1 = 011, CRm = 1011, op2 = 001
CIVAC	when op1 = 011, CRm = 1110, op2 = 001

When FEAT_MTE2 is implemented, the following values are also valid:

IGVAC	when op1 = 000, CRm = 0110, op2 = 011
IGSW	when op1 = 000, CRm = 0110, op2 = 100
IGDVAC	when op1 = 000, CRm = 0110, op2 = 101
IGDSW	when op1 = 000, CRm = 0110, op2 = 110
CGSW	when op1 = 000, CRm = 1010, op2 = 100
CGDSW	when op1 = 000, CRm = 1010, op2 = 110
CIGSW	when op1 = 000, CRm = 1110, op2 = 100
CIGDSW	when op1 = 000, CRm = 1110, op2 = 110

When FEAT_MTE is implemented, the following values are also valid:

GVA	when op1 = 011, CRm = 0100, op2 = 011
GZVA	when op1 = 011, CRm = 0100, op2 = 100
CGVAC	when op1 = 011, CRm = 1010, op2 = 011

CGDVAC when op1 = 011, CRm = 1010, op2 = 101
CGVAP when op1 = 011, CRm = 1100, op2 = 011
CGDVAP when op1 = 011, CRm = 1100, op2 = 101
CGVADP when op1 = 011, CRm = 1101, op2 = 011
CGDVADP when op1 = 011, CRm = 1101, op2 = 101
CIGVAC when op1 = 011, CRm = 1110, op2 = 011
CIGDVAC when op1 = 011, CRm = 1110, op2 = 101

When FEAT_DPB is implemented, the following value is also valid:

CVAP when op1 = 011, CRm = 1100, op2 = 001

When FEAT_DPB2 is implemented, the following value is also valid:

CVADP when op1 = 011, CRm = 1101, op2 = 001

- <op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of [SYS](#) gives the operational pseudocode for this instruction.

C6.2.76 DCPS1

Debug Change PE State to EL1, when executed in Debug state:

- If executed at EL0 changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at EL_x, selects SP_EL_x.

The target exception level of a DCPS1 instruction is:

- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

When the target Exception level of a DCPS1 instruction is EL_x, on executing this instruction:

- [ELR_EL_x](#) becomes UNKNOWN.
- [SPSR_EL_x](#) becomes UNKNOWN.
- [ESR_EL_x](#) becomes UNKNOWN.
- [DLR_EL0](#) and [DSPSR_EL0](#) become UNKNOWN.
- The endianness is set according to [SCTLR_EL_x.EE](#).

This instruction is UNDEFINED at EL0 in Non-secure state if EL2 is implemented and [HCR_EL2.TGE](#) == 1.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see [DCPS<n>](#) on page H2-7366.

C6.2.77 DCPS2

Debug Change PE State to EL2, when executed in Debug state:

- If executed at EL0 or EL1 changes the current Exception level and SP to EL2 using SP_EL2.
- Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS2 instruction is:

- EL2 if the instruction is executed at an exception level that is not EL3.
- EL3 if the instruction is executed at EL3.

When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:

- [ELR_ELx](#) becomes UNKNOWN.
- [SPSR_ELx](#) becomes UNKNOWN.
- [ESR_ELx](#) becomes UNKNOWN.
- [DLR_EL0](#) and [DSPSR_EL0](#) become UNKNOWN.
- The endianness is set according to [SCTLR_ELx.EE](#).

This instruction is UNDEFINED at the following exception levels:

- All exception levels if EL2 is not implemented.
- At EL0 and EL1 if EL2 is disabled in the current Security state.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see [DCPS<n>](#) on page H2-7366.

```

Operation

```
Hint_DGH();
```

C6.2.80 DMB

Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see [Data Memory Barrier \(DMB\) on page B2-147](#).

Encoding

DMB <option>|<imm>

Decode for this encoding

```

case CRm<3:2> of
  when '00' domain = MBReqDomain_OuterShareable;
  when '01' domain = MBReqDomain_Nonshareable;
  when '10' domain = MBReqDomain_InnerShareable;
  when '11' domain = MBReqDomain_FullSystem;
case CRm<1:0> of
  when '00' types = MBReqTypes_All; domain = MBReqDomain_FullSystem;
  when '01' types = MBReqTypes_Reads;
  when '10' types = MBReqTypes_Writes;
  when '11' types = MBReqTypes_All;
  
```

Assembler symbols

<option>	Specifies the limitation on the barrier operation. Values are:
SY	Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.
ST	Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.
LD	Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.
ISH	Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.
ISHST	Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.
ISHLD	Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.
NSH	Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.
NSHST	Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.
NSHLD	Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.
OSH	Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

- OSHST Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.
- OSHLA Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of CRm that are not listed above are reserved, and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see [Data Memory Barrier \(DMB\) on page B2-147](#) or see [Data Synchronization Barrier \(DSB\) on page B2-150](#).

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Operation

`DataMemoryBarrier(domain, types);`

C6.2.81 DRPS

Debug restore process state

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Encoding

DRPS

Decode for this encoding

```
if !Halted() || PSTATE.EL == EL0 then UNDEFINED;
```

Operation

```
DRPSInstruction();
```

C6.2.82 DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see [Data Synchronization Barrier \(DSB\)](#) on page B2-150.

A DSB instruction with the nXS qualifier is complete when the subset of these memory accesses with the XS attribute set to 0 are complete. It does not require that memory accesses with the XS attribute set to 1 are complete.

This instruction is used by the aliases [PSSBB](#) and [SSBB](#). See [Alias conditions](#) on page C6-1017 for details of when each alias is preferred.

Memory barrier

Encoding

DSB <option>|#<imm>

Decode for this encoding

```

boolean nXS = FALSE;

case CRm of
  when '0000' alias = DSBAlias_SSBB;
  when '0100' alias = DSBAlias_PSSBB;
  otherwise alias = DSBAlias_DSB;

case CRm<3:2> of
  when '00' domain = MBReqDomain_OuterShareable;
  when '01' domain = MBReqDomain_Nonshareable;
  when '10' domain = MBReqDomain_InnerShareable;
  when '11' domain = MBReqDomain_FullSystem;
case CRm<1:0> of
  when '00' types = MBReqTypes_All; domain = MBReqDomain_FullSystem;
  when '01' types = MBReqTypes_Reads;
  when '10' types = MBReqTypes_Writes;
  when '11' types = MBReqTypes_All;
  
```

Memory nXS barrier

(FEAT_XS)

Encoding

DSB <option>nXS|#<imm>

Decode for this encoding

```

if !HaveFeatXS() then UNDEFINED;
MBReqTypes types = MBReqTypes_All;
boolean nXS = TRUE;
DSBAlias alias = DSBAlias_DSB;

case imm2 of
  
```

```
when '00' domain = MBRReqDomain_OuterShareable;
when '01' domain = MBRReqDomain_Nonshareable;
when '10' domain = MBRReqDomain_InnerShareable;
when '11' domain = MBRReqDomain_FullSystem;
```

Alias conditions

Alias	is preferred when
PSSBB	CRm == '0100'
SSBB	CRm == '0000'

Assembler symbols

<option>	For the memory barrier variant: specifies the limitation on the barrier operation. Values are:
SY	Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.
ST	Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.
LD	Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.
ISH	Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.
ISHST	Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.
ISHLD	Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.
NSH	Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.
NSHST	Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.
NSHLD	Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.
OSH	Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.
OSHST	Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.
OSHLD	Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of CRm, other than the values 0b0000 and 0b0100, that are not listed above are reserved, and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see [Data Memory Barrier \(DMB\)](#) on page B2-147 or see [Data Synchronization Barrier \(DSB\)](#) on page B2-150.

———— **Note** ————

The value `0b0000` is used to encode SSBB and the value `0b0100` is used to encode PSSBB.

For the memory nXS barrier variant: specifies the limitation on the barrier operation. Values are:

SY	Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm<3:2> = <code>0b11</code> .
ISH	Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm<3:2> = <code>0b10</code> .
NSH	Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm<3:2> = <code>0b01</code> .
OSH	Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm<3:2> = <code>0b00</code> .

<imm> For the memory barrier variant: is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

For the memory nXS barrier variant: is a 5-bit unsigned immediate, encoded in the "imm2" field. It can have the following values:

16	when imm2 = <code>00</code>
20	when imm2 = <code>01</code>
24	when imm2 = <code>10</code>
28	when imm2 = <code>11</code>

Operation for all encodings

```
case alias of
  when DSBAlias_SSBB
    SpeculativeStoreBypassBarrierToVA();
  when DSBAlias_PSSBB
    SpeculativeStoreBypassBarrierToPA();
  when DSBAlias_DSB
    if !nXS && HaveFeatXS() && HaveFeatHCCX() then
      nXS = PSTATE.EL IN {EL0, EL1} && IsHCRXEL2Enabled() && HCRX_EL2.FnXS == '1';
    DataSynchronizationBarrier(domain, types, nXS);
  otherwise
    Unreachable();
```

C6.2.83 DVP

Data Value Prediction Restriction by Context prevents data value predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.

For more information, see [DVP RCTX](#).

This instruction is an alias of the [SYS](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [SYS](#).
- The description of [SYS](#) gives the operational pseudocode for this instruction.

System

(FEAT_SPECRES)

Encoding

DVP RCTX, <Xt>

is equivalent to

SYS #3, C7, C3, #5, <Xt>

and is always the preferred disassembly.

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of [SYS](#) gives the operational pseudocode for this instruction.

C6.2.84 EON (shifted register)

Bitwise Exclusive OR NOT (shifted register) performs a bitwise Exclusive OR NOT of a register value and an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when `sf == 0`.

EON <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit variant

Applies when `sf == 1`.

EON <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
```

```
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.								
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.								
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.								
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.								
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.								
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.								
<shift>	Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values: <table style="margin-left: 20px; border-collapse: collapse;"> <tr> <td style="padding-right: 10px;">LSL</td> <td>when shift = 00</td> </tr> <tr> <td>LSR</td> <td>when shift = 01</td> </tr> <tr> <td>ASR</td> <td>when shift = 10</td> </tr> <tr> <td>ROR</td> <td>when shift = 11</td> </tr> </table>	LSL	when shift = 00	LSR	when shift = 01	ASR	when shift = 10	ROR	when shift = 11
LSL	when shift = 00								
LSR	when shift = 01								
ASR	when shift = 10								
ROR	when shift = 11								
<amount>	For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field. For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,								

Operation

```
bits(datasize) operand1 = X[n];  
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);  
  
operand2 = NOT(operand2);  
  
result = operand1 EOR operand2;  
  
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.85 EOR (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

32-bit variant

Applies when `sf == 0` && `N == 0`.

EOR <Wd|WSP>, <Wn>, #<imm>

64-bit variant

Applies when `sf == 1`.

EOR <Xd|SP>, <Xn>, #<imm>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;
if sf == '0' && N != '0' then UNDEFINED;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Assembler symbols

<Wd WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm>	For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr". For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];

result = operand1 EOR imm;

if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.86 EOR (shifted register)

Bitwise Exclusive OR (shifted register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when `sf == 0`.

EOR <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit variant

Applies when `sf == 1`.

EOR <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
```

```
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift>	Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
LSL	when shift = 00
LSR	when shift = 01
ASR	when shift = 10
ROR	when shift = 11
<amount>	For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
	For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

```
bits(datasize) operand1 = X[n];  
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);  
  
result = operand1 EOR operand2;  
  
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.87 ERET

Exception Return using the ELR and SPSR for the current Exception level. When executed, the PE restores `PSTATE` from the SPSR, and branches to the address held in the ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See *Illegal return events from AArch64 state* on page D1-2486.

ERET is UNDEFINED at EL0.

Encoding

ERET

Decode for this encoding

if `PSTATE.EL == EL0` then UNDEFINED;

Operation

```
AArch64.CheckForERetTrap(FALSE, TRUE);
bits(64) target = ELR[];
```

```
AArch64.ExceptionReturn(target, SPSR[]);
```

C6.2.88 ERETAA, ERETAB

Exception Return, with pointer authentication. This instruction authenticates the address in ELR, using SP as the modifier and the specified key, the PE restores **PSTATE** from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for ERETAA, and key B is used for ERETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See *Illegal return events from AArch64 state on page D1-2486*.

ERETAA and ERETAB are UNDEFINED at EL0.

Integer

(FEAT_PAuth)

ERETAA variant

Applies when M == 0.

ERETAA

ERETAB variant

Applies when M == 1.

ERETAB

Decode for all variants of this encoding

```
if PSTATE.EL == EL0 then UNDEFINED;
boolean use_key_a = (M == '0');
```

```
if !HavePACExt() then
  UNDEFINED;
```

Operation

```
AArch64.CheckForERetTrap(TRUE, use_key_a);
bits(64) target;
```

```
if use_key_a then
  target = AuthIA(ELR[], SP[], TRUE);
else
  target = AuthIB(ELR[], SP[], TRUE);
```

```
AArch64.ExceptionReturn(target, SPSR[]);
```

C6.2.89 ESB

Error Synchronization Barrier is an error synchronization event that might also update DISR_EL1 and VDISR_EL2.

This instruction can be used at all Exception levels and in Debug state.

In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. See Error Synchronization Barrier in the Arm(R) Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for Armv8-A architecture profile.

If the RAS Extension is not implemented, this instruction executes as a NOP.

System

(FEAT_RAS)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	8	7	5	4	3	2	1	0				
1	1	0	1	0	1	0	1	0	0	0	0	0	0	1	1	0	0	1	0	0	0	1	0	0	0	0	1	1	1	1	1	
																					CRm		op2									

Encoding

ESB

Decode for this encoding

```
if !HaveRASExt() then EndOfInstruction();
```

Operation

```
SynchronizeErrors();
AArch64.ESB0peration();
if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then AArch64.vESB0peration();
TakeUnmaskedSErrorInterrupts();
```

C6.2.90 EXTR

Extract register extracts a register from a pair of registers.

This instruction is used by the alias [ROR \(immediate\)](#). See [Alias conditions on page C6-1029](#) for details of when each alias is preferred.

32-bit variant

Applies when `sf == 0 && N == 0 && imms == 0xxxxx`.

EXTR <Wd>, <Wn>, <Wm>, #<lsb>

64-bit variant

Applies when `sf == 1 && N == 1`.

EXTR <Xd>, <Xn>, <Xm>, #<lsb>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
integer lsb;

if N != sf then UNDEFINED;
if sf == '0' && imms<5> == '1' then UNDEFINED;
lsb = UInt(imms);
```

Alias conditions

Alias	is preferred when
ROR (immediate)	Rn == Rm

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<lsb>	For the 32-bit variant: is the least significant bit position from which to extract, in the range 0 to 31, encoded in the "imms" field.

For the 64-bit variant: is the least significant bit position from which to extract, in the range 0 to 63, encoded in the "imms" field.

Operation

```
bits(datasize) result;  
bits(datasize) operand1 = X[n];  
bits(datasize) operand2 = X[m];  
bits(2*datasize) concat = operand1:operand2;
```

```
result = concat<lsb+datasize-1:lsb>;
```

```
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
 - The values of the data supplied in any of its registers.
 - The values of the NZCV flags.

C6.2.91 GMI

Tag Mask Insert inserts the tag in the first source register into the excluded set specified in the second source register, writing the new excluded set to the destination register.

Integer

(FEAT_MTE)

Encoding

GMI <Xd>, <Xn|SP>, <Xm>

Decode for this encoding

```
if !HaveMTEExt() then UNDEFINED;
integer d = UInt(Xd);
integer n = UInt(Xn);
integer m = UInt(Xm);
```

Assembler symbols

- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Xd" field.
- <Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Xm" field.

Operation

```
bits(64) address = if n == 31 then SP[] else X[n];
bits(64) mask = X[m];
bits(4) tag = AArch64.AllocationTagFromAddress(address);

mask<UInt(tag)> = '1';
X[d] = mask;
```

C6.2.92 HINT

Hint instruction is for the instruction set space that is reserved for architectural hint instructions.

Some encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	8	7	5	4	3	2	1	0

```

```
SetTypeCompatible(BTypeCompatible_BTI(op2<2:1>));
otherwise EndOfInstruction();
```

Assembler symbols

<imm> Is a 7-bit unsigned immediate, in the range 0 to 127 encoded in the "CRm:op2" field.
 The encodings that are allocated to architectural hint functionality are described in the "Hints" table in the "Index by Encoding".

Note

For allocated encodings of "CRm:op2":

- A disassembler will disassemble the allocated instruction, rather than the HINT instruction.
- An assembler may support assembly of allocated encodings using HINT with the corresponding <imm> value, but it is not required to do so.

Operation

```
case op of
  when SystemHintOp_YIELD
    Hint_Yield();

  when SystemHintOp_DGH
    Hint_DGH();

  when SystemHintOp_WFE
    Hint_WFE(-1, WFXType_WFE);

  when SystemHintOp_WFI
    Hint_WFI(-1, WFXType_WFI);

  when SystemHintOp_SEV
    SendEvent();

  when SystemHintOp_SEVL
    SendEventLocal();

  when SystemHintOp_ESB
    SynchronizeErrors();
    AArch64.ESB0operation();
    if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then AArch64.vESB0operation();
    TakeUnmaskedSErrorInterrupts();

  when SystemHintOp_PSB
    ProfilingSynchronizationBarrier();

  when SystemHintOp_TSB
    TraceSynchronizationBarrier();

  when SystemHintOp_CSDB
    ConsumptionOfSpeculativeDataBarrier();

  when SystemHintOp_BTI
    SetBTypeNext('00');

otherwise // do nothing
```

C6.2.93 HLT

Halt instruction. An HLT instruction can generate a Halt Instruction debug event, which causes entry into Debug state.

31	30	29	28	27	26	25	24	23	22	21	20					5	4	3	2	1	0	
1	1	0	1	0	1	0	0	0	1	0		imm16						0	0	0	0	0

Encoding

HLT #<imm>

Decode for this encoding

```
if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;
if HaveBTIExt() then
    SetBTypeCompatible(TRUE);
```

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
Halt(DebugHalt_HaltInstruction);
```

C6.2.94 HVC

Hypervisor Call causes an exception to EL2. Software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:

- When EL3 is implemented and `SCR_EL3.HCE` is set to 0.
- When EL3 is not implemented and `HCR_EL2.HCD` is set to 1.
- When EL2 is not implemented.
- At EL1 if EL2 is not enabled in the current Security state.
- At EL0.

On executing an HVC instruction, the PE records the exception as a Hypervisor Call exception in `ESR_ELx`, using the EC value 0x16, and the value of the immediate argument.

Encoding

HVC #<imm>

Decode for this encoding

// Empty.

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```

if !HaveEL(EL2) || PSTATE.EL == EL0 || (PSTATE.EL == EL1 && (!IsSecureEL2Enabled() && IsSecure())) then
    UNDEFINED;

hvc_enable = if HaveEL(EL3) then SCR_EL3.HCE else NOT(HCR_EL2.HCD);

if hvc_enable == '0' then
    UNDEFINED;
else
    AArch64.CallHypervisor(imm16);
  
```

C6.2.95 IC

Instruction Cache operation. For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-399.

This instruction is an alias of the [SYS](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [SYS](#).
- The description of [SYS](#) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0
1	1	0	1	0	1	0	1	0	0	0	0	0	1	op1	0	1	1	1	CRm	op2	Rt	
L											CRn											

Encoding

IC <ic_op>{, <Xt>}

is equivalent to

SYS #<op1>, C7, <Cm>, #<op2>{, <Xt>}

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_IC`.

Assembler symbols

<ic_op>	Is an IC instruction name, as listed for the IC system instruction pages, encoded in the "op1:CRm:op2" field. It can have the following values:
	IALLUIS when op1 = 000, CRm = 0001, op2 = 000
	IALLU when op1 = 000, CRm = 0101, op2 = 000
	IVAU when op1 = 011, CRm = 0101, op2 = 001
<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
<Xt>	Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

Operation

The description of [SYS](#) gives the operational pseudocode for this instruction.

C6.2.96 IRG

Insert Random Tag inserts a random Logical Address Tag into the address in the first source register, and writes the result to the destination register. Any tags specified in the optional second source register or in GCR_EL1.Exclude are excluded from the selection of the random Logical Address Tag.

Integer

(FEAT_MTE)

Encoding

IRG <Xd|SP>, <Xn|SP>{, <Xm>}

Decode for this encoding

```
if !HaveMTEExt() then UNDEFINED;
integer d = UInt(Xd);
integer n = UInt(Xn);
integer m = UInt(Xm);
```

Assembler symbols

- <Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Xd" field.
- <Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Xm" field. Defaults to XZR if absent.

Operation

```
bits(64) operand = if n == 31 then SP[] else X[n];
bits(64) exclude_reg = X[m];
bits(16) exclude = exclude_reg<15:0> OR GCR_EL1.Exclude;

if AArch64.AllocationTagAccessIsEnabled(AccType_NORMAL) then
  if GCR_EL1.RRND == '1' then
    RGSr_EL1 = bits(64) UNKNOWN;
    if IsOnes(exclude) then
      rtag = '0000';
    else
      rtag = ChooseRandomNonExcludedTag(exclude);
  else
    bits(4) start = RGSr_EL1.TAG;
    bits(4) offset = AArch64.RandomTag();

    rtag = AArch64.ChooseNonExcludedTag(start, offset, exclude);

    RGSr_EL1.TAG = rtag;
  else
    rtag = '0000';

bits(64) result = AArch64.AddressWithAllocationTag(operand, AccType_NORMAL, rtag);

if d == 31 then
```

```
    SP[] = result;  
else  
    X[d] = result;
```

C6.2.97 ISB

Instruction Synchronization Barrier flushes the pipeline in the PE and is a context synchronization event. For more information, see *Instruction Synchronization Barrier (ISB)* on page B2-147.

Encoding

ISB {<option>|#<imm>}

Decode for this encoding

// No additional decoding required

Assembler symbols

- <option> Specifies an optional limitation on the barrier operation. Values are:
- SY Full system barrier operation, encoded as CRm = 0b1111. Can be omitted.
- All other encodings of CRm are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.
- <imm> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

Operation

`InstructionSynchronizationBarrier();`

C6.2.98 LD64B

Single-copy Atomic 64-byte Load derives an address from a base register value, loads eight 64-bit doublewords from a memory location, and writes them to consecutive registers, Xt to X(t+7). The data that is loaded is atomic and is required to be 64-byte aligned.

Integer

(FEAT_LS64)

Encoding

LD64B <Xt>, [<Xn|SP> {, #0}]

Decode for this encoding

```

if !HaveFeatLS64() then UNDEFINED;
if Rt<4:3> == '11' || Rt<0> == '1' then UNDEFINED;

integer n = UInt(Rn);
integer t = UInt(Rt);
boolean tag_checked = n != 31;
  
```

Assembler symbols

<Xt> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
 <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```

CheckLDST64BEnabled();

bits(512) data;
bits(64) address;
bits(64) value;
acctype = AccType_ATOMICLS64;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = MemLoad64B(address, acctype);

for i = 0 to 7
    value = data<63+64*i:64*i>;
    if BigEndian(acctype) then value = BigEndianReverse(value);
    X[t+i] = value;
  
```

C6.2.99 LDADD, LDADDAB, LDADDALB, LDADDLB

Atomic add on byte in memory atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDADDAB and LDADDALB load from memory with acquire semantics.
- LDADDLB and LDADDALB store to memory with release semantics.
- LDADD has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STADD, STADDLB](#). See [Alias conditions on page C6-1042](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

LDADDAB variant

Applies when A == 1 && R == 0.

LDADDAB <Ws>, <Wt>, [<Xn|SP>]

LDADDALB variant

Applies when A == 1 && R == 1.

LDADDALB <Ws>, <Wt>, [<Xn|SP>]

LDADD variant

Applies when A == 0 && R == 0.

LDADD <Ws>, <Wt>, [<Xn|SP>]

LDADDLB variant

Applies when A == 0 && R == 1.

LDADDLB <Ws>, <Wt>, [<Xn|SP>]

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UNDEFINED;
```

```
integer t = UInt(Rt);
```

```
integer n = UInt(Rn);
```

```
integer s = UInt(Rs);
```

```
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
```

```
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
```

```
boolean tag_checked = n != 31;
```

Alias conditions

Alias	is preferred when
STADDB, STADDLB	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;  
bits(8) value;  
bits(8) data;  
  
if HaveMTE2Ext() then  
    SetTagCheckedInstruction(tag_checked);  
  
value = X[s];  
if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
data = MemAtomic(address, MemAtomicOp_ADD, value, ldacctype, stacctype);  
  
if t != 31 then  
    X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.100 LDADDH, LDADDAH, LDADDALH, LDADDLH

Atomic add on halfword in memory atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDADDAH and LDADDALH load from memory with acquire semantics.
- LDADDLH and LDADDALH store to memory with release semantics.
- LDADDH has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STADDH, STADDLH](#). See [Alias conditions on page C6-1044](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

LDADDAH variant

Applies when A == 1 && R == 0.

LDADDAH <Ws>, <Wt>, [<Xn|SP>]

LDADDALH variant

Applies when A == 1 && R == 1.

LDADDALH <Ws>, <Wt>, [<Xn|SP>]

LDADDH variant

Applies when A == 0 && R == 0.

LDADDH <Ws>, <Wt>, [<Xn|SP>]

LDADDLH variant

Applies when A == 0 && R == 1.

LDADDLH <Ws>, <Wt>, [<Xn|SP>]

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UNDEFINED;
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);
```

```
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
```

Alias conditions

Alias	is preferred when
STADDH, STADDLH	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;  
bits(16) value;  
bits(16) data;  
  
if HaveMTE2Ext() then  
    SetTagCheckedInstruction(tag_checked);  
  
value = X[s];  
if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
data = MemAtomic(address, MemAtomicOp_ADD, value, ldacctype, stacctype);  
  
if t != 31 then  
    X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.101 LDADD, LDADDA, LDADDAL, LDADDL

Atomic add on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDADDA and LDADDAL load from memory with acquire semantics.
- LDADDL and LDADDAL store to memory with release semantics.
- LDADD has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias **STADD**, **STADDL**. See [Alias conditions on page C6-1046](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

32-bit LDADD variant

Applies when $size == 10 \ \&\& \ A == 0 \ \&\& \ R == 0$.

LDADD <Ws>, <Wt>, [<Xn|SP>]

32-bit LDADDA variant

Applies when $size == 10 \ \&\& \ A == 1 \ \&\& \ R == 0$.

LDADDA <Ws>, <Wt>, [<Xn|SP>]

32-bit LDADDAL variant

Applies when $size == 10 \ \&\& \ A == 1 \ \&\& \ R == 1$.

LDADDAL <Ws>, <Wt>, [<Xn|SP>]

32-bit LDADDL variant

Applies when $size == 10 \ \&\& \ A == 0 \ \&\& \ R == 1$.

LDADDL <Ws>, <Wt>, [<Xn|SP>]

64-bit LDADD variant

Applies when $size == 11 \ \&\& \ A == 0 \ \&\& \ R == 0$.

LDADD <Xs>, <Xt>, [<Xn|SP>]

64-bit LDADDA variant

Applies when $size == 11 \ \&\& \ A == 1 \ \&\& \ R == 0$.

LDADDA <Xs>, <Xt>, [<Xn|SP>]

64-bit LDADDAL variant

Applies when size == 11 && A == 1 && R == 1.

LDADDAL <Xs>, <Xt>, [<Xn|SP>]

64-bit LDADDL variant

Applies when size == 11 && A == 0 && R == 1.

LDADDL <Xs>, <Xt>, [<Xn|SP>]

Decode for all variants of this encoding

```

if !HaveAtomicExt() then UNDEFINED;

integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

integer datasize = 8 << UInt(size);
integer regsize = if datasize == 64 then 64 else 32;
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
  
```

Alias conditions

Alias	is preferred when
STADD, STADDL	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```

bits(64) address;
bits(datasize) value;
bits(datasize) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

value = X[s];
if n == 31 then
  CheckSPAAlignment();
  address = SP[];
else
  address = X[n];

data = MemAtomic(address, MemAtomicOp_ADD, value, ldacctype, stacctype);
  
```

```
if t != 31 then  
    X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.102 LDAPR

Load-Acquire RCpc Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

The instruction has memory ordering semantics as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#), except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Integer

(FEAT_LRCPC)

32-bit variant

Applies when size == 10.

LDAPR <Wt>, [<Xn|SP> {, #0}]

64-bit variant

Applies when size == 11.

LDAPR <Xt>, [<Xn|SP> {, #0}]

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
boolean tag_checked = n != 31;
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if HaveMTE2Ext() then
```

```
SetTagCheckedInstruction(tag_checked);  
  
if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
data = Mem[address, dbytes, AccType_ORDERED];  
X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.103 LDAPRB

Load-Acquire RCpc Register Byte derives an address from a base register value, loads a byte from the derived address in memory, zero-extends it and writes it to a register.

The instruction has memory ordering semantics as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#), except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Integer

(FEAT_LRCPC)

Encoding

LDAPRB <Wt>, [<Xn|SP> {, #0}]

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 1, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.104 LDAPRH

Load-Acquire RCpc Register Halfword derives an address from a base register value, loads a halfword from the derived address in memory, zero-extends it and writes it to a register.

The instruction has memory ordering semantics as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#), except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Integer

(FEAT_LRCPC)

Encoding

LDAPRH <Wt>, [<Xn|SP> {,#0}]

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 2, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.105 LDAPUR

Load-Acquire RCpc Register (unscaled) calculates an address from a base register and an immediate offset, loads a 32-bit word or 64-bit doubleword from memory, zero-extends it, and writes it to a register.

The instruction has memory ordering semantics as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#), except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Unscaled offset

(FEAT_LRCPC2)

32-bit variant

Applies when size == 10.

LDAPUR <Wt>, [<Xn|SP>{, #<sim>}]

64-bit variant

Applies when size == 11.

LDAPUR <Xt>, [<Xn|SP>{, #<sim>}]

Decode for all variants of this encoding

```
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer regsize;

regsize = if size == '11' then 64 else 32;
```

```
integer datasize = 8 << scale;  
boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;  
bits(datasize) data;  
  
if HaveMTE2Ext() then  
    SetTagCheckedInstruction(tag_checked);  
  
if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
address = address + offset;  
  
data = Mem[address, datasize DIV 8, AccType_ORDERED];  
X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.106 LDAPURB

Load-Acquire RCpc Register Byte (unscaled) calculates an address from a base register and an immediate offset, loads a byte from memory, zero-extends it, and writes it to a register.

The instruction has memory ordering semantics as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#), except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Unscaled offset

(FEAT_LRCPC2)

Encoding

LDAPURB <Wt>, [<Xn|SP>{, #<sim>}]

Decode for this encoding

bits(64) offset = [SignExtend](#)(imm9, 64);

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
```

```
    address = SP[];  
else  
    address = X[n];  
  
address = address + offset;  
  
data = Mem[address, 1, AccType_ORDERED];  
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.107 LDAPURH

Load-Acquire RCpc Register Halfword (unscaled) calculates an address from a base register and an immediate offset, loads a halfword from memory, zero-extends it, and writes it to a register.

The instruction has memory ordering semantics as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#), except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Unscaled offset

(FEAT_LRCPC2)

Encoding

LDAPURH <Wt>, [<Xn|SP>{, #<sim>}]

Decode for this encoding

bits(64) offset = [SignExtend](#)(imm9, 64);

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
```

```
    address = SP[];  
else  
    address = X[n];  
  
address = address + offset;  
  
data = Mem[address, 2, AccType_ORDERED];  
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.108 LDAPURSB

Load-Acquire RCpc Register Signed Byte (unscaled) calculates an address from a base register and an immediate offset, loads a signed byte from memory, sign-extends it, and writes it to a register.

The instruction has memory ordering semantics as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#), except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Unscaled offset

(FEAT_LRCPC2)

32-bit variant

Applies when `opc == 11`.

LDAPURSB <Wt>, [<Xn|SP>{, #<simmm>}]

64-bit variant

Applies when `opc == 10`.

LDAPURSB <Xt>, [<Xn|SP>{, #<simmm>}]

Decode for all variants of this encoding

bits(64) offset = `SignExtend`(imm9, 64);

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <simmm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop;
boolean signed;
integer regsize;

if opc<L> == '0' then
```

```

// store or zero-extending load
memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
regsize = 32;
signed = FALSE;
else
// sign-extending load
memop = MemOp_LOAD;
regsize = if opc<0> == '1' then 32 else 64;
signed = TRUE;

boolean tag_checked = memop != MemOp_PREFETCH && (n != 31);

```

Operation

```

bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  if memop != MemOp_PREFETCH then CheckSPAlignment();
  address = SP[];
else
  address = X[n];

address = address + offset;

case memop of
  when MemOp_STORE
    data = X[t];
    Mem[address, 1, AccType_ORDERED] = data;

  when MemOp_LOAD
    data = Mem[address, 1, AccType_ORDERED];
    if signed then
      X[t] = SignExtend(data, regsize);
    else
      X[t] = ZeroExtend(data, regsize);

  when MemOp_PREFETCH
    Prefetch(address, t<4:0>);

```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.109 LDAPURSH

Load-Acquire RCpc Register Signed Halfword (unscaled) calculates an address from a base register and an immediate offset, loads a signed halfword from memory, sign-extends it, and writes it to a register.

The instruction has memory ordering semantics as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#), except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Unscaled offset

(FEAT_LRCPC2)

32-bit variant

Applies when `opc == 11`.

LDAPURSH <Wt>, [<Xn|SP>{, #<simmm>}]

64-bit variant

Applies when `opc == 10`.

LDAPURSH <Xt>, [<Xn|SP>{, #<simmm>}]

Decode for all variants of this encoding

bits(64) offset = [SignExtend](#)(imm9, 64);

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <simmm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop;
boolean signed;
integer regsize;

if opc<L> == '0' then
```

```

// store or zero-extending load
memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
regsize = 32;
signed = FALSE;
else
// sign-extending load
memop = MemOp_LOAD;
regsize = if opc<0> == '1' then 32 else 64;
signed = TRUE;

boolean tag_checked = memop != MemOp_PREFETCH && (n != 31);

```

Operation

```

bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  if memop != MemOp_PREFETCH then CheckSPAlignment();
  address = SP[];
else
  address = X[n];

address = address + offset;

case memop of
when MemOp_STORE
  data = X[t];
  Mem[address, 2, AccType_ORDERED] = data;

when MemOp_LOAD
  data = Mem[address, 2, AccType_ORDERED];
  if signed then
    X[t] = SignExtend(data, regsize);
  else
    X[t] = ZeroExtend(data, regsize);

when MemOp_PREFETCH
  Prefetch(address, t<4:0>);

```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.110 LDAPURSW

Load-Acquire RCpc Register Signed Word (unscaled) calculates an address from a base register and an immediate offset, loads a signed word from memory, sign-extends it, and writes it to a register.

The instruction has memory ordering semantics as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#), except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Unscaled offset

(FEAT_LRCPC2)

Encoding

LDAPURSW <Xt>, [<Xn|SP>{, #<sim>}]

Decode for this encoding

bits(64) offset = [SignExtend](#)(imm9, 64);

Assembler symbols

- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;
bits(32) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  CheckSPAlignment();
```

```
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 4, AccType_ORDERED];
X[t] = SignExtend(data, 64);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.111 LDAR

Load-Acquire Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-152. For information about memory accesses, see *Load/store addressing modes* on page C1-202.

Note

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

32-bit variant

Applies when size == 10.

LDAR <Wt>, [<Xn|SP>{, #0}]

64-bit variant

Applies when size == 11.

LDAR <Xt>, [<Xn|SP>{, #0}]

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer  elsize = 8 << UInt(size);
integer  regsize = if elsize == 64 then 64 else 32;
boolean tag_checked = n != 31;
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAAlignment();
    address = SP[];
else
    address = X[n];
```

```
data = Mem[address, dbytes, AccType_ORDERED];  
X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.112 LDARB

Load-Acquire Register Byte derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire*, *Load-AcquirePC*, and *Store-Release* on page B2-152. For information about memory accesses, see *Load/store addressing modes* on page C1-202.

———— **Note** —————

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

Encoding

LDARB <Wt>, [<Xn|SP>{, #0}]

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 1, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.113 LDARH

Load-Acquire Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it, and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-152. For information about memory accesses, see *Load/store addressing modes* on page C1-202.

———— **Note** —————

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

Encoding

LDARH <Wt>, [<Xn|SP>{, #0}]

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 2, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.114 LDAXP

Load-Acquire Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see [Requirements for single-copy atomicity on page B2-128](#) and [Alignment of data accesses on page B2-160](#). The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See [Synchronization and semaphores on page B2-179](#). The instruction also has memory ordering semantics, as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#). For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

32-bit variant

Applies when `sz == 0`.

LDAXP <Wt1>, <Wt2>, [<Xn|SP>{, #0}]

64-bit variant

Applies when `sz == 1`.

LDAXP <Xt1>, <Xt2>, [<Xn|SP>{, #0}]

Decode for all variants of this encoding

```

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;

boolean rt_unknown = FALSE;
if t == t2 then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE; // result is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();

```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors](#), and particularly [LDAXP on page K1-8415](#).

Assembler symbols

- <Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
- <Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
- <Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

- <Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```

bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, dbytes);

if rt_unknown then
    // ConstrainedUNPREDICTABLE case
    X[t] = bits(datasize) UNKNOWN; // In this case t = t2
elseif elsize == 32 then
    // 32-bit load exclusive pair (atomic)
    data = Mem[address, dbytes, AccType_ORDEREDATOMIC];
    if BigEndian(AccType_ORDEREDATOMIC) then
        X[t] = data<datasize-1:elsize>;
        X[t2] = data<elsize-1:0>;
    else
        X[t] = data<elsize-1:0>;
        X[t2] = data<datasize-1:elsize>;
else // elsize == 64
    // 64-bit load exclusive pair (not atomic),
    // but must be 128-bit aligned
    if address != Align(address, dbytes) then
        AArch64.Abort(address, AlignmentFault(AccType_ORDEREDATOMIC, FALSE, FALSE));
    X[t] = Mem[address, 8, AccType_ORDEREDATOMIC];
    X[t2] = Mem[address+8, 8, AccType_ORDEREDATOMIC];
  
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.115 LDAXR

Load-Acquire Exclusive Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-179. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-152. For information about memory accesses see *Load/store addressing modes* on page C1-202.

32-bit variant

Applies when size == 10.

LDAXR <Wt>, [<Xn|SP>{,#0}]

64-bit variant

Applies when size == 11.

LDAXR <Xt>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
boolean tag_checked = n != 31;
```

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
```

```
// same dbytes-aligned physical address, to allow for the possibility of  
// an atomicity break if the translation is changed between reads.  
AArch64.SetExclusiveMonitors(address, dbytes);  
  
data = Mem[address, dbytes, AccType_ORDEREDATOMIC];  
X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.116 LDAXRB

Load-Acquire Exclusive Register Byte derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See [Synchronization and semaphores on page B2-179](#). The instruction also has memory ordering semantics as described in [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#). For information about memory accesses see [Load/store addressing modes on page C1-202](#).

Encoding

LDAXRB <wt>, [<Xn|SP>{, #0}]

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Assembler symbols

<wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
 <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 1);

data = Mem[address, 1, AccType_ORDEREDATOMIC];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.117 LDAXRH

Load-Acquire Exclusive Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-179. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-152. For information about memory accesses see *Load/store addressing modes* on page C1-202.

Encoding

LDAXRH <wt>, [<Xn|SP>{,#0}]

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Assembler symbols

<wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 2);

data = Mem[address, 2, AccType_ORDEREDATOMIC];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.118 LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB

Atomic bit clear on byte in memory atomically loads an 8-bit byte from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDCLRAB and LDCLRALB load from memory with acquire semantics.
- LDCLRLB and LDCLRALB store to memory with release semantics.
- LDCLRB has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STCLRB, STCLRLB](#). See [Alias conditions on page C6-1077](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

LDCLRAB variant

Applies when A == 1 && R == 0.

LDCLRAB <Ws>, <Wt>, [<Xn|SP>]

LDCLRALB variant

Applies when A == 1 && R == 1.

LDCLRALB <Ws>, <Wt>, [<Xn|SP>]

LDCLRB variant

Applies when A == 0 && R == 0.

LDCLRB <Ws>, <Wt>, [<Xn|SP>]

LDCLRLB variant

Applies when A == 0 && R == 1.

LDCLRLB <Ws>, <Wt>, [<Xn|SP>]

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UNDEFINED;
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);
```

```
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
```

Alias conditions

Alias	is preferred when
STCLRB, STCLRLB	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```

bits(64) address;
bits(8) value;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = MemAtomic(address, MemAtomicOp_BIC, value, ldacctype, stacctype);

if t != 31 then
    X[t] = ZeroExtend(data, 32);
  
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.119 LDCLR, LDCLRAH, LDCLRALH, LDCLRLH

Atomic bit clear on halfword in memory atomically loads a 16-bit halfword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDCLRAH and LDCLRALH load from memory with acquire semantics.
- LDCLRLH and LDCLRALH store to memory with release semantics.
- LDCLR has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STCLR, STCLRLH](#). See [Alias conditions on page C6-1079](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

LDCLRAH variant

Applies when A == 1 && R == 0.

LDCLRAH <Ws>, <Wt>, [<Xn|SP>]

LDCLRALH variant

Applies when A == 1 && R == 1.

LDCLRALH <Ws>, <Wt>, [<Xn|SP>]

LDCLR variant

Applies when A == 0 && R == 0.

LDCLR <Ws>, <Wt>, [<Xn|SP>]

LDCLRLH variant

Applies when A == 0 && R == 1.

LDCLRLH <Ws>, <Wt>, [<Xn|SP>]

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UNDEFINED;
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);
```

```
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
```

Alias conditions

Alias	is preferred when
STCLRH , STCLRLH	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```

bits(64) address;
bits(16) value;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = MemAtomic(address, MemAtomicOp_BIC, value, ldacctype, stacctype);

if t != 31 then
    X[t] = ZeroExtend(data, 32);
  
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.120 LDCLR, LDCLRA, LDCLRAL, LDCLRL

Atomic bit clear on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDCLRA and LDCLRAL load from memory with acquire semantics.
- LDCLRL and LDCLRAL store to memory with release semantics.
- LDCLR has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STCLR, STCLRL](#). See [Alias conditions on page C6-1081](#) for details of when each alias is preferred.

Integer

```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.124 LDG

Load Allocation Tag loads an Allocation Tag from a memory address, generates a Logical Address Tag from the Allocation Tag and merges it into the destination register. The address used for the load is calculated from the base register and an immediate signed offset scaled by the Tag granule.

Integer

(FEAT_MTE)

Encoding

LDG <Xt>, [<Xn|SP>{, #<sim>}]

Decode for this encoding

```

if !HaveMTEExt() then UNDEFINED;
integer t = UInt(Xt);
integer n = UInt(Xn);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);

```

Assembler symbols

- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Xt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Xn" field.
- <sim> Is the optional signed immediate offset, a multiple of 16 in the range -4096 to 4080, defaulting to 0 and encoded in the "imm9" field.

Operation

```

bits(64) address;
bits(4) tag;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;
address = Align(address, TAG_GRANULE);

tag = AArch64.MemTag[address, AccType_NORMAL];
X[t] = AArch64.AddressWithAllocationTag(X[t], AccType_NORMAL, tag);

```

C6.2.125 LDGM

Load Tag Multiple reads a naturally aligned block of N Allocation Tags, where the size of N is identified in GMID_EL1.BS, and writes the Allocation Tag read from address A to the destination register at 4*A<7:4>+3:4*A<7:4>. Bits of the destination register not written with an Allocation Tag are set to 0.

This instruction is UNDEFINED at EL0.

This instruction generates an Unchecked access.

If ID_AA64PFR1_EL1 != 0b0010, this instruction is UNDEFINED.

Integer

(FEAT_MTE2)

Encoding

LDGM <Xt>, [<Xn|SP>]

Decode for this encoding

```
if !HaveMTE2Ext() then UNDEFINED;
integer t = UInt(Xt);
integer n = UInt(Xn);
```

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Xt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Xn" field.

Operation

```
if PSTATE.EL == EL0 then
    UNDEFINED;

bits(64) data = Zeros(64);
bits(64) address;

if n == 31 then
    CheckSPAignment();
    address = SP[];
else
    address = X[n];

integer size = 4 * (2 ^ (UInt(GMID_EL1.BS)));
address = Align(address, size);
integer count = size >> LOG2_TAG_GRANULE;
integer index = UInt(address<LOG2_TAG_GRANULE+3:LOG2_TAG_GRANULE>);

for i = 0 to count-1
    bits(4) tag = AArch64.MemTag[address, AccType_NORMAL];
    data<(index*4)+3:index*4> = tag;
    address = address + TAG_GRANULE;
    index = index + 1;
```

```
X[t] = data;
```

C6.2.126 LDLARB

Load LOAcquire Register Byte loads a byte from memory, zero-extends it and writes it to a register. The instruction also has memory ordering semantics as described in *LoadLOAcquire, StoreLORelease* on page B2-153. For information about memory accesses, see *Load/store addressing modes* on page C1-202.

———— Note ————

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

No offset

(FEAT_LOR)

Encoding

LDLARB <wt>, [<Xn|SP>{, #0}]

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Assembler symbols

- <wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 1, AccType_LIMITEDORDERED];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.127 LDLARH

Load LOAcquire Register Halfword loads a halfword from memory, zero-extends it, and writes it to a register. The instruction also has memory ordering semantics as described in *LoadLOAcquire, StoreLORelease* on page B2-153. For information about memory accesses, see *Load/store addressing modes* on page C1-202.

———— **Note** ————

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

No offset

(FEAT_LOR)

Encoding

LDLARH <wt>, [<Xn|SP>{,#0}]

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Assembler symbols

- <wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 2, AccType_LIMITEDORDERED];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.128 LDLAR

Load LOAcquire Register loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The instruction also has memory ordering semantics as described in *LoadLOAcquire, StoreLORelease* on page B2-153. For information about memory accesses, see *Load/store addressing modes* on page C1-202.

———— **Note** ————

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

No offset

(FEAT_LOR)

32-bit variant

Applies when size == 10.

LDLAR <Wt>, [<Xn|SP>{, #0}]

64-bit variant

Applies when size == 11.

LDLAR <Xt>, [<Xn|SP>{, #0}]

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
boolean tag_checked = n != 31;
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  CheckSPAlignment();
  address = SP[];
else
```

```
address = X[n];  
  
data = Mem[address, dbytes, AccType_LIMITEDORDERED];  
X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.129 LDNP

Load Pair of Registers, with non-temporal hint, calculates an address from a base register value and an immediate offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#). For information about Non-temporal pair instructions, see [Load/store non-temporal pair on page C3-227](#).

32-bit variant

Applies when `opc == 00`.

LDNP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]

64-bit variant

Applies when `opc == 10`.

LDNP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]

Decode for all variants of this encoding

// Empty.

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors](#), and particularly [LDNP on page K1-8415](#).

Assembler symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4. For the 64-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);
if opc<0> == '1' then UNDEFINED;
```

```
integer scale = 2 + UInt(opc<1>);

    data2 = bits(datasize) UNKNOWN;
X[t] = data1;
X[t2] = data2;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.130 LDP

Load Pair of Registers calculates an address from a base register value and an immediate offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Post-index

32-bit variant

Applies when `opc == 00`.

LDP <Wt1>, <Wt2>, [<Xn|SP>], #<imm>

64-bit variant

Applies when `opc == 10`.

LDP <Xt1>, <Xt2>, [<Xn|SP>], #<imm>

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
```

Pre-index

32-bit variant

Applies when `opc == 00`.

LDP <Wt1>, <Wt2>, [<Xn|SP>, #<imm>]!

64-bit variant

Applies when `opc == 10`.

LDP <Xt1>, <Xt2>, [<Xn|SP>, #<imm>]!

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
```

Signed offset

32-bit variant

Applies when `opc == 00`.

LDP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]

64-bit variant

Applies when `opc == 10`.

LDP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]

Decode for all variants of this encoding

```
boolean wback = FALSE;  
boolean postindex = FALSE;
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors](#), and particularly *LDP* on page K1-8415.

Assembler symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the 32-bit post-index and 32-bit pre-index variant: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the "imm7" field as <imm>/4. For the 32-bit signed offset variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4. For the 64-bit post-index and 64-bit pre-index variant: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the "imm7" field as <imm>/8. For the 64-bit signed offset variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.132 LDR (immediate)

Load Register (immediate) loads a word or doubleword from memory and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see [Load/store addressing modes on page C1-202](#). The Unsigned offset variant scales the immediate offset value by the size of the value accessed before adding it to the base register value.

Post-index

32-bit variant

Applies when size == 10.

LDR <Wt>, [<Xn|SP>], #<sim>

64-bit variant

Applies when size == 11.

LDR <Xt>, [<Xn|SP>], #<sim>

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

32-bit variant

Applies when size == 10.

LDR <Wt>, [<Xn|SP>, #<sim>]!

64-bit variant

Applies when size == 11.

LDR <Xt>, [<Xn|SP>, #<sim>]!

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset

32-bit variant

Applies when size == 10.

LDR <wt>, [<Xn|SP>{, #<pimm>}]

64-bit variant

Applies when size == 11.

LDR <Xt>, [<Xn|SP>{, #<pimm>}]

Decode for all variants of this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = LSL(ZeroExtend(imm12, 64), scale);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors](#), and particularly [LDR \(immediate\)](#) on page K1-8417.

Assembler symbols

- <wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
- <pimm> For the 32-bit variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.
 For the 64-bit variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer regsize;

regsize = if size == '11' then 64 else 32;
integer datasize = 8 << scale;
boolean tag_checked = wback || n != 31;

else
    address = X[n];

if !postindex then
    address = address + offset;

data = Mem[address, datasize DIV 8, AccType_NORMAL];
X[t] = ZeroExtend(data, regsize);

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = address + offset;
    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.133 LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses, see [Load/store addressing modes](#) on page C1-202.

32-bit variant

Applies when `opc == 00`.

LDR <Wt>, <label>

64-bit variant

Applies when `opc == 01`.

LDR <Xt>, <label>

Decode for all variants of this encoding

```
integer t = UInt(Rt);
MemOp memop = MemOp_LOAD;
boolean signed = FALSE;
integer size;
bits(64) offset;

case opc of
  when '00'
    size = 4;
  when '01'
    size = 8;
  when '10'
    size = 4;
    signed = TRUE;
  when '11'
    memop = MemOp_PREFETCH;

offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
bits(64) address = PC[] + offset;
bits(size*8) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(FALSE);
```

```
case memop of
  when MemOp_LOAD
    data = Mem[address, size, AccType_NORMAL];
    if signed then
      X[t] = SignExtend(data, 64);
    else
      X[t] = data;

  when MemOp_PREFETCH
    Prefetch(address, t<4:0>);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.134 LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted and extended. For information about memory accesses, see *Load/store addressing modes* on page C1-202.

32-bit variant

Applies when size == 10.

```
LDR <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

64-bit variant

Applies when size == 11.

```
LDR <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
integer scale = UInt(size);
if option<1> == '0' then UNDEFINED; // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

<code><Wt></code>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.								
<code><Xt></code>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.								
<code><Xn SP></code>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.								
<code><Wm></code>	When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.								
<code><Xm></code>	When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.								
<code><extend></code>	Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values: <table style="margin-left: 20px; border-collapse: collapse;"> <tr><td>UXTW</td><td>when option = 010</td></tr> <tr><td>LSL</td><td>when option = 011</td></tr> <tr><td>SXTW</td><td>when option = 110</td></tr> <tr><td>SXTX</td><td>when option = 111</td></tr> </table>	UXTW	when option = 010	LSL	when option = 011	SXTW	when option = 110	SXTX	when option = 111
UXTW	when option = 010								
LSL	when option = 011								
SXTW	when option = 110								
SXTX	when option = 111								
<code><amount></code>	For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values: <table style="margin-left: 20px; border-collapse: collapse;"> <tr><td>#0</td><td>when S = 0</td></tr> <tr><td>#2</td><td>when S = 1</td></tr> </table>	#0	when S = 0	#2	when S = 1				
#0	when S = 0								
#2	when S = 1								

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

#0 when S = 0
#3 when S = 1

Shared decode for all encodings

```
integer n = UInt(Rn);  
integer t = UInt(Rt);  
integer m = UInt(Rm);  
integer regsize;  
  
regsize = if size == '11' then 64 else 32;  
integer datasize = 8 << scale;
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, shift);  
bits(64) address;  
bits(datasize) data;  
  
if HaveMTE2Ext() then  
    SetTagCheckedInstruction(TRUE);  
  
if n == 31 then  
    CheckSPAAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
address = address + offset;  
  
data = Mem[address, datasize DIV 8, AccType_NORMAL];  
X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.135 LDRAA, LDRAB

Load Register, with pointer authentication. This instruction authenticates an address from a base register using a modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit doubleword from memory at this resulting address into a register.

Key A is used for LDRAA, and key B is used for LDRAB.

If the authentication passes, the PE behaves the same as for an LDR instruction. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction is used. In this case, the address that is written back to the base register does not include the pointer authentication code.

For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Unscaled offset

(FEAT_PAuth)

Key A, offset variant

Applies when M == 0 && W == 0.

LDRAA <Xt>, [<Xn|SP>{, #<sim>}]

Key A, pre-indexed variant

Applies when M == 0 && W == 1.

LDRAA <Xt>, [<Xn|SP>{, #<sim>}]!

Key B, offset variant

Applies when M == 1 && W == 0.

LDRAB <Xt>, [<Xn|SP>{, #<sim>}]

Key B, pre-indexed variant

Applies when M == 1 && W == 1.

LDRAB <Xt>, [<Xn|SP>{, #<sim>}]!

Decode for all variants of this encoding

```

if !HavePACExt() then UNDEFINED;
integer t = UInt(Rt);
integer n = UInt(Rn);
boolean wback = (W == '1');
boolean use_key_a = (M == '0');
bits(10) S10 = S:imm9;
bits(64) offset = LSL(SignExtend(S10, 64), 3);
boolean tag_checked = wback || n != 31;
  
```

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, a multiple of 8 in the range -4096 to 4088, defaulting to 0 and encoded in the "S:imm9" field as <sim>/8.

Operation

```
bits(64) address;
bits(64) data;
boolean wb_unknown = FALSE;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable();
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE; // writeback is suppressed
        when Constraint_UNKNOWN wb_unknown = TRUE; // writeback is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();

if n == 31 then
    address = SP[];
else
    address = X[n];

if use_key_a then
    address = AuthDA(address, X[31], TRUE);
else
    address = AuthDB(address, X[31], TRUE);

if n == 31 then
    CheckSPAAlignment();

address = address + offset;
data = Mem[address, 8, AccType_NORMAL];
X[t] = data;

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.136 LDRB (immediate)

Load Register Byte (immediate) loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see [Load/store addressing modes](#) on page C1-202.

Post-index

Encoding

LDRB <Wt>, [<Xn|SP>], #<imm>

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

Encoding

LDRB <Wt>, [<Xn|SP>], #<imm>!

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset

Encoding

LDRB <Wt>, [<Xn|SP>{, #<pimm>}]

Decode for this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 0);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors](#), and particularly *LDRB (immediate)* on page K1-8417.

Assembler symbols

<wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<sim>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = wback || n != 31;

boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable();
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE; // writeback is suppressed
        when Constraint_UNKNOWN wb_unknown = TRUE; // writeback is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
```

Operation for all encodings

```
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

if !postindex then
    address = address + offset;

data = Mem[address, 1, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elseif postindex then
        address = address + offset;
    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.137 LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Extended register variant

Applies when option != 011.

LDRB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]

Shifted register variant

Applies when option == 011.

LDRB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]

Decode for all variants of this encoding

```
if option<1> == '0' then UNDEFINED; // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- <Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- <extend> Is the index extend specifier, encoded in the "option" field. It can have the following values:
 - UXTW when option = 010
 - SXTW when option = 110
 - SXTX when option = 111
- <amount> Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, 0);
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(TRUE);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 1, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.138 LDRH (immediate)

Load Register Halfword (immediate) loads a halfword from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see *Load/store addressing modes* on page C1-202.

Post-index

Encoding

LDRH <Wt>, [<Xn|SP>], #<imm>

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

Encoding

LDRH <Wt>, [<Xn|SP>, #<imm>]!

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset

Encoding

LDRH <Wt>, [<Xn|SP>{, #<pimm>}]

Decode for this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 1);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors](#), and particularly [LDRH \(immediate\)](#) on page K1-8417.

Assembler symbols

<wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<sim>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = wback || n != 31;

boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
  c = ConstrainUnpredictable();
  assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
  case c of
    when Constraint_WBSUPPRESS wback = FALSE; // writeback is suppressed
    when Constraint_UNKNOWN wb_unknown = TRUE; // writeback is UNKNOWN
    when Constraint_UNDEF UNDEFINED;
    when Constraint_NOP EndOfInstruction();
```

Operation for all encodings

```
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  CheckSPAlignment();
  address = SP[];
else
  address = X[n];

if !postindex then
  address = address + offset;

data = Mem[address, 2, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);

if wback then
  if wb_unknown then
    address = bits(64) UNKNOWN;
  elseif postindex then
    address = address + offset;
  if n == 31 then
    SP[] = address;
  else
    X[n] = address;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.139 LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it, and writes it to a register. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Encoding

LDRH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){}, <extend> {<amount>}]

Decode for this encoding

```
if option<1> == '0' then UNDEFINED; // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 1 else 0;
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- <Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- <extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

UXTW	when option = 010
LSL	when option = 011
SXTW	when option = 110
SXTX	when option = 111
- <amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

#0	when S = 0
#1	when S = 1

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, shift);
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(TRUE);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 2, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.140 LDRSB (immediate)

Load Register Signed Byte (immediate) loads a byte from memory, sign-extends it to either 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see [Load/store addressing modes](#) on page C1-202.

Post-index

32-bit variant

Applies when `opc == 11`.

LDRSB <Wt>, [<Xn|SP>], #<sim>

64-bit variant

Applies when `opc == 10`.

LDRSB <Xt>, [<Xn|SP>], #<sim>

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

32-bit variant

Applies when `opc == 11`.

LDRSB <Wt>, [<Xn|SP>, #<sim>]!

64-bit variant

Applies when `opc == 10`.

LDRSB <Xt>, [<Xn|SP>, #<sim>]!

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset

32-bit variant

Applies when `opc == 11`.

LDRSB <Wt>, [<Xn|SP>{, #<pimm>}]

64-bit variant

Applies when `opc == 10`.

LDRSB <Xt>, [<Xn|SP>{, #<pimm>}]

Decode for all variants of this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 0);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors](#), and particularly *LDRSB (immediate)* on page K1-8418.

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
- <pimm> Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
    // store or zero-extending load
    memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
    regsize = 32;
    signed = FALSE;
else
    // sign-extending load
    memop = MemOp_LOAD;

```

```
else  
    X[n] = address;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.141 LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it, and writes it to a register. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

32-bit with extended register offset variant

Applies when `opc == 11` && `option != 011`.

LDRSB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]

32-bit with shifted register offset variant

Applies when `opc == 11` && `option == 011`.

LDRSB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]

64-bit with extended register offset variant

Applies when `opc == 10` && `option != 011`.

LDRSB <Xt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]

64-bit with shifted register offset variant

Applies when `opc == 10` && `option == 011`.

LDRSB <Xt>, [<Xn|SP>, <Xm>{, LSL <amount>}]

Decode for all variants of this encoding

```
if option<1> == '0' then UNDEFINED; // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Wm> When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- <Xm> When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- <extend> Is the index extend specifier, encoded in the "option" field. It can have the following values:
 - UXTW when `option = 010`
 - SXTW when `option = 110`
 - SXTX when `option = 111`
- <amount> Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
    // store or zero-extending load
    memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
    regsize = 32;
    signed = FALSE;
else
    // sign-extending load
    memop = MemOp_LOAD;
    regsize = if opc<0> == '1' then 32 else 64;
    signed = TRUE;

boolean tag_checked = memop != MemOp_PREFETCH;
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, 0);
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    if memop != MemOp_PREFETCH then CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

case memop of
when MemOp_STORE
    data = X[t];
    Mem[address, 1, AccType_NORMAL] = data;

when MemOp_LOAD
    data = Mem[address, 1, AccType_NORMAL];
    if signed then
        X[t] = SignExtend(data, regsize);
    else
        X[t] = ZeroExtend(data, regsize);

when MemOp_PREFETCH
    Prefetch(address, t<4:0>);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.142 LDRSH (immediate)

Load Register Signed Halfword (immediate) loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Post-index

32-bit variant

Applies when `opc == 11`.

LDRSH <Wt>, [<Xn|SP>], #<sim>

64-bit variant

Applies when `opc == 10`.

LDRSH <Xt>, [<Xn|SP>], #<sim>

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

32-bit variant

Applies when `opc == 11`.

LDRSH <Wt>, [<Xn|SP>, #<sim>]!

64-bit variant

Applies when `opc == 10`.

LDRSH <Xt>, [<Xn|SP>, #<sim>]!

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset

32-bit variant

Applies when `opc == 11`.

`LDRSH <Wt>, [<Xn|SP>{, #<pimm>}]`

64-bit variant

Applies when `opc == 10`.

`LDRSH <Xt>, [<Xn|SP>{, #<pimm>}]`

Decode for all variants of this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 1);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors](#), and particularly *LDRSH (immediate)* on page K1-8418.

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
- <pimm> Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as `<pimm>/2`.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
  // store or zero-extending load
  memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
  regsize = 32;
  signed = FALSE;
else
  // sign-extending load
  memop = MemOp_LOAD;
  regsize = if opc<0> == '1' then 32 else 64;
  signed = TRUE;
```

```

boolean tag_checked = memop != MemOp_PREFETCH && (wback || n != 31);

boolean wb_unknown = FALSE;
boolean rt_unknown = FALSE;

if memop == MemOp_LOAD && wback && n == t && n != 31 then
  c = ConstrainUnpredictable();
  assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
  case c of
    when Constraint_WBSUPPRESS wback = FALSE; // writeback is suppressed
    when Constraint_UNKNOWN wb_unknown = TRUE; // writeback is UNKNOWN
    when Constraint_UNDEF UNDEFINED;
    when Constraint_NOP EndOfInstruction();

if memop == MemOp_STORE && wback && n == t && n != 31 then
  c = ConstrainUnpredictable();
  assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
  case c of
    when Constraint_NONE rt_unknown = FALSE; // value stored is original value
    when Constraint_UNKNOWN rt_unknown = TRUE; // value stored is UNKNOWN
    when Constraint_UNDEF UNDEFINED;
    when Constraint_NOP EndOfInstruction();
  
```

Operation for all encodings

```

bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  if memop != MemOp_PREFETCH then CheckSPAlignment();
  address = SP[];
else
  address = X[n];

if !postindex then
  address = address + offset;

case memop of
  when MemOp_STORE
    if rt_unknown then
      data = bits(16) UNKNOWN;
    else
      data = X[t];
      Mem[address, 2, AccType_NORMAL] = data;

  when MemOp_LOAD
    data = Mem[address, 2, AccType_NORMAL];
    if signed then
      X[t] = SignExtend(data, regsize);
    else
      X[t] = ZeroExtend(data, regsize);

  when MemOp_PREFETCH
    Prefetch(address, t<4:0>);

if wback then
  if wb_unknown then
    address = bits(64) UNKNOWN;
  elsif postindex then
    address = address + offset;
  if n == 31 then
    SP[] = address;
  
```

```
else  
    X[n] = address;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.143 LDRSH (register)

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it, and writes it to a register. For information about memory accesses see *Load/store addressing modes* on page C1-202.

32-bit variant

Applies when `opc == 11`.

LDRSH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]

64-bit variant

Applies when `opc == 10`.

LDRSH <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]

Decode for all variants of this encoding

```
if option<1> == '0' then UNDEFINED; // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 1 else 0;
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Wm> When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- <Xm> When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- <extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

UXTW	when option = 010
LSL	when option = 011
SXTW	when option = 110
SXTX	when option = 111
- <amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

#0	when S = 0
#1	when S = 1

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
    // store or zero-extending load
    memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
    regsize = 32;
    signed = FALSE;
else
    // sign-extending load
    memop = MemOp_LOAD;
    regsize = if opc<0> == '1' then 32 else 64;
    signed = TRUE;

boolean tag_checked = memop != MemOp_PREFETCH;
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, shift);
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    if memop != MemOp_PREFETCH then CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

case memop of
when MemOp_STORE
    data = X[t];
    Mem[address, 2, AccType_NORMAL] = data;

when MemOp_LOAD
    data = Mem[address, 2, AccType_NORMAL];
    if signed then
        X[t] = SignExtend(data, regsize);
    else
        X[t] = ZeroExtend(data, regsize);

when MemOp_PREFETCH
    Prefetch(address, t<4:0>);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.144 LDRSW (immediate)

Load Register Signed Word (immediate) loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Post-index

Encoding

LDRSW <Xt>, [<Xn|SP>], #<sim>

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

Encoding

LDRSW <Xt>, [<Xn|SP>, #<sim>]!

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset

Encoding

LDRSW <Xt>, [<Xn|SP>{, #<pimm>}]

Decode for this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 2);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors](#), and particularly *LDRSW (immediate)* on page K1-8418.

Assembler symbols

- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
- <pimm> Is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = wback || n != 31;

boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable();
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE; // writeback is suppressed
        when Constraint_UNKNOWN wb_unknown = TRUE; // writeback is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
```

Operation for all encodings

```
bits(64) address;
bits(32) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

if !postindex then
    address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);
if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = address + offset;
    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.146 LDRSW (register)

Load Register Signed Word (register) calculates an address from a base register value and an offset register value, loads a word from memory, sign-extends it to form a 64-bit value, and writes it to a register. The offset register value can be shifted left by 0 or 2 bits. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Encoding

LDRSW <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]

Decode for this encoding

```
if option<1> == '0' then UNDEFINED; // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 2 else 0;
```

Assembler symbols

- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- <Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- <extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

UXTW	when option = 010
LSL	when option = 011
SXTW	when option = 110
SXTX	when option = 111
- <amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

#0	when S = 0
#2	when S = 1

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, shift);
bits(64) address;
bits(32) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(TRUE);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.147 LDSETB, LDSETAB, LDSETALB, LDSETLB

Atomic bit set on byte in memory atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDSETAB and LDSETALB load from memory with acquire semantics.
- LDSETLB and LDSETALB store to memory with release semantics.
- LDSETB has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STSETB, STSETLB](#). See [Alias conditions on page C6-1144](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

LDSETAB variant

Applies when A == 1 && R == 0.

LDSETAB <Ws>, <Wt>, [<Xn|SP>]

LDSETALB variant

Applies when A == 1 && R == 1.

LDSETALB <Ws>, <Wt>, [<Xn|SP>]

LDSETB variant

Applies when A == 0 && R == 0.

LDSETB <Ws>, <Wt>, [<Xn|SP>]

LDSETLB variant

Applies when A == 0 && R == 1.

LDSETLB <Ws>, <Wt>, [<Xn|SP>]

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UNDEFINED;
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);
```

```
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
```

Alias conditions

Alias	is preferred when
STSETB, STSETLB	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;  
bits(8) value;  
bits(8) data;  
  
if HaveMTE2Ext() then  
    SetTagCheckedInstruction(tag_checked);  
  
value = X[s];  
if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
data = MemAtomic(address, MemAtomicOp_ORR, value, ldacctype, stacctype);  
  
if t != 31 then  
    X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.148 LDSETH, LDSETAH, LDSETALH, LDSETLH

Atomic bit set on halfword in memory atomically loads a 16-bit halfword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDSETAH and LDSETALH load from memory with acquire semantics.
- LDSETLH and LDSETALH store to memory with release semantics.
- LDSETH has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STSETH, STSETLH](#). See [Alias conditions on page C6-1146](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

LDSETAH variant

Applies when A == 1 && R == 0.

LDSETAH <Ws>, <Wt>, [<Xn|SP>]

LDSETALH variant

Applies when A == 1 && R == 1.

LDSETALH <Ws>, <Wt>, [<Xn|SP>]

LDSETH variant

Applies when A == 0 && R == 0.

LDSETH <Ws>, <Wt>, [<Xn|SP>]

LDSETLH variant

Applies when A == 0 && R == 1.

LDSETLH <Ws>, <Wt>, [<Xn|SP>]

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UNDEFINED;
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);
```

```
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
```

Alias conditions

Alias	is preferred when
STSETH , STSETLH	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;  
bits(16) value;  
bits(16) data;  
  
if HaveMTE2Ext() then  
    SetTagCheckedInstruction(tag_checked);  
  
value = X[s];  
if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
data = MemAtomic(address, MemAtomicOp_ORR, value, ldacctype, stacctype);  
  
if t != 31 then  
    X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.149 LDSET, LDSETA, LDSETAL, LDSETL

Atomic bit set on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDSETA and LDSETAL load from memory with acquire semantics.
- LDSETL and LDSETAL store to memory with release semantics.
- LDSET has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STSET, STSETL](#). See [Alias conditions on page C6-1148](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

32-bit LDSET variant

Applies when $size == 10 \ \&\& \ A == 0 \ \&\& \ R == 0$.

LDSET <Ws>, <Wt>, [<Xn|SP>]

32-bit LDSETA variant

Applies when $size == 10 \ \&\& \ A == 1 \ \&\& \ R == 0$.

LDSETA <Ws>, <Wt>, [<Xn|SP>]

32-bit LDSETAL variant

Applies when $size == 10 \ \&\& \ A == 1 \ \&\& \ R == 1$.

LDSETAL <Ws>, <Wt>, [<Xn|SP>]

32-bit LDSETL variant

Applies when $size == 10 \ \&\& \ A == 0 \ \&\& \ R == 1$.

LDSETL <Ws>, <Wt>, [<Xn|SP>]

64-bit LDSET variant

Applies when $size == 11 \ \&\& \ A == 0 \ \&\& \ R == 0$.

LDSET <Xs>, <Xt>, [<Xn|SP>]

64-bit LDSETA variant

Applies when $size == 11 \ \&\& \ A == 1 \ \&\& \ R == 0$.

LDSETA <Xs>, <Xt>, [<Xn|SP>]

64-bit LDSETAL variant

Applies when size == 11 && A == 1 && R == 1.

LDSETAL <Xs>, <Xt>, [<Xn|SP>]

64-bit LDSETL variant

Applies when size == 11 && A == 0 && R == 1.

LDSETL <Xs>, <Xt>, [<Xn|SP>]

Decode for all variants of this encoding

```

if !HaveAtomicExt() then UNDEFINED;

integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

integer datasize = 8 << UInt(size);
integer regsize = if datasize == 64 then 64 else 32;
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
  
```

Alias conditions

Alias	is preferred when
STSET, STSETL	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```

bits(64) address;
bits(datasize) value;
bits(datasize) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

value = X[s];
if n == 31 then
  CheckSPAAlignment();
  address = SP[];
else
  address = X[n];

data = MemAtomic(address, MemAtomicOp_ORR, value, ldacctype, stacctype);
  
```

```
if t != 31 then  
    X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.150 LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB

Atomic signed maximum on byte in memory atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDSMAXAB and LDSMAXALB load from memory with acquire semantics.
- LDSMAXLB and LDSMAXALB store to memory with release semantics.
- LDSMAXB has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STSMAXB, STSMAXLB](#). See [Alias conditions on page C6-1151](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

LDSMAXAB variant

Applies when A == 1 && R == 0.

LDSMAXAB <Ws>, <Wt>, [<Xn|SP>]

LDSMAXALB variant

Applies when A == 1 && R == 1.

LDSMAXALB <Ws>, <Wt>, [<Xn|SP>]

LDSMAXB variant

Applies when A == 0 && R == 0.

LDSMAXB <Ws>, <Wt>, [<Xn|SP>]

LDSMAXLB variant

Applies when A == 0 && R == 1.

LDSMAXLB <Ws>, <Wt>, [<Xn|SP>]

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UNDEFINED;
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);
```

```
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
```

Alias conditions

Alias	is preferred when
STSMAXB , STSMAXLB	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```

bits(64) address;
bits(8) value;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

value = X[s];
if n == 31 then

  address = X[n];

data = MemAtomic(address, MemAtomicOp_SMIN, value, ldacctype, stacctype);
  
```

```
if t != 31 then  
    X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.156 LDTR

Load Register (unprivileged) loads a word or doubleword from memory, and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/store addressing modes on page C1-202*.

32-bit variant

Applies when size == 10.

LDTR <Wt>, [<Xn|SP>{, #<simmm>}]

64-bit variant

Applies when size == 11.

LDTR <Xt>, [<Xn|SP>{, #<simmm>}]

Decode for all variants of this encoding

```
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <simmm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUA0Ext() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
  acctype = AccType_UNPRIV;
else
  acctype = AccType_NORMAL;
```

```
integer regsize;  
  
regsize = if size == '11' then 64 else 32;  
integer datasize = 8 << scale;  
boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;  
bits(datasize) data;  
  
if HaveMTE2Ext() then  
    SetTagCheckedInstruction(tag_checked);  
  
if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
address = address + offset;  
  
data = Mem[address, datasize DIV 8, acctype];  
X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.157 LDTRB

Load Register Byte (unprivileged) loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/store addressing modes on page C1-202*.

Encoding

LDTRB <Wt>, [<Xn|SP>{, #<simmm>}]

Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <simmm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
    acctype = AccType_UNPRIV;
else
    acctype = AccType_NORMAL;

boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
```

```
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 1, acctype];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.158 LDTRH

Load Register Halfword (unprivileged) loads a halfword from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/store addressing modes on page C1-202*.

Encoding

LDTRH <Wt>, [<Xn|SP>{, #<simmm>}]

Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <simmm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
    acctype = AccType_UNPRIV;
else
    acctype = AccType_NORMAL;

boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
```

```
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 2, acctype];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.159 LDTRSB

Load Register Signed Byte (unprivileged) loads a byte from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/store addressing modes on page C1-202*.

32-bit variant

Applies when opc == 11.

LDTRSB <Wt>, [<Xn|SP>{, #<sim>}]

64-bit variant

Applies when opc == 10.

LDTRSB <Xt>, [<Xn|SP>{, #<sim>}]

Decode for all variants of this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_e11 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');
unpriv_at_e12 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_e11 || unpriv_at_e12) then
    acctype = AccType_UNPRIV;
else
    acctype = AccType_NORMAL;
```

```

MemOp memop;

  regsize = if opc<0> == '1' then 32 else 64;
  signed = TRUE;

boolean tag_checked = memop != MemOp_PREFETCH && (n != 31);
  
```

Operation

```

bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  if memop != MemOp_PREFETCH then CheckSPAlignment();
  address = SP[];
else
  address = X[n];

address = address + offset;

case memop of
  when MemOp_STORE
    data = X[t];
    Mem[address, 1, acctype] = data;

  when MemOp_LOAD
    data = Mem[address, 1, acctype];
    if signed then
      X[t] = SignExtend(data, regsize);
    else
      X[t] = ZeroExtend(data, regsize);

  when MemOp_PREFETCH
    Prefetch(address, t<4:0>);
  
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.160 LDTRSH

Load Register Signed Halfword (unprivileged) loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/store addressing modes* on page C1-202.

32-bit variant

Applies when `opc == 11`.

LDTRSH <Wt>, [<Xn|SP>{, #<sim>}]

64-bit variant

Applies when `opc == 10`.

LDTRSH <Xt>, [<Xn|SP>{, #<sim>}]

Decode for all variants of this encoding

`bits(64) offset = SignExtend(imm9, 64);`

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');

  when MemOp_PREFETCH
    Prefetch(address, t<4:0>);
  
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.161 LDTRSW

Load Register Signed Word (unprivileged) loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/store addressing modes on page C1-202*.

Encoding

LDTRSW <Xt>, [<Xn|SP>{, #<simmm>}]

Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <simmm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
  acctype = AccType_UNPRIV;
else
  acctype = AccType_NORMAL;

boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;
bits(32) data;

if HaveMTE2Ext() then
```

```
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 4, acctype];
X[t] = SignExtend(data, 64);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.162 LDUMAXB, LDUMAXB, LDUMAXB, LDUMAXB

Atomic unsigned maximum on byte in memory atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDUMAXB and LDUMAXB load from memory with acquire semantics.
- LDUMAXB and LDUMAXB store to memory with release semantics.
- LDUMAXB has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STUMAXB, STUMAXB](#). See [Alias conditions on page C6-1177](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

LDUMAXB variant

Applies when A == 1 && R == 0.

LDUMAXB <Ws>, <Wt>, [<Xn|SP>]

LDUMAXB variant

Applies when A == 1 && R == 1.

LDUMAXB <Ws>, <Wt>, [<Xn|SP>]

LDUMAXB variant

Applies when A == 0 && R == 0.

LDUMAXB <Ws>, <Wt>, [<Xn|SP>]

LDUMAXB variant

Applies when A == 0 && R == 1.

LDUMAXB <Ws>, <Wt>, [<Xn|SP>]

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UNDEFINED;
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);
```

```
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
```

Alias conditions

Alias	is preferred when
STUMAXB , STUMAXLB	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```

bits(64) address;
bits(8) value;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = MemAtomic(address, MemAtomicOp_UMAX, value, ldacctype, stacctype);

if t != 31 then
    X[t] = ZeroExtend(data, 32);
  
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.163 LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH

Atomic unsigned maximum on halfword in memory atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDUMAXAH and LDUMAXALH load from memory with acquire semantics.
- LDUMAXLH and LDUMAXALH store to memory with release semantics.
- LDUMAXH has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STUMAXH, STUMAXLH](#). See [Alias conditions on page C6-1179](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

```

Alias conditions

Alias	is preferred when
STUMINB, STUMINLB	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;  
bits(8) value;  
bits(8) data;  
  
if HaveMTE2Ext() then  
    SetTagCheckedInstruction(tag_checked);  
  
value = X[s];  
if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
data = MemAtomic(address, MemAtomicOp_UMIN, value, ldacctype, stacctype);  
  
if t != 31 then  
    X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.166 LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH

Atomic unsigned minimum on halfword in memory atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDUMINAH and LDUMINALH load from memory with acquire semantics.
- LDUMINLH and LDUMINALH store to memory with release semantics.
- LDUMINH has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STUMINH, STUMINLH](#). See [Alias conditions on page C6-1186](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

LDUMINAH variant

Applies when A == 1 && R == 0.

LDUMINAH <Ws>, <Wt>, [<Xn|SP>]

LDUMINALH variant

Applies when A == 1 && R == 1.

LDUMINALH <Ws>, <Wt>, [<Xn|SP>]

LDUMINH variant

Applies when A == 0 && R == 0.

LDUMINH <Ws>, <Wt>, [<Xn|SP>]

LDUMINLH variant

Applies when A == 0 && R == 1.

LDUMINLH <Ws>, <Wt>, [<Xn|SP>]

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UNDEFINED;
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);
```

```
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
```

Alias conditions

Alias	is preferred when
STUMINH, STUMINLH	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;  
bits(16) value;  
bits(16) data;  
  
if HaveMTE2Ext() then  
    SetTagCheckedInstruction(tag_checked);  
  
value = X[s];  
if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];  
  
data = MemAtomic(address, MemAtomicOp_UMIN, value, ldacctype, stacctype);  
  
if t != 31 then  
    X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.167 LDUMIN, LDUMINA, LDUMINAL, LDUMINL

Atomic unsigned minimum on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDUMINA and LDUMINAL load from memory with acquire semantics.
- LDUMINL and LDUMINAL store to memory with release semantics.
- LDUMIN has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Load-AcquirePC, and Store-Release on page B2-152](#).

For information about memory accesses see [Load/store addressing modes on page C1-202](#).

This instruction is used by the alias [STUMIN, STUMINL](#). See [Alias conditions on page C6-1188](#) for details of when each alias is preferred.

Integer

(FEAT_LSE)

32-bit LDUMIN variant

Applies when $size == 10 \ \&\& \ A == 0 \ \&\& \ R == 0$.

LDUMIN <Ws>, <Wt>, [<Xn|SP>]

32-bit LDUMINA variant

Applies when $size == 10 \ \&\& \ A == 1 \ \&\& \ R == 0$.

LDUMINA <Ws>, <Wt>, [<Xn|SP>]

32-bit LDUMINAL variant

Applies when $size == 10 \ \&\& \ A == 1 \ \&\& \ R == 1$.

LDUMINAL <Ws>, <Wt>, [<Xn|SP>]

32-bit LDUMINL variant

Applies when $size == 10 \ \&\& \ A == 0 \ \&\& \ R == 1$.

LDUMINL <Ws>, <Wt>, [<Xn|SP>]

64-bit LDUMIN variant

Applies when $size == 11 \ \&\& \ A == 0 \ \&\& \ R == 0$.

LDUMIN <Xs>, <Xt>, [<Xn|SP>]

64-bit LDUMINA variant

Applies when $size == 11 \ \&\& \ A == 1 \ \&\& \ R == 0$.

LDUMINA <Xs>, <Xt>, [<Xn|SP>]

64-bit LDUMINAL variant

Applies when size == 11 && A == 1 && R == 1.

LDUMINAL <Xs>, <Xt>, [<Xn|SP>]

64-bit LDUMINL variant

Applies when size == 11 && A == 0 && R == 1.

LDUMINL <Xs>, <Xt>, [<Xn|SP>]

Decode for all variants of this encoding

```

if !HaveAtomicExt() then UNDEFINED;

integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

integer datasize = 8 << UInt(size);
integer regsize = if datasize == 64 then 64 else 32;
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
  
```

Alias conditions

Alias	is preferred when
STUMIN, STUMINL	A == '0' && Rt == '11111'

Assembler symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```

bits(64) address;
bits(datasize) value;
bits(datasize) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

value = X[s];
if n == 31 then
  CheckSPAAlignment();
  address = SP[];
else
  address = X[n];

data = MemAtomic(address, MemAtomicOp_UMIN, value, ldacctype, stacctype);
  
```

```
if t != 31 then  
    X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.168 LDUR

Load Register (unscaled) calculates an address from a base register and an immediate offset, loads a 32-bit word or 64-bit doubleword from memory, zero-extends it, and writes it to a register. For information about memory accesses, see [Load/store addressing modes](#) on page C1-202.

32-bit variant

Applies when size == 10.

LDUR <Wt>, [<Xn|SP>{, #<sim>}]

64-bit variant

Applies when size == 11.

LDUR <Xt>, [<Xn|SP>{, #<sim>}]

Decode for all variants of this encoding

```
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer regsize;

regsize = if size == '11' then 64 else 32;
integer datasize = 8 << scale;
boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;
bits(datasize) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAAlignment();
```

```
    address = SP[];  
else  
    address = X[n];  
  
address = address + offset;  
  
data = Mem[address, datasize DIV 8, AccType_NORMAL];  
X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.169 LDURB

Load Register Byte (unscaled) calculates an address from a base register and an immediate offset, loads a byte from memory, zero-extends it, and writes it to a register. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Encoding

LDURB <Wt>, [<Xn|SP>{, #<simm>}]

Decode for this encoding

bits(64) offset = [SignExtend](#)(imm9, 64);

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 1, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.170 LDURH

Load Register Halfword (unscaled) calculates an address from a base register and an immediate offset, loads a halfword from memory, zero-extends it, and writes it to a register. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

Encoding

LDURH <Wt>, [<Xn|SP>{, #<sim>}]

Decode for this encoding

bits(64) offset = [SignExtend](#)(imm9, 64);

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 2, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.171 LDURSB

Load Register Signed Byte (unscaled) calculates an address from a base register and an immediate offset, loads a signed byte from memory, sign-extends it, and writes it to a register. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

32-bit variant

Applies when `opc == 11`.

LDURSB <Wt>, [<Xn|SP>{, #<sim>}]

64-bit variant

Applies when `opc == 10`.

LDURSB <Xt>, [<Xn|SP>{, #<sim>}]

Decode for all variants of this encoding

`bits(64) offset = SignExtend(imm9, 64);`

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
    // store or zero-extending load
    memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
    regsize = 32;
    signed = FALSE;
else
    // sign-extending load
    memop = MemOp_LOAD;
    regsize = if opc<0> == '1' then 32 else 64;
    signed = TRUE;

boolean tag_checked = memop != MemOp_PREFETCH && (n != 31);
```

Operation

```
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    if memop != MemOp_PREFETCH then CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

case memop of
    when MemOp_STORE
        data = X[t];
        Mem[address, 1, AccType_NORMAL] = data;

    when MemOp_LOAD
        data = Mem[address, 1, AccType_NORMAL];
        if signed then
            X[t] = SignExtend(data, regsize);
        else
            X[t] = ZeroExtend(data, regsize);

    when MemOp_PREFETCH
        Prefetch(address, t<4:0>);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.172 LDURSH

Load Register Signed Halfword (unscaled) calculates an address from a base register and an immediate offset, loads a signed halfword from memory, sign-extends it, and writes it to a register. For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

32-bit variant

Applies when `opc == 11`.

LDURSH <Wt>, [<Xn|SP>{, #<sim>}]

64-bit variant

Applies when `opc == 10`.

LDURSH <Xt>, [<Xn|SP>{, #<sim>}]

Decode for all variants of this encoding

`bits(64) offset = SignExtend(imm9, 64);`

Assembler symbols

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
  // store or zero-extending load
  memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
  regsize = 32;
  signed = FALSE;
else
  // sign-extending load
  memop = MemOp_LOAD;
  regsize = if opc<0> == '1' then 32 else 64;
  signed = TRUE;

boolean tag_checked = memop != MemOp_PREFETCH && (n != 31);
```

Operation

```
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    if memop != MemOp_PREFETCH then CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

case memop of
    when MemOp_STORE
        data = X[t];
        Mem[address, 2, AccType_NORMAL] = data;

    when MemOp_LOAD
        data = Mem[address, 2, AccType_NORMAL];
        if signed then
            X[t] = SignExtend(data, regsize);
        else
            X[t] = ZeroExtend(data, regsize);

    when MemOp_PREFETCH
        Prefetch(address, t<4:0>);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.173 LDURSW

Load Register Signed Word (unscaled) calculates an address from a base register and an immediate offset, loads a signed word from memory, sign-extends it, and writes it to a register. For information about memory accesses, see *Load/store addressing modes* on page C1-202.

Encoding

LDURSW <Xt>, [<Xn|SP>{, #<sim>}]

Decode for this encoding

bits(64) offset = `SignExtend`(imm9, 64);

Assembler symbols

- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Operation

```
bits(64) address;
bits(32) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.174 LDXP

Load Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see [Requirements for single-copy atomicity on page B2-128](#) and [Alignment of data accesses on page B2-160](#). The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See [Synchronization and semaphores on page B2-179](#). For information about memory accesses, see [Load/store addressing modes on page C1-202](#).

32-bit variant

Applies when `sz == 0`.

LDXP <Wt1>, <Wt2>, [<Xn|SP>{, #0}]

64-bit variant

Applies when `sz == 1`.

LDXP <Xt1>, <Xt2>, [<Xn|SP>{, #0}]

Decode for all variants of this encoding

```

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;

boolean rt_unknown = FALSE;
if t == t2 then
  Constraint c = ConstrainUnpredictable();
  assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
  case c of
    when Constraint_UNKNOWN rt_unknown = TRUE; // result is UNKNOWN
    when Constraint_UNDEF UNDEFINED;
    when Constraint_NOP EndOfInstruction();

```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors](#), and particularly [LDXP on page K1-8419](#).

Assembler symbols

- <Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
- <Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
- <Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

- <Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, dbytes);

if rt_unknown then
    // ConstrainedUNPREDICTABLE case
    X[t] = bits(datasize) UNKNOWN; // In this case t = t2
elseif elsize == 32 then
    // 32-bit load exclusive pair (atomic)
    data = Mem[address, dbytes, AccType_ATOMIC];
    if BigEndian(AccType_ATOMIC) then
        X[t] = data<datasize-1:elsize>;
        X[t2] = data<elsize-1:0>;
    else
        X[t] = data<elsize-1:0>;
        X[t2] = data<datasize-1:elsize>;
else // elsize == 64
    // 64-bit load exclusive pair (not atomic),
    // but must be 128-bit aligned
    if address != Align(address, dbytes) then
        AArch64.Abort(address, AlignmentFault(AccType_ATOMIC, FALSE, FALSE));
    X[t] = Mem[address, 8, AccType_ATOMIC];
    X[t2] = Mem[address+8, 8, AccType_ATOMIC];
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.175 LDXR

Load Exclusive Register derives an address from a base register value, loads a 32-bit word or a 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See [Synchronization and semaphores on page B2-179](#). For information about memory accesses see [Load/store addressing modes on page C1-202](#).

32-bit variant

Applies when size == 10.

LDXR <Wt>, [<Xn|SP>{,#0}]

64-bit variant

Applies when size == 11.

LDXR <Xt>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
boolean tag_checked = n != 31;
```

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
```

```
// an atomicity break if the translation is changed between reads.  
AArch64.SetExclusiveMonitors(address, dbytes);  
  
data = Mem[address, dbytes, AccType_ATOMIC];  
X[t] = ZeroExtend(data, regsize);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.176 LDXRB

Load Exclusive Register Byte derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See [Synchronization and semaphores on page B2-179](#). For information about memory accesses see [Load/store addressing modes on page C1-202](#).

Encoding

LDXRB <Wt>, [<Xn|SP>{, #0}]

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 1);

data = Mem[address, 1, AccType_ATOMIC];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

C6.2.177 LDXRH

Load Exclusive Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See [Synchronization and semaphores on page B2-179](#). For information about memory accesses see [Load/store addressing modes on page C1-202](#).

Encoding

LDXRH <Wt>, [<Xn|SP>{,#0}]

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;
```

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 2);

data = Mem[address, 2, AccType_ATOMIC];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
